Abstract

Background: Cancer survivors and their caregivers, particularly those from disadvantaged backgrounds with limited health literacy or racial and ethnic minorities facing language barriers, are at a disproportionately higher risk of experiencing symptom burdens from cancer and its treatments. Large language models (LLMs) offer a promising avenue for generating concise, linguistically appropriate, and accessible educational materials tailored to these populations. However, there is limited research evaluating how effectively LLMs perform in creating targeted content for individuals with diverse literacy and language needs.

Objective: This study aimed to evaluate the overall performance of LLMs in generating tailored educational content for cancer survivors and their caregivers with limited health literacy or language barriers, compare the performances of 3 Generative Pretrained Transformer (GPT) models (ie, GPT-3.5 Turbo, GPT-4, and GPT-4 Turbo; OpenAI), and examine how different prompting approaches influence the quality of the generated content.

Methods: We selected 30 topics from national guidelines on cancer care and education. GPT-3.5 Turbo, GPT-4, and GPT-4 Turbo were used to generate tailored content of up to 250 words at a 6th-grade reading level, with translations into Spanish and Chinese for each topic. Two distinct prompting approaches (textual and bulleted) were applied and evaluated. Nine oncology experts evaluated 360 generated responses based on predetermined criteria: word limit, reading level, and quality assessment (ie, clarity, accuracy, relevance, completeness, and comprehensibility). ANOVA (analysis of variance) or chi-square analyses were used to compare differences among the various GPT models and prompts.

Results: Overall, LLMs showed excellent performance in tailoring educational content, with 74.2% (267/360) adhering to the specified word limit and achieving an average quality assessment score of 8.933 out of 10. However, LLMs showed moderate performance in reading level, with 41.1% (148/360) of content failing to meet the sixth-grade reading level. LLMs demonstrated strong translation capabilities, achieving an accuracy of 96.7% (87/90) for Spanish and 81.1% (73/90) for Chinese translations. Common errors included imprecise scopes, inaccuracies in definitions, and content that lacked actionable recommendations. The more advanced GPT-4 family models showed better overall performance compared to GPT-3.5 Turbo. Prompting GPTs to produce bulleted-format content was likely to result in better educational content compared with textual-format content.

Conclusions: All 3 LLMs demonstrated high potential for delivering multilingual, concise, and low health literacy educational content for cancer survivors and caregivers who face limited literacy or language barriers. GPT-4 family models were notably more robust. While further refinement is required to ensure simpler reading levels and fully comprehensive information, these findings highlight LLMs as an emerging tool for bridging gaps in cancer education and advancing health equity. Future research should integrate expert feedback, additional prompt engineering strategies, and specialized training data to optimize content accuracy and accessibility.

Introduction

More than 18.1 million individuals with a history of cancer were alive in the United States in 2022, and that number is projected to reach 26 million by 2040 [1]. Cancer survivors receive a wide range of treatments, often experiencing severe symptoms or side effects, including fatigue, depression, anxiety, sleep disturbance, pain, cognitive impairment, nausea, vomiting, and neuropathy [2-7]. These symptoms negatively impact survivors' functional status, quality of life, and overall survival rates [8-11]. Cancer caregivers, typically family members or significant others offering primary emotional and physical support for cancer survivors, experience an array of similar distressing symptoms [12-14]. These symptoms are linked to high caregiving burden, emotional distress, and communication barriers with cancer survivors and providers [15]. In addition, disparities in health care access further exacerbate the challenges faced by cancer survivors and their caregivers, especially those from disadvantaged communities that have limited health literacy or language barriers [16]. Those with limited health literacy and racial and ethnic minorities facing language barriers are at greater risk for poorer access to care [17-19]. Consequently, they tend to experience a heavier symptom burden and poorer health outcomes during and after cancer treatments [20].

With over 3-quarters of the disadvantaged population owning smartphones or computers [21], technology-based intervention programs can bridge the accessibility gap and promote health equity [22,23]. The advent and growth of artificial intelligence have enabled researchers to design tailored and personalized interventions and educational content to meet individual unmet needs [24]. Large language models (LLMs) are advanced artificial intelligence systems that can understand and generate human-like text by training on vast amounts of data [25]. LLMs perform various language tasks, such as answering questions and translating languages. How questions are asked can significantly affect the performance of LLMs. This process, known as prompt engineering, is crucial for obtaining accurate and relevant responses from LLMs [26,27]. While LLMs have demonstrated remarkable potential in cancer research [28-31], their efficacy in real-world scenarios, such as cancer care and education, which often require advanced levels of comprehension, have yet to be thoroughly assessed.

Recent advancements in LLMs, such as GPT-4 and GPT-4 Turbo (OpenAI) [32,33], have demonstrated their exceptional proficiency in completing various tasks, including coding, design, and content summarization. Previous research [34,35] indicates that LLMs can capture large volumes of text effectively, even without specialized domain knowledge. This ability highlights its sophistication in processing and understanding information across a broad spectrum of topics, and its potential to significantly aid in analyzing unstructured data in clinical environments (eg, clinical notes) [34,35]. However, there are several notable gaps in the current knowledge. First, while LLMs have demonstrated high levels of accuracy in understanding extensive texts [34,36,37], even minor inaccuracies can have detrimental effects on patient outcomes [38], particularly regarding actionable advice. Therefore, the content they generate still necessitates additional expert verification to ensure it is error-free and ready to be presented to patients and their caregivers. Second, although previous research [36,37] has demonstrated promising results in content summarization, these LLMs are often not applied in clinical environments, or they specifically address cancer care and education among disadvantaged groups that has limited health literacy or language barriers [39]. Finally, most educational resources for cancer care are available exclusively in English, which can create comprehension challenges for non-English speakers (eg, Hispanic individuals and immigrants). Also, cancer survivors and their caregivers, already overwhelmed by treatment, often lack the time to read lengthy content. Therefore, it is essential to provide educational content in multiple languages and in concise content to ensure effective communication and education [40].

To address these gaps, our team aimed to evaluate how LLMs perform in tailoring educational content to enhance accessibility and comprehension for cancer survivors and their caregivers. In this study, our primary task was to evaluate and compare the capabilities of multiple GPT-based LLMs in generating concise, low-literacy-level, and multilingual educational content tailored for cancer survivors and their caregivers with limited health literacy or language barriers. Specifically, we aimed to evaluate the overall performance of LLMs in generating tailored educational content that adheres to a strict word limit, a sixth-grade reading level, and high-quality criteria (clarity, accuracy, relevance, completeness, and comprehensibility), compare the performances of 3 GPT models (GPT-3.5 Turbo, GPT-4, and GPT-4 Turbo), and explore how different prompt structures (textual vs bulleted format) influence the quality of the generated content. This approach helps them manage their symptoms more effectively, thereby reducing health disparities and promoting health equity.

Methods

Design

This study involved a multistep methodology that included: (1) specifying the exact task requirements for the LLMs, to produce educational content on 30 selected cancer care topics written at a sixth-grade reading level, limited to 250 words, and translated into Spanish and Chinese; (2) generating tailored educational content using 3 GPT models (GPT-3.5 Turbo, GPT-4, and GPT-4 Turbo) with 2 prompt styles (textual and bulleted); (3) expert evaluation of the generated content's adherence to word count, reading level, and 5 quality criteria; and (4) statistical analyses (ANOVA [analysis of variance] and chi-square test) to compare performance across models and prompt formats.

Prompt Engineering

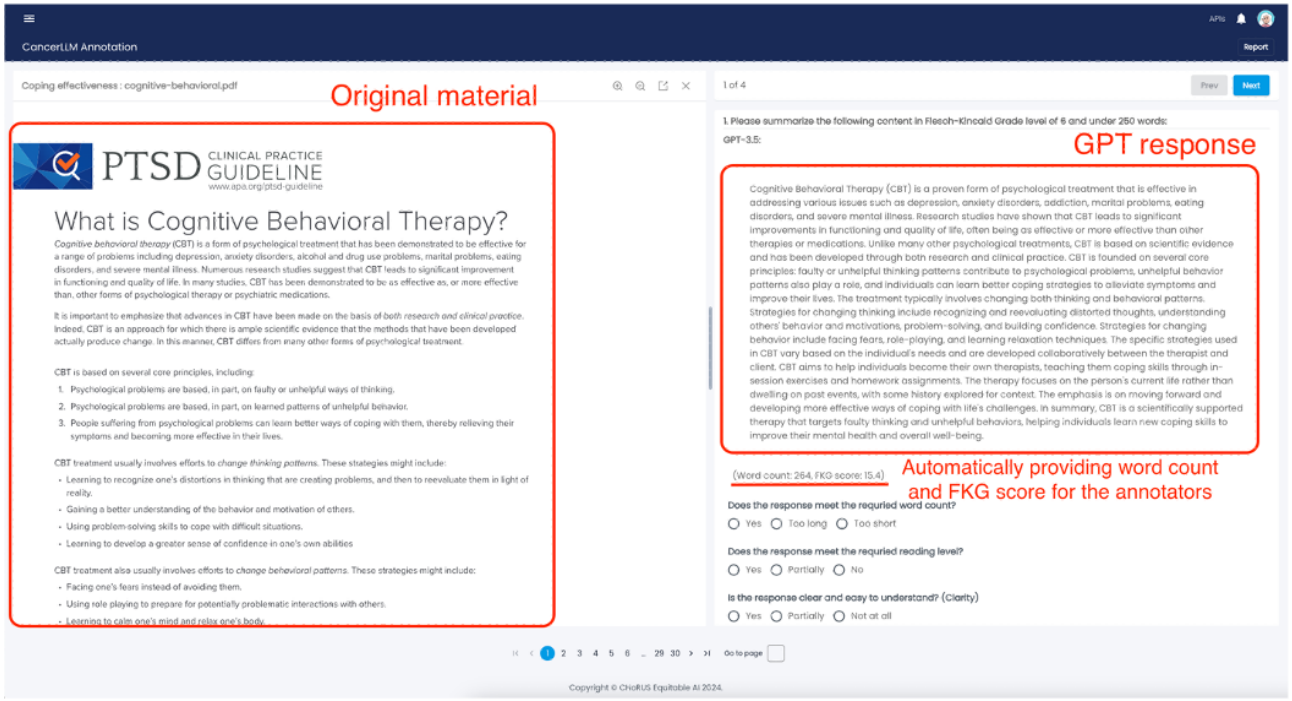
To promote the accessibility and comprehension of educational content for cancer survivors and their caregivers with limited health literacy and language barriers, we structured prompts to have LLMs produce content at a low reading level, maintain a word limit of 250, and provide Spanish and Chinese translations for each topic, as described below [41].

XSL•FO
RenderX

The Flesch-Kincaid Grade Level (FKG) system [42] was used to assess the readability of content produced by the LLMs. The FKG level is a readability test designed to indicate how difficult a text is to understand. It calculates the grade level required for someone to comprehend the text. The FKG is based on word length and sentence length, providing a numerical score that corresponds to US grade levels [42]. The National Institutes of Health (NIH) and the American Medical Association (AMA) suggest that patient education materials should be written at a reading level no higher than the sixth grade [43]. This recommendation is in place to guarantee that the information is reachable by a broad spectrum of individuals, encompassing those with limited health literacy. Therefore, our research targets an FKG level of 6 to align with this guidance.

We set a 250-word limit for our educational content, recognizing that cancer survivors and their caregivers are frequently preoccupied with treatment schedules and daily responsibilities, leaving them with limited time for reading [44]. This word limit is designed to ensure that participants can complete the reading within 5 minutes, making the task both manageable and feasible within their schedules.

Furthermore, it is shown that prompts exert a considerable impact on the responses generated by LLMs [45]. Therefore, we compared different prompts, including both textual and bulleted formats, to determine which approach yields better results.



The prompts we used are as follows:

1. Textual format: “Please summarize the following content in Flesch-Kincaid Grade level of 6 and under 250 words: [original text]”
2. Bulleted format: “Please summarize the following content into bullet points in Flesch-Kincaid Grade level of 6 and under 250 words: [original text]”
3. Spanish translation: “Please translate the following content into Spanish: [tailored text]”
4. Chinese translation: “Please translate the following content into Chinese: [tailored text]”

Expert Evaluation

We assembled a panel of 9 oncology experts, comprising 4 oncology professors, 4 doctoral students, and 1 medical resident. Among them, all are fluent in English, with 4 experts proficient in Chinese and 1 proficient in Spanish. Each response generated by the LLMs was evaluated by at least 2 experts to ensure a comprehensive assessment, except for the Spanish translation task, which was evaluated by a single expert. The panel conducted several Zoom meetings: the initial meeting provided training on content evaluation, and 3 additional meetings were held to discuss the results and feedback. Each expert was assigned 10 topics to evaluate and was required to provide feedback on the errors committed by the LLMs. These experts critically reviewed and annotated the LLM-generated content using a web-based Cohort Adjudication and Data Annotation (CADA) application [34] (Figure 1) developed by our team.

Figure 1. A screenshot of Cohort Adjudication and Data Annotation application.

Data Sources

Our primary sources for content generation were cancer survivors and caregiver education materials from the National Cancer Institute and the National Comprehensive Cancer Network guidelines [46,47]. We selected 30 distinct topics covering a range of content such as fatigue, depression, anxiety, pain, cognitive impairment, nutrition, physical activity, healthy lifestyle, family communication, coping skills, and more. The selection of topics was informed by insights from our previous qualitative interviews with cancer survivors and their caregivers [48] and an extensive review of the literature [49-51]. We identified the key areas of interest and specific needs of cancer

XSL•FO
RenderX

survivors and their caregivers with limited health literacy or language barriers, resulting in these 30 topics.

Appraisal Criteria

Based on a previous study of evaluating responses from LLMs [34], we formulated a set of multidimensional criteria to thoroughly assess the performance of LLMs, which include adherence to a word limit of 250 words, achieving a reading level as per the FKG of below 6, and quality assessment: (1) clarity (ie, ease of understanding in the response); (2) accuracy (ie, the response does not contain errors, like medical or language errors, that could negatively impact patients and their caregivers); (3) relevance (ie, the response is fully grounded in the materials we provided); (4) completeness (ie, the response encompasses all critical points from the materials); (5) comprehensibility (ie, the response is understandable that readers can apply it to their daily routine).

In terms of word limit, "yes" refers to a word limit within 250 words, and "no" refers to a word limit of more than 250 words. The reading level was evaluated using "yes" for an FKG level ≤6; "partial" for an FKG level of 6 to ≤8; and "no" for an FKG level >8). The FKG level was calculated by the Python package Textstat (version 0.7.3, Azu). For the quality assessment criteria, we implemented a scoring system in which evaluations were quantified based on their alignment with the expected outcomes. A score of 2 was assigned for "yes" evaluations, indicating full compliance; a score of 1 was given for "partial" evaluations, reflecting partial compliance; and a score of 0 was allocated for "no" evaluations, indicating noncompliance. The quality assessment included 5 criteria (1-5), each contributing a maximum of 2 points, for a total possible score of 10. The overall quality assessment ranged from 0 to 10, with 0 representing the absence or lowest quality and 10 indicating the highest quality. For translation tasks, "yes" indicates a completely accurate translation, "partially" refers to a generally correct and understandable translation with minor errors, and "no" refers to a completely inaccurate translation containing incorrect or misleading information. Accuracy scores are calculated as the proportion of evaluations labeled as "yes."

Data Analysis

Descriptive analyses were conducted to determine the frequencies, percentages (for word limit, reading levels, and translations), mean and SDs (for quality scores) of major variables. Quality scores were determined by calculating the mean scores for each criterion and then obtaining the overall scores through their summation. To compare the differences in each model or prompt, we used ANOVA or chi-square tests, as applicable. Values of $P<.05$ were considered to indicate a significant level. All analyses were conducted using Python statistical packages.

Ethical Considerations

The study protocol (STUDY00004750) was approved with exemptions by the institutional review board at Emory University. Oral consent was obtained from 9 oncology experts, as no protected health information was collected. All participants were informed of the voluntary nature of their participation and their right to withdraw at any time without consequence. No protected health information or personally identifiable information was collected, and all research data were anonymized to maintain confidentiality. Study materials were securely stored and accessible only to authorized research team members. Participants did not receive any monetary or nonmonetary compensation for their involvement. The study was conducted in accordance with the US Common Rule (45 CFR 46) [52].

Results

Overall Performance of Large Language Models

In this study, 360 annotation values were collected from 9 experts. Overall, LLMs have shown excellent performance in tailoring content based on our criteria. For word limit, 267/360 responses (74.2%) were within the word limit (less than 250 words) set for the task. The result indicates the excellent ability of LLMs to produce responses that adhere to specified word limit requirements. Regarding reading levels, LLMs demonstrated moderate performance, with 105/360 responses (29.2%) fully meeting the specified FKG level (FKG level ≤6), 107/360 (29.7%) being partially satisfactory (FKG level of 6 - 8), and 148/360 (41.1%) not aligning with the provided FKG level (FKG level >8).

LLMs demonstrated consistently high average scores across all quality criteria (total score: 8.933 out of 10). The highest average score achieved was 1.91 on relevance, highlighting the LLMs' ability to generate content that was highly pertinent to the given prompts. The lowest average score observed was 1.58 out of 2 in the category of completeness, indicating a moderate adherence to providing responses that capture all key points. In the translation tasks, the LLMs demonstrated high performance, with 87/90 accuracy translations (88%) for Spanish and 73/90 (81%) for Chinese translation.

Three Generative Pretrained Transformer Models Comparisons: GPT-3.5 Turbo, GPT-4, and GPT-4 Turbo

GPT-4 demonstrated a superior capability in adhering to the specified word limit, with 101/120 responses (84.2%) falling within 250 words (Table 1). In contrast, GPT-3.5 Turbo and GPT-4 Turbo exhibited a relatively lower proficiency, with 86/120 (71.7%) and 80/120 (66.7%) responses meeting the word limit, respectively. As shown in Table 2, when comparing the models based on word limit, the chi-square test demonstrated a significant difference among the three models (P=.006).

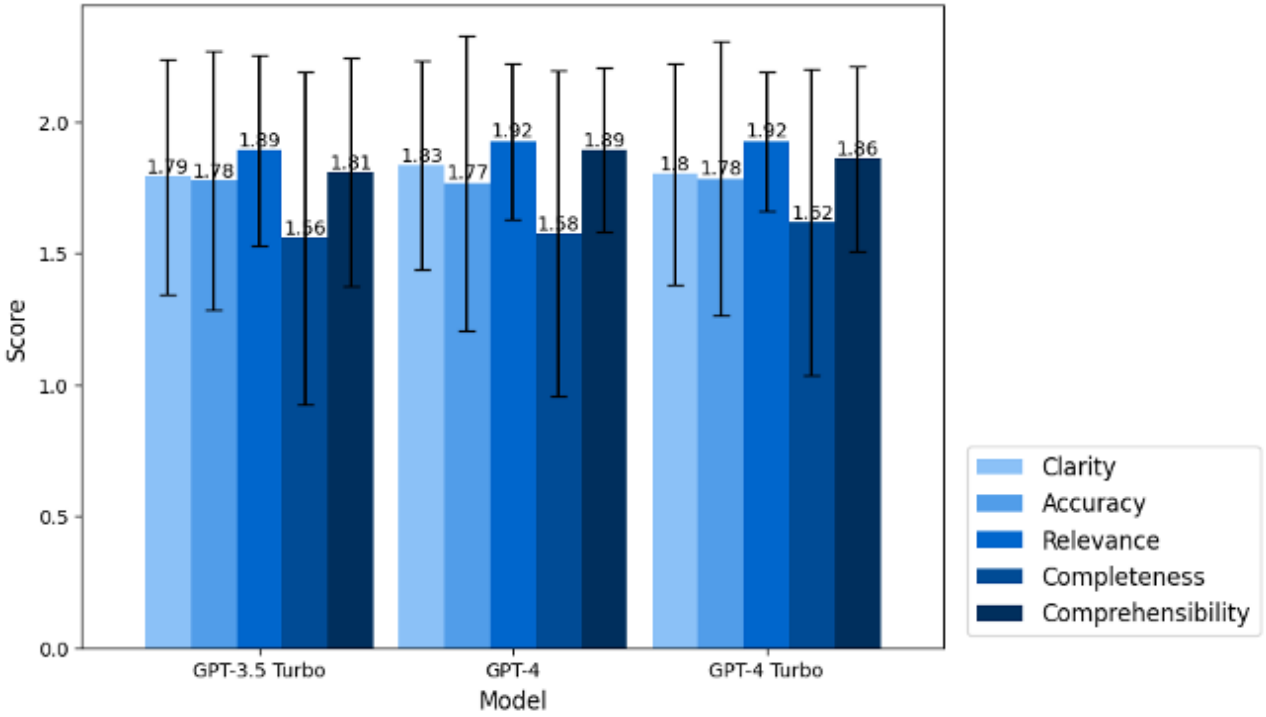
[a] PR(>F): probability that the F-statistic is greater than the observed value under the null hypothesis.

[b] —: not applicable.



Regarding the assessment of reading level, GPT-4 Turbo met the required FKG level of 6 in 51/120 (42.5%) cases, nearly doubling the performance of the other 2 models: 26/120 (21.7%) for GPT-4 and 28/120 (23.3%) for GPT-3.5 Turbo. The result indicated significant discrepancies among the models in adherence to the specified reading level (P<.001), with GPT-4 Turbo performing better compared with the other 2 models.

In terms of quality assessment, each of the LLMs attained a high score exceeding 8.8 out of 10, with GPT-4 and GPT-4 Turbo achieving 8.992 and 8.983, respectively, and GPT-3.5 Turbo trailing slightly at 8.825. Upon evaluation of each criterion, the performance of all models was found to be similar (Figure 2). The application of ANOVA tests to each criterion revealed no significant differences among the 3 models (P=.57).

In the translation tasks, GPT-4 Turbo exhibited perfect accuracy with a 30/30 (100%) success cases in Spanish translation, whereas GPT-4 and GPT-3.5 Turbo exhibited slightly lower, yet commendable success rates of 29/30 (97%) and 28/30 (93%), respectively. For the Chinese translation task, GPT-4 outperformed the other models with an accuracy of 26/30 (87%). In contrast, GPT-3.5 Turbo and GPT-4 Turbo achieved 23/30 (77%) and 24/30 (80%), respectively. The 3 models did not show a significant difference in the translation task (P=.48).

XSL•FO
RenderX

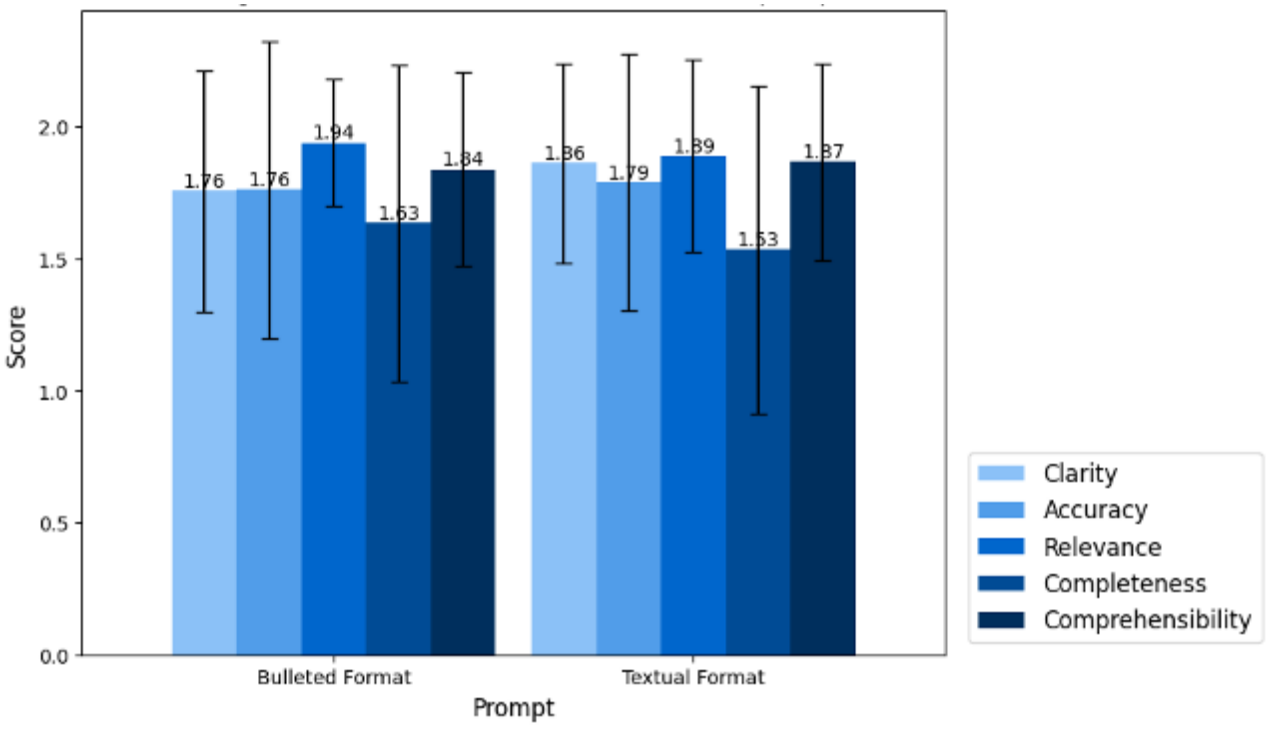


Figure 2. Assessment scores on each criterion between different models. GPT: Generative Pretrained Transformer.

Two Different Prompt Comparisons: Textual and Bulleted Formats

We compared 2 prompting methods in terms of word limits, reading level, and quality assessment. The major difference noted in the comparison of the 2 prompts was that responses generated from prompt 2 (bulleted format) were superior in adhering to the target word limit. Specifically, 153/180 responses (85%) from prompt 2 successfully achieved the word limit, in contrast to 114/180 responses (63.3%) from prompt 1 (textual format) that fully satisfied the word limit. Using prompt 1 resulted in only 56/180 responses (31.1%) meeting our desired reading level, with a slight decrease to 49/180 (27.2%) for prompt 2. For the 5 quality criteria, both prompts achieved high scores (Figure 3). Upon performing an ANOVA test to assess the differences in performance between the 2 prompts (Table 2), it was found that the variations between them were not significant (P=.939). However, the 2 prompt formats demonstrated a significant difference in the clarity criterion (P=.03).

Figure 3. Assessment scores on each criterion between different prompts.

XSL•FO
RenderX

Error Analysis

The errors that LLMs committed were categorized into inaccurate scope, inaccurate definition, inaccurate expression, meaningless points, and inaccurate word. Some examples are shown in Table 3.

Table . Error cases and analysis.

Model	Topic	Output	Error type	Reason
GPT-3.5 Turbo	Nutrition	"It advises limiting animal-based food, processed food, and alcohol consumption."	Inaccurate scope	The chapter only mentions to limit red meat, not all animal-based foods (says it can make up half or less of diet).
GPT-3.5 Turbo	Sexual Health Issues in Men with Cancer	"It is still important to maintain intimacy with a partner."	Inaccurate expression	The tailored content sounds a little judgmental whereas the original document says, "probably still important" and is less assuming.
GPT-3.5 Turbo	Relaxation	"多喝液体"	Inaccurate word	Based on the English sentence: " Drinking plenty of liquids", "liquids" can be better translated into "水."
GPT-4	Mindfulness	"These practices involve focusing the mind on present sensations, such as breathing, a sound, or an image."	Inaccurate definition	It seems to define meditation and mindfulness in one overarching definition, which only defines meditation. The model merged definitions of MBSR[a] and MBCT[b] together and did not include difference between types.
GPT-4	Family Communication	"El apoyo de la comunidad podréda ser beneficioso durante este difícil período."	Inaccurate word	Based on the English sentence: "Support from the community might be beneficial during this difficult period. ", "difícil período" should be "período difícil"
GPT-4 Turbo	Making a Difference	"Learning: Educating yourself about cancer can empower you to assist others. Resources are available online, by phone, and in print."	Meaningless point	The customized content falls short in terms of actionability. The purpose of tailoring content is to educate patients and caregivers, rather than expecting them to educate themselves.

[a]MBSR: Mindfulness-based stress reduction.

[b]MBCT: Mindfulness-based cognitive therapy.

A common error observed with LLMs is their tendency to integrate their own knowledge and interpretation rather than adhering strictly to the provided materials, such as an inaccurate scope. For instance, when the text specified "to limit red meat." in the Nutrition topic, GPT-3.5 Turbo inaccurately generalized this advice to "limiting animal-based food." This interpretation is not entirely correct, as animal-based food encompasses more than just red meat, including white meat such as chicken, which the original material did not intend to restrict.

Other observed errors involve inaccurate expressions. For instance, in the Sexual health issues in men with cancer topic, the original content suggested, "It is probably still important to maintain intimacy with a partner." However, GPT-3.5 Turbo revised this to "it is still important to maintain intimacy with a partner." This alteration results in a tone that may seem judgmental, deviating from the original's more tentative stance.

An example of inaccurate definition was identified within the Mindfulness topic, where GPT-4 defined meditation and mindfulness in one overarching definition for meditation. It also merged definitions of mindfulness-based stress reduction and mindfulness-based cognitive therapy without highlighting differences between the mindfulness interventions.

LLMs may also include information that, while accurate, might not be actionable for patients. For instance, in the Making a difference topic, GPT-4 Turbo correctly sourced from the material that "Learning: Educating yourself about cancer can empower you to assist others. Resources are available online, by phone, and in print." However, this information becomes less useful in the absence of specific links or directions that could guide patients on where to start their education.

Finally, with respect to translation quality, the primary error observed related to inaccurate word choice. In particular, when

XSL•FO
RenderX

an English term offers multiple potential translations, LLMs often encounter difficulty in selecting the most contextually appropriate option. For example, in the Relaxation topic, GPT-3.5 Turbo translated “多喝液体" as “drink more liquids.” Although “液体" does literally translate to “liquids,” the more natural and contextually appropriate term would be “水.”

Discussion

Principal Findings

To our knowledge, this is the first study to evaluate the capability of LLMs in tailoring educational content for cancer survivors and their caregivers with limited health literacy or language barriers. In our study, all 3 LLMs have demonstrated overall excellent performance in most criteria. The more advanced GPT-4 family models showed better overall performance compared with GPT-3.5 Turbo. GPT-4’s high adherence to word limits and GPT-4 Turbo’s better compliance to reading level compliance proved their ability to meet our requirements when tailoring content. Prompting GPTs to produce bulleted-format content is likely to result in better educational content compared with textual-format content. All models exhibit strong capability in generating highly relevant content. However, they fall short in terms of completeness. Overall, it is proven that LLMs are highly effective in tailoring, condensing, and translating educational content for cancer survivors and their caregivers with limited health literacy or language barriers. These findings inform future versions of LLMs to focus more on the reading level and completeness of their output and the development of tailored intervention materials for cancer survivors and their caregivers. These promising results also indicate that LLMs can be a valuable tool in making educational content more accessible and comprehensible to diverse patient populations.

The capabilities of LLMs in text analysis have been well studied. For example, our previous study [34] examined the potential of LLMs to categorize clinical concepts from patient notes. Yet, this study focused solely on the LLMs’ comprehension of patients’ conditions from clinical notes rather than educational content. Study by Veen et al [53] assessed approaches for LLMs to summarize clinical texts. Although it demonstrated overall preferred performance, especially GPT-4, over human experts, the study was limited to the summarization of radiology report findings and confined to 3 attributes: completeness, correctness, and conciseness, whereas our study expanded on this topic by evaluating LLMs against 7 distinct criteria. Furthermore, none of the existing studies focus on education regarding supportive care in cancer, whereas our innovative findings make a significant contribution to the literature in this field.

Despite the excellence of LLMs in adhering to specified word limits and generating high-quality content, several challenges remain. One notable area where LLMs struggle is in adjusting the reading level of the content to accommodate patients from various educational levels. The content tailored by LLMs often does not meet the intended FKG level. This oversight implies that some individuals might find the content overly complex, potentially hindering their understanding of health information and educational content [54,55]. Addressing this challenge is essential for maximizing the applicability of LLMs and ensuring that all cancer survivors receive the support they need to manage their cancer effectively. In future work, in-context learning could be used to offer more detailed guidance to LLMs, focusing on the potential vocabularies frequently appeared in content exceeding the specified FKG level of 6. In addition, retrieval-augmented generation could be implemented to embed vocabularies aligned with an FKG level of 6, thereby enhancing the model’s performance.

It is also observed that the accuracy of Spanish translations is significantly higher than that of Chinese translations. This finding is expected, given the abundance of Spanish content available on the internet compared with Chinese content that can serve as training materials. Previous studies [56,57] have shown that LLMs’ performance in different languages has a clear correlation with the proportion of each language in the pretraining corpus. Without fine-tuning, LLMs have a much higher performance in high-resource languages like German, French, and Spanish, and a significantly lower performance in low-resource languages like Kannada, Occitan, and Western Frisian [56,57]. In future work, integrating high-quality bilingual medical corpora that includes parallel texts of patient education materials, clinical guidelines, and culturally tailored health information could be a promising approach. Fine-tuning LLMs on such specialized corpora may provide them with domain-specific vocabulary and context, thereby increasing their ability to produce accurate, culturally sensitive translations.

The educational content errors could be detrimental to cancer survivors and their caregivers by providing false physical activity, diet, or medication suggestions. Therefore, content produced by LLMs should undergo thorough evaluation and validation before the content is used in a clinical setting [38,58,59]. Our analysis has identified multiple errors in the outputs from LLMs, including inaccuracies in scope, expression, and definition. These types of errors can lead to the dissemination of misinformation, potentially causing harm to patients [60]. Therefore, such inaccuracies must be identified, analyzed, and rectified to prevent any negative impacts on patient care. Our study also detected some meaningless points that were not actionable in LLMs’ outputs, which could increase the reading burden on patients and their caregivers. Recommendations should highlight actionable information for cancer survivors and their caregivers to reduce the burden of reading educational content, emphasizing the need for LLMs to prioritize the use and applicability of the information they present. In addition, education content should be evaluated and validated by content experts before the it is available to cancer survivors and their caregivers.

In addition, both Xiao et al’s and Asthana et al’s studies [36,37] evaluated the performance of fine-tuned LLMs in nonclinical environments. Their results highlighted the significant potential of LLMs in summarizing general text through the adoption of advanced fine-tuning techniques. It is possible that fine-tuning could further improve LLMs’ capacity to analyze educational content specifically tailored for groups such as cancer survivors and their caregivers with limited health literacy or language barriers. With this additional data, more advanced fine-tuning techniques such as instruction tuning [57,61,62] and

XSL•FO
RenderX

parameter-efficient fine-tuning [63] can be implemented, and are likely to further enhance the performance.

Limitations

While the study has shown promising results, it has several limitations. First, the dataset size remains relatively small, which could restrict the generalizability of the findings to broader topics. Second, we lacked participant assessment. Relying solely on oncology experts to evaluate the outputs from LLMs might create obstacles when applying these findings to actual cancer patients and their caregivers. While our oncology experts deeply value caring for disadvantaged populations with limited health literacy or language barriers, it's important to note that they are highly educated and might have unintentional biases. This could make it challenging for them to view educational content from the perspective of individuals with low health education and literacy. Therefore, future studies can be broadened to include a wider range of educational topics and additional annotations from cancer patients and their caregivers. Third, this study was limited to zero-shot learning because of the lack of training data. It could be expanded by collecting tailored content from human experts to serve as training data to incorporate few-shot learning and fine-tuning techniques. In addition, chain-of-thought reasoning and in-context learning also present promising avenues for future exploration, particularly because they do not rely on additional training data. Finally, due to a limited number of annotators from diverse backgrounds, our study was only able to evaluate translations in 2 languages. Our analysis suggests that translation performance can vary between languages, influenced by the availability of content in each language. It is important to note that these findings may not be generalizable to languages spoken by smaller populations, where content availability and linguistic nuances could further affect translation accuracy. In future research, more extensive evaluations of translation tasks involving other languages, especially low-resource languages, should be conducted to expand the applicability.

Conclusions

The study highlights the application of LLMs in cancer care while being cognizant of their potential limitations. All 3 LLMs have demonstrated overall high capability in tailoring educational content for cancer survivors and their caregivers with limited health literacy or language barriers. GPT-4 family models showed better overall performance compared with GPT-3.5 Turbo. Prompting GPTs to produce bulleted-format content can generate better educational content. The findings from this study inform the intervention development and implementation in cancer symptom management and health equity. Additional studies are warranted to expedite the integration of AI-driven solutions into clinical settings.

Acknowledgments

The study was supported by the Oncology Nursing Foundation Research Grant (2022 RE03). The authors also appreciate the support from Emory University School of Nursing and Winship Cancer Institute. During the preparation of this work, the authors used ChatGPT solely to improve language and readability. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Data Availability

The datasets generated and analyzed during the current study are available upon reasonable request. The corresponding author [YL] will coordinate requests for data and maintain documentation for requests and distributions. Emory University has an established Institutional Data Use Agreement that can easily be adapted and deployed.

Authors' Contributions

DL developed scripts to collect responses from LLMs, build the annotation platform, and wrote the manuscript. XH provided technical support and helped with manuscript writing. CX, JB, ZB, LL, CW, LB, and SW performed annotations and supported manuscript writing. DB supported the development of the annotation platform and manuscript writing. YL supervised the entire project, provided valuable insights, and contributed to manuscript writing and revisions. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The introduction of oral anticancer therapies has, at least partially, shifted treatment from clinician-supervised hospital care to patient-managed home regimens. However, patients with breast cancer receiving oral cyclin-dependent kinase 4/6 inhibitor therapy still require regular hospital visits to monitor side effects. Telemonitoring has the potential to reduce hospital visits while maintaining quality care.

Objective: This study aims to develop a digital home-based health care center (DHHC) for acquiring electrocardiograms (ECGs), white blood cell (WBC) counts, side effect photo documentation, and patient-reported quality of life (QoL) data.

Methods: The DHHC was set up using an Apple Watch Series 6 (ECG measurements), a HemoCue WBC DIFF Analyzer (WBC counts), an iPhone SE (QoL assessments and photo documentation), a TP-Link M7350-4G Wi-Fi router, and a Raspberry Pi 4 Model B. A custom-built app stored and synchronized remotely collected data with the clinic. The feasibility and acceptance of the DHHC among patients with breast cancer undergoing cyclin-dependent kinase 4/6 inhibitor therapy were evaluated in a prospective, single-arm, monocentric study. Patients (n=76) monitored side effects—ECGs, WBC counts, photo documentation, and QoL—at 3 predefined time points: study inclusion (on-site), day 14 (remote), and day 28 (remote). After the study completion, patients completed a comprehensive questionnaire on user perception and feasibility. Adherence to scheduled visits, the success rate of the data transfer, user perception and feasibility, and the clinical relevance of remote measurements were evaluated.

Results: Mean adherence to the planned remote visits was 63% on day 14 and 37% on day 28. ECG measurements were performed most frequently (day 14: 57/76, 75%; day 28: 31/76, 41%). The primary patient-reported reason for nonadherence was device malfunction. The expected versus the received data transfer per patient was as follows: ECGs: 3 versus 3.04 (SD 1.9); WBC counts: 3 versus 2.14 (SD 1.14); QoL questionnaires: 3 versus 2.5 (SD 1.14); and photo documentation: 6 versus 4.4 (SD 3.36). Among patients, 81% (55/68) found ECG measurements easy, 82% (55/67) found photo documentation easy, and 48% (33/69) found WBC measurements easy. Additionally, 61% (40/66) of patients felt comfortable with self-monitoring and 79% (54/68) were willing to integrate remote monitoring into their future cancer care. Therapy-induced decreased neutrophil count was successfully detected (P<.001; mean baseline: 4.3, SD 2.2, $\times 10^9$/L; on-treatment: 1.8, SD 0.8, $\times 10^9$/L). All-grade neutropenia and corrected QT interval prolongations were detected in 80% (55/68) and 2% (1/42) of patients, respectively.

Conclusions: Adherence to scheduled remote visits was moderate, with nonadherence primarily attributed to device-related complications, which may have also affected the success rate of data transfer. Overall, patients considered remote monitoring

XSL•FO
RenderX

useful and feasible. The prevalence of reported adverse events was comparable to existing literature, suggesting clinical potential. This initial feasibility study highlights the potential of the DHHC.

breast cancer; digital medicine; telehealth; remote monitoring; cyclin-dependent kinase 4/6 inhibitor; CDK4/6 inhibitor; mobile phone

Introduction

Systemic therapies, such as chemotherapy, targeted therapies, or immunotherapy, are accompanied by several side effects that require continuous and regular monitoring. Monitoring of side effects is particularly important for treatment approaches involving oral medications, as these medications are usually administered at home. Side effect monitoring enables the early detection and prevention of adverse events and is crucial for treatment benefits and adherence to the treatment schedule [1].

In recent years, highly effective oral therapeutic options, such as cyclin-dependent kinase 4 and 6 inhibitors (CDK4/6i), have been introduced for the treatment of patients with hormone receptor-positive breast cancer. Even though these CDK4/6is are administered orally, the associated side effects, such as neutropenia, leukopenia, and corrected QT interval (QTc) prolongation, necessitate regular hospital appointments [2-10]. For patients in rural areas, such appointments present unique challenges. Due to a lack of nearby medical facilities, patients often have to travel long distances to receive adequate medical care, which can be physically and emotionally taxing. If these patients do not receive comprehensive cancer care, including side effect monitoring, they may experience delayed detection and treatment of serious adverse events, potentially affecting their quality of life (QoL), and survival outcomes [11-15]. Remote monitoring and eHealth options may be particularly valuable in addressing these challenges [16].

Remote, home-based monitoring using eHealth options such as apps, wearables, or mobile medical devices can allow health care providers to monitor patients' health status and potential side effects in real time. Multiple studies have shown that remote monitoring of cancer treatment symptoms is linked to improved QoL, fewer treatment disruptions, and increased survival rates [13,17-19]. However, most of these studies included only remote patient-reported outcome assessments. Recently, home- and sensor-based technologies, including various wearable devices, have also been shown to be suitable tools for cancer care. For example, smartwatches and fitness trackers have been used to promote physical activity and monitor heart rate [20-23].

Even though remote monitoring systems, eHealth apps, and wearable devices have the potential to improve cancer care, several challenges still need to be addressed. In particular, while current smartwatch technologies can monitor heart rate and record Food and Drug Administration–approved electrocardiograms (ECGs), and several apps on the market can be used to document patient-reported outcomes, assess QoL, and track side effects, using these individual tools alone is not sufficient to provide comprehensive medical care at home. Therefore, we aimed to establish a digital home-based health care center (DHHC) that includes a smartphone to assess QoL and document visual side effects, a smartwatch to record ECGs, and a white blood cell (WBC) system to analyze a patient's WBCs from capillary blood. The primary focus of this study was to assess the feasibility and acceptance of such a digital remote system for cancer care in order to tailor a patient-centered solution and improve access to quality care.

Methods

Study Design

The SMILER study ("Smart and Interactive Home-Based Health Care Project—A Digital Healthcare Feasibility Pilot Study Including the d.H2C2 Initiative") was a monocentric, single-arm study with the primary objective of assessing the feasibility of remote WBC and ECG measurements, as well as data transmission of remote measurements using a DHHC. The study was conducted at the Department of Gynecology and Obstetrics at the University Hospital Erlangen (Universitätsklinikum Erlangen) in Germany.

Inclusion criteria were an indication for or current treatment with a CDK4/6i (regardless of cycle number) and an age of 22 years or older (in accordance with the minimum age requirements for the use of DHHC devices as specified by their respective manufacturers). Patients could not be included if they had pacemakers or implantable cardioverter defibrillators, severe blood coagulation disorders, abnormalities in the last known ECG, or other comorbidities that might impact at-home measurements. The study was conducted between October 2021 and December 2022.

CDK4/6i therapy was administered according to the Summary of Product Characteristics. All patients who had an indication for CDK4/6i therapy, as determined by the treating physician, or who were already receiving CDK4/6i therapy, were screened for the SMILER study. In general, palbociclib was started at 125 mg/day, and if necessary, reduced to 100 or 75 mg/day. Ribociclib was started at 600 mg/day, and if required, reduced to 400 mg/day and subsequently to 200 mg/day. Abemaciclib was initiated at 300 mg/day, with potential dose reductions to 200 and 100 mg/day.

After study inclusion, participants received the DHHC along with an initial introductory training. Study-relevant measurements were scheduled at study inclusion (on-site), day 14 (d14—remote), and day 28 (d28—remote; Figure 1A). At each of these time points, WBC counts, ECGs, and QoL (Q-5D-3L questionnaire) were monitored. Additionally, photo documentation of the ankle (as an exploratory subproject for the capturing of 3D photo data) was included. The ankle was

XSL•FO
RenderX

chosen as an accessible location for photo acquisition where peripheral edema, a known side effect of CDK4/6i therapy, could be detected.

All participants continued their routine treatment and attended scheduled clinical visits. After the study had been completed, participants filled out a paper questionnaire on the acceptance, success rate, and usability of the DHHC. The SMILER study concluded after the predefined number of patients had been enrolled.

Ethical Considerations

The study was conducted in accordance with local guidelines and regulations. Ethical approval was obtained from the Ethics Committee of the Friedrich-Alexander Universität Erlangen-Nürnberg (April 1, 2020: 47_20B). The original protocol was amended on March 22, 2022, to also include patients already receiving CDK4/6i therapy, as previously, patients could only be enrolled in the SMILER study at the start of CDK4/6i therapy. This change was implemented to improve study enrollment. All participants provided written informed consent before participation. Participants did not receive any form of compensation. Data were collected in a pseudonymized manner.

Outcomes

The outcomes of the study were: adherence (primary objective), success rate of the data transfer, usability and feasibility of the DHHC, and clinical relevance. Adherence to scheduled study visits was assessed as the percentage of patients who completed the prescheduled measurements (±2 d around the scheduled visit). The success rate was evaluated as the number of remotely transferred measurements relative to the number of expected measurements. Feasibility was assessed based on the number of enrolled versus screened patients. Furthermore, patient-reported perception and usability were evaluated using a comprehensive paper-based questionnaire at study completion, which included Likert-scale questions on perceived usability. Usability was further assessed using the System Usability Scale (SUS), with the SUS score calculated as the respective outcome measure [24]. Clinical relevance was determined by the number of detected adverse events, specifically neutropenia and QTc prolongations.

DHHC Hardware

The DHHC consisted of the following components: (1) Apple Watch Series 6 (Apple Inc., Cupertino, CA, United States) for ECG measurements, (2) HemoCue WBC DIFF Analyzer (HemoCue AB, Ängelholm, Sweden) for WBC counts, (3) iPhone SE (Apple Inc.) for QoL questionnaire completion and photo documentation, (4) mobile Wi-Fi router TP-Link M7350-4G (TP-Link Corporation Limited, Düsseldorf, Germany), and (5) Raspberry Pi 4 Model B (Raspberry Pi, Cambridge, United Kingdom).

Two cases were designed to enable safe and easy transport and handling of the devices (Figure 1B-F). Case 01 (Figure 1B-D; Fa. Karl Lettenbauer, Erlangen, Germany) featured a plastic base plate to accommodate the HemoCue WBC DIFF Analyzer, Raspberry Pi, power cable, and socket strip (installed under the upper mount with a 14412 - 02 detachable partition protected against tampering), along with all device cables. The iPhone, Apple Watch, and TP-Link were integrated into a raised platform. Case 02 (Figure 1E-F) consisted of a case from MyCaseBuilder.eu (FOAM Studio, the Netherlands) with a custom Pro-Cell interior and Prolife Soft-Cell foam lid. For both cases, the devices could be charged, and WBC measurements could be taken without the devices being removed from the cases.

SMILER.one App and DHHC Software

The custom study app (SMILER.one) was developed by REFINIO GmbH, based on their REFINIO ONE architecture. REFINIO GmbH is a German company specializing in custom software for secure data collection. The software was programmed in TypeScript on NodeJS and had platform abstractions for internet browsers and Linux. All ONE instances of a person formed a federation called the Internet of Me (IoM), where identities, connections, settings, and content could be distributed, ensuring that devices only needed to be registered once.

Data storage in ONE was based on HTML files containing microdata objects, which were stored in individual files within the file system or in the IndexedDB of the browser or WKWebView on mobile devices. The objects were named according to the hash of their content and referenced through their name in parent objects. Data transmission in ONE was facilitated through WebSocket services provided by a commServer, which established connections between devices. Data sharing was based on subtree sharing and conflict-free replicated data types, with encryption occurring at the individual instance level.

The DHHC integrated several REFINIO ONE software components, including the Web Server, SMILER.one Mobile, SMILER.one Pi, SMILER.one Headless, and the SMILER.one representational state transfer application programming interface (REST API). The Web Server was installed and configured with HTTPD software (nginx) to deliver the SMILER.one Progressive Web App and mobile content. SMILER.one Mobile managed patient data in a WebView (IndexedDB) on an iPhone and synchronized it with the clinic's data (SMILER.one Headless) and the patients' IoM instances. It also imported and synchronized ECG data from the Apple HealthKit on patients' iPhones. SMILER.one Pi was installed on the Raspberry Pi, importing WBC data from the HemoCue device. Within the patients' IoM, it acted as a headless replication of the patients' complete dataset. SMILER.one Headless mirrored all settings and storage operations of SMILER.one Mobile and SMILER.one Pi while incorporating the SMILER.one REST API, which provided pseudonymized patient data to the clinic's SQL server (Figure S1 in Multimedia Appendix 1).

The SMILER.one app served as a user interface for study participants. The app featured a registration or login mechanism with password encryption to ensure restricted private access. Within the app, the "My Tasks" screen allowed participants to complete visits (questionnaires, photo documentation, ECG measurements, and WBC counts) and provided an overview of upcoming tasks (Figure 1G). In the "Data Archive," completed data were stored and could be viewed by the participants (Figure 1H). The "Blood Count Chart" displayed a chart of WBC readings from the HemoCue device (Figure 1I). Patients also had the option to enter additional data beyond the scheduled remote visits under "Voluntary Data Entry."

Data Management

Data from the DHHC was stored in a dedicated relational database on an SQL server. The data transfer from the REFINIO

XSL•FO
RenderX

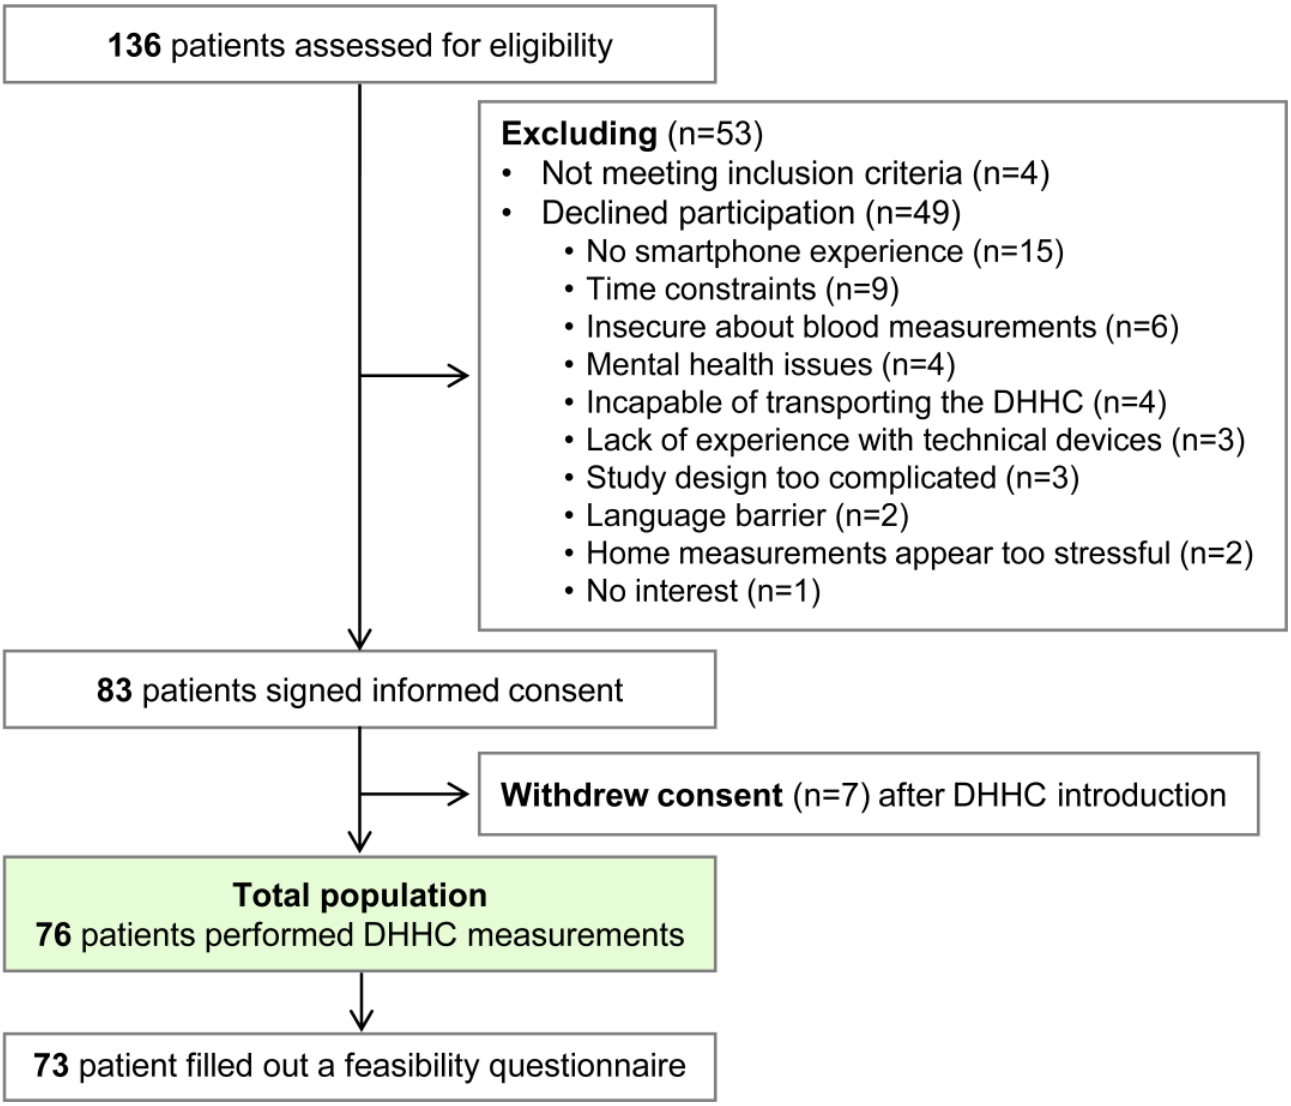
REST API to the SQL database was facilitated via the JSON data format. Parsing of the JSON-formatted data and transformation into a relational tabular format were performed within the database itself. QTc times were calculated from the transmitted ECG curves using the Fridericia formula by a physician (PK). Based on the QTc times and measured neutrophil concentrations, the severity of QTc prolongations and neutropenia was graded according to the Common Terminology Criteria for Adverse Events version 5.0. Clinical data were collected by trained staff and documented in an electronic case report form. Data monitoring was conducted using automated plausibility checks and on-site monitoring. These data included patient and tumor characteristics, as well as details on treatment approaches.

Statistical Analysis

Sample size calculations for this feasibility study were based on the assumption that 70% of ECG measurements and 65% of WBC counts would be successful (two 1-sided exact binomial tests with a significance level of α=2.5%). A total of 212 ECG measurements and 237 blood measurements were required to demonstrate this with a power of 90%, which corresponded to 80 patients, each with three ECG measurements and three WBC count measurements.

The majority of the presented statistics are descriptive. Categorical variables are reported as counts and percentages, while continuous variables are presented as mean (SD). Missing values were omitted from analyses. A 2-sided Wilcoxon rank sum test was used for statistical comparisons, with $P \leq .05$ considered statistically significant. Data are presented as box plots, displaying the median, IQRs, and whiskers representing the 5th and 95th percentiles. Statistical analyses were performed using R (version 4.2.1; The R Foundation) or SPSS Statistics (version 29.0.1.0; IBM Corp). Likert plots were generated using the R library “Likert” (version 1.3.5). The distribution of Likert scale questionnaire scores ranged from 1=I fully agree to 5=I do not agree at all.

Results



Feasibility

Recruitment

Between October 2021 and December 2022, 136 patients with breast cancer were screened for eligibility. Of the 132 eligible patients, 49 patients declined participation. The most common reasons for nonparticipation were lack of smartphone experience (n=15) and lack of time to complete study procedures (n=9; Figure 2). Of the 83 patients who provided informed written consent, 7 patients withdrew their consent after being introduced to the DHHC (Figure 2), resulting in 76 patients who participated in the SMILER study. Of these 76 patients, 73 (96%) completed the questionnaire on acceptance, success rate, and feasibility of the home-based procedures at study completion.

Patient Characteristics

Participants had a mean age of 58.9 (SD 9.74) years (Table 1). The majority of participants received CDK4/6i for advanced or metastatic disease (54/76, 71%). Abemaciclib was administered to 49% (37/76) of participants, while 39% (30/76) and 12% (9/76) of participants received ribociclib and palbociclib, respectively. Additional baseline patient characteristics are listed in Table 1. Case 01 was assigned to 33% (25/76) of participants, while Case 02 was provided to 67% (51/76) of participants.

Adherence

Study-relevant measurements were scheduled at study inclusion (introductory on-site training), day 14 (d14—home-based), and day 28 (d28—home-based). The average adherence was 63% at d14±2d and 37% at d28-2d (Figure 3). Among individual remote measurements, ECGs were recorded most frequently (d14±2d: 57/76, 75%; d28-2d: 31/76, 41%), followed by QoL questionnaires (d14±2d: 54/76, 71%; d28-2d: 36/76, 47%).

Figure 3. Patients who submitted data during the study. The percentage of patients who submitted data via the digital home-based health care center is presented for various measurements, including ECG, WBC counts, photo documentation, and QoL questionnaires. The bars indicate the data submission rates over the study duration, with dark gray sections representing planned study visits (day 14, d14; and day 28, d28) and light gray sections representing the days around the study visits (d14±2, d28-2). The mean percentage represents the average data submission rate for each study visit. ECG: electrocardiogram; QoL: quality of life; WBC: white blood cell.

The most common patient-reported reasons for missing scheduled tasks were device malfunction (ECG or Apple Watch: 11/36, 31%; WBC or HemoCue: 16/43, 37%; photo documentation: 5/31, 16%), handling issues (ECG or Apple Watch: 11/36, 31%; WBC or HemoCue: 12/43, 28%; photo documentation: 2/31, 6%), and time constraints (ECG or Apple Watch: 10/36, 28%; WBC or HemoCue: 10/43, 23%; photo documentation: 11/31, 35%; Table 2). Among the patient-reported reasons listed as "other reasons" for failed adherence were "measurements were not performed in time," "unsure about the handling of the devices," "no reception," "mentally too stressed," or "sickness." Among these, "unsure about the handling of the device" was the most common other reason for missed WBC measurements (5/13, 38%).

XSL•FO

[a]Patients could indicate their reason for nonadherence to the questionnaire upon completion of the study. Participants could choose from predefined reasons, with multiple answers possible. Responses were only requested from study participants who indicated that they were unable to perform all scheduled measurements. When selecting "other reasons," patients could provide additional details in a blank text field.

[b]ECG: electrocardiography.

[c]WBC: white blood cell count.

[d]N/A: not applicable.

Success Rates

Throughout the 28-day study period, data transfer was expected from three ECG measurements, three WBC measurements, three QoL questionnaires, and six photo documentations (each ankle per time point) per patient. The mean number of successfully transferred data per patient during the study period was 3.04 (SD 1.9), ECGs was 2.14 (SD 1.1), WBC measurements was 2.5 (SD 1.1), QoL questionnaires and photo documentations was 4.4 (SD 3.4; Table S1 in Multimedia Appendix 1).

Study participants indicated how many times a measurement had to be repeated before it was successfully completed in the end-of-study questionnaire. The highest number of repetitions was required for WBC measurements, with an average of 1.07 (SD 1.0) additional measurements per patient (Table S1 in Multimedia Appendix 1).

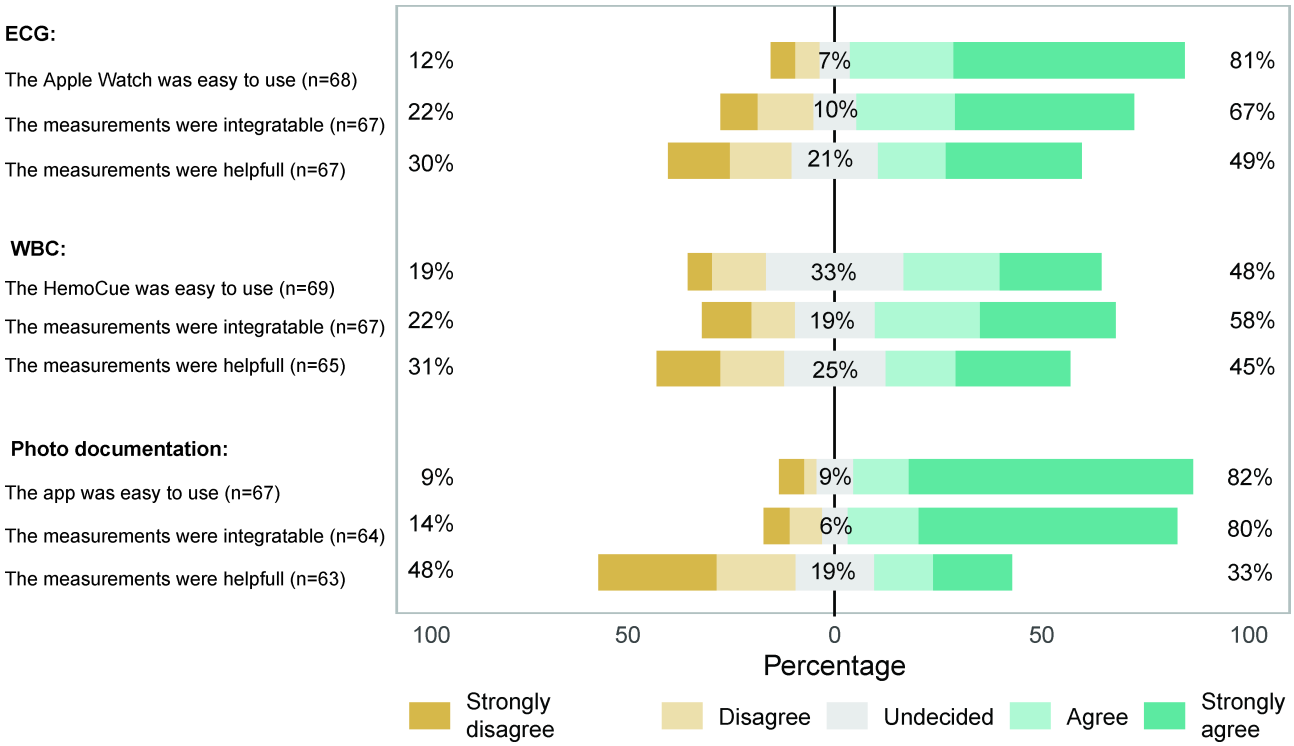
Identified Problems

Several issues may have affected both study adherence and success rates. The incidence of any type of DHHC malfunction (ie, problems with either WBC or ECG measurements) was 24% (18/76) during first use (initial introductory training) and 43% (33/76) during remote measurements (as reported in the end-of-study questionnaire).

For WBC measurements, handling problems with the HemoCue microcuvettes requiring repeat WBC measurements were observed in 8 (out of 76, 10%) patients during on-site training. Of these, 2 (25%) patients also reported handling issues with WBC measurements during remote monitoring. Patients who experienced handling problems during initial training (8/76) and those who reported handling issues as a reason for nonadherence to remote monitoring visits (12/76) appeared to be older than those without handling issues (initial training: handling issues 59.4, SD 9.6 y vs no handling issues 55.0, SD 10.3 y; *P*=.30; remote monitoring: handling issues 63.3, SD 7.6 y vs no handling issues 58.1, SD 9.9 y; *P*=.02).

At initial training, technical problems with the HemoCue WBC DIFF IEC 61010 system (failure to turn on or instant error messaging) prevented measurements in 4 (out of 76, 5%) patients and data transfer from the HemoCue WBC DIFF IEC 61010 system to the SMILER.one app and SQL server in 11 (out of 76, 14%) patients. In two of these cases (2/11, 18%), a lack of an internet connection was reported.

Defective data transfer occurred more often with Case 02 than Case 01 (8/11, 73% vs 3/11, 27%) and in two instances, the same Case 02 DHHC experienced defective data transfer. However, the case type was not statistically associated with defective data transfer (*P*=.80). Among 3 (out of 11, 27%) DHHCs with defective data transfer during on-site training, study participants also reported an inability to perform remote measurements due to device malfunction.



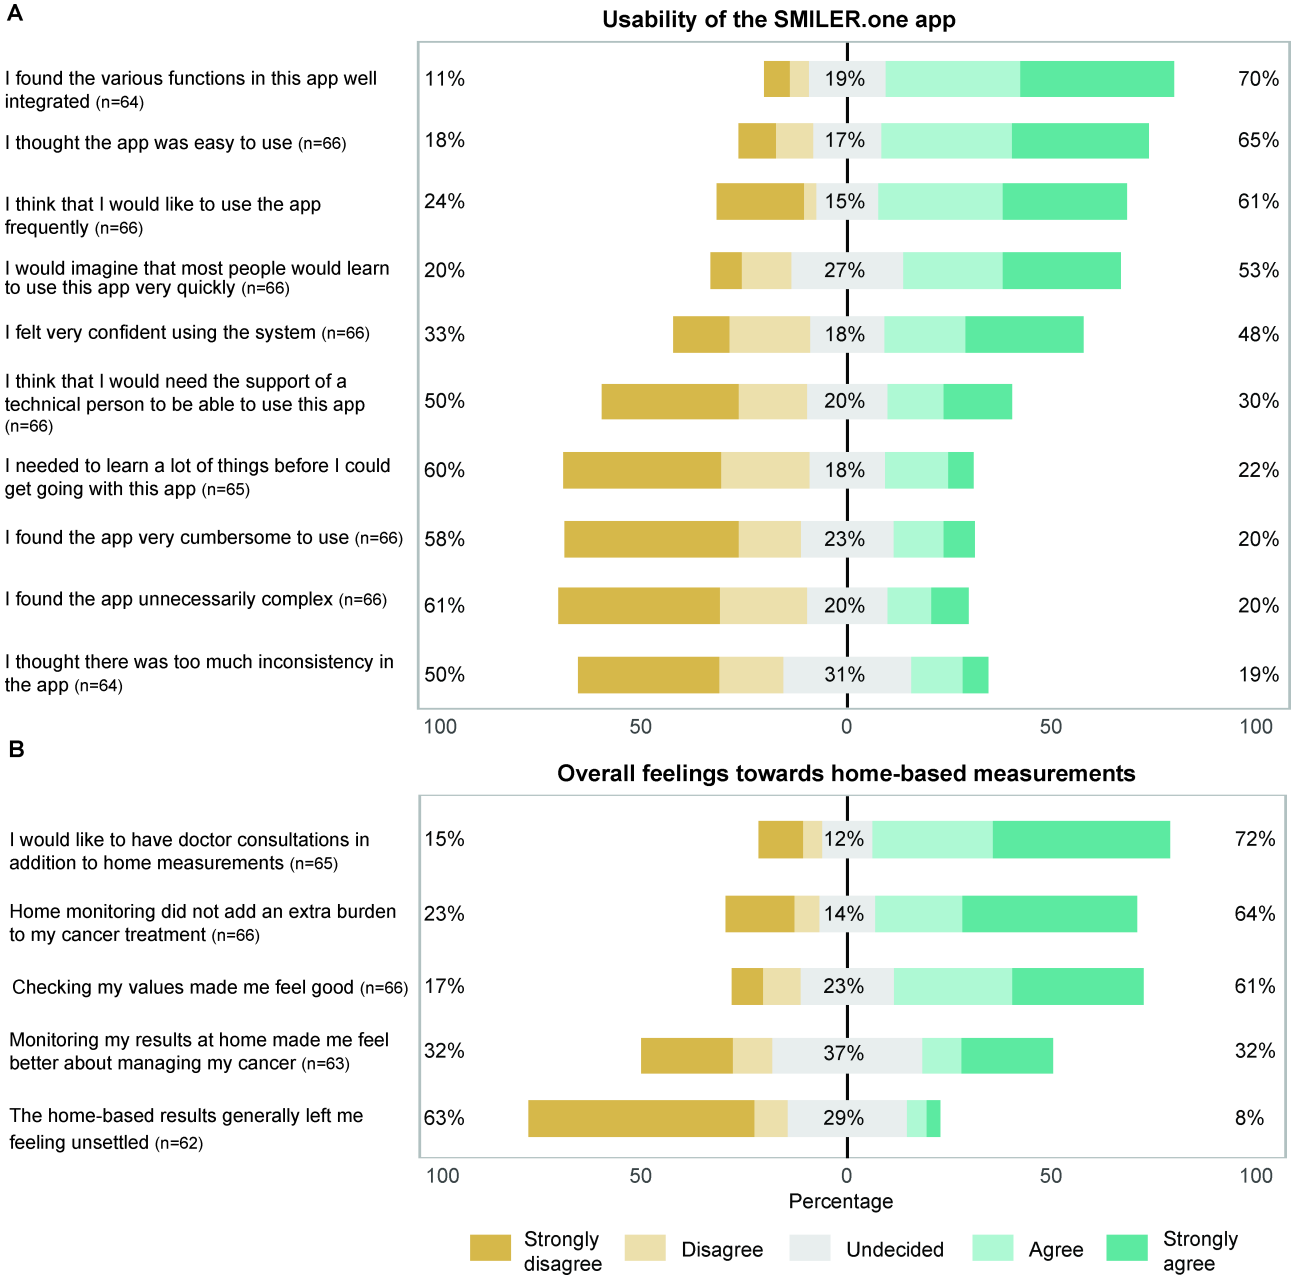
For ECG measurements, defective data transfer was observed in 3 (out of 76, 4%) individual DHHCs during on-site training, and 1 (out of 3, 33%) patient also reported subsequent technical issues with the Apple Watch during remote monitoring. Additionally, 4% (3/76) of patients reported being unable to use the SMILER.one app due to a lack of mobile network coverage.

User Perception of Feasibility

The feasibility of home measurements was assessed at study completion. While most patients found photo documentation with the SMILER.one app (55/67, 82%) and ECG measurements with the Apple Watch (55/68, 81%) easy to use, only 48% (33/69) of patients found the HemoCue System easy to use. Good integration into daily life was most commonly reported for photo documentation (51/64, 80%), followed by ECG (45/67, 67%) and WBC measurements (39/67, 58%). ECG and WBC measurements were seen as helpful by 49% (33/67) and 45% (29/65) of patients, respectively, while only 33% (21/63) of participants found photo documentation helpful (Figure 4).

XSL•FO
RenderX

Figure 4. User perception of the home-based health care system's feasibility. The Likert scale illustrates responses from a user perception questionnaire regarding the Apple Watch ECG, HemoCue WBC measurement, and photo documentation via the SMILER.one app. ECG: electrocardiogram; WBC: white blood cell.



Acceptance

User acceptance of the SMILER.one app and the perception of the DHHC and its future use were assessed through the end-of-study questionnaire. For the SMILER.one app, 70% (45/64) of participants agreed that the technical features of the app were well-integrated, 65% (43/66) of participants found the app easy to use, and 61% (40/66) of participants could imagine using the app regularly. However, 30% (20/66) of participants reported that they would need technical support to use the app (Figure 5A). The corresponding SUS score for the SMILER.one app was 65.2. Regarding the DHHC, 61% (40/66) of participants felt comfortable with self-monitoring, and 64% (42/66) of participants did not consider home-based measurements to be an additional burden. However, 72% (47/65) of participants stated that they would like to have consultations with a doctor in addition to the DHHC measurements (Figure 5B).

When asked about their intention to use, 79% (54/68) of participants expressed a willingness to use home measurements as part of their future cancer care. Additionally, 79% (54/68) of participants were willing to collect data for research purposes at home using the SMILER.one app. Participants who were unwilling or reluctant to integrate the DHHC and remote data collection into future cancer care reported that they would need help interpreting results (9/17, 53%), were concerned about the time required for data collection (11/23, 48%), and would experience difficulties or stress related to the technology (home-based measurements: 3/17, 18%; collection and sharing of data with the SMILER.one app: 7/23, 30%; Table S2 in Multimedia Appendix 1).

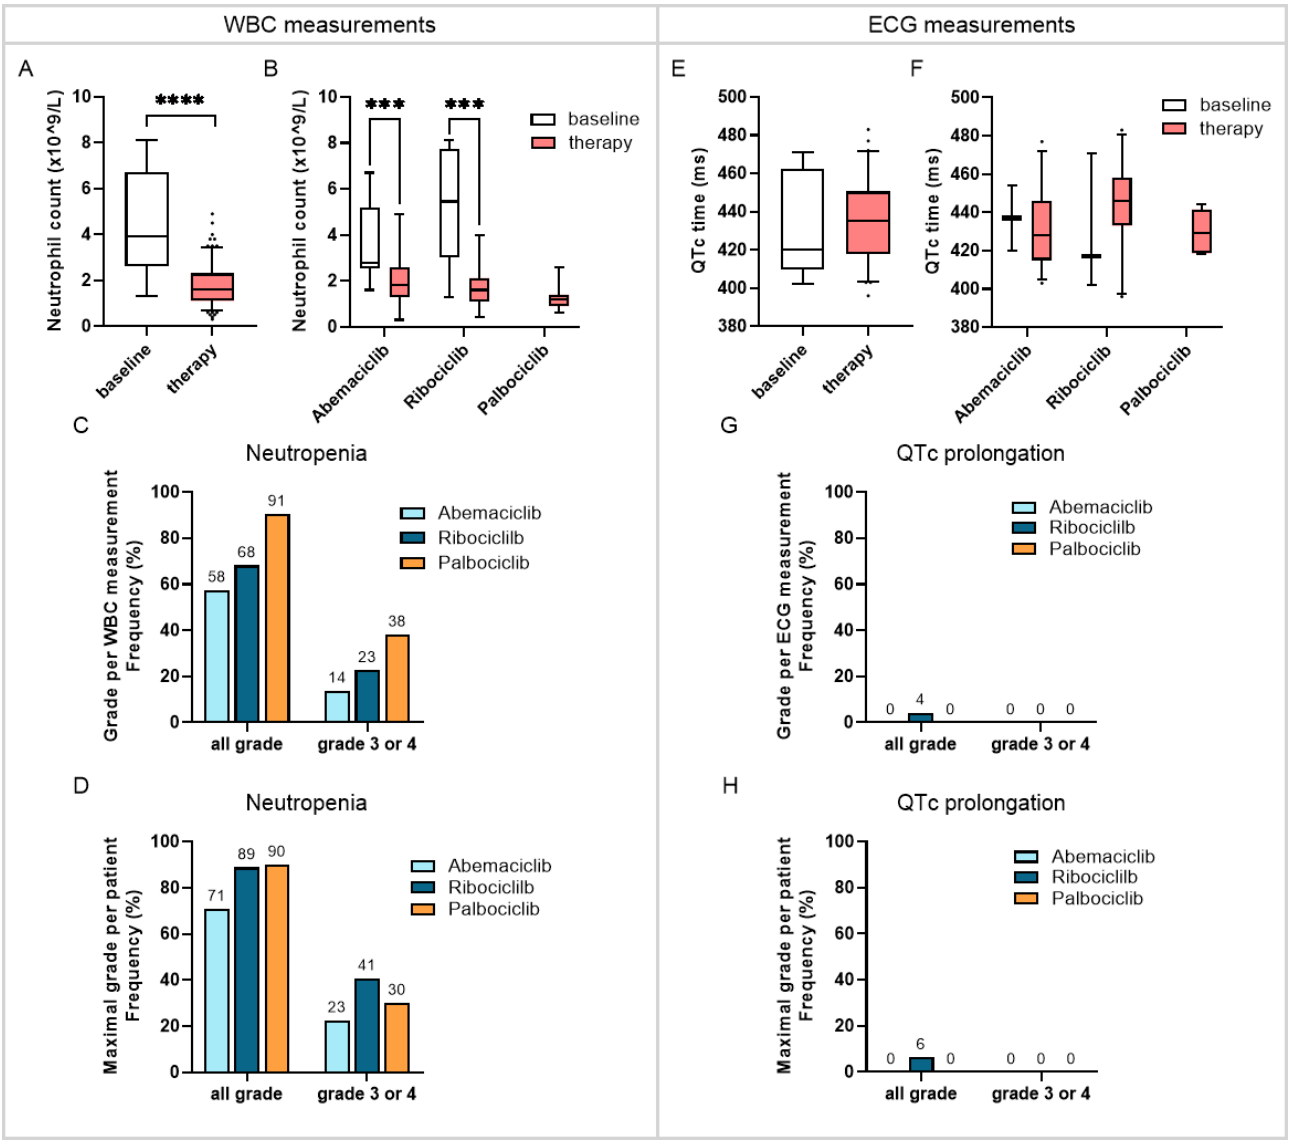
Clinical Relevance



Transferring routine monitoring from the clinical setting to the at-home environment requires the evaluation of WBC counts and ECG values. WBC monitoring is necessary for all CDK4/6i therapies, whereas ECG monitoring, specifically assessing QTc intervals, is required only for ribociclib treatment.

Compared with patients initiating CDK4/6i therapy, those who had been on treatment for more than five days had lower neutrophil counts (mean 4.3, SD 2.2, $\times 10^9$/L vs mean 1.8, SD 0.8, $\times 10^9$/L; P<.001; Figure 6A), regardless of the specific CDK4/6i received (Figure 6B). Mild neutropenia (grade 2) was present in 27% (45/167) of WBC measurements, while severe neutropenia (grade 3 or 4) was detected in 20% (34/167) of WBC measurements (Table S3 in Multimedia Appendix 1). At the patient level, this corresponded to 32% (22/68) of patients experiencing mild neutropenia and 31% (21/68) presenting with severe neutropenia under CDK4/6i therapy, as detected by the DHHC (Table S4 in Multimedia Appendix 1). Regarding individual CDK4/6i therapies, grade 3 or 4 neutropenia was observed in 23% (7/31) of patients receiving abemaciclib, 41% (11/27) of those on ribociclib, and 30% (3/10) of those on palbociclib (Figure 6C-D and Table S5 in Multimedia Appendix 1).

QTc time remained stable under CDK4/6i therapy (Figure 6e,f). Only one measurement indicated QTc prolongation, corresponding to 2% (1/61) of all quantifiable QTc times from ECG measurements and 2% (1/42) of all patients (Tables S5 and S6 in Multimedia Appendix 1). The affected patient was receiving ribociclib (Figure 6g.h and Tables S5 and S6 in Multimedia Appendix 1).

Figure 6. Detection of adverse events with the digital home health care center. Neutrophil counts were measured with the HemoCue system. (A) Neutrophil count before starting CDK4/6i therapy (n=15) and under therapy (>5 days; n=167) of all combined WBC measurements and (B) per CDK4/6i (baseline: abemaciclib, n=9; ribociclib, n=6; under therapy: abemaciclib, n=80; ribociclib, n=66; palbociclib, n=21). Neutropenia was graded according to CTCAE version 5.0. Frequency of neutropenia under CDK4/6i therapy as (C) the grade of each individual WBC measurement (abemaciclib, n=80; ribociclib, n=66; palbociclib, n=21) and (D) the maximal observed grade per patient (abemaciclib, n=31; ribociclib, n=27; palbociclib, n=10). QTc times were calculated from ECGs measurements with the Apple Watch. (E) QTc time before starting CDK4/6i therapy (n=5) and under therapy (>5 days; n=61) of all combined ECG measurements and (F) per CDK4/6i (baseline: abemaciclib, n=2; ribociclib, n=3; under therapy: abemaciclib, n=33; ribociclib, n=23; palbociclib n=5). QTc prolongation was graded according to CTCAE version 5.0. Frequency of QTc prolongation under CDK4/6i therapy as (G) the grade of each individual QTc measurement (abemaciclib, n=33; ribociclib, n=23; palbociclib n=5) and (H) the maximal grade per patient (abemaciclib, n=21; ribociclib, n=16; palbociclib n=5). ***$P \leq .001$, ****$P < .001$; Wilcoxon rank sum test. CDK4/6i: cyclin-dependent kinase 4/6 inhibitor; CTCAE: Common Terminology Criteria for Adverse Events; ECG: electrocardiogram; QTc: corrected QT interval; WBC: white blood cell.

Discussion

Principal Findings

The SMILER study assessed the feasibility and acceptance of a DHHC system for remote monitoring of side effects in patients with breast cancer receiving CDK4/6i therapy. Adherence to remote study visits was moderate and declined over time, with patients who were unable to perform measurements reporting time constraints and handling issues with the devices. Correspondingly, the transfer of remotely collected data was lower than expected, and patients reported needing to perform repeat measurements. Self-monitoring of ECGs and side effect photo documentation was considered easy to use and easily integrable into daily life, whereas WBC measurements were generally found to be more challenging. Nevertheless, the majority of participants felt positive about self-monitoring and expressed a willingness to incorporate home-based measurements into their future cancer care. Additionally, home-based ECG and WBC measurements were effective in detecting QTc time prolongations and neutropenia, demonstrating the clinical relevance of the DHHC.

Comparison to Prior Work

Our findings contribute to the emerging field of digital health and remote monitoring, highlighting the potential of such

XSL•FO
RenderX

interventions in improving patient care and outcomes. Patients receiving oral CDK4/6i therapy can take their anticancer medication at home; however, clinic visits remain necessary to monitor potential side effects [25-27]. Severe neutropenia (grade 3 or 4) is commonly observed under CDK4/6i therapy (ribociclib: 57% - 62% of patients in randomized controlled trials [RCTs] and 15% - 69% of patients in real-world studies [3,28-33]; abemaciclib: ~20% of patients in RCTs and 2% - 24% in real-world studies [9,31,33,34]; palbociclib: 62% - 70% of patients in RCTs and 60% - 63% in real-world studies [5,33,35-37]). Home-based WBC measurements by patients with breast cancer detected severe neutropenia in 41% of patients on ribociclib, 23% of patients on abemaciclib, and 30% of patients on palbociclib, aligning with real-world data for abemaciclib and ribociclib. Severe neutropenia under palbociclib may be underestimated due to the small number of patients receiving palbociclib in this study population. Nevertheless, these findings support the clinical relevance of home-based WBC monitoring with the DHHC.

QTc prolongation is a specific potential side effect of ribociclib therapy and has been reported in 2% - 5% of patients in the different RCTs [2-4]. In this study, prolonged QTc times were detected in one patient, corresponding to 6% (1/76 patients) of those receiving ribociclib therapy, which is in line with RCT findings [2-4]. Patients receiving abemaciclib or palbociclib did not develop QTc prolongations during the SMILER study.

Further research is needed to evaluate the clinical and psychological effects of home-based monitoring. A recent randomized trial involving patients with breast cancer receiving palbociclib therapy found that patients using an eHealth app (CANKADO PRO-React) experienced a longer time to QoL deterioration compared with those who did not use the app [19]. This study further highlights the clinical potential of digital interventions in improving patient outcomes and well-being. Notably, mobile health apps developed by health care professionals appear to have the highest overall quality [38], emphasizing the need to integrate clinical expertise with innovative digital approaches.

User perception and acceptance of the DHHC were generally positive. Both the ECG measurements with the Apple Watch and the photo documentation with the SMILER.one app were considered easy to use. The integration of the measurements into daily life was perceived favorably. However, concerns about result interpretation, time-consuming data collection, and technological difficulties were reported as barriers to engagement. The SUS score also indicated moderate usability. These findings emphasize the importance of providing adequate support and guidance to patients in using and interpreting the collected data. Additionally, the preference for consultations with health care professionals highlights the need to integrate home-based monitoring with clinical care and medical expertise. For future developments, integrating a communication tool into the provided app could be a suitable solution. Implementing a direct, automated digital feedback system based on home-based measurements could offer patients a more immediate and informed understanding of their health status, potentially reducing the need for frequent consultations with doctors. Interestingly, both using medical apps for medical questions and consulting Google appear to result in comparable adverse emotional and behavioral effects associated with cyberchondria [39].

Virtual and remote trials often have high dropout rates or low adherence to visits [40-42]. In the SMILER trial, adherence rates varied across different measurements, with the highest adherence for QoL questionnaires and lower adherence for WBC and ECG measurements. Additionally, adherence to the scheduled remote visits gradually declined over the course of the study, with 63% on d14±2d and 37% on d28-d2. Notably, several patients performed home-based measurements before or after the scheduled visits. Some patients also reported being unable to complete the final measurement due to the automatic deactivation of the SMILER.one app at the end of the study (day 28), suggesting that adherence rates may be underestimated.

The most common reason for missed scheduled measurements was device malfunction, with both technical and handling issues reported. Notably, the incidence of any type of malfunction during the first on-site introductory training was 24% (18/76 participants), and patients reported problems with 43% (33/76) of the DHHCs during remote monitoring. Not all patients with partially malfunctioning DHHC devices at the introductory training reported subsequent issues during remote monitoring, which may indicate that these devices were functional again during remote measurements or that the patient-reported failure rate was incomplete. Technical problems with the HemoCue device and the lack of an internet connection may partly explain DHHC malfunctions. Although the underlying cause of defective data transfer could not be definitively determined, server issues and complications with the Raspberry Pi software may have contributed. It is possible that unplugging the DHHC between remote measurements affected the Raspberry Pi and its software, which facilitates data transfer from the HemoCue device to the SMILER.one app. While there was no clear correlation between case design and the reported issues, data transfer problems occurred at varying rates across the different cases.

Handling problems with the HemoCue microcuvettes, such as an incomplete filling or air bubbles in the sample, was observed in approximately 10% (8/76) of patients during their first on-site WBC measurement. This is comparable to findings from another study that evaluated the feasibility of WBC self-testing with the HemoCue system in patients with cancer [43]. Additionally, handling issues during WBC measurements were associated with older age, highlighting the need for either a more intensive training session or remote assistance from a trained nurse, particularly for older patients. In general, tailoring support to specific patient needs may be essential to ensure successful implementation alongside a robust and reliable technological infrastructure.

Recruitment and patient characteristics also play a crucial role in the success of a study. In the SMILER study, only 76 out of the 136 screened women ultimately participated. Reasons for nonparticipation included lack of smartphone experience, time constraints, and concerns about performing WBC count independently. This underscores the importance of understanding the target population and their readiness to engage with digital health interventions. It is crucial to design digital

XSL•FO
RenderX

interventions in a way that ensures a lack of digital literacy does not contribute to health inequality [44,45].

Strengths

This study demonstrates several strengths in the implementation and evaluation of a DHHC system for patients receiving CDK4/6i therapy. First, it confirms the clinical relevance of remote monitoring by detecting known side effects, such as neutropenia and QTc prolongations, consistent with the established side effect profiles of these therapies. Although not designed to detect differences in the incidence of neutropenia or ECG changes between CDK4/6i, commonly known differences were observed [46]. Patients treated with ribociclib and palbociclib experienced neutropenia more frequently than those treated with abemaciclib. The only patient who had a QTc prolongation was receiving ribociclib.

Second, the study successfully integrated multiple technologies, including WBC measurement systems, smartwatches, and smartphones, into a comprehensive system tailored to the patient's needs. The high level of patient acceptance, with 79% (54/68) of participants expressing a willingness to use such systems in their future care, highlights the feasibility of this patient-centered approach. Moreover, the developed DHHC system and study findings underscore the potential of remote monitoring to reduce disparities in cancer care, particularly for patients in rural areas.

Limitations

This study has several limitations. First, the small sample size, specific patient population, and potential selection bias due to nonparticipation may limit the generalizability of the results. Second, adherence rates were suboptimal, and technical issues were encountered, highlighting challenges in implementing and maintaining home-based health care systems. Further optimization of the remote monitoring system is needed to improve usability. Additionally, a detailed analysis of the reliability of the DHHC could not be performed due to insufficient data. Third, self-reporting bias may have influenced the reported perceptions and experiences of the participants. Fourth, the short study duration limits our understanding of the long-term feasibility and acceptance of remote monitoring interventions. Fifth, the study lacked a control arm with patients receiving traditional nursing care, making direct comparisons with standard care models difficult. Sixth, as this was a pilot study, we did not predefine specific thresholds for the evaluated outcomes, such as adherence, usability, and feasibility, which limits our ability to determine whether the observed rates met predefined success criteria. Finally, this study did not include an analysis of the economic feasibility of the DHHC.

Future Directions

Based on the outcomes of this first feasibility study, several areas for improvement were identified. The technical issues encountered may be related to the DHHC devices, internet connection, server, Raspberry Pi software, and other factors that need to be addressed. Furthermore, longer-term randomized controlled studies are needed to better assess patient compliance, system reliability, and economic impact.

Conclusions

The findings of this study demonstrate that implementing remote monitoring of side effects in the care of patients with breast cancer undergoing CDK4/6i therapy is feasible. Patients with breast cancer generally accepted the idea of remote monitoring, which successfully identified clinically relevant side effects. Future studies with an improved system are required to further evaluate the potential clinical, socioeconomic, and individual benefits of this approach.

Acknowledgments

This research was partially funded by Pfizer (grand 61016789) and supported by the Bavarian State Ministry of Health and Care (grant MGP-2008 - 0003-digiOnko). Pfizer played no role in study design, data collection, analysis, and interpretation of data, or the writing of this manuscript. Adrian Kottas contributed to this publication in partial fulfillment of the requirements for obtaining the doctoral degree "Dr med."

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

HH designed the digital home-based health care center (DHHC) and the feasibility study, analyzed and visualized data, wrote the original manuscript draft, and managed and supervised the project. LAW designed the DHHC and the feasibility study, and managed and supervised the project. CG provided patients with on-site training, analyzed and visualized data, wrote the original manuscript draft, and managed the project. ME analyzed and visualized data, and performed statistical analyses. AM recruited patients for the feasibility study. AK recruited patients for the feasibility study. MK maintained the DHHC software and hardware during the feasibility study. JG and ML developed the DHHC software. KS recruited patients for the feasibility study. MR provided scientific input and designed the DHHC setup. PK analyzed electrocardiogram data. FH recruited patients for the feasibility study. MH recruited patients for the feasibility study. BV helped set up the DHHC hardware and provided scientific input. ER maintained the DHHC software and hardware during the feasibility study. CCH recruited patients for the feasibility study. MWB provided funding and infrastructure. SU supervised the data management and provided scientific input. PAF designed the DHHC and the

XSL•FO
RenderX

feasibility study, supervised the project, wrote the original manuscript draft, and provided funding. All authors reviewed the final manuscript.

Conflicts of Interest

PAF has received institutional funding from BioNTech, Cepheid, and Pfizer and personal honoraria from Novartis, Pfizer, Roche, Daiichi Sankyo, AstraZeneca, Lilly, Eisai, Merck Sharp & Dohme, Pierre Fabre, SeaGen, Agendia, Sanofi Aventis, Gilead, and Mylan for consulting, participation in advisory boards, and steering committees, or lectures. His institution conducts research for Novartis. HH received speaker honoraria from Novartis Pharma GmbH and LEO Pharma GmbH, and grant or research support from Novartis Pharma GmbH. KS received travel support from Gilead and Lilly. CCH received honoraria from AstraZeneca, Daiichi Sankyo, Eisai, Novartis, Pfizer, Roche, Gilead, and MSD, as well as support for attending meetings from Daiichi Sankyo. AK received honoraria from Gilead, as well as support for attending meetings from Lilly. CG received speaker honoraria from Novartis Pharma GmbH and ClinSol GmbH & Co. KG. MH received travel support from AstraZeneca, Lilly Deutschland GmbH, and Novartis. LAW received speaker honoraria from LEO Pharma GmbH.

Abstract

Background: Cancer-care complexity heightens communication challenges between health care providers and patients, impacting their treatment adherence. This is especially evident upon hospital discharge in patients undergoing surgical procedures. Digital health tools offer potential solutions to address communication challenges seen in current discharge protocols. We aim to explore the usability and acceptability of an interactive health platform among discharged patients who underwent oncology-related procedures.

Methods: A 4-week exploratory cohort study was conducted. Following hospital discharge, a tablet equipped with an integrated Personal Virtual Assistant (PVA) system was provided to patients who underwent oncology-related procedures. The PVA encompasses automated features that provide personalized care plans, developed through collaboration among clinicians, researchers, and engineers from various disciplines. These plans include guidance on daily specific assignments that were divided into 4 categories: medication intake, exercise**,** symptom surveys, and postprocedural specific tasks. The aim was to explore the acceptability of the PVA by quantification of dropout rate and assessing adherence to each care plan category throughout the study duration. The secondary aim assessed acceptability of the PVA through a technology acceptance model (TAM) questionnaire that examined ease of use, usefulness, attitude toward use, and privacy concerns.

Results: In total, 17 patients were enrolled. However, 1 (5.8%) patient dropped out from the study after 3 days due to health deterioration, leaving 16/17 (94.2%) completing the study (mean age 54.5, SD 12.7, years; n=9, 52% Caucasian; n=14, 82% with a gynecological disease; n=3, 18% with a hepatobiliary disease). At the study end point, adherence to care plan categories were 78% (SD 25%) for medications, 81% (SD 24%) for exercises, 61% (SD 30%) for surveys, and 58% (SD 44%) for specific tasks such as following step-by step wound care instructions, managing drains, administering injectable medications independently, and performing pelvic baths as instructed. There was an 80% patient endorsement (strongly agree or agree) across all TAM categories.

Conclusion: This study suggests the potential acceptability of the PVA among patients discharged after oncology-related procedures, with a dropout rate of less than 6% and fair-to-good adherence to tasks such as medication intake and exercise. However, these findings are preliminary due to the small sample size and highlight the need for further research with larger cohorts to validate and refine the system.

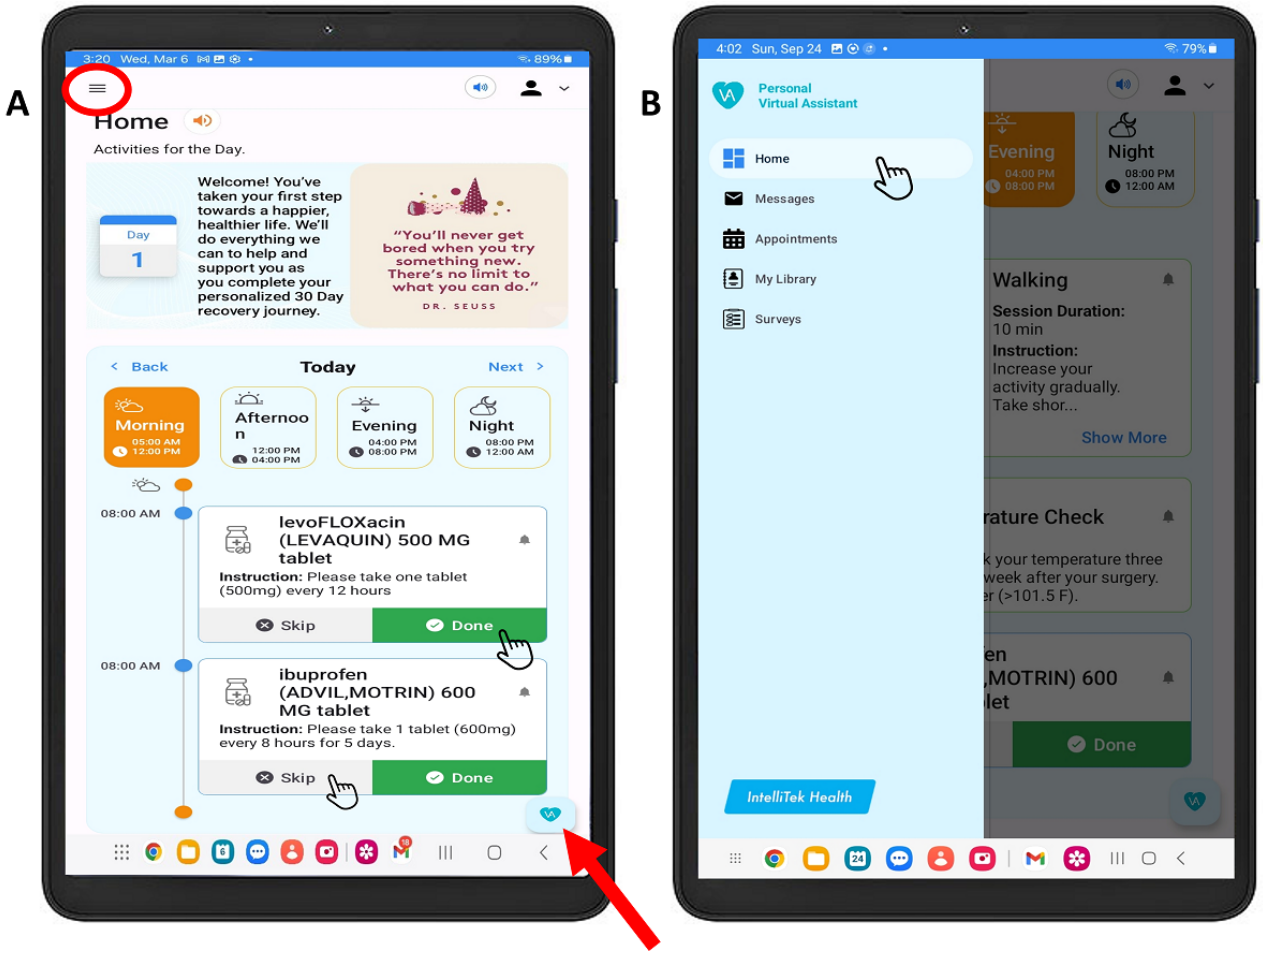
Introduction

Ineffective communication between cancer patients and health care providers can result in heightened distress, compromised quality of life [1], reduced treatment adherence [2,3], and suboptimal quality of care [4]. The complexity of cancer care, coupled with the necessity for a multidisciplinary approach, exacerbates communication challenges in this population [4,5]. For instance, multiple health care professionals including surgeons, medical and radiation oncologists, pathologists, nurses, physical therapists, social workers, and nutritionists, amongst others, can be involved in one single treatment plan [6]. This multidisciplinary approach, while essential to provide comprehensive care, often results in multiple hospital follow-ups, varied medication regimens and heterogeneous instructions, which can lead to misunderstandings, failure of cancer treatment protocols, and physical and psychological harm [4].

These communication issues in cancer patients become especially evident in those undergoing surgical procedures and transitioning from hospital to home settings [7]. Upon hospital discharge, cancer patients are commonly provided with a list of extensive instructions based on written or printed summaries, which are lengthy and tedious [8-11], making it difficult to understand and follow [12,13]. In recent years, there has been a shift toward using computer generated programs to create quick and interactive materials in the form of educational websites, audio, and videos [14]. However, they still fall short in providing interactive and bidirectional communication with health providers.

During the COVID-19 pandemic, digital health emerged as an alternative to address communication challenges through technology platforms and remote health monitoring [15]. Digital tools such as telemonitoring, telemedicine, mobile health apps, and wearable devices [16] became useful tools for improving treatment compliance, symptom management, and patient communication. However, as these tools become more widely adopted, it has become evident that numerous challenges must be addressed to improve their usability, accessibility, and effectiveness, particularly in cancer care. Key challenges in adopting digital technologies for cancer patients include disparities in technology literacy, poor integration into clinical workflows, time-intensive processes, and limited bidirectional communication. Furthermore, content may be biased if created by those without health-related expertise. To address these challenges, a collaboration between academia (Baylor College of Medicine, Houston) and industry (Smartek21, Seattle) developed an interactive digital platform, called Personal Virtual Assistant (PVA). The PVA is designed to virtually coach patients in adhering to their postoperative care plans and enhance communication after hospital discharge. This exploratory study examined the usability and acceptability of the PVA among patients undergoing oncology-related procedures, aiming to identify its successful components, adoption barriers and areas for improvement.

Methods



Personal Virtual Assistant Development

The PVA streamlines posthospital discharge care plans through 3 key elements: an interactive patient platform, a care provider portal, and a secure cloud backend interface.

The Interactive Patient Platform uses an app integrated into a tablet that works through internet connection. Upon launching the app, the home screen displays the patient daily care plan (Figure 1A), which can include “prescribed medications,” “exercises,” “symptom surveys,” and “postprocedural specific tasks.” The assignments that appear on the home screen depend on the time and day of recovery. Patients have the option to navigate through these assignments by manual selection or by using natural language voice-commands upon pressing the “voice-command” button and speaking aloud the category name. In addition, the app has an alert notification system to remind patients to complete the assignments by marking each one as “done.”

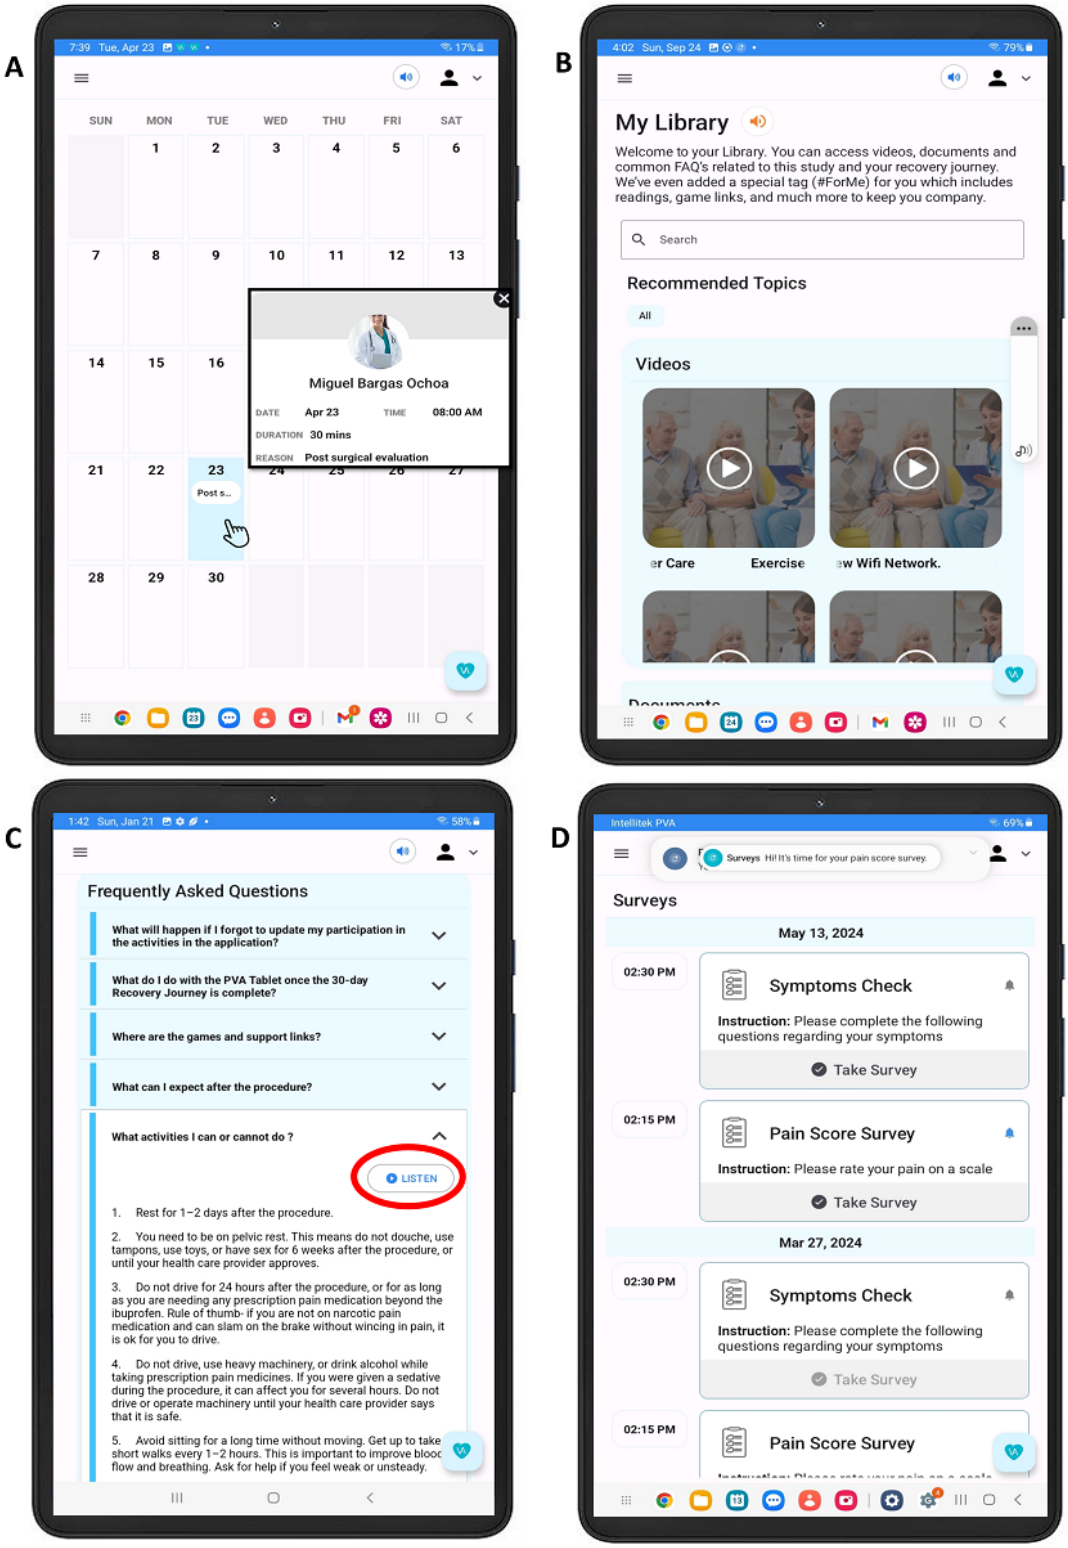

Figure 1. Personal Virtual Assistant displaying the patients' portal home screen. (**A**) Personal Virtual Assistant displaying the home screen once opened. When scrolling down, all 4 categories (medications, exercises, symptom surveys, and specific tasks) are seen. The red circle represents the button to navigation sidebar and the red arrow depicts the voice-command button. (**B**) Navigation sidebar options displaying additional navigation tools such as messages, appointments, my library, and symptom surveys.

On the top left side of the screen, a menu sidebar button is available to allow patients to navigate into other aspects of their care plan such as "Appointments," "My Library," "Messages," and "Surveys," (Figure 1B). By manually selecting or speaking aloud "Appointments" on the PVA, a calendar appears displaying upcoming clinic visits. Then, more details are available upon selecting the desired appointment (Figure 2A). The "My library" tab offers educational video content covering various topics such as guidance on how to use the tablet, exercise during cancer care, and guidance on postsurgical recovery (Figure 2B). Within this tab, a frequently asked questions section is also available, in which patients have the option to listen to them outload by pressing the "listen" button located above the text (Figure 2C). In addition, the "My Messages" tab opens a chat box where patients can communicate with the user behind the care provider portal, in this case the clinical research team. Finally, the "My Surveys" tab redirects to the home-screen symptom surveys.

XSL•FO

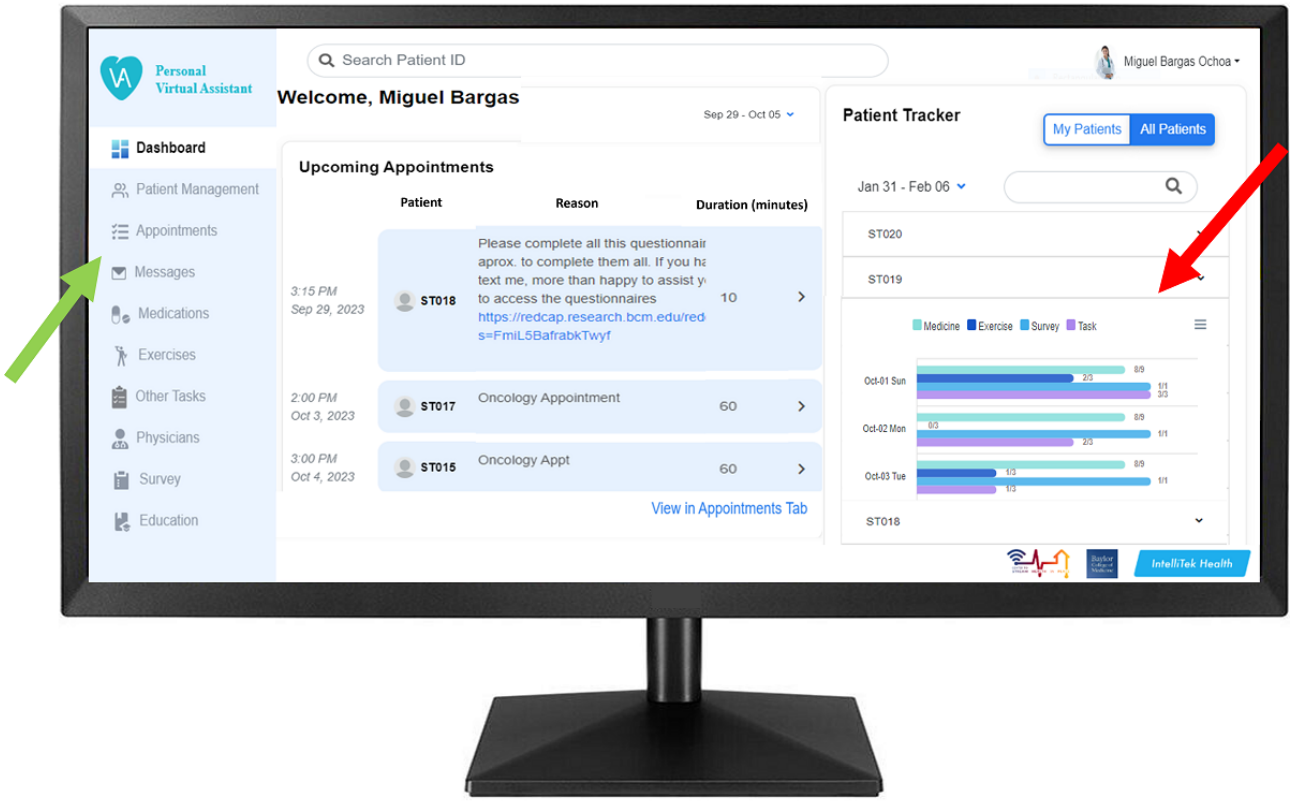

Figure 2. Personal Virtual Assistant displaying the patients' portal additional navigation tabs. (**A**) Appointment tab displays a calendar. Details appear upon clicking on the date. (**B**) My Library contains educational content about Personal Virtual Assistant and surgical recovery. (**C**) Frequently Asked Questions about technology troubleshooting and recovery process includes audio option for listening to these explanations. (**D**) Surveys patient must complete that inquire about symptoms and pain.

The Care Provider Portal is accessed through a website on any computer with an internet connection. In this study, the portal was personalized for use by the clinical research team. Once accessed by the user, a dashboard screen listing all patients with their upcoming appointments and weekly logins to the PVA system is displayed (Figure 3). On the left side of the screen, a menu sidebar including 10 different tabs allows the user to individually customize each patient care plan. For instance, in the "Patient Management" tab, the user can customize each patient's posthospital discharge instructions. In the "Medications" and "Exercises" tabs, users can manage drug dose, frequency, duration, and mobility sessions, respectively. All information provided through these tabs are stored as repositories, feeding an electronic library for future care plans.

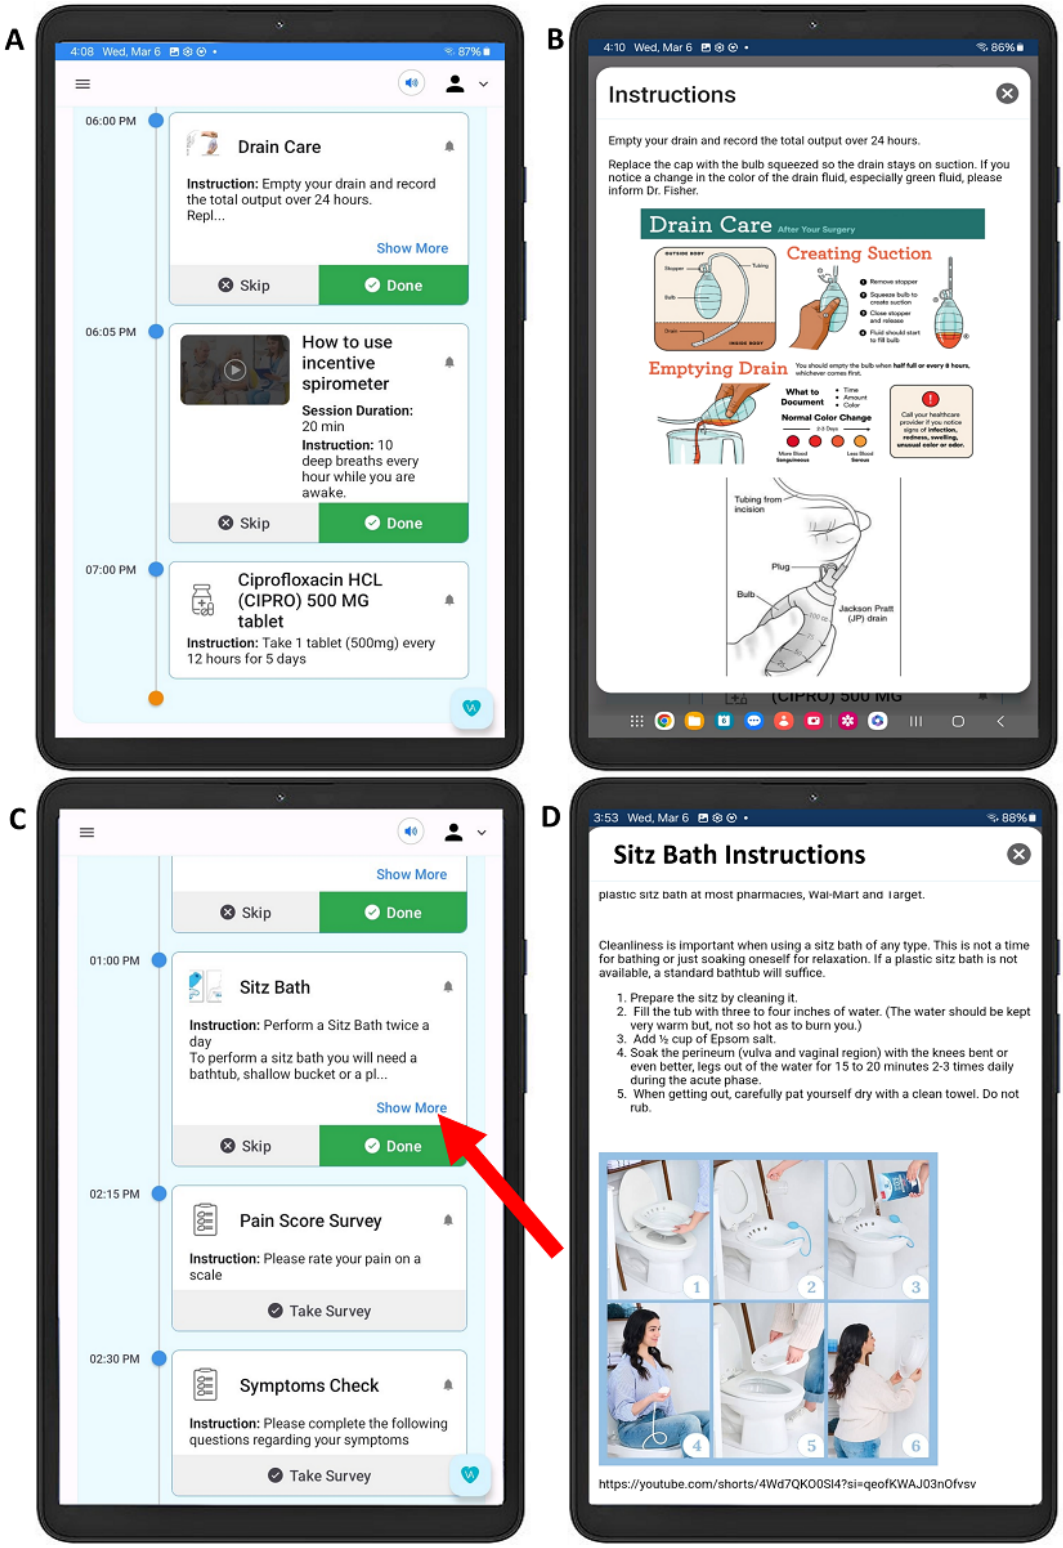
Red arrow: points at the adherence tracker, which opens a drop-down menu that shows daily adherence for each of the 4 categories in the care plan.

The cloud backend is a secure cloud-based platform that allows for instant updates to care plans, sends alerts, monitors adherence to care plans, arranges appointments, enables communication, and creates a resource library with relevant content for patients and care providers.

Integration of Clinical Content Into the Personal Virtual Assistant

The PVA clinical content was developed by a multidisciplinary team including expert physicians in surgical oncology, medical oncology, pulmonology and critical care, and medical researchers from 1 academic institution (Baylor College of Medicine, Houston). As a result, specific discharge care content was created for 2 medical specialties: hepatobiliary surgery and gynecologic oncology. Engineers from 1 industry (Smartek21, Seattle) assigned the developed content into the different PVA features previously described.



The hepatobiliary surgery content was directed to pancreatic cancer procedures (ie, distal pancreatectomies and Whipple procedure). Content displayed in the home screen included prescribed medications, exercise guidance on respiratory therapy, symptom surveys, and specific tasks detailing wound care for surgical incisions, drain management, and video guides for self-administration of medications (Figure 4A and 4B).

The gynecologic oncology content focused on hysterectomies, radical vulvectomies, and cytoreductive surgeries. Content displayed in the home screen included prescribed medications, exercise guidance on lower extremity mobility (ie, walking, calf pumps, and leg raises), symptom surveys, and specific tasks detailing step-by-step incision care, and revision of instructions for healing of pelvic and genital areas (ie, sitz baths description, Figure 4C and 4D). In addition, information on postsurgery expectations, permissible and prohibited activities, warning signs requiring immediate medical attention, and recommended over-the-counter medications were included in the “My Library” tab.

In total, 2 symptom surveys were included in the content for both specialties, 1 monitored pain through a 10-point Likert scale, and the other monitored deep vein thrombosis (DVT) and assessed bleeding signs from mucosa or surgical incisions, using questions suggested by the clinical team.

Study Design

To test the PVA's feasibility, a 4-week pilot prospective study in individuals undergoing hepatobiliary and gynecologic oncology procedures was performed between November 2022 and October 2023.

Eligible patients were aged ≥18 years old; scheduled to undergo ambulatory surgery due to suspected malignancy; willing to engage with a PVA for 4 weeks following hospital discharge. Patients were excluded if they had: major foot and ankle problems (eg, major amputation and severe neuropathy); unable to provide informed consent; documented (confirmed through

XSL•FO
RenderX

electronical medical records) major cognitive impairment, a psychiatric condition or abnormal laboratory results that, in the judgment of the clinical investigator, would interfere with the ability to participate in the study; active thrombotic condition or were using therapeutic anticoagulants; and were non-English speakers. In addition, individuals with uncorrected severe vision or hearing impairments that prevented them from effectively interacting with the PVA tablet, as determined by the investigators' judgment, were excluded.

Before their surgery, patients received a 10-minute tutorial on PVA navigation. At hospital discharge (baseline), the research team manually customized the patients' PVA content, incorporating the standard care plan detailed in their electronic medical record (EMR) by the attending surgeon. Demographic information was collected, and the patients were given the tablet with instructions to begin using it within 24hrs. After 4 weeks (end point), acceptability, and perceptions of the PVA were assessed by telemedicine, and adherence data was collected through a built-in tracking system within the PVA. Then, patients were asked to ship back the tablet. Weekly phone or video calls by the research team were performed during the study to address questions regarding the PVA functionality, content, or updates on their postoperative care according to their EMR.

Feasibility, Adherence, and Acceptability Outcomes

Feasibility was assessed by quantification of dropout rate set to ≤10% throughout the study period (4 weeks). Adherence was quantified by completion of assignments (marked as "done") in each of the 4 categories included in the care plan (ie, prescribed medications, exercises, symptom surveys, and specific tasks). For each patient, the percentage of each category was calculated by dividing the number of completed assignments by the number of days in which they were assigned during the study period.

Acceptability was assessed using a 12-item Technology Acceptance Model (TAM) questionnaire rated with a 5-point Likert Scale and ranging from strongly agree to strongly disagree, or very easy to very difficult. The TAM assessed 4 key areas: perceived ease of use, perceived usefulness, attitude toward use, and privacy concerns [19].

Furthermore, open-ended questions collected feedback on the user experience and suggestions for enhancing the PVA in Multimedia Appendix 1.

Ethical Considerations

Patients signed an informed consent at the Dan L Duncan Comprehensive Cancer Center at Baylor College of Medicine before study enrollment. The protocol was approved by Baylor College of Medicine's Institutional Review Board (protocol number: H-51654), and research procedures were conducted in accordance with the Declaration of Helsinki.

Results

Patient Characteristics

A total of 212 potential candidates were screened from the Duncan L Cancer Center at Baylor College of Medicine. Out of these, 166 were not eligible for surgery, 12 were non-English speakers, 7 did not respond to calls, and 7 declined to participate. This led to 20 eligible patients who consented and enrolled in the study, however 3 were withdrawn before study initiation due to surgery cancellation. In total, 17 patients initiated the study and received a tablet with the PVA app integrated. All patients were female (mean age 54.5, SD 12.7, years; mean BMI 33, SD 11.5, kg/m2). Out of these, 14 patients had gynecologic oncology procedures, and 3 had hepatobiliary oncology procedures. Ten out of 17 (59%) patients confirmed malignancy on biopsy (Table 1).

	Malignant (n=10)		
		Gastrointestinal	3 (30%)
		Gynecological	7 (70%)

Feasibility and Adherence

One out of 17 patients (5.8%) dropped out from the study at postoperative day (POD) 3 due to health deterioration (reported feeling very weak and sick) and unwillingness to interact with the tablet. All other patients (16/17, 94.2%) completed the study and were included in the adherence and acceptability analyses. Among the analyzed patients, there was a mean adherence rate of 78% (SD 25%) for prescribed medications, 81 (SD 24%) for exercises, 61 (SD 30%) for symptom surveys, and 58 (SD 44%) for specific tasks. Detailed adherence data for each patient over the 4-week period is available in Multimedia Appendix 1. The responses to the open-ended questionnaire regarding technology acceptance, including perceived ease of use and perceived benefits, are available in Multimedia Appendix 2.

Acceptability

There was an 80% patient endorsement across all TAM categories (Table 2 and Table 3). The highest endorsed items were regarding the simplicity of managing daily tasks (93.8%) and medications (93.8%), in the perceived ease of use category. Perception assessment is depicted in Multimedia Appendix 1.

Table . Responses (n=16) to perceived ease of use in the Technology Acceptance Model (TAM) questionnaire of patients who completed 4 weeks.

Perceived ease of use	Responses, n					Endorsement (very easy + easy), %
	Very easy	Easy	Neutral	Difficult	Very difficult	
Navigating my patient engagement app	11	1	3	1	0	75
Managing my appointments	11	2	1	2	0	81
Managing my medications	12	3	1	0	0	94
Managing daily tasks	11	4	0	1	0	94
Managing my messages	11	3	2	0	0	88
Connecting to my video calls	8	1	6	1	0	56
Accessing my exercise guidance	10	4	4	0	0	88

XSL•FO

Table . Responses (n=16) to perceived usefulness, attitude toward use, and privacy concerns in Technology Acceptance Model (TAM) questionnaire of patients who completed 4 weeks.

Category and item		Responses, n					Endorsement (strongly agree + agree), %
		Strongly agree	Agree	Neutral	Disagree	Strongly disagree	
Perceived usefulness							
	I do not need the support of a technical person to use this app	10	1	1	3	1	69
	The patient engagement app is a useful resource in managing my post hospital care	8	4	4	0	0	75
	Reminders via the app effectively reminded me to complete my tasks	8	5	3	0	0	81
Attitude toward use							
	When this patient engagement app becomes available, I will use it	8	4	2	0	0	75
	I would recommend this patient engagement app to other friends or family members who are discharged from the hospital	8	5	3	0	0	81
Privacy concerns							
	I do not have privacy concerns while using this patient engagement app	10	0	4	1	1	62

Reported Events During Study

Events were retrospectively collected via EMR in patients who completed the study. Three events were found; all were noted from patients undergoing gynecologic oncology procedures. One patient reported a falling incident to the research staff by phone call, but not through the PVA. This event did not require hospital readmission. Furthermore, 1 patient visited the emergency room (ER) on POD-17 due to sepsis secondary to acute cystitis or intra-abdominal abscess (per EMR note). Symptoms included pain during urination, lower back pain, and chills, which were not reported in the PVA chat. Symptom surveys recorded pain levels of 2/10 and 3/10 days before the ED visit. Treatment included computed tomography–guided needle aspiration, drain placement, and antibiotics. Another patient visited the ER on POD-28 due to lower abdominal pain and was diagnosed with an intramuscular rectus sheath hematoma (per EMR note). The patient experienced pain the previous week but did not report it in the PVA chat. Pain levels recorded in the PVA surveys were 7/10 just 2 days before the ER visit. The patient reported ineffective pain control through EMR chat (EPIC MyChart) and was advised to visit the ER by the health care team. Treatment consisted of analgesics and hospital observation for 24 hours.

Discussion

Principal Findings

This study explored the usability and acceptability of providing individualized postoperative care plans through a PVA system in patients undergoing hepatobiliary and gynecologic oncology procedures. This system is composed of 3 key elements, a tablet

XSL•FO
RenderX

with an integrated app provided to the patient (patient portal), a website for care providers to manage from any computer (care provider portal), and a secure cloud backend system that links both portals. Through the care provider's portal, the research team entered the patients' postoperative care plans assigned by their attending physician which included guidance on daily personalized assignments divided into 4 categories (ie, medications, exercise, symptom surveys, and specific tasks). Then, a tracking system assessed the adherence to such categories. In total, 16 (93.7%) patients completed the study, showing an 80% acceptability rate evaluated through a technology acceptance model questionnaire. Adherence to the care plan surpassed 70% of assignments completed in the medications and exercise categories.

Digital health applications for postoperative recovery have shown efficacy for enhancing communication between patients and care providers in different areas [20,21]. Strategies used for such enhancement include symptom monitoring surveys [21-29] educational videos for wound care [17] and exercise implementation [30], which support patients in complying with their postoperative management. Other apps may alert care providers to detect warning signs for faster communication of adverse events [21,29,31]. Our multidisciplinary team integrated these features in an interactive, practical, and simple manner through a personalized tablet (Figure 2). This strategy ensures that compliance notifications remain separate from personal devices, thereby minimizing the risk of overlooking care management assignments. In addition, this system's integrated "voice-enabled" navigation commands facilitate usability in those who have challenges on interpreting and inputting text. Emphasis was placed on presenting care plan assignments in an organized format, starting with the home screen, with the objective of creating a daily routine that patients could complete. Importantly, all features were integrated through direct consultation with clinicians, something we believe was crucial for patient engagement. Subhi et al [32] emphasized that without adequate professional input, digital health tools may deliver content that fails to meet patients' needs and deploy interventions that are ineffective. Thus, the success of digital health tools relies on the proper combination of evidence-based systems with realistic content that involves individualized care plans guided by clinical minds.

Today, few authors have explored digital health applications for postsurgical oncologic care, all reporting high feasibility. Graetz et al [31] designed a mobile app for 26 patients undergoing gynecologic oncology procedures, incorporating progressive reminders regarding discharge instructions, medication adherence and completion of symptom surveys. The study was performed in 4 weeks, resulting in 88% of participants completing the study. In a similar population, Temple-Oberle et al [33] conducted a 6-week randomized controlled trial using a mobile app, in which patients uploaded wound pictures, drain volume data, reported symptoms or wound complications, and received unidirectional messages from their physicians. The approach was compared to standard of care, having only 1/36 patients (2%) in the intervention group dropping out of the study. Similarly, the majority of participants in the present 4-week study who used the PVA were those undergoing gynecological oncologic procedures, with 13/14 (93.7%) completing the study. We attribute this rate to the personalized content that was created for each patient. For instance, gynecologic patients undergoing surgery are recommended to perform sitz baths to relieve pain, swelling, and improve wound healing in the pelvic area [34]. However, proper instructions on the right equipment, water level and temperature, duration, and frequency of baths, are often forgotten [35]. The PVA reminds and guides patients to perform this task by notifications and banners on the screen (Figure 4C). This notification system has been shown to increase usability of digital health tools in gynecologic oncology patients [31]. Noteworthy, it is difficult to ascertain if the notification system influenced patient compliance and study completion the most. In addition, the known low-risk of postoperative complications in the group of gynecologic oncology patients could have been another factor contributing to a less pronounced dropout rate [31,33].

Another important aspect for assessing feasibility of digital health tools is the quantification of adherence to such systems. For instance, Mata et al [36] considered adherence as completion of 5 specific daily tasks (ie, early mobilization, gum chewing, consumption of oral liquids, breathing exercises, and consumption of protein drink) by following instructions from a tablet in 40 hospitalized patients who underwent colorectal surgery. Among these, 60% had a cancer diagnosis. Interestingly, a 94% adherence rate was seen on POD-1 but declined to 43% at POD-3. Similarly, Low et al [37] measured in-hospital adherence among patients undergoing abdominal cancer surgery, based on symptom survey responses via a mobile app and quantification of daily usage of a smart band (Fitbit). Adherence rates reported were 22% and 35%, respectively. However, when measuring adherence in the posthospital discharge phase, both rates increased (41 and 65%, respectively). This highlights how the timing and setting of digital health tools usage can impact adherence, particularly in those employed once patients have cleared hospitalization. In this study, posthospital discharge adherence was evaluated upon completing the assignments within the 4 care plan categories. This resulted in a high adherence rate for medications and exercises (78% and 81%, respectively). However, the patients' freedom to mark each assignment as "done" could have biased our results, as it is difficult to verify whether these were truly completed. On the other hand, there was a 61% and 58% adherence rate for symptom surveys and specific tasks, respectively. Perhaps this was reflected on the 46% rate of patients who recommended including fewer surveys and questions in the PVA in Multimedia Appendix 1. Nonetheless, an interventional study evaluating clinical outcomes (ie, faster recovery, adverse events, and hospital readmission) is warranted to confirm associations with adherence.

To evaluate acceptability, the present study used a TAM questionnaire tailored for the PVA system, showing an 88.75% ease of use, 86.62% perceived usefulness, 85% attitude toward use, and 81% privacy concerns rates. No notable differences in technology acceptability were observed between younger (<60 years old) and older (>60 years old) patients, with overall scores appearing similar across age groups. While a small number in both groups indicated needing technical support or gave neutral

XSL•FO
RenderX

responses regarding app usage, these differences were minimal and not statistically analyzed. Other cancer digital health apps using acceptability queries have shown similar high rates. Karlsson et al [38] utilized the System Usability Scale revealing a 77% ease of use score for an app that encourages mobility in patients recovering from abdominal cancer surgery (Pedatim, Phystec), surpassing the threshold (68 points) for high acceptability of this query [39]. Hwang et al [40] used the Patient Satisfaction Survey to evaluate an app that enables remote monitoring of wounds and communication with care providers in patients undergoing breast cancer surgery (Medeo), revealing a 90% ease of use, 90% attitude toward use, 95% perceived usefulness, and 100% of privacy concern rates. These results reflect the potential use of digital health tools in cancer patients recovering from surgical procedures and encourage researchers for future and continuous development of such systems.

Although the present study focused on exploring the PVA's feasibility and acceptability, we sought to retrospectively collect incidents that happened during the study period to understand the challenges that can be addressed for future system improvement of the PVA. For example, one patient was readmitted to the hospital on POD-28 due to rectus sheath hematoma. Interestingly, this patient reported a poor adherence rate in all categories (39% for medications, 61% for exercises, 54% for symptom surveys, and 0% to specific tasks). Despite patients being instructed to directly communicate postoperative incidents or complications to their care providers, our system's alternative monitoring options (ie, bidirectional chat and Likert pain scales) failed to collect such incidents. In fact, neither the patient's care providers nor the PVA system had evidence of the three reported incidents. We attribute this to the lack of warning sign surveys evaluating fever, wound complications, urinary tract infections, hematomas, or ileus (in gynecologic procedures) [41]. We also believe that proper patient education on warning signs should be included in the home screen. In addition, the system could be equipped with advanced monitoring features such as vital signs (ie, temperature, heart rate, and respiratory rate) and symptom reporting surveys integrated with automated alarms to alert users when certain thresholds are exceeded. These technological enhancements could facilitate prompt detection of postoperative complications to avoid hospital readmissions.

The study findings highlight opportunities to enhance the clinical application of this interactive digital technology, particularly in improving adherence to symptom reporting and supporting the successful completion of specific tasks, that may benefit from more detailed, step-by-step education incorporating comprehensive images or videos. Acceptability and usability are essential first steps in deploying interactive digital solutions to support posthospital discharge care plans. While these solutions hold promise for preventing surgical complications and reducing hospital readmissions, such outcomes remain the ultimate goals of these technologies and require further validation. Research suggests that remote patient monitoring during postsurgical recovery phases can significantly lower hospital readmissions and minimize unnecessary clinic visits compared to standard of care [40]. We speculate that the PVA could meaningfully improve clinical outcomes by enhancing patient adherence to postdischarge care plans, including medication adherence, exercise routines, symptom reporting, and task completion. However, this speculation requires validation through future interventional studies. Further research should also explore how the PVA can optimize communication between patients and care providers, fostering a more seamless and effective recovery process.

Limitations

There are several limitations to our study. Major limitations of this study are its exploratory design, small sample size, and the absence of a control group. These factors restrict our ability to evaluate the PVA's effectiveness compared to standard postdischarge care, limiting our understanding of its overall impact. The low dropout rate and high adherence observed could be attributed to the weekly monetary compensation offered to patients, which may have influenced their participation levels. The questions included in the TAM for evaluating participant's adherence and perceptions might have introduced an acquiescence bias, with patients predisposed to agree with the assessment statements. In addition, we did not examine variations in technology acceptance across different age groups, ethnicities, or cancer types. Such an analysis could provide valuable insights and broaden the applicability of our findings. In the next phase of the study, we plan to incorporate demographic analysis to better understand PVA acceptability and tailor its use to diverse patient populations. Another significant limitation was the lack of integration between the PVA system and electronic medical records, requiring research teams to manually enter each participant's discharge plan. This manual process was not only time-consuming but also involved transcribing detailed instructions in each category of the care plan. Even though the system adherence tool identifies which specific assignments within each category of the care plan (ie, medications, exercise, tasks, and surveys) have been completed by the patient, the clinical study coordinator or health care provider must continuously revise this data on a daily basis. In addition, the health care provider portal, although intended for provider use, was managed by the research team. Thus, the absence of direct contact between patients and health care providers could have affected their experience or willingness to engage fully with the PVAs messaging tool. Regarding the surveys used in the PVA (ie, pain scales and DVT symptoms), patients' answers require continuous revision on a daily basis by the user. However, the research team only reviewed these surveys at the end of the study, highlighting a critical limitation. The absence of real-time symptom collection likely affected the ability to assess the PVA's effectiveness in early prevention and detection of common postsurgical complications.

To address this limitation, future iterations will focus on redesigning surveys to facilitate real-time symptom reporting and efficient review by the clinical care team. This redesign aims to enhance usability while avoiding time-consuming processes, ultimately improving the PVA's role in patient care and early intervention. Furthermore, the app requires internet connection to function and receive real-time updates to the care plan. At the time of this study, it was not available on Google Play Store or Apple platforms, which meant that updates had

XSL•FO
RenderX

to be manually downloaded through a link provided by our industry partner (Smartek21) from the web. Finally, while the PVA allows for picture uploads through a secure chat with researchers, this feature was not instructed as part of the study protocol. We believe this feature should be used in future studies, as it is crucial for the prompt identification of clinical warning signs [21,22,24,25,27-29,42].

Conclusion

This exploratory study demonstrated the usability and acceptability of an interactive digital solution designed to provide an organized, step-by-step guide for postsurgical care, and simplify adherence to care plans in patients undergoing gynecological oncology and hepatobiliary oncology procedures. The findings suggest perceived acceptability, ease of use, and intention to use the platform, although privacy concerns remain a limitation for broader scalability. The results showed fair-to-good adherence to certain postdischarge tasks, such as recommended exercises and prescribed medications, while adherence to symptom surveys and specific tasks was notably lower. Integrating additional features, such as notification reminders and voice-enabled systems, appeared promising for improving compliance. Furthermore, information retrospectively gathered from postsurgical complications provided valuable insights for enhancing the PVA system in future iterations. These findings underscore the potential for interactive digital health solutions to improve communication between patients and care providers while coaching patients to adhere to prescribed postdischarge tasks, which may ultimately enhance recovery outcomes. However, these observations are preliminary and need to be confirmed in studies with larger sample sizes. In addition, future research should focus on validating the effectiveness of this solution in improving posthospital discharge outcomes.

Acknowledgments

The authors would like to thank Drs William E Fisher, Ernest Ramsay Camp, Ang Li, Amir Sharafkhaneh, and Feibi Zheng from Baylor College of Medicine for their expert advice in evaluating and building content for the Personal Virtual Assistant (PVA). The authors would also like to thank Martyn Molnar, Paul Costello, and Dr Sammer Sood from SmartTek21 and IntelliTek Health for their in-kind and technical support for PVA used in this study. We also extend our gratitude to Maria Noun and Naima Rodriguez for their support with the institutional review board and operations, and to the Digital Health Access Center team as well as the clinical team at the Baylor College of Medicine (BCM) Dan L Duncan Comprehensive Cancer Center and the BCM St. Luke’s Medical Center for their assistance with patient referral and recruitment. This research was supported by the National Science Foundation's Industry-University Cooperative Research Centers program under award numbers NSF 2052514 and C2SHIP (Center to Stream HealthCare in Place) Y01-BCM-P026. Additional support was provided by the National Institutes of Health, National Cancer Institute under award number 5P30CA125123-17S1, and in-kind support from Smartek21 and IntelliTek Health. The content is solely the responsibility of the authors and does not necessarily represent the official views of the sponsors.

Authors' Contributions

MBO contributed to writing – original draft, writing – review and editing, patient recruitment, data collection, visualization, PVA connect development, and formal analysis. AZR handled writing – original draft, and writing – review and editing. MGF managed review and editing, and data analysis. ABC handled patient referral, patient care, PVA content development, and review and editing. AFC conducted patient recruitment, data collection, PVA content development, and review and editing. ROB managed patient recruitment, data collection, PVA content development, and review and editing. MP conducted patient recruitment, data collection, and review and editing. TP contributed to patient recruitment, data collection, data analysis, and review and editing. AK managed patient recruitment, data collection, data analysis, and review and editing. BN contributed to conceptualization, writing – review and editing, and supervision.

Conflicts of Interest

BN serves as a consultant for BioSensics LLC on projects unrelated to the scope of this study. The other authors report no conflicts of interest relevant to this study.

Abstract

Background: In the modern era, the use of technology can substantially impact care access. Despite the extent of its influence on several chronic medical conditions related to the heart, lungs, and others, the relationship between one's access to digital resources and oncologic conditions has been seldom investigated in select pathologies among gastrointestinal and head-neck regions. However, studies on the influence of this "digital inequity" on other cancers pertaining to nasal and paranasal sinus cancer (NPSC) have yet to be performed. This remains in stark contrast to the extent of large data approaches assessing the impact of traditional social determinants/drivers of health (SDoH), such as factors related to one's socioeconomic status, minoritized race or ethnicity, and housing-transportation status, on prognostic and treatment outcomes.

Objective: This study aims to use the Digital Inequity Index (DII), a novel, comprehensive tool that quantifies digital resource access on an area- or community-based level, to assess the relationship between inequities in digital accessibility with NPSC disparities in prognosis and care in the United States.

Methods: Patients with NPSC from 2008 to 2017 in the Surveillance, Epidemiology, and End Results Program were assessed for significant regression trends in the long-term follow-up period and treatment receipt across NPSCs with increasing overall digital inequity, as measured by DII. DII was based on 17 census-tract level variables derived from the summarized values overlapping that same time period from the US Census/American Community Survey and Federal Communications Commission Annual Broadband Report. Variables were categorized as infrastructure-access (ie, electronic device ownership, internet provider availability, and income-broadband subscription ratio) or sociodemographic (education, income, age, and disability), ranked, and then averaged into a composite score to encompass direct and indirect factors related to digital inequity.

Results: Across 8012 adult patients with NPSC, males (n=5416, 67.6%) and White race (n=4293, 53.6%) were the most represented demographics. With increasing digital inequity, as measured by increasing total DII scores, significant decreases in the length of long-term follow-up were observed with nasopharyngeal (P<.01) and maxillary sinus cancers (P=.02), with decreases as high as 19% (35.2 to 28.5 months, nasopharynx). Electronic device and service availability inequities showcased higher-magnitude contributions to observed associated regression trends, while the income-broadband ratio contributed less. Significantly decreased odds of receiving indicated surgery (lowest odds ratio 0.87, 95% CI 0.80-0.95, maxillary) and radiation (lowest odds ratio 0.78, 95% CI 0.63-0.95, ethmoid) for several NPSCs were also observed.

Conclusions: Digital inequities are associated with detrimental NPSC care and surveillance trends in the United States, even when accounting for traditional SDoH factors. These results prompt the need to include digital factors into the discussion of contextualizing SDoH-based analyses of cancer care disparities, as well as the specific factors from which prospective implementations and initiatives can invest limited public health resources to alleviate the most pertinent drivers of disparities.

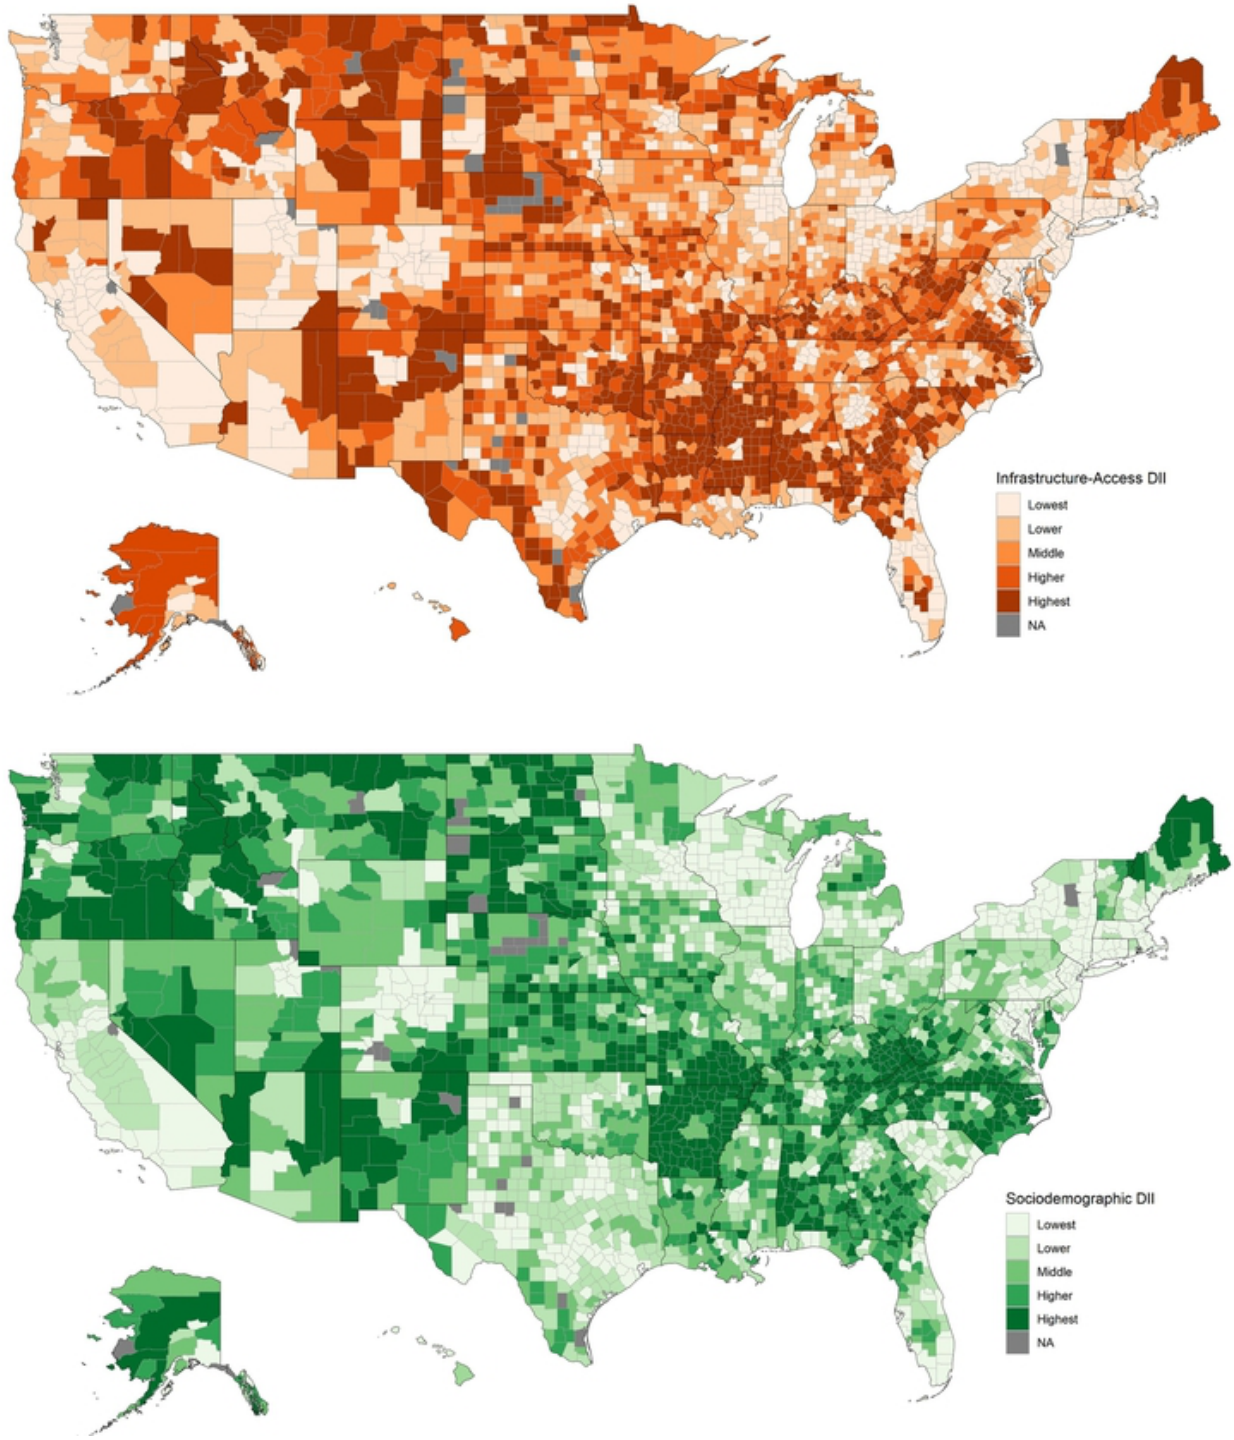
Introduction

Despite multiple studies highlighting the clinical factors of nasal and paranasal sinus cancer (NPSC) prognosis [1-4], the rare occurrence of NPSC has limited investigations of how nonclinical factors, namely social determinants/drivers of health (SDoH), come to influence prognosis. Among the few that have analyzed SDoH, most investigations have focused on components of socioeconomic status (SES) and race-ethnicity for their significant impactful associations with NPSC outcomes. For instance, Sharma et al [5] showed that patients with paranasal cancers had higher mortality and advanced staging on preliminary diagnosis associated with worse SES. In addition, London et al [6] concluded that SES alongside race-ethnicity significantly impacted survival, stage at diagnosis, and treatment in patients with nasopharyngeal carcinoma.

As the United States was plunged into the COVID-19 era, technology and internet access became crucial; yet, confounding elements in how SDoH affect clinical intervention use. During this period, telehealth modalities saw increasing importance in bringing patients with cancer from varying levels of SES equivalent means of health care, including through diagnostic testing and prescribing symptomatic treatment [5,7,8]. As this use became more prevalent, disparities in technology access became more apparent with a demonstrated potential to impact the already present associations between possessing worse social determinant factors and poor health outcomes [9].

This intersection between health equity and digitization of health care has brought a unique aspect of otolaryngologic care for vulnerable patient populations to the forefront. Among the few efforts to assess this relationship, Darrat et al [10] observed 1162 patients with head-neck malignancies from a single tertiary care center who showed worsening SES being associated with decreased use of telehealth. Despite this demonstrated impact on the local level, investigations of the health impact of these digital factors on a national scale have sparsely been performed, let alone for their effects on influencing NPSC care and prognosis.



Among the few initiatives to comprehensively assess this "digital inequity," state-level efforts, such as the Digital Divide Index from the Rural Indiana Stats database, or national-level ones, such as the Federal Communications Commission Connect2Health Broadband Map, have been created. However, they have key flaws in not contextualizing digital access alongside traditionally investigated SDoH (ie, SES, race-ethnicity, and disability status), encompassing a limited geographic scope, or using old raw data sources [11,12].

To address this crucial deficit, this study aims to apply the Digital Inequity Index (DII) to assess how digital inequity is associated with NPSC disparities in the United States. This study hypothesized that increasing digital inequity would be associated with poorer NPSC outcomes in long-term follow-up and decreased receipt of indicated treatment modalities (ie, surgery and radiation therapy) while adjusting for validated, traditional SDoH.

The DII is a US-based, geographically differentiated tool that comprehensively assesses digital inequity across a variety of factors encompassing broadband infrastructure, electronic device access, and internet access affordability while adjusting for traditional SDoH nationally (Figure 1). It was previously developed and implemented as a means of using validated multivariate models of digital resources and traditional SDoH measures while sourcing from updated, publicly available data from the American Community Survey (ACS) and the US Census. Among prior uses of this tool, GI-aerodigestive cancers were observed to have vast differences in mortality, lack of follow-up care access, and disparities in first-line treatment receipt independent of the effects of traditional SDoH [13]. However, to our knowledge, there is a lack of investigations into whether digital inequities are associated with the care and prognosis of NPSC across a national patient population.

Methods

Overview

This research was conducted in Chicago, Illinois, United States, during the period of September 2022 to July 2023. No generative artificial intelligence was used in conducting any part of this research, nor any written parts of this manuscript.

Ethical Considerations

Prior institutional review board/ethics committee approval or waiver of informed consent was exempted per Northwestern University's institutional review board. The research is not considered participant research due to the databases queried consisting of publicly available, deidentified data and secondary analyses of such without additional institutional review board approval per the university.

XSL•FO
RenderX

The DII

The DII was based on 17 census-tract level variables derived from the ACS 5-year estimates spanning 2008 - 2017 and the Federal Communications 14th Broadband Report. Per ACS-derived methodologies, the use of the 5-year estimates allowed adjustments for differing chronological periods covered in order to adjust for temporal changes in digital access during this period. Variables were extracted and grouped into themes of "infrastructure-access" comprised of the measures representing "households without a desktop or laptop," "without access to non-mobile broadband," "without access to broadband: DSL," "without access to broadband: cable," "without access to broadband: fiber," "without access to broadband: terrestrial fixed wireless," "without a mobile or non-mobile internet subscription of any type," "without an internet subscription of cable, fiber, or DSL," "without a broadband subscription in households making $20,000 or less," "without a broadband subscription in households making $20,000 - $74,999," and "without a broadband subscription in households making $75,000 or more"; and "sociodemographic" comprised of "25+ aged people without high school diploma," "25+ aged people without an associate's degree or higher," "25+ aged people without a bachelor's degree or higher," "below poverty level within the last 12 months," "below 150% of poverty level within the last 12 months," and "disability status pertaining to cognitive, ambulatory, or self-care difficulties." Additionally, "infrastructure-access" variables were split into the subthemes of "Device Access," "Internet Availability," and "Income-Access." These subthemes and variables have been summarized in Multimedia Appendix 1.

Ranked scores were then assigned to each ACS variable based on their relative value compared with all other census tracts nationwide. These were then adjusted by tract population to calculate weighted mean scores on the county level within their respective DII categories. DII scores were then arranged into 5 ordered classes by natural break (Jenks) classification by comparing the sum of squared deviations between classes to each array mean and using a goodness of variance fit. These 5 classes were then labeled as "Lowest," "Lower," "Middle," "Higher," and "Highest" (Figure 1). DII scores were abstracted and matched to patient data based on county of residence at the time of diagnosis.

Patient Database and Clinicodemographic Variables

The National Cancer Institute-Surveillance, Epidemiology, and End Results Program (NCI-SEER) database contains national patient data on pathological characteristics, treatment modalities, and prognostic outcomes. It is the main program of the NCI in order to support cancer surveillance activities and acts as the national governmental authority for collecting information on cancer incidence and survival in the United States. These patient data were collected across 18 NCI-designated cancer registries across institutions from all regions of the United States, representing over 48% of the US population. Months under surveillance represent a length-of-care measurement reflecting the active follow-up a patient receives for their primary malignancy up until the last provider interaction. The end point was designated by the SEER database as the last point when a patient received care due to being lost to follow-up or experienced a mortal outcome per the SEER-designated variable of "vital status." Delineations of months were the lowest-level strata available due to compliance with HIPAA (Health Insurance Portability and Accountability Act), deidentified status. Primary surgery and radiation occurrence represent whether patients received surgery or radiation for their primary malignancy.

Population Definitions

SEER was queried for adult (20 years and older) patients diagnosed with NPSC from 2008 to 2017. Primary sites were extracted using the *ICD-O-3* (*International Classification of Diseases for Oncology, Third Edition*) topographic codes (C11.0 - 11.9; C30.0 - 31.9). Patients with incomplete data across the clinicodemographic variables were excluded from respective analyses necessitating those variates.

Statistical Methods: Demographics Tables, Linear and Logistic Regressions, and Boxplots

Demographics tables were grouped by DII scores delineated by a natural break (Jenks) classifications of "Lowest," "Lower," "Middle," "Higher" and "Highest."

Months under surveillance within each primary malignancy were analyzed by DII-category scores. DII scores were split into relative, equivalently sampled quintiles based on actual DII scores within each primary malignancy. The relative-DII quintiles were delineated by "<20", "20 - 39.99," "40 - 59.99," "60 - 79.99," and "80 - 99.99" representing their relative percentiles per malignancy type (eg within disease A, patients with the lowest DII scores are grouped into the "<20" quintile group).

Among these DII-quintiles, differences between the mean months under the surveillance period for the lowest and highest DII-scored quintiles were calculated. Trend significance was assessed by linear regression across relative-DII quintiles for both continuous measures, and boxplots were generated to assess the median, IQR, and 1.5 times the IQR. Mean values were also calculated per relative quintile group.

Primary surgery and radiation occurrence within different malignancy types were analyzed with univariate logistic regression across relative-DII quintiles per DII category.

Statistical significance was set as P value <.05. Two-sided P values were reported for analyses. Analyses were conducted in R (version 4.2.3; R Project for Statistical Computing).

Results

Overview

A total of 8012 adult patients with primary NPSC were extracted from SEER including nasal cavity (n=1821, 22.7%), nasopharynx (n=4225, 52.7%), sinus ethmoid (n=276, 3.4%), sinus maxillary (n=1187, 14.8%), and sinus other (n=383, 4.8%). DII scores ranged from "Lowest" (n=6099, 76%) to "Highest" (n=172, 2.1%), signifying "lowest digital inequity" and "highest digital inequity," respectively. Males (n=5416, 67.6%) and White race (n=4293, 53.6%) were the most represented in the

XSL•FO

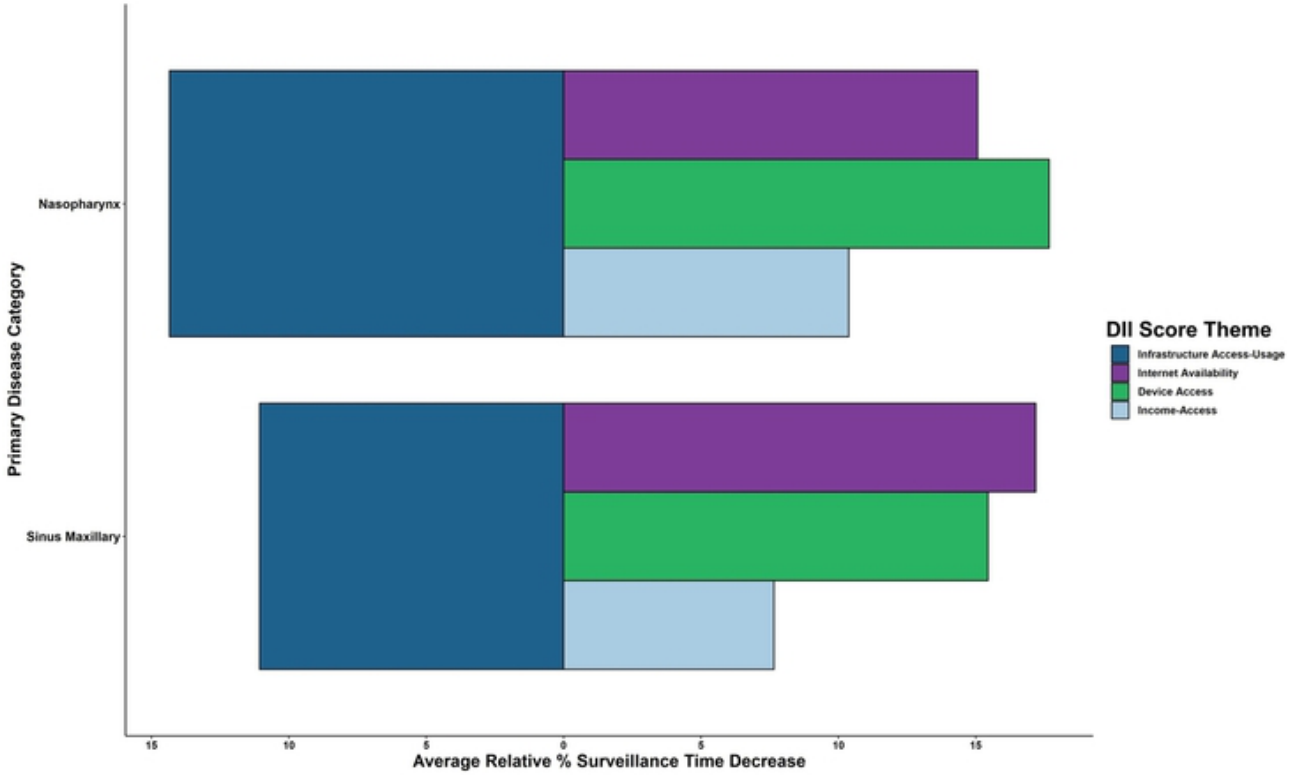
Malignancy-Type Trends in Months Under Surveillance by Relative DII Percentile

Substantial decreases in mean surveillance period were observed among patients with NPSC with the lowest (ie, having the least digital inequity) to the highest-DII quintiles. These decreases were significant and ranged from the following: 14.4% decreases in mean surveillance/follow-up period from 32.54 (SD 28) months to 27.85 (SD 26) months for nasopharyngeal cancers (P<.01), and 11.1% decreases from 26.37 (SD 26) months to 23.45 (SD 23) months in maxillary sinus cancers (P=.02; Figures 2 and 3). Contributing to this overall trend, inequities in electronic device and service availability largely contributed to these decreases, while the income-broadband ratio contributed less (Figure 3).



XSL•FO
RenderX

Figure 2. Linear regression trends in months surveyed across increasing Digital Inequity Index quintiles. Linear regressions across all the represented values (ie, not the mean values) in each of the boxplot quintiles were performed to assess for continuous trend significance of the surveillance period for increasing the total Digital Inequity Index. Boxplots=median, IQR, 1.5*IQR; mean months surveyed per quintile=maroon diamonds; outliers=blackdots; *P* value for regression.

Patients with nasal and paranasal sinus cancer were assigned DII scores and split into relative quintiles. DII: Digital Inequity Index.

Malignancy-Type Trends in Surgery and Radiation Therapy by Relative DII

With increasing digital inequity/DII scores, patients with maxillary sinus showed markedly decreased odds of receiving indicated surgery for their primary tumor (odds ratio [OR] 0.87, 95% CI 0.80 - 0.95; *P*=.01; Table 2). Similarly, increasing digital inequity/DII scores were associated with markedly decreased odds of receiving indicated radiation therapy for patients with primary ethmoid sinus (OR 0.78, 95% CI 0.63 - 0.95; *P*=.01) and nasopharyngeal tumors (OR 0.90, 95% CI 0.85 - 0.95; *P*<.01; Table 3).

Discussion

Principal Findings and Significance

By using a novel, comprehensive area-based SDoH-index called the DII, this investigation showcased significant associations between increasing levels of digital inequity with nasal-paranasal sinus cancer outcomes in care and prognosis. Overall, NPSC surveillance and treatment receipt decreased with increasing levels of digital inequity. To our knowledge, this is the first and largest study to apply a national index using prior-validated multivariate models of evaluating digital inequity associations with NPSC care and prognosis while accounting for nondigital, traditional social determinants. In doing so, this study found significant, detrimental trends of surveillance and treatment receipt with increasing digital inequity.

Comparison to Prior Work

With nasal cavity cancers having high recurrence rates and rapid progression of such recurrences [3,14], understanding how surveillance is affected by factors of digital inequity becomes of utmost importance. As we showcased significant decreases in the length of follow-up associated with increasing DII, our study highlights how present technological disparities could exacerbate lacking surveillance for cancer recurrence among socially vulnerable populations. Moreover, beyond the window of high risk of primary NPSC recurrence within 2 years, understanding mechanisms of unequal follow-up, such as the contributions of digital inequity, beyond this length of time points to the observed 33% chance that patients with NPSC will develop a second primary head and neck cancer [14]. Further studies also showed that, although advances in imaging and surgery may help to decrease the rates of recurrence and secondary malignancy occurrence, diagnosis at an earlier stage, whether primary or recurrent disease, was the largest contributor to prognosis [15]. In turn, for a disease with such a high rate of recurrence and increased risk of a second primary malignancy, understanding how digital inequities impact long-term and lifelong follow-up and surveillance is crucial.

Our findings of digital inequity associations with NPSC help contextualize prior investigations of technology use in contributing to earlier diagnosis of primary malignancies. For instance, a study in Italy evaluated the use of telemedicine in breast cancer and cardiovascular disease detection and reported that telemedicine screening allowed for significantly earlier detection [16]. Furthermore, another study evaluated the use of telemedicine and monitoring in head and neck cancers, finding that a recent telemedicine model by Beswick et al [17,18] allowed for quicker access to surgery and increased financial benefit among patients with head and neck cancer [18]. In addition, telemonitoring in patients with head and neck issues has been shown to detect early occurrence of health problems [18]. Earlier detection of disease using digital advancements may allow for the detection of cancers at earlier stages. As such, these prior investigations infer that early screening technologies that lead to superior head-neck cancer outcomes, such as NPSC, would depend on digital resource accessibility. These relationships suggest possible mechanisms of how digital resource inequity associations observed in this study could inversely contribute to worse outcomes by limiting this early step in cancer diagnosis and the eventual cause of treatment delay, which is especially relevant to rarer cancers with incidental symptoms such as NPSC. However, to fully characterize this possibility, future prospective investigations across multiple patients with NPSC demographics should observe individual-level circumstances related to their surrounding digital inequity factors that may pose a potential prognostic difference.

XSL•FO
RenderX

As the mainstay of NPSC treatment involves both surgical intervention and radiation therapy [14], our study showcases how worse digital access is associated with unequal receipt of these indicated modalities akin to prior traditional SDoH studies showcasing similar disparities. Specifically, prior studies have found significant differences among individuals with paranasal sinus cancer and differing SES. A cross-sectional analysis by Sharma et al [5] found that among those with regional/distant disease, those in the middle and lowest SES tertile were significantly less likely to receive multimodal therapy. Furthermore, a radiation therapy noncompliance study involving the head and neck among other cancers found that low SES was associated with radiation therapy noncompliance, defined as missing 2 or more scheduled radiation therapy appointments [19]. Given that our analyses account for both nondigital SDoH, such as SES, and digital factors, our observed associations of treatment disparities among patients with NPSC necessitate further exploration of how digital resource inequities can affect present-day health outcomes.

Despite the numerous geospatial, national indices assessing traditional social determinants, the absence of tools to assess technological and internet-access factors in a similar, multifactorial fashion necessitated the use of the DII. Aside from using a validated set of measures in its multivariate settings, the DII reached the quantitative veracity of these established indices, such as the Social Vulnerability Index or Area Deprivation Index, by sourcing from identical, publicly available databases, with those being the ACS/US Census and Federal Communications Commission. Our application of the DII through the differential weighing of these ranked scores to form composite measures of social determinant themes remains aligned with the statistical considerations used by prior work in large-data SDoH-contextualizations in otolaryngology, alongside the application of DII to gastrointestinal-aerodigestive cancer disparities [13,20]. In turn, the application of the DII in this study was well-warranted for assessing the lesser-investigated factors of digital inequity in a geospatial, multifactorial manner.

Strengths and Limitations

This study used a comprehensive novel index to assess a wide variety of digital inequity determinants and the potential impacts they may have on NPSC surveillance and treatment plans. Additionally, our populace was large for such a rare malignancy and consisted of individuals across all regions in the United States.

The authors recognize that this study had several limitations. First, this study was localized to the United States. Second, our populace was majority male and White. Although this accurately represents the majority of patients with NPSC, future studies exploring the relationship between the chosen strata for this study and the impact of observed DII should be investigated further. Third, the validated set of variables used in the DII does not encompass the entirety of digital and nondigital factors that would be of interest and follow the convention of its predecessors. Last, although the chronology of patients and DII measures was aligned, further actions to conduct updated investigations for more recent time periods (given the changes in digital resource access) would be warranted.

Conclusions

In conclusion, using the validated multivariate models of the DII, disparities in NPSC follow-up and treatment were significantly associated with national digital inequities while accounting for traditional SDoH factors such as SES, education, and disability. Using novel, large-data tools such as the DII presents the means of identifying vulnerable sociodemographics and modern-day factors to inspire discourse on how digital resources affect care delivery and access. In turn, these findings further facilitate investigation into how equitable NPSC care and outcomes play out in modern-day environments while highlighting key targets for policy makers and public health advocates to conduct prospective initiatives against.

Data Availability

The datasets analyzed in this work can be found from the following: Surveillance, Epidemiology, and End Results Program data available from administrators; Digital Inequity Index data derived; and available from the American Community Survey and Federal Communications Commission Broadband Report.

Abstract

Background: Patients with cancer frequently encounter complex treatment pathways, often characterized by challenges with coordinating and scheduling appointments at various specialty services and locations. Identifying patients who might benefit from scheduling and social support from community health workers or patient navigators is largely determined on a case-by-case basis and is resource intensive.

Objective: This study aims to propose a novel algorithm to use scheduling data to identify complex scheduling patterns among patients with transportation and housing needs.

Methods: We present a novel algorithm to calculate scheduling complexity from patient scheduling data. We define patient scheduling complexity as an aggregation of sequence, resolution, and facility components. Schedule sequence complexity is the degree to which appointments are scheduled and arrived to in a nonchronological order. Resolution complexity is the degree of no shows or canceled appointments. Location complexity reflects the proportion of appointment dates at 2 or more different locations. Schedule complexity captures deviations from chronological order, unresolved appointments, and coordination across multiple locations. We apply the scheduling complexity algorithm to scheduling data from 38 patients with breast cancer enrolled in a 6-month comorbidity management intervention at an urban hospital in the Washington, DC area that serves low-income patients. We compare the scheduling complexity metric with count-based metrics: arrived ratio, rescheduled ratio, canceled ratio, and no-show ratio. We defined an aggregate count-based adjustment metric as the harmonic mean of rescheduled ratio, canceled ratio, and no-show ratio. A low count-based adjustment metric would indicate that a patient has fewer disruptions or changes in their appointment scheduling.

Results: The patients had a median of 88 unique appointments (IQR 60.3), 62 arrived appointments (IQR 47.8), 13 rescheduled appointments (IQR 13.5), 9 canceled appointments (IQR 10), and 1.5 missed appointments (IQR 5). There was no statistically significant difference in count-based adjustments and scheduling complexity bins (χ^2_4=6.296, *P*=.18). In total, 5 patients exhibited high scheduling complexity with low count-based adjustments. A total of 2 patients exhibited high count-based adjustments with low scheduling complexity. Out of the 15 patients that indicated transportation or housing insecurity issues in conversations with community health workers, 86.7% (13/15) patients were identified as medium or high scheduling complexity while 60% (9/15) were identified as medium or high count-based adjustments.

Conclusions: Scheduling complexity identifies patients with complex but nonchronological scheduling behaviors who would be missed by traditional count-based metrics. This study shows a potential link between transportation and housing needs with schedule complexity. Scheduling complexity can complement count-based metrics when identifying patients who might need additional care coordination support especially as it relates to transportation and housing needs.

Introduction

Background

Patients with cancer frequently encounter complex treatment pathways, often characterized by challenges with coordinating and scheduling appointments at various specialty services and locations [1-3]. Previous studies have shown that the burden of scheduling and attending visits across multiple providers and specialties not only burdens patients, but also has ripple effects on families, work, and personal lives [4-6]. In a qualitative study with patients with metastatic breast cancer, patients pointed to the need for someone to coordinate appointments and a need for managing work-related barriers to attending appointments [7]. Furthermore, scheduling complexities do not fall on all patients equally. Patients facing social inequalities, such as unequal access to transportation, housing, and social support, face additional complexities in their cancer care appointments. For instance, patients with cancer without insurance, indicating financial vulnerability, are at high risk of no-show appointments [8,9]. A recent review illustrates that most research on multiappointment scheduling problems in oncology focus on solutions using metaheuristics and multiagent methods to ensure appointment adherence [2]. However, if scheduling complexities reflect underlying socioeconomic barriers, such solutions may not solve the structural issues.

To address structural access challenges around scheduling appointments, some health care institutions employ individuals such as community health workers (CHWs) or patient navigators, who play a pivotal role in guiding patients with cancer through their care journey by offering support for nonmedical needs [10]. CHWs and patient navigators have a wide variety of skills and can provide critical assistance coordinating appointment scheduling and overcoming barriers to attending care [4,11,12]. Patients who might benefit from this additional assistance are largely identified manually by CHWs or by care providers aware of possible challenges and social needs [13], or some clinics may assign all patients to CHWs to screen, a resource intensive process [14-16]. Workflows reliant on staff to identify those who might benefit the most from navigation can be time-consuming and resource-intensive, making it difficult to comprehensively identify patients in need of assistance. While ideally all patients would be offered navigation services, in light of staffing shortages and overall limited patient navigation resources, many institutions may be limited in who they can provide extra supportive services to [17]. A data-driven solution that alleviates burden from support staff (ie, reviewing charts to identify patient needs) or relying on clinician referrals would be ideal to effectively and efficiently allocate limited CHW and patient navigator resources.

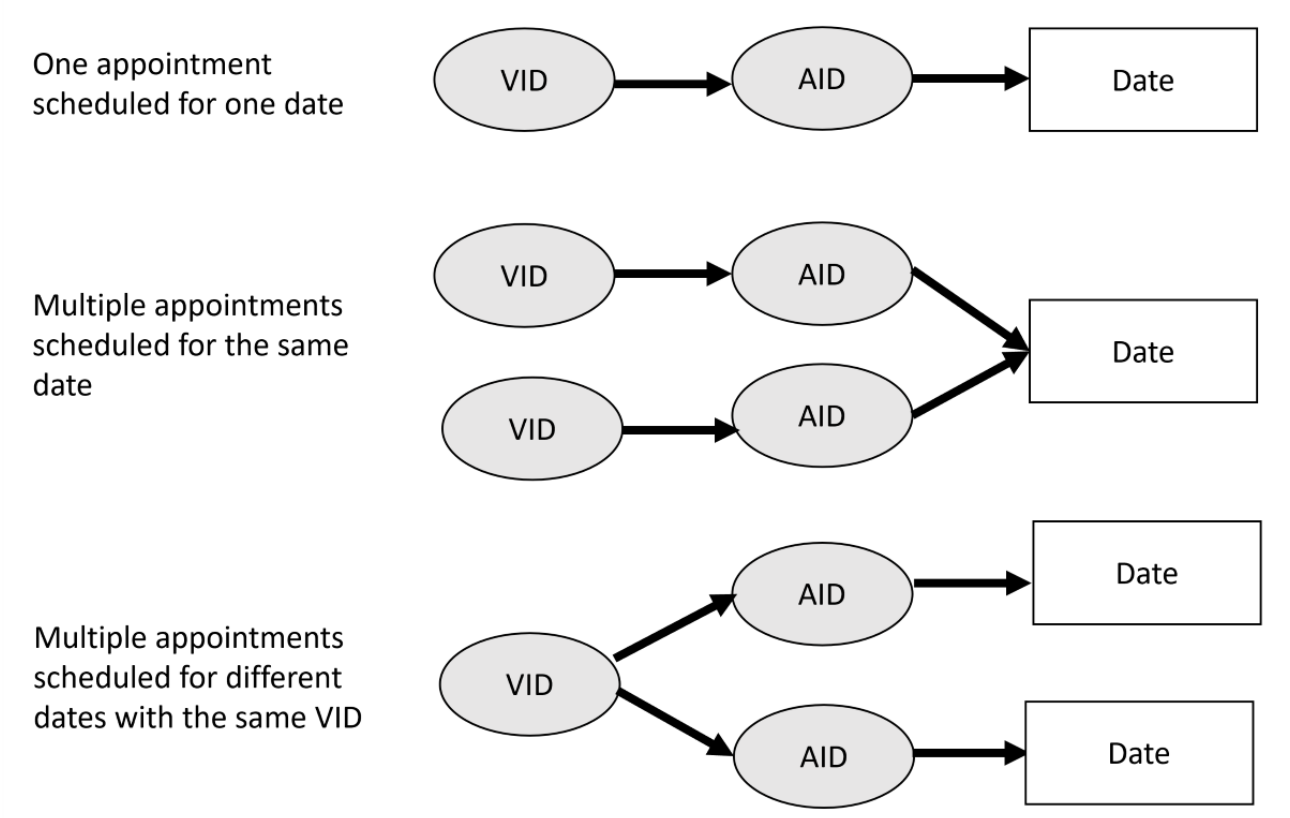
Potential of Scheduling Data

A potential way to identify patients with unmet transportation or housing needs is to use scheduling data to examine who is experiencing high scheduling complexities. Scheduling data for most cancer care is electronic, providing detailed data about when appointments are scheduled, cancelled, rescheduled, or no shows. This data is automatically recorded, and thus could be used to identify patients who are struggling to manage the complexity of cancer care. In past research, appointment data has primarily been used to optimize appointment scheduling for patient satisfaction and resource allocation [18-21]. Analyses tend to focus on developing and testing scheduling methods to best balance patient satisfaction (eg, wait times) with clinic resources. For example, using model simulations to optimize the scheduling of oncology visits and chemotherapy treatments [19], or optimizing scheduling rules based on chemotherapy infusion [21]. Other research using scheduling data examines the efficiency of appointment self-scheduling processes [22], optimizing scheduling for cost savings [20], and identifying ways to reduce wait times for patients [18]. A study designed an algorithm that used appointment data to identify patients' primary care physician [23]. However, to our knowledge, researchers have yet to design tools for analyzing scheduling data to identify patients with possible unmet transportation or housing needs during their cancer care.

Contributions

Our study used existing scheduling data to identify patients with complex scheduling patterns which may reflect unmet social needs in transportation and housing. We introduce a novel algorithm to calculate scheduling complexity from scheduling data using a sample of patients with breast cancer with initiating cancer treatment from a larger parent study intervening on comorbidity management [24]. Scheduling complexity is an aggregation of sequence, resolution, and facility components. Each component is motivated by the characteristics of scheduling data, an appointment's anatomy, and possible outcomes. The scheduling complexity algorithm is then applied to the scheduling data of 38 patients with breast cancer as a case example. The resulting scheduling complexities are compared with count-based metrics and call notes between CHWs and patients to identify unmet transportation or housing needs.

Methods



Anatomy of an Appointment

Every appointment has a unique appointment identification (AID) and is scheduled on a specific date and time and scheduled for a specific date, time, and location. An appointment is scheduled for a specific visit reason and is associated with the corresponding visit identification (VID). Typically, 1 date will have 1 appointment scheduled with 1 associated VID, Figure 1 (top). Figure 1 is an illustration of AID and VID possible scenarios. Sometimes there can be multiple appointments with different VIDs scheduled for the same date. This is illustrated in an example patient schedule in Table 1. A magnetic resonance imaging (MRI) and mammogram are both scheduled for January 15, 2023. The MRI and mammogram appointments have different AIDs (AID-5 and AID-6 respectively) and VIDs (VID-4 and VID-5 respectively) because they have different reasons for visit and will be at different locations, 1 on the ground floor and 1 on the second floor of the hospital. There can also be multiple AIDs for different dates associated with the same visit reason and at the same location, VID, Figure 1 (bottom). A common example of this pattern is for daily treatments as illustrated in Table 1. There are 4

XSL•FO
RenderX

appointments for the same treatment at the same location with the same VID (VID-7) but with different AIDs (AID-9, AID-10, AID-11, and AID-12). All the AIDs are for the same treatment and at the same location and would have the same VID.

Appointment Action Outcomes

There are 4 possible action outcomes for an appointment: arrived, rescheduled, canceled, or no show as illustrated in Figure 2. Figure 2 illustrates 4 possible action outcomes for an appointment. Arrived occurs when the patient arrives on the scheduled appointment date. Rescheduled occurs when the appointment needs to be rescheduled for another date. This can be due to multiple reasons, such as patient's preference, medical necessity, financial or transportation issues, circumstances or system related factors, such as being bumped, unresolved insurance authorization, etc. Rescheduling an appointment will result in a new AID. An appointment can also be canceled by the patient or the hospital. For example, a provider could be unavailable due to illness or a scheduling conflict. Similarly, canceled appointments can be caused by a variety of patient or hospital system reasons. Finally, no show occurs when a patient doesn't arrive to an appointment and does not cancel the appointment.

XSL•FO

Figure 2. The 4 possible action outcomes for an appointment. AID: appointment ID.

Sources for Scheduling Complexities

Sequence Complexity: Appointment Ordering Sequence

We define schedule sequence complexity as the degree to which appointments are scheduled and arrived to in a nonchronological order. While there are several ways to define temporal complexities, we choose a queuing approach as it most closely aligns with patient scheduling experience [25,26]. As such schedules with low sequence complexity are those where appointments are scheduled and arrived in chronical order. This follows the general queuing rule of first in-first out: appointments scheduled first are arrived to first which minimizes the number of outstanding appointments at any given time. Schedules with more sequence complexity are those where appointments are scheduled and arrived to in a nonchronological order. Using the illustration in Table 1, AID-1 and AID-3 are examples of appointments scheduled and arrived in chronical order. AID-1 is scheduled before AID-3 and AID-1 is arrived to before AID-3. AID-4 and AID-5 are examples of appointments scheduled and arrived in nonchronological order. AID-4 is scheduled before AID-5 but the patient arrived to AID-5 before AID-4. This complexity can be caused by many factors such as appointments scheduled for the far future, canceling and rescheduling of appointments, or emergent appointments. These factors can increase schedule challenges both for the patient and scheduling systems.

Resolution Complexity: Unresolved Appointments

No shows or canceled appointments without rescheduling or reason can increase scheduling complexity in a patient's care. Missing appointments leads to increase patient risk for cancer recurrence and mortality [27,28], and inefficiency for the health care system including lost revenue [29-31]. These unresolved appointments have no resolution, leaving uncertainty about potential delays in treatment and care. However, there are sometimes canceled appointments because of changes in treatment plans or no shows that are resolved through another action. Actions for these resolved appointments often co-occur with action dates for arrived or rescheduled appointments. Hence, we define resolution complexity as the number of no shows or canceled appointments on dates that do not co-occur with other action dates divided by the total number of no shows or canceled appointments.

Location Complexity: Appointments at Multiple Facilities

Having care at multiple facilities or locations can also increase scheduling complexities as this usually means more coordination and travel between facilities. Intuitively, a schedule with lower location complexity will have fewer facilities for care on the same day. A schedule with higher location complexity will more often require the patient to attend different facilities for care on the same day. Location complexity is calculated as the number of arrived dates involving 2 or more different locations divided by the total number of arrived dates.

XSL•FO
RenderX

Calculating Scheduling Complexity

The algorithm for calculating a schedule's scheduling complexity is described below (Textbox 1) . First, schedule data is separated into arrived and not arrived appointments, "ARRIVED" and "NONARRIVED" respectively. ARRIVED appointments are aggregated at the date level. For each AID in ARRIVED, if there exist other AIDs with scheduled on dates preceding the current AID's scheduled on date and these subsequent appointments were attended after the current AID's date, then the count of out-of-order occurrences is increased. Sequence complexity is calculated as the ratio of out-of-order counts to the total count of distinct arrived dates in ARRIVED. Next, for each AID in the NONARRIVED group, an action date is determined, representing the date when an appointment was either canceled, bumped, or scheduled but resulted in a no-show. If this action date does not appear in the dataset of ARRIVED appointments, then the count of unresolved cases is increased by 1. Resolution complexity is then computed as the ratio of unresolved counts to the total count of AIDs within the NONARRIVED group. Location complexity is calculated as the number of arrived dates in ARRIVED involving 2 or most different locations divided by the total number of arrived dates in ARRIVED. Finally, a composite metric scheduling complexity is the harmonic mean of sequence complexity, resolution complexity, and location complexity.

Textbox 1. ALGORITHM: Deriving scheduling complexity

ARRIVED, NONARRIVED ← Separate data into arrived and not arrived appointments

For each AID in **ARRIVED**:

If there are other AID date that was made before current AID date and arrived to after current AID date

Out of order count += 1

sequence complexity = out of order count / total count of unique arrived to dates in **ARRIVED**

For each AID in **NONARRIVED**:

Action date = canceled or bumped date or scheduled date for no-show

If Action date not in Arrived_data:

unresolved += 1

resolution complexity = unresolved count / total count of nonArrived AIDs

For each arrived date with multiple AIDs in **ARRIVED**

If AIDs are at different locations:

Location count += 1

location complexity = location count / total number of arrived dates with multiple AIDs in **ARRIVED**

scheduling complexity = 3 / (1/sequence complexity + 1/resolution complexity + 1/facility complexity)

Case Example and Study Background

To evaluate the use of scheduling complexity, we calculated the scheduling complexity for 38 patients with breast cancer who had hypertension or diabetes, as part of a larger health disparities project to support Black patients with cancer with comorbidities by mobile health and CHW support [24]. The 38 patients with breast cancer were enrolled in a 6-month comorbidity management intervention at an urban hospital in the Washington, DC area that serves low-income patients. This data was collected through the parent study whereby Black patients with breast and prostate cancer were recruited for a 6-month comorbidity management intervention. For tthis analysis, we focused on the association between scheduling patterns and social needs. Given significant differences in course of treatment by cancer site and time since diagnosis we limited the sample to those who had a diagnosis of breast cancer, all of whom had been diagnosed within the previous year. We further limited the sample to the 38 patients with breast cancer whom we had reliable appointment level data. The women in our sample were from an urban hospital in the Washington, DC area that primarily serves low-income patients. Black women with breast cancer in the DC area are a high priority sample, due to the increased mortality rate relative to White women [32].

CHW Call Logs

In addition, as part of the parent study, we conducted a qualitative context analysis of CHWs' call logs to identify social needs that arose throughout the study [33]. We used a deductive approach, first applying discrete categories from the health system screening tool focused on domains of food insecurity, housing instability, transportation, employment, financial strain, and utilities. Additional needs that were documented but did not fit into a predetermined category, such as access to wigs or special bras, were added as new codes using an inductive descriptive coding method to match social needs domain described by the Social Interventions Research and Evaluation Network (SIREN) [34].

Data Analysis

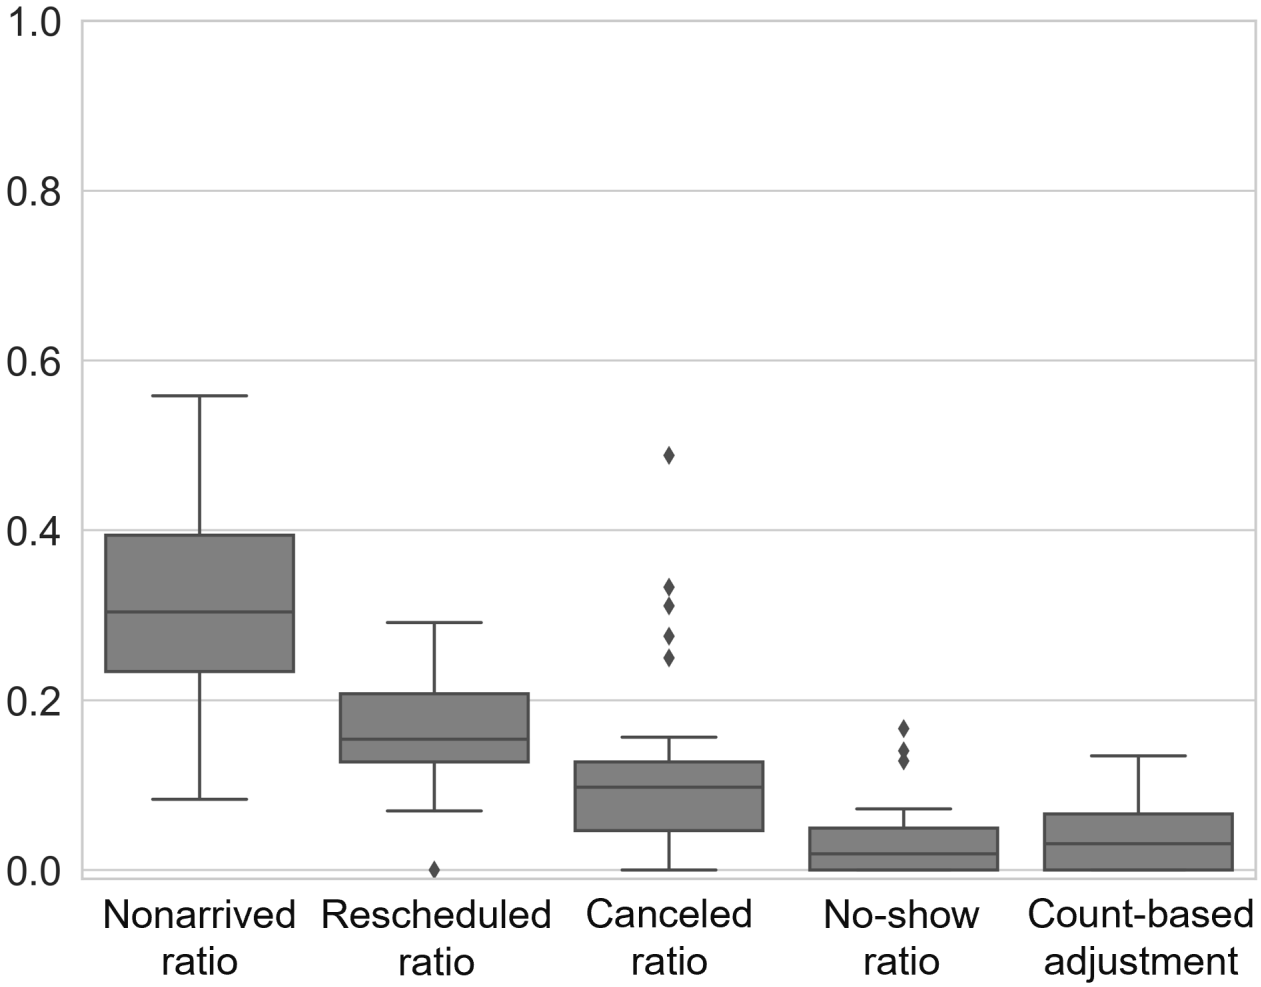
For this pilot evaluation, we use 1 year of scheduling data for each patient starting from their date of diagnosis. Furthermore, 1 year of scheduling data was chosen because the majority of patients completed curative treatment within the first year after diagnosis. Sequence complexity, resolution complexity, location

XSL•FO
RenderX

complexity, and scheduling complexity was calculated for each patient separately. In addition, we calculated count-based metrics: arrived ratio, rescheduled ratio, canceled ratio, and no-show ratio. We define an aggregated count-based adjustment metric as the harmonic mean of rescheduled ratio, canceled ratio, and no-show ratio. Count-based adjustments and scheduling complexities are stratified using quartiles and compared. We stratify patients into high, medium, and low complexities using the upper quartile, middle quartiles, or lower quartiles respectively. We used χ^2 test to compare our scheduling complexity metric to count-based adjustments because they are commonly used in first order analysis of scheduling data. All analysis was done in Python (version 3.0; Python Software Foundation).

Ethical Considerations

This research was approved by the Georgetown University Institutional Review Board (STUDY00003543). This study was registered with ClinicalTrials.gov (NCT04836221). Written informed consent was obtained before conducting all study procedures, which allowed for secondary analysis of participant data without additional consent. A Health Insurance Portability and Accountability Act waiver and access to medical record data was included in the signed informed consent. All data included in this manuscript are deidentified and reported in aggregate. Data obtained through the study adhere to data protection and institutional review board standards as determined by the governing institution. Participants were compensated US $50 at the completion of the study.



Results

Schedule Descriptives

A total of 38 female patients with breast cancer with an average age of 67.1 (SD 8.5), from 3 referring oncology providers had a median of 88 unique AID (IQR 60.3: first quartile [Q1]=59, third quartile [Q3]=119.3), 62 arrived appointments (IQR 47.8: Q1=38.7, Q3=86.5), 13 rescheduled appointments (IQR 13.5: Q1=7.5, Q3=21), 9 canceled appointments (IQR 10.0: Q1=3, Q3=13), and 1.5 missed appointments (IQR 5: Q1=0, Q3=5). The median nonarrived ratio was 0.304 (IQR 0.161: Q1=0.233, Q3=0.394). The median rescheduled ratio was 0.154 (IQR 0.080: Q1=0.127, Q3=0.207). The median canceled ratio was 0.098 (IQR 0.081: Q1=0.046, Q3=0.127) and the median no-show ratio was 0.019 (IQR 0.049: Q1=0, Q3=0.049). Figure 3 is a summary boxplot of nonarrived, rescheduled, canceled, and no-show ratios with nonarrived ratio being the largest. The median sequence complexity was 0.200 (IQR 0.100: Q1=0.140, Q3=0.240). Figure 4 is a summary boxplot of sequence, resolution, location, and scheduling complexities with location complexity being the largest. The median resolution complexity was 0.372 (IQR 0.398: Q1=0.188, Q3=0.586). The median location complexity was 0.464 (IQR 0.371: Q1=0.279, Q3=0.650). Finally, the median scheduling complexity was 0.239 (IQR 0.173: Q1=0.156, Q3=0.329).

Comparison of Count-Based Adjustments With Scheduling Complexity

A total of 18 patients exhibited medium count-based complexities, 10 patients exhibited high count-based complexities, and 10 patients exhibited low count-based complexities. Similarity, 18 patients exhibited medium scheduling complexities, 10 patients exhibited high scheduling complexities, and 10 patients exhibited low scheduling complexities. There was no statistically significant difference in count-based adjustments and scheduling complexity bins (χ^2_4=6.296, P=.18). Table 2 shows the count-based and scheduling complexities were the same for 16 patients, 11 of which had both medium scheduling and count-based complexities. Furthermore, 5 patients exhibited high scheduling complexity with low count-based adjustments and 2 patients who exhibited high count-based adjustments with low scheduling complexity.

Table . Correlation of scheduling and count-based complexities binned by low, medium, and high.

Scheduling complexity	Count-based adjustments		
	Low	Medium	High
Low	3	5	2
Medium	2	11	5
High	5	2	3

In addition, Figure 5 gives examples of high scheduling complexity and low count-based adjustments, high count-based adjustments and low scheduling complexity, low scheduling complexity and low count-based adjustments, and high scheduling complexity and high count-based adjustments. Patient A had both low count-based adjustments and low scheduling complexity. Patient A's schedule is a good example of appointments following the first-in first-out pattern, that is appointments scheduled first will be arrived to first. In addition, Patient A only had 3 rescheduled appointments. Patient B had high count-based adjustments but low scheduling complexity; 40% (8/20) of Patient B's AID were rescheduling actions which likely contributing to a high count-based adjustments. However, Patient B had low scheduling complexity because these

XSL•FO
RenderX

rescheduling actions occurred only on 2 separate days and followed a first-in first-out sequence. Patient C had low count-based adjustments and high scheduling complexity. Although Patient C had few rescheduling actions (resulting in a low count-based adjustments), her appointments were largely scheduled and arrived to not in chronical order (resulting in a high scheduling complexity). Patient D had both high count-based adjustments and high scheduling complexity. In addition to nonchronical ordering of action, Patient D had 2 canceled and 1 no-show appointment action outcomes.

Figure 5. Examples of high scheduling complexity and low count-based adjustments, high count-based adjustments and low scheduling complexity, low scheduling complexity and low count-based adjustments, and high scheduling complexity and high count-based adjustments. AID: appointment identification; VID: visit identification.

Context From Call Logs: Transportation and Housing Needs

A total of 15 patients specifically indicated transportation or housing insecurity issues. Transportation concerns included "legally blind and worried about metro access," "[patient] feeling unsafe on metro," "transportation challenges to and from appointments," "extensive travel requirements," "making medical transportation rides," and "needing transportation assistance." Housing concerns included "help with finding affordable housing options," concerns related to advocating for tenant rights, home repair needs, "[patient] moving in with relative for a few months to save money," "having to find temporary housing while home is being repaired," "help finding rental assistance programs." Additional examples of identified social needs included a demanding work schedule, complexities with an eye surgery, and the additional responsibility of caring for an ill mother. Scheduling complexity was more sensitive to housing and transportation needs. 86.7% (13/15) of patients specifically indicated transportation or housing insecurity issues were identified as medium or high scheduling complexity compared with 65.2% (15/23) of patients who did not specifically indicate transportation or housing insecurity issues. On the other hand, 60% (9/15) of patients specifically indicated transportation or housing insecurity issues were identified as high with count-based adjustments compared with 82.6% (19/23) of patients who did not specifically indicate transportation or housing insecurity issues Table 3.

Table . Percentage of patients with medium or high complexities by transportation or housing insecurity needs.

Complexity type	Indicated transportation or housing needs (n=15), n (%)	Did not indicate transportation or housing needs (n=23), n (%)
Count-based adjustments	9 (60)	19 (82.6)
Scheduling complexity	13 (86.7)	15 (65.2)

Discussion

Principal Findings

Scheduling complexity stratification provides a novel lens to complement traditional count-based metrics for analyzing scheduling data. The results show that scheduling complexity can identify patients with complex but nonchronical scheduling behaviors missed by traditional count-based metrics. In addition, the study highlights that resolution and location complexity can also serve as an indicator for additional care requirements.

Comparison With Previous Work

This study shows a potential link between transportation and housing needs with schedule complexity. This study reinforces previous research relating social risk factors and schedule complexities [4,9]. Our results complement these findings as it relates to transportation and housing needs and highlights the potential use of the scheduling complexity algorithm to identify patients who might benefit from additional CHW support. Through earlier identification from CHWs, scheduling complexity could help narrow inequities in cancer-care which emerge from social needs. Future studies are needed to better understand temporal sensitivity of this approach, or how quickly in-need patients could be identified.

Support for CHW and Patient Navigators

By examining the temporal patterns of health care use, we gain a more comprehensive view of patients' experiences. Instead of relying solely on infrequent screeners, scheduling complexity can give CHWs and patient navigators a more "real-time" view of patients who might require more support in managing their health care journey, for example patients with changing, complex, and distributed care and changes in living conditions or social needs. In addition, scheduling complexity could also be used to identify care plans that might involve more complexity and preemptively identify patients that might need more support. This data-driven approach can help complement the often manual process for identifying patients who might benefit from additional assistance, potentially affording CHWs and patient navigators more time to directly care and help patients [13]. Additional research is needed to evaluate the utility of this algorithm in near "real-time" applications for CHWs.

Limitations and Future Directions

There are several limitations to consider in this pilot work. First, this research is constrained by its retrospective analysis design, relying on historical data and records. Second, a naïve weighting approach was taken in which sequence, resolution, and location complexity are weighted equally in the algorithm. These components might require different weights depending on circumstances. For example, for cancer care at integrated cancer centers, location complexity would probably be less important than sequence and resolution complexities. Third, the study exclusively focuses on the scheduling system of a single urban cancer institute. As such, the results only reflect the central tendencies given the specific conditions and scheduling pattern characteristics of our patient cohort. The generalizability this approach and interpretation of the metrics to other health care systems and patient conditions will need to be explored. Fourth, while this approach has provided insights, it does not fully capture the entirety of factors that contribute to scheduling intricacies, such as resource allocation, patient preferences, and staff availability. Further validation is needed beyond this case example, particularly with a larger patient sample to better capture variations in the scheduling complexity data. Nevertheless, this method could complement other approaches such as patient and scheduler interviews. This work should also be explored in a larger sample size to further explore our hypotheses generated about scheduling complexity.

Conclusion

Patients facing complex health care journeys often experience significant impacts on various aspects of their lives, including family dynamics and work commitments. While there was no

XSL•FO
RenderX

statistically significant difference in count-based adjustments and scheduling complexity bins, we showed that scheduling complexity can uniquely identify patients with complex and nonchronical schedule behaviors. We highlight the potential use of scheduling complexity in identifying patients who might need care coordination support especially as it relates to transportation and housing needs.

Abstract

Background: "Patient Voices" is a software developed to promote the systematic collection of electronic patient-reported outcome measures (ePROMs) in routine oncology clinical practice.

Objective: This study aimed to assess compliance with and feasibility of the Patient Voices ePROM system and analyze patient-related barriers in an Italian comprehensive cancer center.

Methods: Consecutive patients with cancer attending 3 outpatient clinics and 3 inpatient wards were screened for eligibility (adults, native speakers, and being able to fill in the ePROMs) and enrolled in a quantitative and qualitative multimethod study. Compliance, reasons for not administering the ePROMs, patients' interaction needs, and patient-perceived System Usability Scale (range 0-100) were collected; semistructured interviews were carried out in a subsample of patients.

Results: From June 2020 to September 2021, a total of 435 patients were screened, 421 (96.7%) were eligible, and 309 completed the ePROMs (309/421, 73.4%; 95% CI 69.8%-77.5%; mean age 63.3, SD 13.7 years). Organization problems and patient refusal were the main reasons for not administering the ePROMs (outpatients: 40/234, 17.1% and inpatients: 44/201, 21.9%). Help for

XSL•FO
RenderX

tablet use was needed by 27.8% (47/169) of outpatients and 10.7% (15/140) of inpatients, while the support received for item interpretation was similar in the 2 groups (outpatients: 36/169, 21.3% and inpatients: 26/140, 18.6%). Average System Usability Scale scores indicated high usability in both groups (outpatients: mean 86.8, SD 15.8 and inpatients: mean 83.9, SD 18.8). Overall, repeated measurement compliance was 76.9% (173/225; outpatients only). Interviewed patients showed positive attitudes toward ePROMs. However, there are barriers to implementation related to the time and cognitive effort required to complete the questionnaires. There is also skepticism about the usefulness of ePROMs in interactions with health care professionals.

Conclusions: This study provides useful information for future ePROM implementation strategies, aimed at effectively supporting the routine clinical management and care of patients with cancer. In addition, these findings may be relevant to other organizations willing to systematically collect PROMs or ePROMs in their clinical routines.

Trial Registration: ClinicalTrials.gov NCT03968718; https://clinicaltrials.gov/study/NCT03968718

Introduction

Patient-reported outcome measures (PROMs) are questionnaires for the self-assessment of patients' symptoms, well-being, and functional status associated with their health condition, without interpretation by a clinician or anyone else [1,2]. Well-validated PROMs are considered the gold standard for the collection of subjective health-related outcomes [3,4].

PROMs were initially developed to be used in research, but interest has been growing in integrating them into cancer clinical practice to facilitate personalized care management [5]. There is now a wealth of evidence indicating that PROMs may improve symptom control, communication, patient satisfaction, quality of life, and overall survival. In addition, consistent use of PROMs may contribute to reduce emergency room access and hospitalization rates [6-11].

Despite the generally positive effects and favorable attitudes reported by health care professionals (HCPs) [12-15], PROMs are not systematically implemented in routine oncology practice [16,17]. Potential facilitators to the routine use of PROMs have been highlighted, such as automatic scoring, immediate availability of above cut-off values, and time-trend visualization, along with automatic triggers and recommendations for clinical action. However, the barriers to PROM implementation act at many levels [18-20]. At the HCP and service level, major barriers include the workload associated with administering questionnaires, the lack of clear guidelines and confidence in routine use, difficulties in scoring and interpreting the results, and integration of PROMs into clinical workflows [17,19].

Electronic PROMs (ePROMs) have been proposed [21] to improve their applicability and acceptability by HCPs. Yet, inadequate IT infrastructures and ePROM systems that are not integrated with the electronic medical record (EMR) [22,23] emerged as critical issues. Relevant among these is the need for HCPs to connect to multiple systems, the increased risk of poor care coordination, inefficiencies in activating clinical pathways and referrals, and missed opportunities for care improvement [18,24].

Patient-related barriers also hinder the use of PROMs and include the negative perception of PROMs as time-consuming and burdensome to complete, difficulties in using electronic devices, lack of adequate explanations and support, and privacy concerns [19,22].

The Patient Voices project started in 2018 at the Fondazione IRCCS Istituto Nazionale dei Tumori (INT) in Milan (Italy), with the purpose of promoting the systematic collection of ePROMs in routine cancer care through a software system integrated into the hospital EMR that has not yet been implemented [25]. The system was designed in compliance with recommendations provided by the European Society for Medical Oncology clinical practice guideline on the role of PROMs in the continuum of cancer care [26]. The aim of the project was 2-fold: on the one hand, to explore the technical viability and the attitude of HCPs toward such an integrated ePROM system; on the other hand, to test its workability in a pilot implementation in routine oncology clinical practice in different settings of the hospital. This study aims at reporting on the assessment of compliance and feasibility of ePROM implementation as well as identifying patient-related implementation barriers.

Methods

Study Design

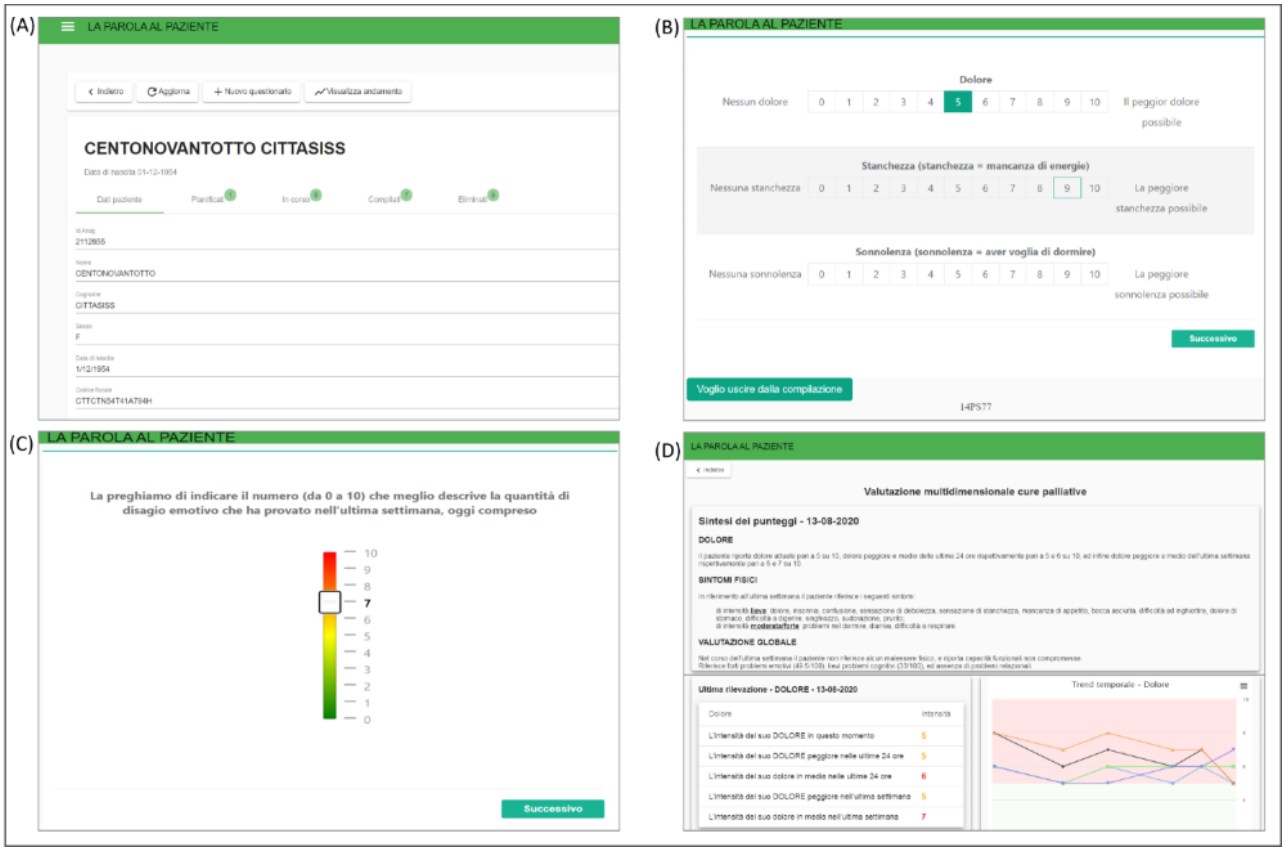
This study used a multimethod design based on concurrent quantitative and qualitative data collection. The aim was to increase the chances of getting varied and extensive research findings on the feasibility of the systematic use of ePROMs.

Data were collected and analyzed from the following substudies:

- Quantitative longitudinal substudy A: ePROMs were used for symptom screening and monitoring in patients with cancer who attended 3 outpatient clinics at INT, that is, palliative care, genitourinary oncology, and radiotherapy clinics.
- Quantitative cross-sectional substudy B: ePROMs were used to assess psychological distress among inpatients

XSL•FO
RenderX

admitted to urological surgery, medical oncology, and colorectal surgery wards.
- Qualitative feasibility substudy C: Semistructured interviews were carried out with a subgroup of patients involved in the previous quantitative substudies, with the aim to explore in depth the patient-related barriers to successful implementation.



More methodological details are reported elsewhere [25].

Patient Voices ePROM System

The Patient Voices ePROM system was developed in 2020 at INT in collaboration with Politecnico of Milan (Italy). After a predevelopment phase, running an ad hoc analysis of technical and user requirements, the web-based application was integrated with the INT information system, including the EMR, and runs only under the hospital network. The system involves 4 kinds of users [25]: the administrator, who operates through a dedicated dashboard to authorize users to system access and to download PROM data for reports and research; the data collection coordinator (DCC), who registers patients and trains them to use the system; the patient, who completes the assigned questionnaires through a tablet provided by the hospital; and the clinician, who has access to real-time textual and graphical PROM data from the EMR.

Figure 1 shows sample screenshots from the Patient Voices ePROM system for the different users (fictional data).

Figure 1. Screenshots from the Patient Voices electronic patient-reported outcome measure system for the different users. (A) Patients' data registration by the data collection coordinator. (B) Edmonton Symptom Assessment Scale questionnaire compilation by the patient. (C) Distress Thermometer questionnaire compilation by the patient. (D) Visualization of Therapy Impact Questionnaire scores by the clinician.

Questionnaires (ePROMs)

The Patient Voices system was designed to allow for flexibility in the choice of questionnaires to be administered to patients. For the feasibility substudies A and B, the following questionnaires could be electronically administered:

- Edmonton Symptom Assessment Scale (ESAS) [27]: It requires the patient to rate a list of physical and psychological symptoms on a 0-10 numerical scale and was used in genitourinary cancer and radiotherapy clinics in substudy A.
- Therapy Impact Questionnaire (TIQ) [28]: It includes questions on physical symptoms (24 items), overall well-being (1 item), functional and emotional status (3 and 4 items, respectively), as well as cognitive and relational status (2 items each). The reference time is the previous week, and responses are collected on verbal rating scales (no or a little bit or quite a bit or very much). For this study, TIQ was complemented with five 0-10 numerical rating scales assessing pain intensity with different time referral. As this implementation project aimed to meet the needs of clinicians, the TIQ and the pain scales were chosen in place of the ESAS in the palliative care outpatient clinic, as these were the paper-and-pencil PROMs routinely used in that ward.
- Distress Thermometer (DT) [29]: It is a single 0-10 numerical scale on which participants rate their level of distress from any cause in the previous week. The DT is supplemented by a 35-item problem list, which prompts patients to identify their problems in practical,

XSL•FO
RenderX

family-related, emotional, spiritual or religious, and physical domains. Scores of 4 or higher suggest clinically significant distress. The DT was used with inpatients involved in substudy B.

All the above ePROMs are validated in the Italian language [28,30-32].

Quantitative Substudies

Study Participants

Consecutive adult patients with cancer (aged ≥18 years) attending one of the previously listed outpatient clinics and inpatient wards during pre-established days in the enrollment period (1 to 2 months for each ward or clinic) were potentially eligible to be enrolled in substudies A and B. Patients with inability to complete the questionnaires due to physical or cognitive impairment, psychological disturbances, or nonnative language issues were not eligible for the study. All participants attended as volunteers and gave their written informed consent to participate in the research.

Data Collection Procedures

A systematic screening of all patients attending inpatient wards and outpatient clinics was performed by a dedicated research nurse, who acted as the DCC. Reasons for not administering ePROMs were collected and classified as patient related (cognitive impairment, physical conditions, and language issues), institution related (organizational problems and patient already enrolled in another clinical trial), or patient refusal. After the eligibility screening and informed consent collection, the DCC provided basic training on how to use the tablet and explained how to fill in the questionnaire. Patients involved in substudy A filled in the ePROM at all subsequent visits during the data collection period, while patients involved in substudy B filled in the DT on admission only.

The DCC supported the patients while filling out the questionnaire, recording whether and how often the patient needed help in using the device or interpreting the questions. A specific DCC "structured form" was used for collecting such data, which were then analyzed using descriptive statistics. The time needed to complete the questionnaire by each patient was registered by the system.

After ePROM completion, patients were asked to fill in a paper-based questionnaire on their educational level and familiarity with electronic devices and internet use. Patients' demographic and clinical data (sex, date of birth, tumor site, year of cancer diagnosis, and visit or hospitalization reason) were extracted from the institutional data warehouse. Data collection was performed using REDCap (Research Electronic Data Capture; Vanderbilt University) electronic case report form [33,34]. Patients' perception and usability of the Patient Voices system were assessed, only for patients filling in the questionnaire, by the System Usability Scale (SUS), a standardized 10-item questionnaire with a final score ranging from 0 to 100 with higher values indicating higher usability [35].

Study End Points

The main end point of the study was compliance with the Patient Voices system, defined as the percentage of eligible patients completing the ePROMs assigned. Secondary end points were the percentage of screened patients who received the ePROMs; the average perceived system usability measured through SUS; the proportion of patients asking for interaction with the DCC to complete the tasks; the average time to fill in the questionnaire; and the successful administration of the questionnaire during subsequent visits (among patients attending outpatient clinics, at least twice during the follow-up period in substudy A).

Sample Size and Data Analysis

In the hypothesis that the compliance is 50% (hypothesis of maximum variability and then maximum imprecision), a sample size of 200 (in both in- and outpatient settings) allows the estimation of a 95% CI for the percentage of compliance with a precision (half-width) of 6.9% [36]. Basic descriptive statistics were applied to characterize the study sample. Point and interval estimates (95% CI) of proportion and averages described in the study end points were calculated for the whole sample and by inpatient ward or outpatient clinic. Cronbach α is used to measure the internal consistency of the SUS in this sample. Values above 0.70 indicate acceptable reliability [37]. The analyses were performed using the standard software packages Stata (StataCorp) and R (R Foundation for Statistical Computing).

Qualitative Substudy

Study Participants

Patients in the qualitative interview substudy were recruited among those who had completed at least 1 of the ePROMs administered in substudies A or B. Purposive sampling was undertaken to guarantee the inclusion of participants with a broad range of characteristics, such as disease site and stage, age, and sex.

Data Collection Methods and Procedures

A topic guide developed by the research team and based on a literature review [19,24,38,39] was used to structure the interviews with patients. This guide included questions on the feasibility and acceptability of the routine use of ePROMs, the difficulties encountered while completing the questionnaire, the information and help received about ePROMs, and the perception of the impact of these tools on clinical consultation. In addition, there was scope to digress from the guide if participants raised new and relevant topics.

After an initial training session, face-to-face interviews were conducted, audio recorded, and transcribed ad verbatim by volunteers from *Associazione Italiana Malati di Cancro* (AIMAC; Italian Association of Cancer Patients). The interviews were conducted between May and November 2021 and lasted an average of 28 (SD 11.02) minutes. The interviews (and participant involvement) were carried on until thematic saturation had been reached and no new insights could be drawn from additional participants [40].

XSL•FO
RenderX

Data Analysis

Interview transcripts were imported into NVivo (version 12; Lumivero) for data management, coding, and analysis [41]. Patients' names were transformed into textual and numeric strings to ensure data pseudoanonymization. Verbatim transcripts were analyzed using a thematic analysis approach, as described by Braun and Clarke [40]. Initial coding was done by 1 author (L Lombi), then supervised and verified by other 2 authors (C Brunelli and SA). Once the interviews had been initially coded, a finer analysis was conducted to identify themes, sample quotes, and interconnections between themes.

Some results of this qualitative study, particularly regarding participants' perspectives on the implications of using ePROMs for the clinical encounter, were discussed in Lombi et al [42]. In this work, we focused on findings concerning the perceived barriers to ePROM integration into oncological clinical routine.

Ethical Considerations

This study was approved by the institutional ethics committee of Fondazione IRCCS INT (Milan, Italy; INT 167/18) and complied with the Declaration of Helsinki. Participants provided written consent before the visit or during hospitalization. Participants were informed about (1) research purposes, (2) privacy, (3) use of the information obtained, (4) that participation was voluntary and unrewarded, and (5) that they could leave the research at any time without giving explanations. All the data were deidentified before data analysis and storage. There was no compensation for participation in the study.

Results

Quantitative Results

From June 2020 to September 2021, a total of 435 consecutive patients were screened, 421 (96.7%) were eligible, and 309 filled in the ePROMs, which indicates compliance of 73.4% (309/421; 95% CI 69.8%-77.5%). All patients who were administered the ePROM completed it, and no one stopped before completing the questionnaire.

Overall feasibility (percentage of patients, among those screened, who could be administered the ePROMs) was 71% (309/435; 95% CI 66.5%-75.2%). Table 1 shows comparable feasibilities by in- and outpatients; 69.6% (140/201; 95% CI 62.8%-75.2%) and 72.2% (169/234; 95% CI 66%-77.8%), respectively. Organization problems, such as pressure on time and difficult patient flow management, were the main reason for not administering ePROMs among outpatients (40/234, 17.1% vs inpatients: 5/201, 2.5%), whereas patient refusal was the main reason for inpatients (44/201, 21.9% vs outpatients: 10/234, 4.3%).

While the feasibility rates were similar in the 3 inpatient wards (colorectal surgery: 44/60, 73.3%; medical oncology: 48/70, 68.6%; and urological surgery: 48/71, 67.6%), higher heterogeneity was found in outpatient clinics, with the palliative care clinic showing the higher feasibility (59/65, 90.8%), followed by the radiotherapy clinic (42/54, 77.8%), and the genitourinary oncology clinic (68/115, 59.1%; Figure 2).

Table 2 reports demographic, disease characteristics, and the use of technological tools by patients who filled in the ePROMs.

Most of the responders stated that they regularly used smartphones (240/309, 77.7%) and the internet (203/309, 66%). About half of them (159/309, 51.5%) were quite familiar with computer, while tablet use was less common (65/309, 21%). In total, 24 (7.8%) patients reported they were not using any electronic devices or the internet.

Table 3 shows the interaction and help needed by patients during ePROM filling in. More help and interaction with the DCC to use the tablet was needed by outpatients (47/169, 27.8% vs 15/140, 10.7%), and overall, 244 (78.9%) out of 309 patients did not need help to use the tablet. Help received for the interpretation of questions was similar in the 2 settings (outpatients: 36/169, 21.3% and inpatients: 26/140, 18.6%). Of note, 216 (70%) out of 309 patients did not need any kind of interaction to fill in the ePROM (data not shown in table).

In a limited number of patients, although considered eligible for the study in the enrollment phase, the ePROM was filled in by the nurse upon patient interview (10/140, 7.1% vs 13/169, 7.7% in the inpatient and outpatient group, respectively) mainly because of physical issues (2/140, 1.4% of inpatients and 6/169, 3.6% of outpatients) and pain or asthenia (3/140, 2.1% of inpatients and 3/169, 1.8% of outpatients), which prevented them from being completely independent when filling in the questionnaire.

System usability, as measured by the SUS, was above 80 for both inpatient and outpatient groups (mean 86.8, SD 15.8 and mean 83.9, SD 8.9, respectively). Cronbach α was 0.84 (95% CI 0.77-0.88) in the overall sample. On average, the TIQ and DT required more time to be filled in (mean 6.63, SD 5.52 minutes and mean 6.25, SD 4.17 minutes, respectively) compared to the ESAS (mean 3.70, SD 2.79 minutes), as expected due to the different length of the questionnaires.

Figure 3 shows the repeated administration of ePROMs among outpatients who underwent at least 1 follow-up visit (n=225). The maximum number of completed questionnaires was 6 (including baseline ePROMs) of a total of maximum 7 visits recorded for this study, with 76.9% (n=173) of the overall follow-up ePROMs filled out.

Figure 3. Electronic patient-reported outcome measure (ePROM) administration at follow-up for patients undergoing at least 1 follow-up visit. Cross symbols: ePROM completed; circle symbols: ePROM not administered.

Qualitative Results

Sociodemographic Characteristics of Participants

A total of 19 one-to-one interviews were conducted. Participants' age ranged from 35 to 78 (mean 57, SD 12.63) years, 10 (53%) were female, and 11 (58%) had completed secondary education. In total, 9 (47%) participants completed the DT, 8 (42%) completed the ESAS, and 4 (21%) completed the TIQ and pain scales. Some participants completed repeated ePROMs.

Attitude Toward ePROMs and Barriers to Successful Implementation

Participants were generally satisfied with ePROM administration and had positive attitudes toward their use in routine oncology practice. Many of their comments focused on the benefits of ePROMs, including improvement of quality and personalization of care through a holistic approach, increased chances of talking about their symptoms over time, increased awareness of both clinicians and patients about symptoms in real time, aid in rapidly detecting abnormal parameters, and perception to be engaged in scientific research.

Five key dimensions emerged from thematic analysis, relating to potential barriers to successful implementation of ePROMs in routine oncological care. The dimensions are reported in Table 4 alongside significant quotes from patients.

XSL•FO
RenderX

Table 4. Summary of dimensions identified from patient interviews (qualitative substudy C).

Barrier	Illustrative quotes
1. Skepticism toward ePROM[a] use during consultation with health care professional	• "...The way I see it, even the doctor or whoever is visiting you, that is, if he has to study your medical record, read your questionnaire, in one day he has so many patients, that is, it becomes a bit complicated to receive..." [Interview 18, male, 43 years old]. • "It doesn't help anybody. Because often it can happen, so we make a lot of papers, we put a lot of news...On the tablet, on the patient's health record...But if they are not read...They remain a dead letter, as they say, nobody needs them" [Interview 2, female, 74 years old].
2. Skepticism toward ePROMs as tools to examine symptoms	• "(The questionnaire is) very general...We should go into the specifics, everyone has different symptoms according to their history, their life, their way of living and everything...I mean...To their way of living" [Interview 10, female, 72 years old]. • "Definitely a self-limited questionnaire, in the sense, with specific questions, with closed answers, therefore it can be filled in...details should be provided, if necessary. If one feels compelled to write something else, related to each of these issues, the possibility of further compilation could be considered" [Interview 13, male, 38 years old].
3. Cognitive difficulties	• "In fact, the first time...I was wrong, because I went to the right, because...I gave 'No pain = 10', meaning I don't have any. And instead, she told me 'No, look, 10 is the worst'. Well, I hadn't looked closely, I had looked here...I hadn't understood, do you see?" [Interview 11, female, 61 years old]. • "I assumed that at first glance I would have said, probably because of the professional deformation I have...that 0 was the minimum and 10 the maximum. Instead, in some situations it is the opposite...That is, I didn't stop to think that no pain was zero and maximum pain was 10. I said, 'no pain, OK no pain, 10!'. Because I was fine, you know?" [Interview 1, female, 65 years old].
4. Technological issues	• "I'm bad with technology, so I'll tell you, sometimes I mess up so much with the phone that half is enough and so others always have to step in, but whatever." [Interview 4, female, 78 years old]. • "Paper for me is always better...a book for me is a paper book...when I feel paper...I like it! Then at home we have tablets, we have computers, we have everything...but...it's always nice to be able to write...I like it..." [Interview 3, male, 66 years old].
5. ePROMs as time-consuming tasks	• "Yes, it's counterproductive...And then it makes people feel less inclined because the person is there for the visit, not to fill out the form...The form is given to him, he fills it out, but if it takes half an hour to fill out the form when the visit was scheduled at two o'clock and he goes in at half past two he's upset...Because he's wasting time and because it's not correct in short" [Interview 6, male, 59 years old].

[a]ePROM: electronic patient-reported outcome measure.

The five key dimensions are as follows:

1. Skepticism toward ePROM use during consultation with HCPs: During the interviews, several participants complained that their ePROM results were not discussed or even mentioned during the clinical encounter. As a result, many patients doubted that clinicians had consulted their responses likely because of time pressure and work overload.
2. Skepticism toward ePROMs as tools to examine symptoms: Some patients criticized the use of a questionnaire based on close and structured questions to explore their health status and well-being, as these are dimensions that should be investigated through more flexible tools, that is, open questions also including descriptive comments.
3. Cognitive difficulties: Several participants, mostly among those who were asked to complete the TIQ and pain scale, mentioned problems to fill out the questionnaire due to the perceived complexity of the scales.
4. Technological issues: Patients, although older patients, generally stated that they had no difficulties using the tablets to fill out the ePROMs, with the only exception of 1 person who acknowledged limited digital skills and required direct support from the DCC. Two patients said they had no difficulties with the tablet, but they would have preferred to fill out the ePROMs in paper format.
5. ePROMs as time-consuming tasks: Mentioned by only 1 participant, the time required to complete the ePROMs was perceived as potentially lengthening the waiting time and delaying the visit.

Discussion

Principal Findings and Comparison With Prior Work

This study explored the compliance and feasibility of implementing an ePROM system integrated with the EMR in the clinical management of patients with cancer attending hospital wards or outpatient clinics. Potential patient-related barriers to the routine use of ePROMs were analyzed, collecting both reasons for not filling in and patients' views on the difficulties encountered while filling in the questionnaires.

The results showed good compliance and feasibility both by inpatients and outpatients. Most of them (244/309, 78.9%) were able to fill out the questionnaire without any help in using the device, which suggests that the electronic format was not a major barrier. In support of this, many participants stated that they regularly used smartphones, computers, and the internet, indicating a certain degree of familiarity with technology tools. Besides, system usability scores confirmed that the experience with the ePROM system was more than satisfactory by most of the patients in both clinical settings, and the qualitative results

XSL•FO
RenderX

also point in this direction. Indeed, in planning this project, we chose to use a system for ePROM collection that would facilitate the procedure from the patient's standpoint. Patients neither had to download any app or software nor register or log in via password; instead, they were provided with a tablet ready to fill out the questionnaire. Clearly, more proactivity by the patient would be needed in case of remote ePROM assessment on the patient's own personal devices. In any case, as already highlighted by several studies [19,22,43,44], basic IT literacy remains a prerequisite for electronic assessment, and addressing this issue, especially among older patients, is a priority.

The feasibility for outpatients at follow-up visits was also good: three-quarters of the total number of ePROMs administered after the baseline visit were completed, and more than half of the patients filled in the questionnaire at each consecutive visit, indicating an overall positive attitude toward regular use of health technologies. When interviewed, patients reported several benefits from ePROMs, including actively participating in their health care and improving patient-clinician communication.

Approximately 3 in 4 patients successfully filled in the questionnaire regardless of clinical setting. This is a very positive result considering that the administration of ePROMs took place in the context of a research study, which implies that data can be collected only after going through preliminary procedures concerning patient information, privacy, and consent to participation. If, as recommended, ePROMs were part of routine clinical practice, they would be administered to patients by default just like any other medical test or diagnostic noninvasive procedure.

Feasibility was similar in the 2 clinical settings, but the reasons for not filling in the ePROMs were different. In all 3 hospital wards, the main reason was patient refusal, which was 21.9% (44/201). Unfortunately, we could not collect any further information on refusal because patients were not specifically asked and did not spontaneously explain why they preferred not to participate in the study. Another important reason for not filling in was the language barrier for people not fluent in Italian (9/201, 5%), which, however, could be easily overcome by implementing different languages within the same ePROM to offer questionnaires also to nonnative speaking patients. In contrast to inpatient wards, outpatient clinics showed mainly institution-related reasons for not filling in, with organizational problems significantly affecting the feasibility rate. It is noteworthy that the palliative care outpatient clinic showed the highest feasibility (59/65, 90.8%), probably because in this clinical setting, both clinicians and patients are particularly well trained and accustomed to the use of paper-based PROMs that have been part of routine patient care for decades.

Similar studies exploring the compliance and feasibility of an ePROM system integrated into an existing clinical setting have reported good acceptance of both patients and HCPs [43,45-48], suggesting there is potential to use such instruments to improve the quality of information collected from patients by hospital systems. Yet, some challenges need to be addressed, including the patient-related barriers, which are also reported here (ie, time and cognitive burden upon patients to complete the questionnaires and skepticism toward ePROM use during a consultation with HCP) and are highly dependent on contextual factors. For example, a limitation of this study is that the 2 groups of patients were not administered the same ePROMs. This did not allow to distinguish the effect of the clinical setting (inpatient vs outpatient) from the effect of the type of questionnaires offered to inpatients (DT) and outpatients (ESAS and TIQ) on their different refusal rates. It can be assumed that patients awaiting surgery are less willing to take part in a research project than outpatients. On the other hand, filling in a questionnaire on psychological distress may be perceived as more burdensome than reporting about physical symptoms [49]. However, a combined effect of both these aspects on the higher inpatient refusal rate cannot be excluded.

Patients' perception that ePROMs are not valid tools to explore their own symptoms and well-being and share this information with clinicians has been reported by several studies [3,13,19,22,50]. Therefore, efforts should be made to ensure that patients receive adequate information about the questionnaire they are asked to complete and understand the value of PROM collection.

The time needed to fill out the PROMs and difficulties met in completing some items are also relevant barriers already reported in the literature [19,22,23,46]. Patients with cancer may perceive ePROMs as burdensome, as they see them as additional tests that negatively impact on the time already spent in visits, procedures, and treatments. For some patients, the questionnaire can also be difficult to complete without help, as our results showed, and this can be frustrating. Thus, selecting ePROMs that are both sufficiently informative and not overly burdensome for the patient is a critical aspect for their successful implementation.

Limitations and Future Work

This study has some limitations that should be considered. First, we acknowledge that this study was carried out in a single comprehensive cancer center, and this aspect may limit the generalizability of the results. However, existing evidence recommends that individual clinical settings independently examine local barriers in order to adopt ad hoc solutions [19,22,48,50,51].

Second, our results were obtained in the context of a research study. This implies that, on one side, compliance might be underestimated (patient refusal might be about the clinical study and not about filling in the ePROMs); on another side, feasibility might be overestimated, as data collection with a dedicated nurse might be difficult to replicate in real-world implementations due to lack of resources.

For ePROMs to supplement clinician-reported outcomes with useful information and help in patient's care, they should be efficient, effective, and satisfactory for stakeholders [21,52,53]. The European Society for Medical Oncology guideline recommends that PROMs evaluate outcomes that are clinically meaningful and actionable in the reference population and emphasizes that a single software system with PROM functionalities suitable for any stage of cancer disease would be the optimal solution, although technically challenging. However, evidence supporting the implementation of PROM

XSL•FO
RenderX

systems along the entire cancer trajectory is limited and largely based on studies under highly controlled conditions rather than on real-world data from routine clinical settings [26]. Based on these recommendations, this study contributes real-world evidence to support the integration of ePROMs into the hospital information system for their use in routine oncology practice.

Conclusions

At this feasibility stage, the patient-related barriers reported in this study provide useful information for improving future implementation strategies, which will be aimed to effectively support the routine clinical management and care of patients with cancer. In addition, these findings may be relevant to other organizations willing to implement a systematic use of PROMs or ePROMs in their clinical routines. Finally, current evidence suggests that the creation of a cultural infrastructure that values PROMs, that encourages and instructs HCPs to use these tools routinely, and that actively involves patients in their health care process is a key element in fostering the uptake of PROMs in real-world clinical settings [3,48,51].

Acknowledgments

The authors would like to thank Dr Michela Monfredini for her contribution to data collection. The Patient Voices study group includes GA, Marco Bellazzi, Filiberto Belli, C Borreani, C Brunelli, Giuseppi Capri, AC, Paolo Casali, Paolo Corradini, Filippo de Braud, Anna Maria Foschi, Secondo Folli, Marina Garassino, Lisa Licitra, NN, Chiara Pellegrini, MP, GP, AR, Roberto Salvioni, Pierangelo Spada, Riccardo Valdagni, and E Zito and Fondazione IRCCS Istituto Nazionale dei Tumori-Milano. Abstract

Background: Computer-aided detection and diagnosis (CAD) systems can enhance the objectivity of visual inspection with acetic acid (VIA), which is widely used in low- and middle-income countries (LMICs) for cervical cancer detection. VIA's reliance on subjective health care provider (HCP) interpretation introduces variability in diagnostic accuracy. CAD tools can address some limitations; nonetheless, understanding the contextual factors affecting CAD integration is essential for effective adoption and sustained use, particularly in resource-constrained settings.

Objective: This study investigated the barriers and facilitators perceived by HCPs in Western Cameroon regarding sustained CAD tool use for cervical cancer detection using VIA. The aim was to guide smooth technology adoption in similar settings by identifying specific barriers and facilitators and optimizing CAD's potential benefits while minimizing obstacles.

Methods: The perspectives of HCPs on adopting CAD for VIA were explored using a qualitative methodology. The study participants included 8 HCPs (6 midwives and 2 gynecologists) working in the Dschang district, Cameroon. Focus group discussions were conducted with midwives, while individual interviews were conducted with gynecologists to comprehend unique perspectives. Each interview was audio-recorded, transcribed, and independently coded by 2 researchers using the ATLAS.ti (Lumivero, LLC) software. The technology acceptance lifecycle framework guided the content analysis, focusing on the preadoption phases to examine the perceived acceptability and initial acceptance of the CAD tool in clinical workflows. The study findings were reported adhering to the COREQ (Consolidated Criteria for Reporting Qualitative Research) and SRQR (Standards for Reporting Qualitative Research) checklists.

Results: Key elements influencing the sustained use of CAD tools for VIA by HCPs were identified, primarily within the technology acceptance lifecycle's preadoption framework. Barriers included the system's ease of use, particularly challenges associated with image acquisition, concerns over confidentiality and data security, limited infrastructure and resources such as the internet and device quality, and potential workflow changes. Facilitators encompassed the perceived improved patient care, the potential for enhanced diagnostic accuracy, and the integration of CAD tools into routine clinical practices, provided that

XSL•FO
RenderX

infrastructure and training were adequate. The HCPs emphasized the importance of clinical validation, usability testing, and iterative feedback mechanisms to build trust in the CAD tool's accuracy and utility.

Conclusions: This study provides practical insights from HCPs in Western Cameroon regarding the adoption of CAD tools for VIA in clinical settings. CAD technology can aid diagnostic objectivity; however, data management, workflow adaptation, and infrastructure limitations must be addressed to avoid "pilotitis"—the failure of digital health tools to progress beyond the pilot phase. Effective implementation requires comprehensive technology management, including regulatory compliance, infrastructure support, and user-focused training. Involving end users can ensure that CAD tools are fully integrated and embraced in LMICs to aid cervical cancer screening.

(JMIR Cancer 2025;11:e50124) doi:10.2196/50124

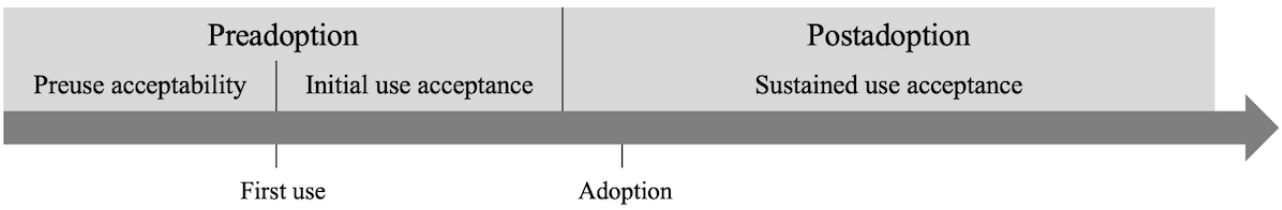
Introduction

Background

In low- and middle-income countries (LMIC), visual inspection with acetic acid (VIA) is a common low-cost method for screening and triage. This method involves applying diluted acetic acid to the cervix during gynecological examination. This induces tissue whitening, which a trained observer assesses to guide the diagnosis. Despite VIA's cost-effectiveness and accessibility, a major limitation is its high subjectivity owing to variability in the training and experience of the observer [1].

With advancements in artificial intelligence (AI), its potential to assist in diagnosis has been extensively explored and investigated [2]. Tools that aid health care providers (HCPs) in detecting diseases and identifying abnormalities are clinical decision support (CDS) systems and, more specifically, computer-aided detection and diagnosis (CAD) systems [3]. In cervical cancer, CAD tools can mitigate the subjectivity inherent in VIA by providing standardized evidence for clinical decision-making [4].

Despite the promising potential of CAD systems, their implementation and sustained use in LMICs are limited, irrespective of the target disease. These barriers include the risk of workflow disruption, dependency on computer literacy, poor data quality, lack of transportability and interoperability (ie, system compatibility), and financial challenges [5]. In addition, frameworks exist to guide the implementation, evaluation, and regulation of these digital health tools [6-10]. However, the lack of harmonization across different entities compounds their development complexity. The technology may not progress beyond the pilot stage because of the previously mentioned reasons—a common phenomenon referred to as "pilotitis" [11].



This study examines the barriers and facilitators to deploying a VIA CAD tool to enhance and standardize cervical cancer diagnosis using AI. User perspectives were collected to understand the challenges and enablers of implementing this technology. This study provides insights into deploying AI-enhanced diagnostic tools in LMICs to bridge the gap between technological development and real-world implementation.

Theoretical Framework

In the context of VIA CAD tools for LMICs, the following definitions are used throughout the paper: (1) acceptability: "the quality of being satisfactory and able to be agreed to or approved of," according to the Cambridge Dictionary [12]; (2) acceptance: "general agreement that something is satisfactory or right," as stated by the Cambridge Dictionary [13]; and (3) adoption: "a multiphase process starting with deciding to adopt [a technology] (selecting, purchasing, or committing to use it) and then achieving persistent use," provided by Carroll et al [14].

These 3 concepts are combined in successive steps in the technology acceptance lifecycle (TAL) proposed by Nadal et al [15]. The model (Figure 1) reveals that technology preadoption is a 2-stage process. First, acceptability before use is preuse acceptability, followed by initial use acceptance once the technology has been used for the first time. Postadoption is considered sustained use acceptance, implying that the device is fully adopted and sustainably used.

Figure 1. Technology acceptance lifecycle adapted from Nadal et al [15].

The TAL model was chosen because it captures key factors in the preadoption phase, which is crucial previous to integrating CAD tools in resource-constrained health care settings. Furthermore, the postadoption phase addresses specific barriers, such as infrastructure and data security, while simultaneously supporting sustained adoption and mitigating pilotitis risk.

XSL•FO
RenderX

Objective

This study focused on the challenges perceived by HCPs that would prevent the sustained use of CAD tools for VIA in clinical settings. The primary objective of this study was to identify the common barriers to adopting CAD tools for VIA, and facilitators were the secondary objective. Barriers and facilitators were studied within the framework of the TAL, especially in the preadoption phase. The study was conducted in Western Cameroon; however, the results are critically interpreted for generalizability to other geographical settings within sub-Saharan Africa or other LMICs.

Methods

Overview

This study is reported per the COREQ (Consolidated Criteria for Reporting Qualitative Research; Multimedia Appendix 1) and SRQR (Standards for Reporting Qualitative Research; Multimedia Appendix 2) checklists.

Study Settings and Recruitment

This study was conducted as part of a cervical cancer screening program in the Dschang district, Western Cameroon. A larger study, the 3T program (for test-triage-treatment), was initiated in 2018 at Dschang District Hospital with the support of the Ministry of Health and in collaboration with Geneva University Hospital [16]. This program includes patient recruitment through awareness campaigns in rural and urban areas, tests for HPV, followed by VIA triage (if the HPV test is positive), and treatment, if necessary. The cervical cancer screening was performed by midwives who welcomed the patients, explained the study, conducted the gynecological examination, and, if required, administered treatment. In the case of severe lesions, the patient was treated by a midwife and gynecologist. Within the scope of this program, images were collected during the colposcopy for peer review of the diagnoses and to develop a CAD tool for VIA. This technology relies on image processing and machine learning [17].

Participants were recruited from trained teams at the Dschang District Hospital and the Regional Hospital of Bafoussam, a second 3T program site approximately 60 km east of Dschang. Every HCP in the 3T program is Cameroonian, better to understand the local context and its specific culture. Participants were compensated for their transportation expenses and provided with refreshments during discussions.

Study Design and Procedure

A qualitative methodology was chosen to capture nuances in participants' views, experiences, and behaviors regarding technology and their environment [18]. Compared with a quantitative approach, a qualitative approach provides better insight into participants' perspectives and provides the flexibility required for participants to highlight information they may not have anticipated [19,20].

A mixed approach composed of individual interviews and mini–focus group discussions (mFGDs) was adopted. Individual interviews contributed to in-depth data collection [21], and mFGDs facilitated the exchange of participants' perspectives and the compilation of collective perceptions [20]. The term "mini" denotes the small group size of 3 participants, which was chosen because of the limited availability of individuals with relevant expertise and the sensitivity of the topic, which benefits from an intimate setting [22]. Due to the HCPs' various educational levels, training, and daily duties, the participants were grouped into homogeneous professional mFGDs. The aim was to create a climate of trust, enabling all participants to express themselves freely and reduce authority bias [23].

Therefore, 2 mFGDs, each with 3 midwives and 3 individual interviews with gynecologists, were conducted between March and May 2022. All discussions were moderated in French—the official language—by a female Cameroonian anthropologist who had worked on the 3T program for several years and had intimate knowledge and familiarity with the professional community. During focus group discussions, in which the perspectives of the HCPs were collected at the Dschang District Hospital, a second female Cameroonian anthropologist took notes to capture nonverbal cues and additional context. An individual interview was conducted via videoconferencing because the medical doctor was traveling. The remaining discussions occurred in clinical settings, either in a confidential conference room at the hospital or a private medical office.

Each interview began with an introduction to the CAD tools for VIA, and the procedure was described in detail. The slides supported the verbal explanation and clarified the following steps. During the gynecological examination, the HCP first applied diluted acetic acid to the cervix, corresponding to the routine VIA. Second, cervical images were recorded using a dedicated mobile app. Subsequently, the algorithm integrated into the mobile app processed the sequence of images and provided an analysis to the user. Finally, the HCP interpreted the results to determine whether treatment was necessary. The entire procedure can be conducted offline; nonetheless, internet-based synchronization with a server is also feasible, ensuring data backup and compliance with data privacy and confidentiality requirements.

A mobile app was specifically developed for the demonstration to concretize the concept for the participants. The mobile app allowed users to capture a series of pictures and generate simulated predictions of cervical cancer. The participants could manipulate the mobile app and take pictures of their surroundings to familiarize themselves with CAD tools for cervical cancer. A semistructured questionnaire was then used to (1) investigate HCPs' perceptions of smartphone use for medical applications, cervical cancer, and AI and (2) identify the challenges and facilitators for integrating CAD tools for VIA in clinical settings.

All interview guide questions were fully addressed, and the participants were given opportunities to ask questions. Finally, participants could share their thoughts and comments. All discussions were audio-recorded, transcribed, and anonymized. Triangulation was applied within and across sessions to enhance data reliability.

XSL•FO
RenderX

Data Processing and Analysis

A total of 4 audio recordings were transcribed verbatim in French, categorized, and coded using content analysis [24]. Therefore, coding was initially deductive based on a codebook, guided by the topics outlined in the interview guide, followed by the generation of inductive codes directly from the transcriptions. Around 2 female coresearchers (MJC and AMDM) independently coded transcripts using the computer-assisted qualitative data analysis software (ATLAS.ti, version 22.2.3) to support scientific rigor and reflexivity. The data were double-coded by a researcher from a different cultural context to address the potential reporting bias that could arise from the shared experience between the anthropologist and the HCPs. The coding was then compared, discussed when diverging, combined, and finally assessed for consistency following the open discussion method [25].

The coded data were analyzed to identify relationships between the categories and hierarchically ordered, with the TAL framework applied as a theoretical lens for interpreting the coded data. Data were analyzed with team members from diverse professional and cultural backgrounds. This combination of expertise and cultural insights strengthened the study design and analysis. Data saturation was confirmed through consistent responses across the mFGDs and interviews. Each mFGD was included, and all sessions were audio-recorded while maintaining confidentiality. Suppose quotations were selected for publication; in that case, they were translated from French into English.

Ethical Considerations

This study was approved by the Ethical Cantonal Board of Geneva, Switzerland (CCER, 2017-01110 and CER-amendment no. 4) and the Cameroonian National Ethics Committee for Human Health Research (2022/12/1518/CE/CNERSH/SP). The participants verbally consented after being informed of the study's purpose, topics, duration, benefits, and risks. Participants were compensated for their transportation expenses. All transcripts were anonymized and analyzed in a fully deidentified manner to ensure privacy and confidentiality. The achievement of data saturation, the presence of 2 researchers during the mFGDs, audio recordings, and triangulation of information attest to the rigor and trustworthiness of the data collection and analysis.

Results

Participants

The study involved all HCPs from both 3T program sites, encompassing 6 midwives and 2 gynecologists, of whom 5 were females and 3 were male participants aged 30-55 years. All participants specialized in cervical cancer, with experience between 6 months and over 10 years, providing insights for evaluating the technology across different stages of professional development. They all owned a smartphone, used it daily, and were familiar with smartphone apps in clinical settings through the 3T program. None of the participants dropped out of the study, and the discussion duration was 42-92 minutes.

Main Results

HCPs' perceptions of adopting a CAD tool for VIA were mainly positive. The HCP highlighted 8 facilitators and 5 barriers that should be addressed in the future.

The barriers were:

- Restriction of the HCP's movement due to the smartphone's position.
- Constraining requirements for the image quality.
- Confidentiality concerns for sensitive data, especially in case of data breach.
- Workflow changes may encourage HCPs to heavily depend on the technology.
- Limited access to internet connection and smartphones.

The facilitators were:

- Improved patient care through rapid and reliable diagnosis.
- Improved diagnosis.
- Reduced workload because of improved efficiency.
- Reinforcement of visual inspection with acetic acid (VIA) protocol.
- Clinical evaluation of the technology in conditions reflecting real-life conditions.
- Automated assessment of image quality.
- Training of the users.
- Provision of smartphones and tripods.

Barriers to CAD Tools for VIA

System Usability Challenges

The smartphone was positioned on a tripod between the gynecological chair and HCP to capture the images. This positioning restricted the movement of professionals during the examination.

> *When pipetting [acetic acid] and the whole cervix is not captured on the smartphone but the recording already started, then we need to twist and turn to finish. For those difficulties, we could pull the trip away, pipet to remove all the acetic acid well, and then position the device.* [P6]

In addition, image quality requirements entail acquisition conditions that are difficult to achieve. These quality assessment criteria can be affected by video movements, light changes, reflections, and the presence of blood or mucus. Furthermore, some HCPs raised concerns that the high-quality images required for an accurate diagnosis would be difficult to achieve, possibly leading to misdiagnosis.

> *[…] So that artificial intelligence provides an accurate result, one will need to fulfill all acquisition conditions. It means that if you make a small mistake in the process, the risk of a false positive or false negative will be high […]* [P2]

Confidentiality

Most HCPs expressed apprehension regarding the handling and storage of sensitive data. Their concerns revolved around potential breaches of medical data confidentiality and the unauthorized sharing of VIA images. Furthermore, they feared

XSL•FO
RenderX

the loss of images due to the misfunctioning or mishandling of smartphones.

> *[…] If I send a picture to someone, they can easily forward it to someone else without asking my permission. There were so many scandals in the field of medicine because someone took a picture with their smartphone, which was shared multiple times and leaked […]* [P8]

An HCP emphasized that framing the picture around the cervix alone can aid confidentiality concerns because it is anonymizing.

> *When using a smartphone to take photos of the cervix, it is beneficial as long as it preserves the woman's privacy by capturing solely the cervix. That way, the woman cannot feel frustrated about her face potentially being seen elsewhere.* [P2]

In addition, using a private mobile phone to take pictures during the gynecological examination was not allowed. The device should be dedicated to only clinical settings and not leave the screening area.

> *[…] the personal mobile phone is never fully private… when you drop it at home, kids may search into it and access the image […] Personally, I believe the mobile phone used needs to be professional only and to stay at the screening site, never reaching someone's home […]* [P8]

Workflow Changes

Several HCPs were concerned that the adaptation of the device might change the workflow, and users might heavily depend on CAD tools, neglecting their expertise. An HCP explained:

> *For me, and my colleagues, if this device is given to medical doctors, they might become lazy. They will not have to do their work fully. As soon as there is a case, they would take the smartphone and would not think about the diagnosis themselves.* [P1]

Therefore, their gynecological knowledge might be affected, possibly limiting patient care in complicated cases.

Limited Infrastructure and Resources

Another challenge regarding adopting the technology is the limited access to resources. Some HCPs were concerned about access to reliable internet connections and smartphones, along with their quality. The wear of the smartphone battery was also a concern.

> *[…] Everyone cannot access a smartphone, everyone cannot access the internet […]* [P8]

Facilitators of CAD Tools for VIA

Patient Care Improvement

Most HCPs agreed that the technology would improve patient care by providing a rapid and reliable diagnosis. According to them, accelerating the diagnosis speed benefited the patients and HCPs. First, patients would not return home with unanswered questions and directives to wait, which could induce stress and unnecessary worry.

> *They [patients] will accept the technology since when coming out of here [the hospital], they will know their diagnosis; they will think, 'They told me that I come back home with a clear head, not like before when I came and I had to wait for a phone call with the results […]* [P3]

Second, the technology could help HCPs provide a diagnosis or mitigate the lack of resources for conducting biopsies. Some professionals also believed that the workload could be reduced using technology that would enable the screening of more women for cervical cancer.

Furthermore, some HCPs mentioned that adopting a CAD tool for cervical cancer could enhance diagnosis by identifying lesions that are challenging to detect with the human eye. This can reduce the potential for human error.

> *If it is efficient, then it would be a very important tool because visual inspection is now very subjective. But if we manage to generate a diagnosis from a simple image, that would be a very good progress.* [P7]

This technology may also reinforce the protocol for performing appropriate VIA. For example, the predetermined duration of the recording constrains the user to wait until the recording is completed. Diagnosis improvements may also reduce the rate of overtreatment, which is currently considered crucial, as illustrated by one of the HCPs.

> *[…] in the approach to screen and treat, we are afraid, on the one hand, not to treat someone who should have, until the point it develops into a cancer. On the other hand, we may treat someone who did not need it, which is called overtreatment, but if we have this technology helping, then we will win in both cases […]* [P7]

Clinical Evaluation

Before this technology can be used in clinical settings, approval and validation by health care professionals is required. This implies comparing the technology's diagnosis in real conditions and that of HCPs, histopathology results, and a usability study regarding the tool's features and interface. The HCPs confirmed the need to validate the technology because they were concerned about its performance and their ability to distinguish accurate diagnoses from misdiagnoses.

Automated Assessment of Image Quality

Some HCPs apprehend that automating the technology would induce misdiagnosis and false-positive and false-negative predictions because of cervical abnormalities such as blood, mucus, and benign lesions. Therefore, an automated pipeline for assessing image quality was indicated as an essential technological feature preventing misdiagnosis by not allowing the application of the algorithm to images that are of extremely low quality or ineligible.

> *For instance, we could have a feature that gives us an ok when all acquisition criteria are fulfilled and that the analysis of the images can be conducted. Or, if criteria are not fulfilled, then there would be a*

XSL•FO
RenderX

message telling you not to launch the analysis and to, maybe, retake images. [P4]

Training and Resources Provision

The participants highlighted the importance of comprehensive training on properly using the CAD tool for its clinical adoption. In addition, resources such as smartphones and tripods are required for effective implementation.

[…] One needs to ensure that the user of the technology is well trained to create conditions allowing the capture of a good image because… bad acquisition conditions result in bad image quality. [P7]

Discussion

Principal Findings

This study identified 4 barriers and 4 facilitators each to adopting CAD tools for VIA during the preadaptation phase of the TAL model (Figure 1), either related to preuse acceptability or to initial use acceptance (Table 1). These included structural components such as limited infrastructure, confidentiality, data management, and personal factors such as workflow changes and user interaction with the CAD tool. HCPs emphasized the overall benefits, including improved patient care through better clinical evaluation, enhanced training, and technical advantages, such as ease of use of the system. The following section discusses the barriers and facilitators identified in both phases, contextualized within this literature, and highlights the barriers observed in previous studies but not encountered in this one.

Table 1. Synthesis of principal findings under the preadoption phases of the technology acceptance life cycle.

	Preuse acceptability	Initial use acceptance
Barriers	• Confidentiality and data management • Limited infrastructure and resources	• User interaction • Change in workflow
Facilitators	• Patient care improvement • Training	• Clinical evaluation • Ease of use

Barriers to Preuse Acceptability

Confidentiality and Data Management

Confidentiality concerns were highlighted as a significant factor affecting pre-use acceptability. HCPs expressed reservations about data loss and breaches and the acquisition of cervical images with smartphones. Patients also expressed concerns about the image frame. However, these concerns are not specific to the use of AI but are raised by the use of digital, sensitive images. Lodhia et al [26] observed that assuring patients of confidentiality was crucial to their mHealth intervention study for eye care in Kenya and recommended a robust data protection system. Prioritizing confidentiality, incorporating a secure data management system, and transparent communication about security measures are essential for alleviating privacy concerns and building trust among HCPs and patients. Practically, some HCPs have suggested showing the acquired data to patients to reassure them about the content of the images.

Limited Infrastructure and Resources

A lack of infrastructure and resources can affect the preuse acceptability of CAD tools for VIA in cervical cancer. Equipping HCPs with the necessary devices (such as smartphones and tripods) and ensuring regular maintenance of the devices is essential for limiting technical challenges and providing uninterrupted and effective health care services to patients.

Limited access to reliable internet connections, smartphone quality, and smartphone battery wear concerns during prolonged use have been highlighted as barriers by HCPs. These challenges align with findings from the existing literature in which infrastructure-related challenges have been identified in other health care settings. A study by Elahi et al [27] on a CAD tool for traumatic brain injury in Uganda emphasized the importance of internet connection and the associated costs. Spence et al [28] and Knoble and Bhusal [29] reported reliable electricity as a key challenge in the studies of childhood pneumonia diagnostic tools and electronic diagnostic algorithms.

A viable solution to overcome internet-related constraints is developing a CAD tool that can function offline. Internet access might be occasionally needed for maintenance, updates, and data sharing or backup; however, the device would provide CDS, irrespective of internet coverage and connectivity. In addition, ensuring access to electricity is essential to keep the smartphones charged. Therefore, adopting good practices, such as switching off the device at night or when it is not in use for several days, can help preserve battery life. Furthermore, optimizing the CDS algorithm to minimize smartphone power consumption can contribute to its ease of use without frequent recharging. By implementing these strategies, HCPs can confidently use CAD tools, even in remote areas with limited internet access and electricity.

Facilitators for Preuse Acceptability

Patient Care Improvement

CAD tools for VIA have diverse benefits that may contribute to improvements in cervical cancer screening and diagnosis [30]. A key advantage is rapid and reliable diagnosis, which reduces waiting time for patients who can receive test results and treatment in a single appointment. This point-of-care

XSL•FO
RenderX

approach can enhance patient satisfaction and positively impact mental health by providing a timely, near–real-time diagnosis [31]. In addition, this technology serves as a valuable supplementary test, assisting HCPs and making the diagnostic process less subjective. This technology limits cases of overtreatment and mitigates the risk of unnecessary treatment-related complications, such as pregnancy-related morbidity, by enhancing diagnosis accuracy [32].

Training

Comprehensive training is essential for users to understand and use the technology accurately. HCPs should not rely solely on the suggested diagnosis but use it as an assistive device that provides supplementary evidence to be considered in addition to their clinical knowledge and experience. Training must be tailored to the specific contexts of use and encompass geographical, cultural, and educational considerations [33]. The objective is to equip users with the ability to comprehend, interpret, and integrate recommendations from CAD tools into their decision-making processes.

Barriers to Initial Use Acceptance

User Interaction

The initial acceptance of the system can be hindered by difficulty in use. Demanding acquisition conditions are challenging for HCPs to comply with, potentially hindering technology adoption. The CDS algorithm requires adherence to specific acquisition conditions to address issues, such as movement, light, and mucus or blood in the cervix. The HCPs suggest that this could be facilitated by an automated quality assessment pipeline that assesses image quality in real time and provides immediate feedback to users, indicating whether the image quality is sufficient. Such a process could assess the visibility of the cervix, monitor movement, detect blurriness, or detect external objects (eg, pipettes).

Beyond the acquisition process, interaction with the device must be satisfactory to the HCPs. Knoble [29] conducted a comprehensive study on electronic diagnostic algorithms in Nepal and uncovered that HCPs found the device's size too small and the touchscreen sensitivity too low. This highlights the importance of considering all usability aspects while developing the technology and iteratively testing it with users.

Workflow Changes

Potential changes in the HCPs workflow also need to be assessed because they could hinder the initial acceptance of CAD tools for VIA [34]. Furthermore, a few HCPs expressed concerns about the risk of neglecting their expertise because of heavy reliance on the new technology. This observation is consistent with current literature. Despite the potential educational purposes of AI-driven CDS tools, the tendency to rely heavily on automation, described as automation bias, has been highlighted by Khera et al [35]. Furthermore, Jabbour et al [36] observed a decline in diagnostic performance when clinicians used AI support, even when visual explanations of AI-driven diagnoses were provided.

Introducing a novel technology can also increase the workload during the initial learning phase. Melas et al [37] observed that reduced time consumption was a vital factor influencing clinicians' intentions to adopt it. In contrast, Ellington et al [38] reported that HCPs need to practice using technology before using it with patients to improve efficiency. This preparatory practice would allow HCPs to become familiarized with the technology's functionalities and workflows, ensuring a smoother and more efficient integration of the technology into their clinical practice.

Facilitators for Initial Use Acceptance

Clinical Evaluation

The technology should undergo rigorous evaluation to assess its clinical and cost benefits to ensure initial use acceptance and foster sustained use acceptance [9]. The tool's performance can be evaluated using metrics such as sensitivity, specificity, accuracy, and false-positive rate. Evaluating the efficiency of the device and its integration into patient care contributes to assessing its clinical benefits. This involves examining the clinical utility of the technology, its compatibility with specific clinical settings, and its impact on patient outcomes. In addition, a user-centered design highlights the importance of user feedback for validating the technology, particularly its interface, features, and ease of use [39]. Cost benefits should also be assessed by estimating cost savings and implementation costs, including initial setup, training, and maintenance costs.

Laka et al [40] highlighted that evaluation frameworks should consider the dynamic nature of clinical settings and CDS (eg, through software updates). However, such devices need to be continuously monitored to ensure their safe and effective integration in clinical settings [41]. Papadopoulos et al [42] illustrated this challenge in a systematic literature review, revealing that only a few studies included "any form of evaluation," with often insufficient methodologies.

Ease of Use

In addition to facilitating the acquisition and quality assessment processes, simplicity in using CAD tools is crucial for their successful adoption in clinical settings [28]. Panicker et al [43] indicated that easy-to-use CAD tools save time because of their simple operation, fast access, effective recording, and information retrieval. These features contribute to the perceived usefulness and potential for extensive system adoption in clinical practice.

Comparison to Previous Studies

The barriers identified mostly align with those in the existing literature. However, these studies also reported barriers not mentioned by the participants of this study.

A common barrier highlighted in the literature is the limited resources to finance the technology, cope with increased diagnosis, and provide follow-up and treatment when necessary [26-28,44]. In the 3T program, external funding covers all costs, including salaries, clinical materials (gloves, speculum, acetic acid, etc), equipment (smartphone, tripod, etc), and patient travel cost compensation, eliminating immediate financial constraints.

Another barrier emerging from the literature, but not specifically addressed in this study, is the risk of mobile device theft [26].

XSL•FO
RenderX

This could be a relevant consideration in less controlled settings. Community and political support are also lacking in the literature [38,43]. The 3T program receives support from the Health Ministry, albeit financed through foreign grants.

The literature indicates a lack of user experience or skill (ie, phone literacy) as a potential barrier, even though the participants were comfortable handling smartphones [26,29,38,43]. This may result in misuse or an increased workload. In the 3T program, all HCPs follow comprehensive training, ensuring their proficiency in using the technology.

In summary, the absence of these barriers identified in the international scientific literature but not encountered in the 3T program might be attributed to the specific context and controlled environment provided by the program, as well as the active involvement of the study participants in it.

Further Recommendations

The World Health Organization (WHO) proposes 3 main solutions for barriers to the general use of medical devices [45]. First, the technology should be designed to fit the context of use. Second, the device system should be managed comprehensively, including its regulatory aspects, installation, maintenance, and monitoring. Finally, professionals need to be trained for proper use, maintenance, and presentation to patients. In alignment with the WHO recommendations to avoid pilotitis, this study identified barriers and facilitators to integrating CAD tools for VIA in cervical cancer diagnosis.

Addressing specific barriers to deploying CAD systems involves the fundamental element of trust. Patients and HCPs must trust the technology to ensure its successful implementation and sustained use. Trust might motivate HCPs to integrate CAD systems into their workflows and enhance patients' acceptance and comfort through a diagnostic process facilitated by CAD tools.

Trust can be built by involving users from the outset of technological development and integrating their feedback. Early engagement allows the understanding of their specific needs and ensures that the technology addresses relevant challenges. Involving various user profiles (eg, profession, degree, and working experience) from different clinical settings introduces a range of perspectives that can be leveraged to tailor the technology to diverse contexts.

In addition, providing evidence of the technology's trustworthiness is key to building trust [46]. Explainability, which makes the decision-making process of the technology transparent and understandable to users, builds confidence in its reliability. Traditionally, CDS are knowledge-based and rely on medical literature and conditional logic [47]. This approach tends to be more transparent than the current AI-leveraged CDS systems. Comprehensive training further reinforces trust for knowledge- and AI-based CDS by ensuring the appropriate use of the technology through stepwise instructions and presentation of its limitations.

The TAL framework provides valuable perspectives on the current stages of technological adoption. However, it should be considered as an iterative tool, acknowledging that perceptions and acceptance may evolve as the technology progresses. Continuous monitoring of these changes is essential to ensure the successful adoption and use of CAD tools for VIA in clinical practice.

Strengths and Limitations

To our knowledge, this is one of the first studies in sub-Saharan Africa that investigates the adoption of CAD tools for cervical cancer from the perspective of HCPs. The various professional backgrounds of the participants, years of experience in cervical cancer screening, and sex allowed us to gain in-depth insights into the barriers and facilitators present during the preadaptation phase.

The qualitative method allowed for collecting different perspectives; however, several limitations were observed. First, the study involved a limited number of nonrandom samples of participants familiar with the use of smartphones for cervical cancer diagnosis. In addition to potential selection bias and limited generalizability, mini–focus groups have been acknowledged in the scientific literature, especially among participants with intense experience with a topic, which was the case in our study, allowing for a more in-depth discussion [48]. The mFGDs were complemented by individual interviews to capture a wider range of perspectives and mitigate this bias. Second, the study was conducted in a controlled program in Western Cameroon, which may not reflect other settings with varying resources and infrastructure. Therefore, we recommend replicating the study in other contexts for broader validation. Third, this study focused on HCPs; however, patient perspectives, crucial for understanding technology adoption, were not included but addressed in a separate study [49]. Finally, barriers can be attributed to the use of CAD tools or smartphones. This study was conducted during the preadaptation phase; however, the technology and user attitudes have evolved. Iterative research is needed to determine whether factors can be attributed to specific digital tools and capture changing perceptions after implementing the CAD tool.

Some of the encountered barriers (such as workflow changes) might be addressed through adaptation and facilitator reinforcement (such as training); therefore, the findings of this study provide a crucial foundation for future work. In summary, further qualitative and quantitative studies should be conducted among HCPs with less smartphone experience and in various clinical settings to enhance the generalizability of findings and guide tailored strategies for implementing CAD tools in cervical cancer diagnosis.

Conclusions

Interviewing HCPs from various backgrounds with diverse working experience—midwives and gynecologists—was essential to better understand their concerns, perceptions, and expectations regarding a CAD tool for cervical cancer and to avoid "pilotitis."

Even if a CAD tool is designed to fit its context of use perfectly, understanding the barriers and facilitators is key to its successful implementation and use. In this study, the CAD tool was appreciated by the HCP for its ease of use and crucial role as an assistive device to improve patient care and support clinical

XSL•FO
RenderX

decisions. The barriers encountered (confidentiality and data management, limited infrastructure and resources, workflow changes, and user interaction) are specific to the study setting and might vary with the context. However, these challenges can be addressed in line with the WHO recommendations [40] by ensuring proper management of the technology (eg, regulation and maintenance) and involving the end user at every step of developing the solution. HCPs will help define the appropriate way of introducing new technology to patients and their peers, as well as how to train them for proper use. These measures aim to derisk the deployment of the technology and contribute to overcoming pilotitis.

Acknowledgments

The authors would like to thank all health care providers (HCPs) who dedicated some of their time to discussing with anthropologists from the project. This work was supported by the Swiss Federal Institute of Technology Lausanne through its Programme Tech4Dev.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to confidentiality and privacy concerns but from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to the conceptualization and design of the study. The methodology was developed collaboratively by AMDM, MJC, and NCS. For the investigation, AMDM conducted participant recruitment and data collection, while VFY attended the mini–focus group discussions and took notes. In terms of data curation, AMDM and VFY transcribed the audio recordings. The formal analysis and interpretation of the data were carried out by MJC, AMDM, and NCS. MJC wrote the original draft, while all authors contributed to reviewing and editing multiple versions of the paper.

Abstract

Background: Kentucky has the highest all-site cancer incidence and mortality rates in the United States. Conducting needs assessments in a large geographic area, such as an entire state, poses challenges in collecting qualitative data from diverse rural and urban contexts. In 2021, a steering committee was formed to drive a multimethod, statewide cancer needs assessment (CNA) to identify the future priorities for all cancer-related care in Kentucky.

Objective: We aimed to report on the online focus group component of the CNA by documenting existing community resources and perceived needs across the cancer care continuum. In addition, we aimed to explore the impacts of social determinants of health among populations experiencing health disparities.

Methods: Through existing partnerships and a national research registry, we recruited adult Kentucky residents who were not employed in health occupations to participate in 11 online 60-minute focus groups, stratified to include multiple target populations and geographic areas. We based our semistructured discussion guide on the cancer care continuum and focused on social determinants of health, health equity, and factors affecting cancer diagnoses and outcomes. We conducted a qualitative line-by-line analysis of the recorded transcripts to identify themes.

Results: The participants (N=51; mean 4.63, SD 2.26 per group) lived in 25 different counties, including 35% (18/51) from rural communities, 14% (7/51) from the Appalachian area of Kentucky, and 31% (16/51) who self-identified with a racial or ethnic minority group. We identified 17 primary themes representing community-perceived needs and potential solutions across the cancer care continuum, including novel approaches to make information accessible; messaging not interpreted as blaming or shaming; messaging from individuals who engender trust; screening efforts to reach individuals where they are; ways to address practical barriers to screening and treatment, such as cost and transportation; and ways to increase knowledge about insurance coverage. In addition, we found 83 emergent subthemes specific to race, ethnicity, rural and urban residence, sexual orientation and gender identity, and age. The participants described the need to promote positive, culturally sensitive patient–health care provider communication and to create safe care spaces that consider the ways in which social norms affect cancer care, fight stigma, and improve health equity.

XSL•FO
RenderX

Conclusions: By conducting statewide qualitative data collection online, we provided valuable depth of understanding for future programs and research to address cancer incidence and mortality in Kentucky. The findings pointed to several potential actions to address community-perceived needs across the cancer care continuum, including increasing accessible risk reduction information, expanding ways to overcome challenges to screening and treatment, building patient navigation resources, and increasing positive patient–health care provider communication. The findings also suggest that online focus groups can be a valuable component of CNAs to capture cancer-related needs and solutions across large geographic areas and diverse populations.

Introduction

Background

The Commonwealth of Kentucky has the highest all-site cancer incidence and mortality rates in the United States [1]. In 2021, a group of academic and community partners collaborated on a comprehensive, statewide cancer needs assessment (CNA) to address the state's extensive cancer burden. The use of CNAs has increased in recent decades, grounded in their promotion by the Affordable Care Act and accreditation boards, as well as requirements by the National Cancer Institute (NCI) for NCI-designated cancer centers to assess the needs of their catchment areas. In this case, the catchment area of focus consisted of the entire state of Kentucky. In this CNA, we sought to explore the lived experiences of community members through the examination of specific topics across the cancer care continuum, from risk reduction to treatment follow-up, through online focus groups. This approach allowed us to reach individuals throughout the diverse geographic regions and cultural contexts of the state, encompassing multiple urban areas and a large rural population, which includes the predominantly rural Appalachian region.

In CNAs and other community health needs assessments, qualitative methods can complement quantitative data to identify and shed additional light on the needs and inequities, such as those by race, ethnicity, and geography, in services across the cancer care continuum [2-5]. Qualitative methods provide an ideal way to understand the depth and richness of experiences behind the patterns and trends noted in quantitative data [2,6] and to include community perspectives in the prioritization of needs [4,7]. Speaking directly with community members can highlight their varying perspectives compared to those of health care providers. For example, health care providers often focus clinically on cancer needs, whereas community members more regularly focus on ways to address relevant social barriers and health disparities [6,8].

Previous qualitative research suggests that community member perspectives about needs across the cancer care continuum may vary across groups [5]. For example, rural and urban residents may obtain information about cancer risk reduction from different sources; rural individuals may be more exposed to misleading information around risk reduction and screening due to reduced access to the internet or health care providers capable of verifying accurate information [9]. Individuals in underserved populations (eg, those with limited access to resources, services, or health care) also display variation in the amount of knowledge they possess about when, where, and how to secure treatment, and many may have trouble accessing care because of distance or clinic hours [3]. Similarly, members of racial and ethnic minority groups desire culturally appropriate educational materials about screening and treatment specific to their communities [3,6]. Previous studies [3,10] have identified unique needs for cancer support or support programs among rural populations and racial and minority groups, such as concerns about paying for services and an increased need for survivorship services, including community-specific support groups. Among populations who experience cancer-related health inequities, previous studies [2,3,6] have indicated a wide range of factors, including environment (eg, political and physical), discrimination, stigma, distrust, and strategies to improve access to health care (eg, geographic distance and costs).

Traditionally, qualitative focus groups have been conducted in person, yet technological advances within the past decade have made it possible to conduct online groups using videoconferencing [11,12]. Although the use of online focus groups in health research was relatively uncommon before 2020, the COVID-19 pandemic stimulated a rapid increase in the uptake of videoconferencing technology for work, education, telehealth, and personal uses [13]. The pandemic restrictions on in-person contact caused disruptions to data collection activities, prompting many researchers to explore online data collection options, such as online focus groups [12]. Some studies [11,14] have reported successfully using online focus groups during the pandemic with hard-to-reach populations and for uncovering cancer-related needs, such as colorectal [15] and breast cancer screening [16]. Although technological limitations can occur with online administration, promising advantages also exist, including reduced travel barriers for participants who live further away, increased comfort from the ability to participate at home or other convenient locations, and increased flexibility of scheduling. Online focus groups have demonstrated the ability to gather data on par with in-person focus groups while maintaining the pandemic safety protocols, allowing research teams to gather important and timely data [11,14].

Objectives

To the best of our knowledge, this is the first use of online focus groups as a part of a statewide cancer-focused CNA. Specifically, the objectives of the CNA focus group component were (1) to document existing community resources and needs across the cancer care continuum domains (risk reduction, screening, diagnosis, treatment, follow-up, and survivorship)

XSL•FO
RenderX

[5] and (2) to explore ways that the social determinants of health affect cancer care throughout Kentucky and the unique needs of groups that experience cancer health disparities based on race, ethnicity, geographic area, sexual orientation, or gender identity.

Methods

Kentucky CNA and Community-Engagement Overview

In 2021, the Community Impact Office (CIO) in the University of Kentucky Markey Cancer Center (UKMCC) convened a steering committee to collaborate on a new CNA for Kentucky. The 27 steering committee members represented diverse organizational partners with statewide reach and interest in cancer, including staff of the Kentucky Cancer Consortium (KCC), the Kentucky Cancer Program (KCP), the Kentucky Cancer Registry, the American Cancer Society, the Foundation for Healthy Kentucky, the Kentucky Department for Public Health, and the University of Louisville. The overall CNA used a mixed methods approach, which is described in more details elsewhere [17]. Quantitative data were compiled from state and national data sources [18] (eg, the US Census Bureau's American Community Survey, the Kentucky Cancer Registry as part of the NCI's Surveillance, Epidemiology, and End Results Program, and the Centers for Disease Control and Prevention's Behavioral Risk Factor Surveillance System [19-21]) to describe patterns in key indicators and areas of cancer disparities in Kentucky. To complement the quantitative data, the CNA design included gathering qualitative data to better understand the experiences, perceptions, and needs of Kentuckians.

The CNA steering committee, including the KCP and the KCC members, gave valuable feedback on the focus group sampling design, recruitment strategies, discussion guide questions, and incorporation of the findings into the overall CNA. The steering committee used the CNA conceptual framework, the development of which is described elsewhere [17], to create the focus group discussion guide. Coauthors of this publication wrote the questions, followed by the review and revision by the steering committee members, who included individuals with relevant expertise and partner organizations. The KCP is co-led by the UKMCC CIO and the University of Louisville Brown Cancer Center. Founded in 1982 by the state legislature, the KCP is a statewide community-based cancer prevention and control program served by regionally located staff covering each of Kentucky's 15 area development districts. The regional KCP staff manage District Cancer Councils comprising local and regional organization partners, such as health providers, faith-based leaders, cancer survivors, and educators. The KCP staff plan and implement evidence-based programs, in collaboration with these and other partner organizations, focused on cancer risk reduction, early detection, and survivorship. The KCC, created in 2002 and funded by the Centers for Disease Control and Prevention Comprehensive Cancer Control Program, is the state's comprehensive cancer control coalition and is managed by staff in the UKMCC CIO. The KCC convenes a wide range of statewide partner organizations, who collectively develop, implement, and evaluate the state's cancer plan with particular focus on health equity and policy, systems, and environmental changes. The KCP and the KCC staff members contributed to the focus group question guide, distributed the focus group recruitment flyer throughout their partner networks, sat in on the focus group discussions, and provided feedback in the postgroup debrief discussions with facilitators.

Study Population and Recruitment

For inclusion, participants had to be aged ≥18 years and a resident of Kentucky. Because our target population was lay community members, we excluded individuals who reported working in public health, health care, or another health-focused position. If participants voiced a lack of experience with Zoom (Zoom Communications, Inc), we provided one-on-one training to ensure comfort with the online setting. We excluded participants who reported not feeling comfortable participating in an online focus group via Zoom and declined our one-on-one support [22]; less than 5% (2/51) of the participants expressed concerns over participation in this format, all of whom received one-on-one support.

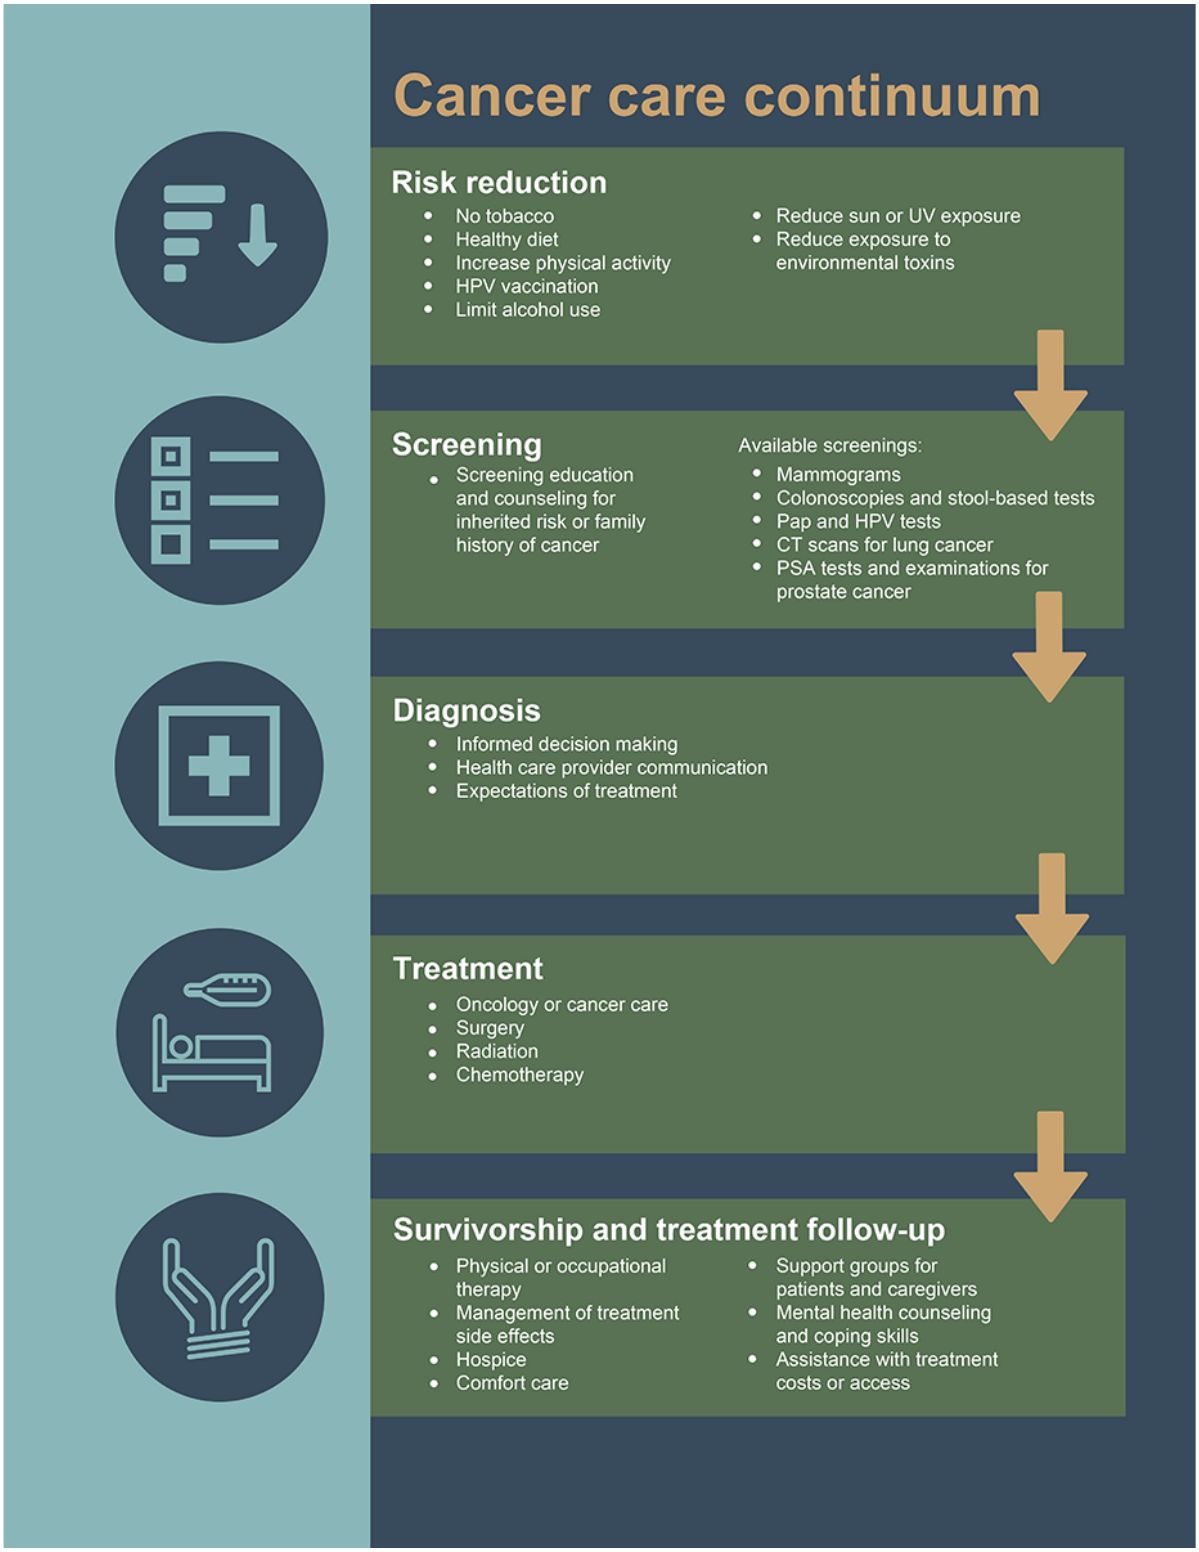
Through the KCC and the KCP partnership networks, we distributed flyers that linked participants to an eligibility screener in REDCap (Research Electronic Data Capture; Vanderbilt University) [23]. The KCC develops and distributes a weekly e-newsletter to more than 600 subscribers. The flyer was included in the newsletter over multiple weeks. The KCP members distributed flyers to their existing email lists of partners throughout Kentucky and posted printed flyers at public community events. We also used ResearchMatch, a national registry created by several academic institutions and supported by the US National Institutes of Health as part of the Clinical Translational Science Award program, to identify potential participants [24]. Within ResearchMatch, we developed a search for adult residents in Kentucky. ResearchMatch allows for the direct distribution of recruitment materials and eligibility screener link to potential participants in the search results.

To increase heterogeneity and diversity, we used a stratified purposive sampling strategy based on race and ethnicity; geography (rural and urban, as well as Eastern and Western Kentucky, to capture varying cultural contexts); and sexual orientation or gender identity, with intentional oversampling of Black and LGBTQ+ (lesbian, gay, bisexual, transgender, queer, and other minority) individuals. We determined rural-urban designations at the county level from the 2013 rural-urban continuum codes [25]. We gathered the aforementioned demographics in the eligibility screener and assigned participants to focus groups based on these characteristics and preferences for group participation. The recruitment continued until we had enough participants to schedule each of the following groups: (1) urban eastern Kentucky (mixed race or ethnicity), (2) urban eastern Kentucky (Black or African American), (3) urban western Kentucky (mixed race or ethnicity), (4) urban western Kentucky (Black or African American), (5) rural western Kentucky, (6) rural eastern or Appalachian Kentucky, (7) Hispanic or Latine (any location), and (8) LGTBQ+ (any

XSL•FO
RenderX

location). We recruited enough participants in a few of these groups to warrant multiple focus group sessions.

Ethical Considerations



The study team contacted eligible participants based on identified preference (phone, text, or email) to provide consent information via a cover letter, schedule the focus group, and provide a link to a brief demographic questionnaire in REDCap. All participants received consent information via email when starting the demographic questionnaire, as well as by oral review before starting the focus group. The consent explanation included a description of actions taken to ensure privacy, including the removal of any identifying information in the dataset and the deletion of recordings once completing analysis. We proceeded with data collection once receiving verbal consent from all participants in each group. Participants received a US $50 e-gift card for participation. We received a waiver to document consent for this project, and all procedures were approved by the University of Kentucky Institutional Review Board as an expedited study (65451).

Data Collection

From July to September 2021, we conducted 11 focus groups. A trained facilitator (JRT) and a research assistant and notetaker (KF) conducted the 2-hour sessions on Zoom. Before proceeding with the semistructured discussion guide questions (Multimedia Appendix 1) to introduce the cancer care continuum domains [5] and allow the participants to ask clarifying questions, the facilitator used Zoom's screen sharing feature to show a visual graphic of the relevant factors for risk reduction, screening, diagnosis, treatment, treatment follow-up, and survivorship (Figure 1). One continuum domain was discussed at a time. To discuss risk reduction, we highlighted various health behaviors and exposures that increase cancer risk, including tobacco use, diet, physical activity, sun exposure, and exposure to environmental toxins. For the screening discussion, we provided participants with examples of available screening types, including mammography for breast cancer, Papanicolaou and human papillomavirus tests for cervical cancer, colonoscopies and stool-based tests for colon cancer, low-dose computerized tomography scans for lung cancer, prostate-specific antigen tests and examinations for prostate cancer, and genetic testing for inherited risk. To set the stage for discussing diagnosis and treatment, we expressed our interest to the participants in understanding more about conversations that occur at the point of diagnosis and the types of treatment available in their communities, such as surgery, radiology, and chemotherapy. In our discussion of cancer treatment follow-up and survivorship, we covered an array of potential resources, such as support groups, physical and occupational therapy, financial supports, mental health supports, and palliative care, as well as side effects from treatment. For each continuum area, the questions focused on participant awareness of local resources and the challenges that the individuals faced in their community related to each domain. Through the intentional scheduling of participants in the focus groups with people sharing similar demographic characteristics, we also sought to identify emergent themes and compare them across groups.

XSL•FO
RenderX

Figure 1. Graphic representation of the cancer care continuum displayed during the focus groups (informed by the Institute of Medicine, 2013 [5]). CT: computed tomography; HPV: human papillomavirus; PSA: prostate-specific antigen.

Analysis

We audio- and video-recorded each session and transcribed the resulting recordings verbatim. The facilitator (JRT) and research assistant (KF) double-coded 20% of the transcripts in Microsoft Excel with >90% initial agreement. To ensure coding alignment and analysis rigor, we resolved discrepancies through discussion and consultation with a third author (PCH). All 3 authors identify as female and have experience in public health and qualitative research; two of the authors (JRT and PCH) have doctoral degrees in health and extensive expertise in community-engaged approaches, including with low-income, rural, and minority populations. For coding, we combined two approaches: (1) a deductive approach based on the semistructured focus group questions to isolate the specific resources and needs across the cancer care continuum and (2)

XSL•FO
RenderX

an inductive approach to identify emergent themes from demographic groups who experience cancer health disparities related to race and ethnicity, geographic location, and sexual orientation or gender identity [26,27]. The deductive approach resulted in 13 primary themes across the continuum of care, along with the considerations related to the COVID-19 pandemic. We conducted the focus groups until thematic saturation was reached within these 13 primary themes in order to provide sufficient feedback in each of the cancer care continuum domains. The subsequent inductive approach resulted in 83 emergent subcodes, including specific differences across the demographic groups experiencing health disparities.

Results

Participant Characteristics

A total of 51 adults from 25 of Kentucky's 120 counties participated in the 11 focus groups. We scheduled 79 participants, resulting in an attendance rate of 65% (51/79). The mean focus group size was 4.63 (SD 2.26) participants. The sample had a mean age of 49 years. Among the 51 participants, 18 (35%) were from rural communities, 7 (14%) were from Appalachian Kentucky, and 16 (31%) self-identified as Black, American Indian, Asian, or Hispanic or Latino. Table 1 provides a summary of the participant demographic characteristics. Although the stratified purposive sampling design was not intended to yield a sample that is directly representative of the Kentucky population, the participant demographics were similar to the state, with intentional oversampling of Black and LGBTQ+ individuals.

Table 1. Demographics of the cancer needs assessment focus group participants (N=51) compared to state-level demographics (N=4,449,052).

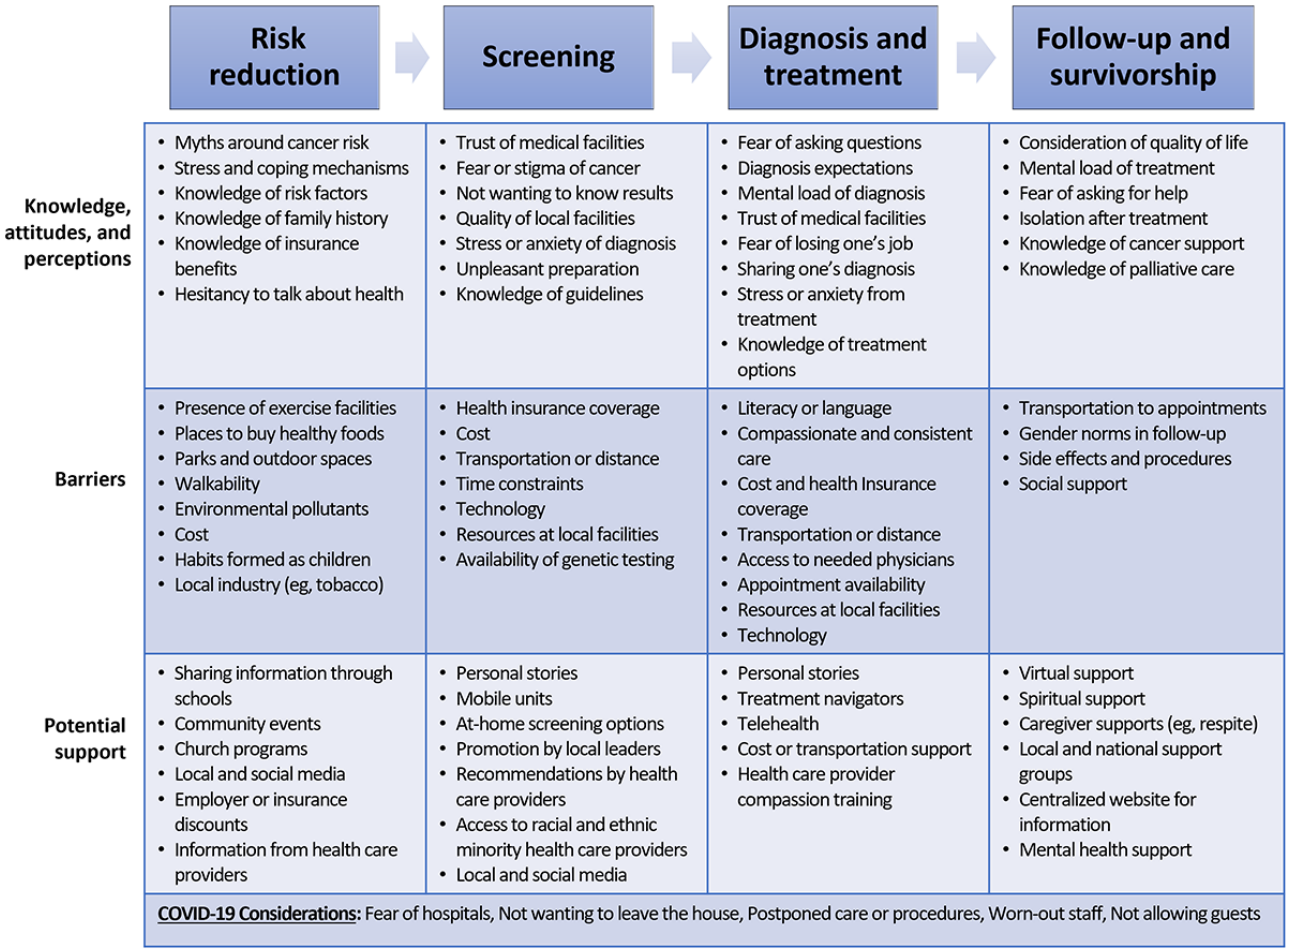
Demographic variables	Sample	State of Kentucky
Age (y), median	49.0	39.1
Sex or gender identity, n (%)		
Female	40 (78.4)	2,258,130 (50.8)
Male	11 (21.6)	2,190,922 (49.2)
Nonbinary	0 (0)	—[a]
Rural or urban residency[b], n (%)		
Urban (metro) county	33 (64.7)	2,619,409 (58.9)
Rural (nonmetro) county	18 (35.3)	1,829,643 (41.1)
Appalachian County	7 (13.7)	1,165,722 (26.2)
Race and ethnicity[c], n (%)		
American Indian	2 (3.9)	9386 (0.2)
Asian	2 (3.9)	65,191 (1.5)
Black	11 (21.6)	358,928 (8.1)
Hispanic or Latino	1 (2)	162,994 (3.7)
White	35 (68.6)	3,868,479 (87)
LGBTQ+[d] identity	4 (7.8)	—

[a]Not available.

[b]Determined by the county-level rural-urban continuum codes; a code ≥4 represents a rural county.

[c]Responses are not mutually exclusive because the participants could choose more than one.

[d]LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other minority.



Major Themes Across the Cancer Care Continuum

Overview

In reaction to the cancer care continuum graphic (Figure 1), participants described the needs and associated potential solutions for each domain of the continuum—risk reduction, screening, diagnosis, treatment, treatment follow-up, and survivorship. Refer to Figure 2 for a list of the 83 identified subcodes within each of the 13 primary themes, which are organized into the 12 blocks within the table, along with the considerations of the COVID-19 pandemic that apply to the entire continuum of care. The identified representative quotes for each continuum domain are provided in Table 2.

XSL•FO
RenderX

Figure 2. Summary of the themes and subcodes of the cancer needs assessment focus group categorized by the cancer care continuum.

XSL•FO
RenderX

Table 2. Representative quotes by cancer care continuum area.

Continuum area	Representative quotes
Risk reduction	• "There's a lot of folks that don't live in the downtown area or a walkable part of our town that will never make it 5 miles to the [University of Kentucky Cooperative] Extension Office [or] don't know that the Extension Offices have fabulous nutritional programming." [White woman from a rural county; aged 31 y] • "My husband still smokes heavily, and he knows all the risk and he still does it because he's addicted to it. I think that preventing it from happening [in the first place] is definitely a concern. I know in my area, my dad and mama did, their uncle did, their grandpa did. [When I] ask, they say, 'Well, I started smoking at seven when I got a cigarette from my grandpa,' and it's just old family mentality circles." [Asian woman from a rural county; aged 31 y] • "We could definitely have a bigger presence [of environmental pollutant awareness] in my specific area, especially with how much agriculture we have...the runoff can cause a lot more issues than I think most of our residents are aware of." [White woman from a rural county; aged 32 y] • "It's about people feeling attacked, so I think it just really goes back to messaging, and I think...people always want to know why, like what's your motivation for doing it, so I think the better you can communicate that." [White woman from an urban county; aged 36 y]
Screening	• "Well, you know the colon [screening], it's not so much that the procedure's horrible but the process of getting ready for the procedure is not pleasant, and I know that I'm aware of that. And even though my best friend has gone through the process, she shared it, so I'm trying to hold off." [Black woman from an urban county; aged 45 y] • "I can remember when they cut back on pap smears I was shocked. I don't see the benefit, and, okay, now I only need one every 3 years, and I'm like, that doesn't seem to make sense to me." [White woman from an urban county; aged 36 y] • "Another issue is that even people that have insurance and then all the things [she] said, like people that work all the time that are working two jobs or they don't have someone to watch their kids. They don't have transportation. That's a big problem here, we don't have public transit." [White woman from an urban county; aged 44 y; LGBTQ+[a] identity] • "I think it was mammogram screening...the mobile clinic, so I think that's a really good idea that they came up with, and you know, it's able to go around and meet the people where they are." [Black woman from an urban county; aged 48 y] • "Well, I think even people that have insurance, the deductibles are so high on a lot of them that there are people that will not [get screened]. I mean there's a few things on this list that are now because of the ACA [Affordable Care Act] you can get screened once a year, and you don't have to pay for it [if you know about it]." [White woman from a rural county; aged 45 y]
Diagnosis and treatment	• "These [radiation and chemotherapy] are available in my community, but most people that have means don't want to receive them here...A lot of people that have means would go elsewhere. They would go to [hospital in nearby city] or somewhere else. Or, I know people that may go there [locally] the first time, and then when they get diagnosed, if they have the means they go to [hospitals in larger nearby cities]." [White woman from a rural county; aged 44 y; LGBTQ+ identity] • "The ease of medical information being shared...would help with treatment, knowing all your doctors are on the same page...knowing what each person, what the right hand is doing and what the left hand is doing at the same time." [White woman from an urban county; aged 45 y] • "The way that the health care system is set up right now takes too long. So, if you go in and find a lump or whatever, its 2 weeks or a month before you go to the next step and then it's even more time after that, before you know what stage it is, and then a treatment plan. That is a lot of heavy mental load for somebody to have to carry for that long." [Black woman from an urban county; aged 48 y] • "I think a lot of times, you have to recognize when you need a proxy or for the health care staff to recognize when someone needs a proxy because you're saying something to somebody and saying, 'do you understand?' They're going to say 'yes' because they don't want to appear that they don't know, but just being able to understand and to ask the type of questions they need to." [Black woman from an urban county; aged 28 y]
Follow-up and survivorship	• "I think they gave her family false hope and did things that work for some people because they're younger...but probably lowered her quality of life at the end when it was inevitable that she was going to pass away." [White woman from an urban county; aged 73 y; LGBTQ+ identity] • "They found that she had Medicaid it's like 'oh we're sorry, this is an experimental treatment, and this isn't covered by Medicaid.' So, [we asked] how much does this cost. It will cost you about $100,000, and it might as well have been a million dollars. I have followed the research and it has been phenomenal, and it's so sad that we live in a world that $100,000 is worth more than an extra 10 to 15 years of my mother's life." [White man from an urban county; aged 41 y; LGBTQ+ identity] • "And the other person I met with...was like 'well, I don't understand why a young, pretty women like you wouldn't...want to have that surgery done.' So, I think that there is sort of pressure to meet traditional gender stereotypes in reconstruction, and you know, like how you deal with that that sort of thing, and also with like fertility issues." [White woman from a rural county; aged 45 y] • "We probably need more mental health professionals down here. When I first got a cancer diagnosis, the insurance company sent me a letter in the mail that I could talk to an oncology nurse, and I talked with her and that was really helpful to have like a third-party person not involved in like my achieving my plan and not family or friend who has any emotional investment but also not my doctor to talk to. That was a really great support." [White woman from an urban county; aged 74 y]

RenderX

[a]LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other minority.

Risk Reduction

Knowledge, Attitudes, and Perceptions

The participants identified several knowledge, attitude, and perception-based factors that affect cancer risk reduction behaviors. The factors included myths around cancer risk; knowledge of risk factors, family history, and insurance benefits; stress and related coping mechanisms; and a hesitancy to talk about health or cancer.

Barriers

The participants also described various barriers to risk-reduction behaviors. For example, participants cited the absence or lack of access to places to buy healthy foods, exercise facilities, parks, and outdoor spaces, as well as walkable neighborhoods, as adversely affecting their diet and physical activity. Walkability and proximity also affected access to community risk reduction resources, such as tobacco cessation, radon testing, and other resources found at local health departments or extension offices. Participants also perceived family history and historical livelihoods as barriers to cancer risk reduction, including health habits formed as children (eg, diet and exercise) and generational influences (eg, tobacco use). Similarly, participants expressed a lack of awareness around the role of local industry (eg, tobacco farming, mining, and factories) in creating potential environmental pollutants. Finally, participants identified cost as a major barrier to healthy eating and physical activity.

Potential Solutions

When discussing potential solutions to these challenges, the participants described strategies to increase education and knowledge of resources to support risk-reduction behaviors, including several modes to share information. Participants named community events (eg, health fairs and local festivals), schools, churches, local and social media, local major employers, insurance companies, and health care providers as possible strategies to convey information and increase knowledge around cancer risk reduction in Kentucky communities. In addition, participants emphasized that information and messaging should be free from shame or blame language, using positive and constructive suggestions.

Screening

Knowledge, Attitudes, and Perceptions

The participants described a variety of knowledge, attitudes, and perceptions affecting the receipt of screening, falling into two major categories: (1) perceptions of medical facilities and (2) personal concerns or knowledge of screening. The former included aspects such as trust in medical facilities and health care providers, and the quality of screening resources available at local facilities. The latter included aspects such as fear or stigma surrounding cancer, stress or anxiety of diagnosis, unpleasant preparation, knowledge of screening guidelines, and not wanting to know the results due to the cost, stress, and other next steps related to a potential cancer diagnosis. For example, participants described the effects of unpleasant colon screening preparation and the confusion that individuals may feel in light of changing screening guidelines.

Barriers

The participants identified practical challenges in receiving cancer screening. The most commonly raised barriers were cost, health insurance coverage, and transportation or distance to facilities. In addition, participants mentioned time constraints (eg, clinic hours, ability to take time off work, and childcare responsibilities); technology barriers; and availability of local resources for screening and genetic testing.

Potential Solutions

As solutions for screening challenges, the participant recommendations fell into two areas: (1) increasing access by reaching people where they are and (2) ways to boost or promote screening messaging. Increasing access included the use of mobile units and at-home screening options (eg, stool-based tests for colon cancer). Participants suggested that screening messaging could have a greater impact if it came from local leaders, trusted local health care providers, providers of similar racial or ethnic minority background and gender identity, and personal stories from cancer survivors. As with risk reduction, participants recommended that screening messaging or opportunities could be effectively implemented or shared through community events, schools, churches, local and social media, and insurance companies. Participants recommended developing strategies to increase knowledge of which preventive screenings are covered by insurance, as well as their eligibility and frequency.

Diagnosis and Treatment

Knowledge, Attitudes, and Perceptions

At the point of diagnosis, the participants indicated that individuals experience a large mental load and various associated effects. Discussion of the diagnosis mental load included stress, anxiety, fear of losing one's job, fear of asking questions, and understanding diagnosis expectations. Participants also expressed a need for skills around discussing one's cancer diagnosis with family and friends and to gain self-efficacy in order to make confident treatment choices, ask health care providers questions, or receive second opinions. As with screening, participants described that their trust in medical facilities and health care providers, as well as their perceptions of the quality of treatment resources at local facilities, affected their treatment decisions.

Barriers

The participants discussed a wide variety of communication challenges with health care providers related to diagnosis and treatment decisions. For example, they described the importance of literacy and language barriers; compassion and understanding among health care providers; and challenges with consulting multiple specialists, including the sharing of information among these physicians. As with screening, participants named several logistical and practical barriers, such as cost, health insurance coverage, transportation and distance to health facilities that

XSL•FO
RenderX

provide the needed treatments, appointment availability, and technology barriers to telehealth.

Potential Solutions

For potential solutions, the participants discussed the importance of navigators in the diagnosis experience to offset the mental load and to assist in explaining prognosis and treatment options. Similarly, social supports and personal stories from friends and family were key to diagnosis and treatment decision-making and appointment keeping. Participants also requested more information on cost or transportation supports, as well as telehealth options, for those with technological access and skills to complete these visits. Finally, to improve patient–health care provider communication, participants recommended increased training in compassion and humility for health care providers.

Treatment Follow-Up and Survivorship

Knowledge, Attitudes, and Perceptions

The participant perceptions included the continued mental load during treatment, isolation after treatment, fear of asking for continued help, and considerations of the quality of life during treatment decisions. In addition, participants described the need for knowledge about cancer support, support programs, and palliative care, particularly before the patient or family needs them.

Barriers

Transportation to health facilities and the cost of treatment continued to be a challenge during this period. Participants expressed the need for social supports and the complexities of receiving referrals for therapy or other supports. In addition, participants discussed the side effects from procedures and medications and the way social norms around gender and age affect health care provider and community perspectives on treatment follow-up choices, such as breast reconstruction. Follow-up support or support programs varied based on location, age, and cancer diagnosis, where some had plentiful and others had few resources available for their diagnosis or age group.

Potential Solutions

The participants described the continued need for survivor supports, including through local and national support groups. Participants suggested the use of online support groups, as well as those at faith-based locations, to increase access. In addition, participants discussed the importance of caregiver supports, such as respite, and for reducing stigma around mental health, along with increasing access and knowledge of these forms of support. Finally, participants requested a single location, such as a centralized website, to find information on available treatments and supports.

Social Determinants of Health and Health Equity: Population Differences

Overview

We found several specific differences between the groups that elucidated the ways in which social determinants of health affect populations across the cancer care continuum. Figure 3 includes the emergent themes across the continuum of care that were particularly emphasized by the specific population groups. In Table 3**,** we provided the representative quotes for each population comparison group.

Figure 3. Summary of the emergent themes across the cancer care continuum, specifically raised among population groups who experience cancer health disparities. LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other minority.

	Risk reduction	Screening	Diagnosis and treatment	Follow-up and survivorship
Race and ethnicity	• Knowledge of risk factors • Hesitancy to talk about health	• Access to racial or ethnic minority health care providers • Fear or stigma of cancer • Support of local leaders • Quality of local facilities • Trust of medical facilities	• Consistent care • Fear of asking questions • Literacy or language • Health care provider compassion training • Transportation support • Trust of medical facilities	• Fear of asking for help • Local and national support groups
Rural or urban residence	• Environmental pollutants • Knowledge of risk factors • Local industry (eg, tobacco) • Places to buy healthy foods • Presence of exercise facilities • Walkability	• At-home screening options • Fear or stigma of cancer • Mobile units • Quality of local facilities • Resources at local facilities • Technology • Transportation or distance • Trust of medical facilities	• Access to needed physicians • Appointment availability • Consistent care • Resources at local facilities • Technology • Telehealth • Transportation or distance • Trust of medical facilities	• Fear of asking for help • Local or national support groups • Transportation to appointments

Table 3. Representative quotes for population differences among the groups who experienced cancer health disparities.

Population differences	Representative quotes
Race and ethnicity	• "Sun exposure, we don't really hear too much about that, especially for African Americans, you think 'oh, we don't really need [to know about the risks of] the sun exposure,' but we need to [watch sun exposure] just as much as everybody else does." [Black woman from an urban county; aged 29 y] • "The Latino community, generally speaking, when parents bring their daughters to their appointments and the doctor starts talking about the HPV [human papillomavirus] vaccination, the doctors also start talking about if the teen's been sexually active and that doesn't click so well...perhaps there is a deep cultural and religious background, but many moms are like 'I don't see the need for that vaccination, because my daughter is not sexually active.'" [Latina woman from an urban county; aged 50 y] • "Some people really don't go to the doctor unless they know for a fact, something is wrong with them. And, sometimes I think in the Black community, there is a lack of trust with health care providers, and I think that sometimes there's a lot of fear. It's more out of sight, out of mind. If I don't have anybody telling me that there's nothing wrong with me, then I don't have anything to worry about. So, kind of that type of thing is a cultural thing as well, and people just don't go to the doctor. It's just not something that's done unless you know, something is wrong." [Black woman from an urban county; aged 30 y]
Rural and urban residency	• "Transportation and the fact we only have two clinics. If those clinics don't offer screenings, then they have to go outside the county...And [it's] not only transportation, it's...the gas money, eating if you're gone very long, and all that goes along with that." [White woman from a rural county; aged 49 y] • "I think that there is a lot available now, more now than there used to be. I still feel that a lot of people still travel. They still travel to larger hospitals in the larger cities because they feel like they can get better treatment, better care. I think a lot of it has to do with trust and outcomes and seeing that there's success in this area, with treating it. People don't want to risk their lives going through treatment in a small town where they're just starting this treatment." [White woman from a rural county; aged 58 y] • "We need to have the doctor that will stay for years. I mean when I was young, the doctor that I saw until I was 18 was the doctor that birthed me, and I know that that is so rare. But, there's just no relational aspects to health care. You're just a number, and you're lucky if you can get a doctor that'll stay for a few years in a small town. So that's, you know, I think that's the big thing is just access, and access doesn't mean 30 minutes away, it means I can walk there." [White woman from a rural county; aged 55 y]
Gender norms and LGBTQ+[a] identity	• "It was after the surgery, my follow-up, and I was going to get the pathology report from the breast surgeon. My partner came with me, and I don't think they even offered to have her sit down. They didn't ask her if she had any questions. There was just no, you know, they just kind of ignored her, and it was, you know, not a fun time at all. So, I don't know how prejudiced they were, but we felt it anyway." [White woman from an urban county; aged 73 y; LGBTQ+ identity] • "I mean, my father was very anti-doctor. No matter what I would say to him...he wouldn't go to a doctor. But at the chiropractor, they said 'hey, I'm not qualified to say this, but it looks like you have cancer, you're a very sick man and you need to go to the hospital.' He died six weeks later. I'd hear him say it many times, he felt like it [health care] was only for the rich...if you can figure out how to change that mentality. [White man from an urban county; aged 41 y; LGBTQ+ identity]
Generational differences	• "My mom is in her 60s...this morning, she asked me if her camera was capable of videos...I think not knowing how to do it is a barrier, but maybe you can walk them through how you set it up." [Black woman from an urban county; aged 29 y] • "I think within my family the 30 and under group, we're much more open to [genetic] information and talking to each other about it. Whereas my mom...she's much more, 'Why are you sending off your DNA, I don't want to know,' and I feel there's a generational difference in sharing information and understanding why it's important." [Black woman from an urban county; aged 30 y]

[a]LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other minority.

Race and Ethnicity

The participants expressed several concerns unique to Black and Hispanic or Latino communities, which are the largest minority populations in Kentucky. For example, participants described the need for greater understanding of risk factors specific to their communities, such as obesity or risks from sun exposure. Concerns were regularly raised related to the trust in medical facilities or health care providers, grounded in both historical incidents and current experiences. For example, participants mentioned the need for communication strategies to overcome language barriers and cultural differences. Similarly, they desired an increase in health care providers from racial or ethnic minority groups. Participants often connected trust and cultural factors to reduced receipt of screening and treatment, which co-occurs with fear and the tendency to avoid seeking care until something is wrong. In addition, participants indicated that reduced receipt of support or support programs in racial and ethnic minority communities may be connected to stigma around mental health and fear of asking for help.

Rural and Urban Residency

In urban areas, participants identified that most of the risk reduction, screening, treatment, and support discussed in the focus groups were available. Although these resources exist for the most part in larger urban areas such as Lexington and

XSL•FO
RenderX

Louisville, participants continued to identify challenges, such as cost, transportation, appointment availability, and perceptions of the quality of local facilities, for urban individuals to access the existing cancer care and support programs.

In rural areas, participants described the presence of regional facilities in some of the smaller urban centers in their vicinity, which may have some resources, although some perceived the quality to be lower than the resources in the larger metropolitan urban areas. Most participants with the ability to do so described choosing to seek out care in larger hospitals with specialized cancer expertise, even if it required driving, finding a place to stay, and taking time off work. Participants expressed the disadvantage faced by individuals lacking resources in receiving quality care, alongside experiences with transient health care in rural areas, which often have shortages of health care professionals. Similarly, participants expressed similar concerns for accessing risk reduction resources, such as healthy foods, places to be physically active, and community programs for tobacco use, which may be available in some rural communities but not accessible to all.

Gender Norms and LGBTQ+ Identity

The participants who identified as members of the LGBTQ+ community expressed concerns and frustration with gender and sexuality norms in cancer care. Concerns included the involvement of their partner, or lack thereof, by health care providers in their care experiences; the presence of religious messaging or iconography creating fear or discomfort in cancer care; and ways that traditional gender norms were expressed in treatment decision-making by health care providers and other acquaintances. In addition, among the participants who identified as male, we heard an increased reference to cultural norms surrounding traditional masculinity and a hesitancy to seek medical care.

Generational Differences

We also heard some specific differences by age group in cancer experiences. Among older individuals, the participants identified low technology awareness and skills as challenges in the receipt of cancer screening and care, particularly for recent increases in telehealth. Similarly, participants expressed a greater hesitancy in certain screening and treatment options among older individuals, such as an increased skepticism and fear around genetic testing. Younger participants described a lack of attention to resources or support programs targeted toward them and the need to increase the diversity of resources to account for their specific needs.

The COVID-19 Pandemic and Cancer Care

Finally, given that the focus groups were conducted in 2021, the COVID-19 pandemic played an active role in our conversations, particularly regarding its impact on cancer health care experiences. For example, the participants commented that the COVID-19 pandemic had influenced their trust in medical facilities; caused postponed screening and procedures, thereby potentially contributing to worsening late-stage diagnoses or treatment outcomes; and affected their overall future health due to changes in risk reduction and care-seeking behaviors during this time. Participants described a growing fear of hospitals, not wanting to leave their house, worn-out staff, and not allowing guests during appointments as significant impacts of the COVID-19 pandemic on cancer-related health care, including screening and treatment.

Discussion

Principal Findings

Through our online focus groups, we were able to capture a wide range of perspectives on needs across the care continuum throughout the state of Kentucky. Although many excellent risk reduction resources exist in Kentucky, the findings suggest that novel approaches are needed to make information accessible to all communities and to use messaging that will not be interpreted as blaming or shaming. A unique opportunity exists to share information on environmental exposures, as participants knew less about such exposures compared to other risk areas. Similarly, screening efforts need to continue to reach individuals in their respective environments (eg, mobile units, at-home screening, and increasing local screening availability) and to include messaging from individuals who engender trust (eg, local leaders, faith communities, local community events, and schools). Continued efforts are also needed to address practical concerns for both screening and treatment. Despite the increase in potential screening opportunities from improved health insurance coverage from the Affordable Care Act, many individuals continued to identify cost and transportation as playing a role in decision-making and a lack of knowledge on the forms of screening or preventive measures that are covered by insurance.

Particularly among our minority group participants, categorized by race, ethnicity, sexual identity, and gender identity, there is a need for enhanced methods to promote positive and understanding communication between patients and health care providers. This is essential for creating safe care spaces that consider how cultural and gender norms influence cancer care. To address the community-specific challenges faced by individuals, messaging and resources specific to these communities are needed to fight stigma and to improve health disparities. In addition, the participants identified treatment navigation as of particular importance for patients with cancer, with generally positive but varying experiences. Finally, the COVID-19 pandemic has shaped a wide variety of cancer care experiences over the past few years, which has affected receipt of care and may continue to have lasting effects on cancer-related behaviors and health decision-making in the future.

Comparison With Previous Research

Our findings align with and support the expansion of previous findings using qualitative methods in cancer-focused community health needs assessments. For example, our participants reiterated the importance of culturally appropriate educational materials for cancer screening and treatment by race and ethnicity or rural and urban designation that was found in previous studies [3,6]. Our participants additionally suggested considerations for such materials by gender identity, sexual orientation, and age. Similarly, as in past research, our study participants highlighted the importance of the source of

XSL•FO
RenderX

information, connecting this source with experiences of stigma, distrust, and discrimination [2]; however, they requested new and additional information in educational materials, such as environmental exposures and survivorship resources specific to their communities. Similarly, our participants described continuing challenges related to accessing cancer care (eg, distance to care, transportation, and cost) that have also been found in existing studies, as well as specific, unique challenges for rural and urban Kentucky communities [2-4,6].

Our work also adds to the currently described data collection processes used in CNAs among NCI-designated cancer centers, which are required to assess and respond to the needs of their catchment areas [28,29]. Recent studies [2,30-32] have described various methods of capturing community needs for catchment area assessments. However, most of these assessments focus on quantitative analysis of community-based surveys or secondary data, and a few describe the explicit inclusion of qualitative data collection. One recent study [2] included qualitative key informant interviews with organizational partners as a part of their assessment; however, to the best of our knowledge, focus group findings with community members for this purpose have not yet been reported. Furthermore, qualitative data have been more widely used in cancer-related needs assessments or studies focused on specific localities [3,6] or population groups, such as rural [33], gender-based [34], immigrant [35], and racial and ethnic minority populations [15,36], rather than for broader assessments of the needs across a statewide catchment area. Our findings support several key areas identified in the previously reported catchment area assessments. For example, several assessments [2,30-32] highlighted similar findings about the importance of social factors related to health care provider interactions, discrimination, and trust, as well as access to care challenges, such as financial, geographic, and insurance-related barriers.

We used an online format to reach the diverse population of Kentucky to capture in-depth community perspectives across a state with wide-ranging geographic and cultural contexts. Using this format allowed us to successfully document the resources and needs across the cancer care continuum domains. Although online focus groups have been possible for decades, the COVID-19 pandemic has compelled researchers and health professionals to adapt to existing restrictions and caused a rapid expansion in the use of this technology for qualitative data collection [37]. Researchers have established that online focus groups meet the previously determined standards of in-person focus groups [38]; however, with the pandemic-stimulated increase in uptake and technology improvements, more work is needed to establish best practices for the online format [37]. As in previous studies, we obtained substantial data from participants who may not otherwise have been able to participate due to barriers associated with in-person focus groups, such as the need for a central meeting location, transportation, and childcare [11,14]. In addition, a few potential participants indicated that technology would pose a challenge for their participation, which aligns with previous findings of satisfaction or even preference for this format [14]. Although many focus group studies seek to recruit homogeneous samples based on defined characteristics [39], online focus groups gave us the ability to broadly recruit participants in 25 different Kentucky counties. This geographic breadth allowed for a broader perspective than is typically obtained for in-person groups within specific communities.

Previous studies have recommended that CNAs include individuals from the most susceptible populations who experience cancer health disparities [2,31,32]. Our study followed this recommendation through our stratified design, strategically oversampling key target groups, including racial and ethnic minority groups, sexual and gender minority groups, and rural Appalachian communities. By intentionally recruiting a wide variety of Kentuckians, we were able to uncover social determinants of health that influence health equity in the state.

Strengths and Limitations

In this study, we faced several recruitment and technology-based limitations. First, as conducting recruitment during the pandemic limited face-to-face opportunities, we supplemented these efforts with online strategies, such as digital flyers through the KCP and the KCC listservs and ResearchMatch. The REDCap eligibility screener could be completed on a mobile device or computer, which increased potential participation but could have resulted in higher participation among those with increased access to technology. Second, we sought to address potential technology challenges that may arise from conducting the focus groups on Zoom, such as a lack of internet access or low technology literacy. We asked participants about their comfort level during recruitment and provided support to those who expressed discomfort with the online video format to ensure their ability to participate (only n=2, 4% of the 51 participants requested and received this one-on-one assistance). Third, we tried to ensure we captured lay community member perspectives by recruiting those who do not currently hold a position in health care; however, some participants were particularly knowledgeable about health services in their community due to a background in social services or education, which may intersect with health resources.

Finally, while fairly robust for a qualitative study, our sample size may not have allowed us to capture the full range of thoughts on cancer care in Kentucky, and the purposive sampling design is not intended to be transferable to other states or throughout the United States. Considering our statewide focus, our sample was fairly representative of the state of Kentucky's population demographics. Our study had an oversampling of female participants, which is a common challenge in qualitative research, and despite our sampling design, we had an underrepresentation of Appalachian counties. Although we successfully oversampled Black or African American and LGBTQ+ participants, we did not recruit enough participants in other racial or ethnic groups to explore their perspectives at a more granular level, and nor did we meet our target for Hispanic or Latino individuals. To address this limitation and to allow for participation in Spanish, we are conducting a supplemental needs assessment focused on the Hispanic or Latino population in Kentucky. In addition, we did not perform member checking for the focus group findings; however, we subsequently collected additional data with CNA participants, allowing for further feedback on these results.

XSL•FO
RenderX

Future Directions

After this study, we combined the focus group findings with our quantitative data to conduct concept mapping [40,41] to prioritize the diverse needs and strategies uncovered in the CNA process. This prioritization and active participation by community members and partners in the process will allow for the steering committee and other organizations focusing on cancer in Kentucky to hone and deliver programs grounded in community recommendations. In addition, our success with conducting online focus groups in a catchment area needs assessment suggests that this method could be an excellent supplement to future CNAs. Cancer centers and researchers interested in broadly capturing the needs in a large, diverse geographic area may benefit from this approach. This method can also be used by cancer centers in partnership with state, tribe, and territorial cancer control programs and coalitions to inform their cancer plans, aligning with efforts to build communities of solution [42].

Conclusions

Overall, the high-quality data gathered from our online CNA focus groups will inform future studies and cancer prevention and control efforts in Kentucky, as well as CNAs conducted by cancer centers across the country. Using an online format, we uncovered a wide variety of factors affecting Kentuckians across the cancer care continuum, highlighted the role of social determinants of health, and identified health equity issues affecting different population groups. By conducting community-engaged, qualitative data collection, we provided valuable depth of understanding to complement the interpretation of quantitative data and created a platform for ways to develop future programs and research to address cancer incidence and mortality in Kentucky. These findings suggest that the inclusion of online focus groups can be a valuable component of multimethod CNAs to capture cancer-related needs and solutions in large geographic areas and diverse populations. Structuring focus group questions and analysis based on the cancer care continuum domains provides useful data for CNAs and stratifying the focus groups based on similar demographic characteristics facilitates identifying unique needs of specific groups that experience cancer health disparities.

Acknowledgments

The authors would like to thank the community partners and study participants for their valuable contributions as well as the additional members of the Kentucky Cancer Needs Assessment Steering Committee, who represent the Kentucky Cancer Registry (Bin Huang and Jaclyn McDowell), the Kentucky Cancer Program (Jamie Smith), the Kentucky Cabinet for Health and Family Services (Sarojini Kanotra, Janie Cambron, Vivian Lasley-Bibbs, Emily Messerli, Carissa Adams, Carrie Conia, and Elizabeth Owen), the American Cancer Society (Elizabeth Holtsclaw and Julie Waters), the Foundation for a Healthy Kentucky (Allison Adams), and the University of Louisville (Stephanie Boone).

This research was supported in part by the National Institutes of Health (NIH) National Cancer Institute (grant P30CA177558), the NIH National Center for Advancing Translational Sciences (grant UL1TR001998), the Centers for Disease Control and Prevention (grants NU58DP007144 and NU58DP006313), and the William Stamps Farish Endowed Chair in Cancer Research (Hull).

Abstract

Background: Cancer is a life-threatening disease and a leading cause of death worldwide, with an estimated 611,000 deaths and over 2 million new cases in the United States in 2024. The rising incidence of major cancers, including among younger individuals, highlights the need for early screening and monitoring of risk factors to manage and decrease cancer risk.

Objective: This study aimed to leverage explainable machine learning models to identify and analyze the key risk factors associated with breast, colorectal, lung, and prostate cancers. By uncovering significant associations between risk factors and these major cancer types, we sought to enhance the understanding of cancer diagnosis risk profiles. Our goal was to facilitate more precise screening, early detection, and personalized prevention strategies, ultimately contributing to better patient outcomes and promoting health equity.

Methods: Deidentified electronic health record data from Medical Information Mart for Intensive Care (MIMIC)–III was used to identify patients with 4 types of cancer who had longitudinal hospital visits prior to their diagnosis presence. Their records were matched and combined with those of patients without cancer diagnoses using propensity scores based on demographic factors. Three advanced models, penalized logistic regression, random forest, and multilayer perceptron (MLP), were conducted to identify the rank of risk factors for each cancer type, with feature importance analysis for random forest and MLP models. The rank biased overlap was adopted to compare the similarity of ranked risk factors across cancer types.

Results: Our framework evaluated the prediction performance of explainable machine learning models, with the MLP model demonstrating the best performance. It achieved an area under the receiver operating characteristic curve of 0.78 for breast cancer (n=58), 0.76 for colorectal cancer (n=140), 0.84 for lung cancer (n=398), and 0.78 for prostate cancer (n=104), outperforming other baseline models (*P*<.001). In addition to demographic risk factors, the most prominent nontraditional risk factors overlapped across models and cancer types, including hyperlipidemia (odds ratio [OR] 1.14, 95% CI 1.11 - 1.17; *P*<.01), diabetes (OR 1.34, 95% CI 1.29 - 1.39; *P*<.01), depressive disorders (OR 1.11, 95% CI 1.06 - 1.16; *P*<.01), heart diseases (OR 1.42, 95% CI 1.32 - 1.52; *P*<.01), and anemia (OR 1.22, 95% CI 1.14 - 1.30; *P*<.01). The similarity analysis indicated the unique risk factor pattern for lung cancer from other cancer types.

Conclusions: The study's findings demonstrated the effectiveness of explainable ML models in assessing nontraditional risk factors for major cancers and highlighted the importance of considering unique risk profiles for different cancer types. Moreover, this research served as a hypothesis-generating foundation, providing preliminary results for future investigation into cancer diagnosis risk analysis and management. Furthermore, expanding collaboration with clinical experts for external validation would be essential to refine model outputs, integrate findings into practice, and enhance their impact on patient care and cancer prevention efforts.

Introduction

Cancer is a life-threatening disease and leading cause of death worldwide. In 2024, 611,000 people were estimated to have died from cancer in the United States, and the estimated new cancer cases will reach more than 2 million for the first time [1]. This surge includes rising incidence rates for major cancers, including breast, prostate, lung, and colorectal cancers, which display the trend of increasingly affecting younger individuals who have many more years of life expectancy [1]. The US Preventive Services Task Force modified the recommended age for colorectal cancer screening from 50 to 45 years for people at average risk in 2021 and adjusted the recommendation for breast cancer screening for all women to start at the age of 40 years in 2024 [2,3]. Similar upward trends in the incidence of early-onset cancers are observed in other high-income countries, suggesting shared risk factors and exposures across these regions. However, besides those uncontrollable risk factors, such as previous cancer diagnosis, family history of cancer, and genetics or inherited cancer syndrome, many cancer risk factors, including lifestyle factors, are modifiable and can be managed to decrease people's risk for cancer [4].

Extensive evidence highlights the potential benefits of early identification of individuals at high risk for cancer, which can contribute to improved prevention, more effective treatment, reduced cancer burden, and better long-term outcomes. However, demonstrating a clear survival advantage [5] from screening remains challenging, with notable exceptions such as cervical cancer [6]. It is essential to address biases like lead-time and length bias in screening, as they can overestimate its benefits, ensuring accurate evaluations [7]. In the context of breast cancer, it was estimated that early access to treatment services following breast cancer screening could have reduced breast cancer mortality by 25% - 40% [8]. Given the tremendous benefits of early identification of high-risk patients, an increasing number of cancer risk prediction models have been developed [9]. However, Traditional models used for cancer risk prediction, such as logistic regression (LR) and Cox regression, often demonstrate moderate discrimination accuracy, with an area under the receiver operating characteristic curve (AUC) ranging from 0.53 to 0.64 [10-13]. These models frequently emphasize family history and may have limited generalizability, potentially introducing biases when applied to specific subpopulations [14,15]. Furthermore, nontraditional risk factors, such as chronic diseases, are often overlooked, despite evidence suggesting that chronic conditions can elevate cancer risk similarly to lifestyle factors [16]. This highlights the need for more advanced methods to enhance cancer diagnosis risk prediction and support effective cancer prevention strategies.

Machine learning has shown promising potential in cancer prediction by leveraging electronic health record (EHR) data to identify risk factors [17]. Current applications range from developing predictive models for early cancer detection to personalized treatment recommendations and outcome predictions, based on various patient characteristics and biomarkers. Despite these advancements, several challenges remain in cancer prediction using machine learning [18]. A key issue is the need for a deeper understanding of risk factors within and across different cancer types [19]. As research progresses, explainable machine learning offers a meaningful step forward in improving the efficacy and transparency of predictive models [20-22]. These models not only enhance predictive accuracy but also provide interpretable insights into how predictions are made, fostering trust and facilitating clinical decision-making [23]. By systematically identifying and excluding irrelevant features, explainable approaches can reduce noise and streamline the prediction process. However, it is important to recognize that feature selection algorithms can be sensitive to dataset characteristics, where small changes in the data may lead to differing results [24]. This underscores the importance of carefully selecting features that are most relevant, contributing to a deeper understanding of cancer diagnosis risk factors and improving predictive performance.

Hence, this study presented comprehensive research aimed at uncovering the association between pivotal factors and the risks of 4 major cancer diagnoses (breast, prostate, lung, and colorectal) through the use of explainable machine learning techniques on penalized LR, random forest (RF), and multilayer perceptron (MLP). Our primary objective was to pinpoint the significant features that exert an influence on the risks associated with the diagnosis of these major cancers and to delineate the patterns of risk factors corresponding to each cancer type. Such insights can contribute to enhanced risk monitoring and patient stratification and provide valuable support for clinicians in their decision-making processes, ultimately improving the quality patient care. By elucidating these critical factors and their associated risk factor patterns, we provided clinicians valuable insights through rigorous analysis for enhancing risk monitoring and patient care across various cancer types.

Methods

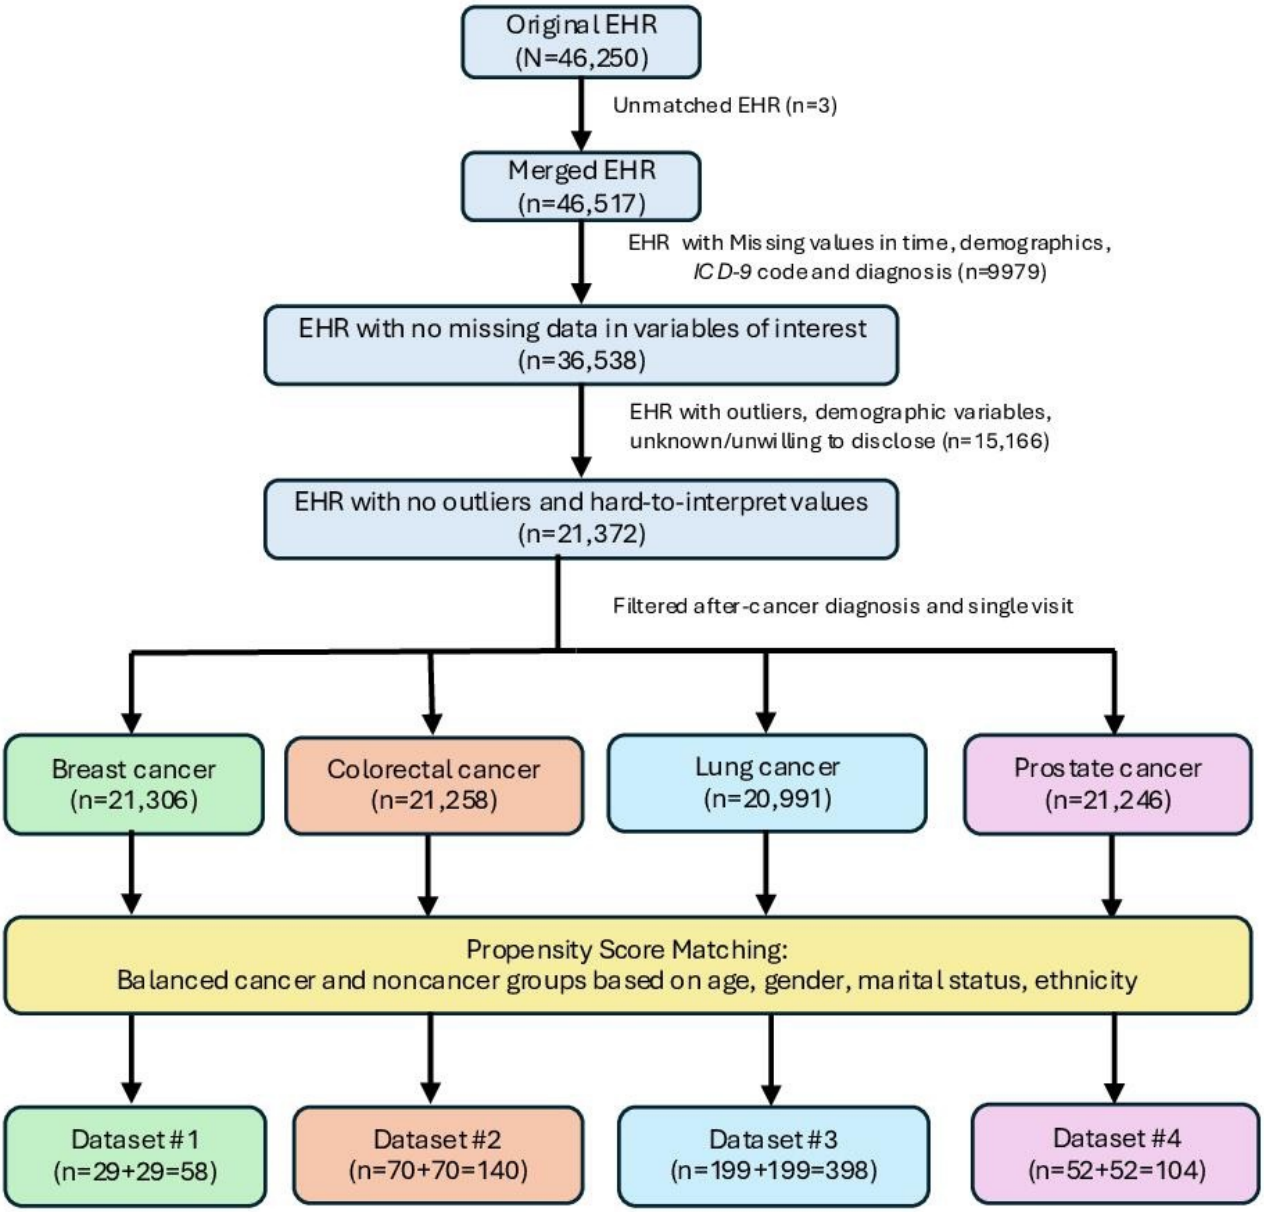
Experimental Dataset

Our study was conducted using data from Medical Information Mart for Intensive Care (MIMIC)–III, a comprehensive, structured, longitudinal EHR dataset that is publicly available [25]. This dataset contains deidentified, detailed clinical data from intensive care unit (ICU) admissions between 2001 and 2012 at Beth Israel Deaconess Medical Center in Boston, Massachusetts, and is accessible to the global research community under a data use agreement. We used the most recent version (v2.0 released in January 2023) for this work which contains a broad spectrum of data, including information on individual patients' health and health care from various inpatient and outpatient visits, such as diagnoses, prescriptions, lab tests, and procedures. These visits include emergency room admissions and subsequent hospital transfers, where a patient's transfer to a ward or subsequent re-admission to the ICU within the same hospitalization period was considered a single visit. In total, this dataset contains 58,976 admissions of 46,520 patients.

Additionally, we investigated the health status and prevalence of a few common chronic diseases for the MIMIC-III dataset, compared with the prevalence of these chronic diseases in the US population. The MIMIC-III dataset shows that hypertension

XSL•FO
RenderX

affects 47.97% of ICU patients, while in the US population, prevalence ranges from 46.9% to 49.4% [26,27]. Diabetes mellitus is present in 21.20% of MIMIC-III patients, whereas it affects 11.6% of the US population and 14.7% of adults [28]. Hypercholesterolemia appears in 14.94% of ICU cases, with US estimates between 10% and 11.4% [29,30]. Congestive heart failure is recorded in 27.38% of MIMIC-III patients, while the lifetime risk in the US is 24% [31]. Esophageal reflux affects 15.33% of ICU patients and 20% of people in the US [32]. Pneumonia is diagnosed in 12.46% of ICU patients, while 24.9% of US adults have reported cases [33]. Anemia affects 14.02% of ICU patients, while 5.6% of the US population has the condition [34]. Acquired hypothyroidism is observed in 10.71% of MIMIC-III patients and 4.6% of US adults [35]. Tobacco use is recorded in 7.76% of ICU cases, while 19.8% of US adults report smoking [36]. Depressive disorders affect 8.17% of ICU patients, while 9.5% of American adults have been diagnosed [37]. Chronic airway obstruction is reported in 10.24% of MIMIC-III cases, while national estimates range from 6.0% to 6.1% [38].



Data Preprocessing

We included patients with 4 types of cancers (breast, colorectal, lung, and prostate) identified using *International Classification of Diseases, Ninth Revision* (*ICD-9*) codes associated with the diagnosis of each type of cancer (Table S1 in Multimedia Appendix 1).

We took a few steps to preprocess the experimental dataset, starting with the consolidation of 3 main tables from the MIMIC-III database. These included: (1) foundational patient information, capturing demographics and initial hospital admission data; (2) a reference table for *ICD-9* codes, detailing both codes and corresponding diagnostic labels; and (3) logs of patient visit sequences with associated *ICD-9* codes. This consolidation linked the records via patient IDs to construct a detailed longitudinal dataset. Figure 1 illustrates the data processing workflow of this study. Patients' ages were determined by deducting their date of birth from their initial hospital admission date, with the result rounded to the nearest year. Any patient records missing demographic details (such as ethnicity, marital status, or religion) were omitted, narrowing the dataset to a total of 21,372 unique individuals. Our study focused on patients who had multiple hospital visits prior to their cancer diagnosis presence in the record to identify potential risk factors. After a cancer diagnosis code was recognized, further visits were disregarded. These records were combined with those of patients without a cancer diagnosis. A label was created as 1 if a visit included an *ICD-9* code for a cancer diagnosis and 0 if not. To ensure a balanced dataset in terms of cancer diagnosis, the study matched patients diagnosed with cancer with those without cancer using propensity score matching based on demographic factors. Table 1 contains a detailed description of patient characteristics for 4 cancer types.

Feature Selection

Our experiment’s initial dataset comprised thousands of diagnosis codes intended for predicting cancer diagnosis risk. Aware of some features’ potential redundancy and less informative nature, we did a feature selection process. This involved assessing the relevance and importance of each feature in relation to 4 specific types of cancer. We performed a correlation-based feature selection process to identify a subset of features that were highly correlated with the target cancer outcomes. This was followed by a thorough review of relevant literature and consultation with experts to validate and refine the selected features.

Framework

In this work, we applied 3 advanced models, penalized LR, RF, and MLP, based on their demonstrated accuracy and robustness in handling high-dimensional datasets. RF and MLP excel at identifying complex, nonlinear interactions among variables without requiring predefined interaction terms. This capability is crucial for analyzing interactions between risk factors and cancer outcomes. Our choice of RF and MLP was determined by a desire to balance complexity with interpretability, as well as to ensure computational efficiency. Both methods are straightforward and offer high interpretability, which makes

XSL•FO
RenderX

them excellent foundational models for exploring how different features influence cancer diagnosis risk.

Since the task aimed at forecasting cancer diagnosis risk by considering important and relevant risk factors, we evaluated the efficacy of our methodologies by employing several critical performance metrics: AUC, accuracy, specificity, sensitivity, and the F_1-score for each model. We partitioned the dataset into 3 sections for model development: 70% for training, 10% for validation, and 20% for testing. The model that exhibited the best results on the validation set was further subjected to an in-depth analysis of the test set, using a 3-fold cross-validation technique to calculate its AUC precisely. To enhance our understanding of how our machine learning models contribute to cancer prevention, we also quantified the impact of each feature on the prediction of 4 cancer types. We then ranked these features according to their significance. All statistical analyses and model implementations were coded using Python, with the scikit-learn library serving as the foundation for our predictive framework [39]. To assess the generalizability of the model, we validated its performance using an independent ICU dataset from MIMIC-IV-ED ((Medical Information Mart for Intensive Care), which represents an extended patient population. For each cancer type, we randomly sampled 200 cases and 200 matched controls from MIMIC-IV-ED, ensuring no patient overlap with the MIMIC-III experimental dataset.

To investigate the similarity of features ranking by different cancer types, we applied rank biased overlap (RBO) [40], a similarity measure of 2 ranked lists. The RBO score ranges between 0 and 1, where a higher score indicates greater similarity between the lists. A score of 1 implies perfect overlap, meaning the 2 lists are identical in both order and content. On the other hand, a score of 0 suggests no overlap between the lists.

Mathematically, let xi be the high-dimensional feature input. Let yi∈ {0,1} be the corresponding label. yi=0 means not affected, and yi=1 means affected. Our goal is to learn a predictive function f that best classifies the data. We built 3 state-of-the-art models for 4 cancer types respectively in this study:

- Penalized LR: given M training instances, we considered L1 regularized LR by minimizing the following function: ∑i=1M−loglogp(x(i);θ)+β||θ||1.
- RF [41]: a robust ensemble learning method that constructs multiple decision trees during training to improve prediction accuracy and prevent overfitting, where f is the decision tree as base learners. The RF model was trained by iteratively selecting features from root to leaf nodes and aggregating multiple trees with the weights from a subset of the training instances. The nodes and the weights in the model reflect their importance to the final prediction.
- MLP [42]: a type of artificial neural network that consists of at least 3 layers of nodes: an input layer, one or more hidden layers, and an output layer. Each node, or artificial neuron, in one layer, connects with a certain weight to every node in the following layer, and nodes do not connect within the same layer. The nonlinear activation functions, such as the sigmoid, or Rectified Linear Unit, are applied to the weighted sum of inputs to a neuron, determining its output signal.

To rank the impact on predictive models of the features, relative to all 3 models, we used a permutation importance score to rank all features in the training models for MLP [43]. The scores were defined by the mean decrease in accuracy of the trained model when each feature was permuted.

Ethical Considerations

MIMIC-III data are the result of a collaboration between Beth Israel Deaconess Medical Center (BIDMC) and Massachusetts Institute of Technology. Data collected at BIDMC as part of routine clinical care are deidentified, transformed, and made available to researchers who have completed training in human research and signed a data use agreement. The Institutional Review Board (HUM00230096) at the BIDMC granted a waiver of informed consent and approved the sharing of the research resource. This study was determined to be exempt from further ethical review. The contributing author, XH, obtained the necessary authorization to access the anonymized dataset and oversaw the meticulous data extraction process.

Results

Feature Selection

We conducted a feature selection process to refine thousands of diagnosis codes for predicting cancer diagnosis risk, using correlation-based selection to identify the most relevant features for 4 cancer types. Through this rigorous analysis, we aimed to distill the dataset down to a more manageable and meaningful subset of features. Eventually, we identified 33 features (recategorized into 20 factors for further analysis, Table 2) that emerged as particularly crucial for accurately predicting cancer diagnosis risk. These features were meticulously curated, ensuring that only the most informative and pertinent variables were retained for our predictive models.

XSL•FO
RenderX

Table . Features selected for predicting cancer diagnosis risks.

Features	Factors
Acidosis	Acidosis
Acute kidney failure, unspecified	Acute kidney failure
Age	Age
Anemia, unspecified	Anemia
Acute posthemorrhagic anemia	Anemia
Depressive disorder, not elsewhere classified	Depressive disorder
Diabetes mellitus without mention of complication, type II or unspecified type, not stated as uncontrolled	Diabetes
Esophageal reflux	Esophageal reflux
Ethnicity	Ethnicity
Gender	Gender
Cardiac complications, not elsewhere classified	Heart disease
Aortocoronary bypass status	Heart disease
Coronary atherosclerosis of native coronary artery	Heart disease
Old myocardial infarction	Heart disease
Congestive heart failure, unspecified	Heart disease
Atrial fibrillation	Heart disease
Subendocardial infarction, initial episode of care	Heart disease
Pure hypercholesterolemia	Hyperlipidemia
Other and unspecified hyperlipidemia	Hyperlipidemia
Unspecified essential hypertension	Hypertension
Other iatrogenic hypotension	Hypotension
Unspecified acquired hypothyroidism	Hypothyroidism
Marital status	Marital status
Religion	Religion
Acute respiratory failure	Respiratory or pulmonary diseases
Unspecified pleural effusion	Respiratory or pulmonary diseases
Pneumonia, organism unspecified	Respiratory or pulmonary diseases
Pneumonitis due to inhalation of food or vomitus	Respiratory or pulmonary diseases
Pulmonary collapse	Respiratory or pulmonary diseases
Chronic airway obstruction, not elsewhere classified	Respiratory or pulmonary diseases
Unspecified septicemia	Sepsis
Personal history of tobacco use	Tobacco use
Urinary tract infection, site not specified	Urinary tract infection (UTI)

Model Performance

For each predicted cancer outcome, we carried out the experiment by predicting cancer using the entire diagnosis history of the patient by building LR, RF, and MLP models. Table 3 illustrates the accuracy, specificity, sensitivity, and F_1-score of these 3 models for breast, colorectal, lung, and prostate cancers. Figure 2 shows the receiver operating characteristic plots of 3 models for 4 types of cancer, respectively. Both Table 3 and Figure 2 show that within the 3 models, MLP performs the best, RF falls in the middle, and LR ranks last. It is worth noting that MLP achieved an AUC of 0.78 for breast cancer, 0.76 for colorectal cancer, 0.84 for lung cancer, and 0.78 for prostate cancer, demonstrating a higher AUC over traditional risk factor-based models and a statistically significant superiority over random chance. The underwhelming results from the LR model led us to investigate the complexity of risk factors for prediction. Compared with LR, MLP reveals the intricate, nonlinear associations between risk factors and the likelihood of cancer, offering meaningful insights into the

XSL•FO
RenderX

collective influence of these risk factors on cancer diagnosis risk.

Table . Comparison of model performance across 4 types of cancer on Medical Information Mart for Intensive Care (MIMIC)–III.

[a]LR: logistic regression.

[b]RF: random forest.

[c]MLP: multilayer perceptron.

Figure 2. Area under the receiver operating characteristic curve (AUC) performance of the 3 binary classification models (logistic regression [LR], random forest [RF], and multilayer perceptron [MLP]). The figure shows AUC curves of breast cancer, colorectal cancer, lung cancer, and prostate cancer for LR, RF, and MLP, respectively.

Additionally, Table S2 in Multimedia Appendix 1 presents the AUC, accuracy, specificity, sensitivity, and F_1-score for the 3 models across breast, colorectal, lung, and prostate cancers. Among the models evaluated, MLP demonstrated the highest performance, achieving an AUC of 0.88 for breast cancer, 0.83

XSL•FO
RenderX

for colorectal cancer, 0.90 for lung cancer, and 0.85 for prostate cancer.

Feature Importance Analysis

We analyzed the feature importance for each cancer type further to investigate the potential impact of risk factors on cancer. Tables 4 and 5 present the feature importance analysis of RF and MLP, showcasing the top-ranked risk factors for each type of cancer. The ranks of these factors were relatively different by model and cancer type, although some consistency can be observed across cancer types. Age emerged as the top risk factor across all 4 types of cancer; race/ethnicity ranked among the top 10 factors for all cancers from all models except for the RF-based lung cancer and prostate cancer models; gender was ranked among the top 10 in MLP-based models but not in any RF-based models; marital status and religion were presented for some types of cancer in some of the models; and tobacco use as an important factor for patients with lung and prostate cancer exclusively. However, all these demographic risk factors were included in the top 20 factors for all cancer types (Table S3 in Multimedia Appendix 1). Similarly, RF-based models identified hypertension, heart diseases, respiratory/pulmonary diseases, and acute kidney failure as the common top risk factors for all types of cancers, while MLP-based models highlighted hyperlipidemia, diabetes, depressive disorder, and heart diseases. We calculated the odds ratio (OR) for each highlighted feature to assess its association with overall cancer diagnosis risk across 4 cancer types. The results indicated that hyperlipidemia had an OR of 1.14 (95% CI 1.11 - 1.17; P<.001), while diabetes showed a stronger association with an OR of 1.34 (95% CI 1.29 - 1.39; P<.01). Similarly, depressive disorders were linked to an OR of 1.11 (95% CI 1.06 - 1.16 P<.01), and heart diseases exhibited the highest association with an OR of 1.42 (95% CI 1.32 - 1.52; P<.01). Last, anemia was also significantly associated with cancer diagnosis risk, with an OR of 1.22 (95% CI 1.14 - 1.30; P<.01). These findings suggest a statistically significant relationship between these conditions and an increased risk of developing these 4 types of cancer. In MLP-based models, respiratory/pulmonary diseases and acute kidney failure were only presented as the top 10 for lung cancer. Both RF and MLP-based models pinpointed anemia as the top risk for breast cancer. Figure 3 shows the RBO similarity scores of risk factors for 4 types of cancer according to MLP-based models. Low similarity scores are presented between lung cancer and any other 3 cancer types, all around 0.58, suggesting distinct patterns of risk factors associated with lung cancer. Risk factors for breast and prostate cancers show the most similar ranking with an RBO similarity score of 0.76. A moderate similarity score between colorectal and breast cancers is about the same as the score between colorectal and prostate cancer, both around 0.70.

Table . Top-10 ranked features generated across 4 different cancer types in random forest.

Ranking	Breast cancer	Colorectal cancer	Lung cancer	Prostate cancer
1	Age	Age	Age	Age
2	Hypertension	Respiratory or pulmonary diseases[a]	Hypertension	Hypertension
3	Religion	Hypertension	Religion	Religion
4	Marital status	Acute kidney failure	Hyperlipidemia	Heart diseases[c]
5	Respiratory or pulmonary diseases	Diabetes	Heart diseases	Marital status
6	Heart diseases	Heart diseases	Acute kidney failure	UTI[c]
7	Race or ethnicity	Hyperlipidemia	UTI	Respiratory or pulmonary diseases
8	Depressive disorders	Race or ethnicity	Respiratory or pulmonary diseases	Anemia
9	Acute kidney failure	Religion	Marital status	Hyperthyroidism
10	Anemia	Acidosis	Anemia	Diabetes

[a]Respiratory or pulmonary diseases include pneumonia, acute respiratory failure, chronic airway obstruction, and other respiratory or pulmonary complications.

[b]Heart diseases include atrial fibrillation, myocardial infarction, congestive heart failure, coronary atherosclerosis, and other cardiac complications.

[c]UTI: urinary tract infection.

Discussion

Principal Findings

This study used comprehensive patient diagnosis histories to evaluate the association between key risk factors and cancer outcomes and identify risk factor patterns across different cancer types using penalized LR, RF, and MLP models. The analysis identified the top-ranking risk factors, including nontraditional risk factors such as the diagnosis of hyperlipidemia, diabetes, depressive disorders, heart diseases, and anemia, in addition to demographic factors such as age, sex, race/ethnicity, for the most prevalent 4 types of cancer, including breast, colorectal, lung, and prostate cancers. The model performance evaluation revealed the valuable potential of neural network-based models, especially MLPs, in oncology for predicting cancer diagnosis risks across cancer types. MLPs exhibit a strong capability to model complex, nonlinear interactions among diverse risk factors, making them potentially valuable tools for identifying patterns in cancer diagnosis risk and informing early detection strategies. However, their application in clinical interventions should be guided by a solid scientific rationale and supported by pathological models that explain the role of these risk factors in disease development. Additionally, validation across different cohorts and, ideally, prospective studies are necessary to ensure their reliability and clinical utility. This advantage is particularly important given the model's capacity to integrate and interpret the intricate relationships between clinical factors present in EHRs. In contrast to simpler models like LR, which struggle with the multidimensional nature of risk factors on cancer diagnosis in many cases, MLPs offer a more detailed and comprehensive analysis, enhancing our understanding of how these factors collectively impact cancer diagnosis risk and improving the precision of preventive strategies in clinical settings. Last, this study does not aim to establish causal inference but rather to examine significant overlapping risk factors that may contribute to cancer diagnosis risk, particularly those observed in patients with other medical conditions. While these diagnoses are not independent causal determinants of cancer, their presence may be associated with an increased risk. Careful consideration of these associations is essential for a comprehensive understanding of cancer risk factors and their potential interactions.

Comparison to Prior Work

Prior cancer risk prediction models usually focus on lifestyle factors like smoking, diet, alcohol consumption, physical activity, and sun exposure as key variables [44-46]. Some models have also incorporated genetic risk factors [47,48]. However, many of these models reported less optimal performance, such as a high specificity but low sensitivity [46] or a low AUC of around 0.65 [48]. Chronic diseases are often overlooked as risk factors for cancer, and they are not often targeted in cancer prevention strategies. The association between some of these diseases and cancers may partly be due to shared risk factors, such as aging, obesity, diet, and physical inactivity. However, they can also be independent risk factors for cancer. For example, diabetes mellitus has been identified as an independent risk factor for colon and rectal cancer in a meta-analysis of studies that either controlled for smoking and obesity, or smoking, obesity, and physical exercise [49]. As nontraditional risk factors, the influence of certain chronic conditions on cancer has been brought to researchers' attention in the past decade. A prospective cohort study with 405,878 participants followed for an average of 8.7 years demonstrated that 8 common chronic diseases accounted for more than 20% of cancer risk, which are comparable to 5 major lifestyle factors, such as smoking and lack of physical activity [16]. These 8 chronic diseases or markers included blood pressure, total cholesterol, heart rate, diabetes, proteinuria, glomerular filtration rate, pulmonary disease, and gouty arthritis marker [16]. However, as these diseases or markers were pre-selected by the researchers based on their disease burden worldwide, some other essential influential conditions might be missed. Our models confirmed most of these 8 diseases as the top-ranking risk factors. Additionally, some new conditions were revealed in our models among the top 10 factors for 4 types of cancer, such as depressive disorder, anemia, hypothyroidism, sepsis, urinary tract infection, and acidosis, which encourages further exploration. Certainly, some of these diagnoses may be directly related to the cancer itself. For example, anemia is a common symptom of metastatic breast cancer and a side effect of chemotherapy [50]. In addition, sepsis and colorectal cancer have demonstrated a complex relationship and may have shared pathophysiological traits and potential bacterial associations reported by the literature [51]. Notably, tobacco use and respiratory/pulmonary diseases emerged as pivotal risk factors, specifically for lung cancer, which is not surprising based on our knowledge in the field. Diabetes and anemia were highlighted as significant risk factors for colorectal cancer, which is congruent with the literature [52,53]. Iron deficiency has been recognized long-term as an independent predictor of colorectal cancer, which may be due to chronic blood loss from the gastrointestinal tract and the inflammation associated with malignancy [54,55]. These conditions could have shared risk factors with cancer. However, emerging evidence implies that they may have more complicated relationships, including shared pathophysiological mechanisms that need further exploration [56]. Moreover, cancer prevention strategies should consider the impact of comorbid conditions on the incidence of cancer and particularly their joint impact on cancer risks [53].

Understanding the relationships between various risk factors and cancer diagnosis risk is pivotal for the early detection and prevention of cancer. In this context, our feature importance analysis using RF and MLP models pinpointed critical risk factors for different cancer types and explored patterns of these risk factors across various cancers. Although the ranks of risk factors for cancers were slightly different by the RF and MLP-based models, similar patterns were presented among the top 10 factors (Tables 4 and 5), which are interpretable and supported by the literature. Both models highlighted age as the predominant risk factor across all 4 types of cancer, which is evident that as age increases, the incidence rates for cancer overall climb steadily, and alongside age, demographic variables such as gender, race/ethnicity, marital status, and religion emerged within the top 10 features [57]. Racial/ethnic disparities in cancer incidence and outcomes are well-known. Employing culturally tailored community awareness and education programs may increase cancer screening to improve early-stage

XSL•FO
RenderX

diagnoses and modify risk behaviors for cancer prevention [58]. Although there may not be existing evidence to confirm that marital status is an independent risk factor for cancer, observational studies demonstrate that married status is associated with reduced risk of cancer-specific and all-cause mortality [59,60]. Religion and spirituality are important in patient cancer care, and specifically, a systematic review suggests a positive association between religious attendance and cancer screening use [61]. Our models not only confirmed the significance of these risk factors for each cancer type but also our RF-based model facilitated an interpretable analysis, allowing us to clearly rank the significance of each risk factor, while the MLP-based model provided deeper insights into complex, nonlinear interactions among the risk factors. This approach enriches our understanding of how specific risk factors influence cancer diagnosis, enhancing the potential for developing tailored intervention strategies that address the unique risk profiles associated with different cancer types and potentially shared risk patterns across prevalent cancer types.

The analysis of the similarity among risk factors for the diagnosis of 4 types of cancer also revealed interesting findings. As breast and prostate cancer are both hormone-dependent cancers, it is understandable that their importance-ranked risk factors share a high level of similarity. However, lung cancer had more unique ranked risk factors than other types of cancer, which may be because lung cancer is more sensitive to environmental risk factor exposure. The findings from our analysis underscore the shared risk factors and heterogeneous nature of cancer and highlight the importance of considering unique risk profiles for different cancer types. This also urges us to address the fundamental mechanism of risk factors leading to cancers. Such insights are crucial for developing tailored prevention strategies, optimizing screening protocols, and informing personalized treatment approaches to mitigate the burden of lung cancer and improve patient outcomes.

Limitations

First, the use of the MIMIC-III dataset in this study on explainable machine learning for cancer risk prediction presents certain limitations that may impact the generalizability of the findings, Since the data are derived from ICU patient records, it primarily represents individuals with severe conditions, and the available *ICD* codes may not fully capture disease complexity, potentially leading to incomplete representations of patient conditions. Additionally, the limited sample size for patients with cancer may impact predictive performance and increase the risk of overfitting. Both limitations may affect the generalizability of the findings. To enhance the robustness of future research, integrating more recent and varied data sources and validating findings across different cohorts are essential steps. Second, one limitation comes from the application of explainable machine learning models for cancer risk prediction. Employing advanced techniques like penalized LR, RF, and MLP, this research seeks to optimize predictive accuracy. However, each model inherently embodies trade-offs: while more complex models, such as multi-layer perceptron, may enhance performance, they often compromise on interpretability. This presents significant challenges in clinical settings, where understanding the reasoning behind model predictions is crucial for acceptance and trust by medical practitioners. Third, another limitation of this study arises from the inherent nature of machine learning models, which are primarily designed to detect correlations in data and associations between features and the outcome rather than establish causal relationships. These models rely on the quality and comprehensiveness of the input data, and while they can reveal significant associative patterns, they do not focus on differentiating whether the associations observed are causal. Meanwhile, given the limited availability of patient lifestyle and socioeconomic information, additional factors related to social determinants of health, such as socioeconomic status, employment, and family size, can be considered as potential confounders within the model for future improvement. To address all the above, future work should integrate causal inference frameworks to validate the relationships suggested by the machine learning predictions and provide insights into underlying mechanisms.

Conclusions

In conclusion, our study established a predictive framework using EHR data to assess the association between risk factors and cancer outcomes using explainable ML models across major cancer types. We reported critical nontraditional chronic condition risk factors in addition to common demographic risk factors and outlined distinct patterns for each of the 4 cancer types studied. Additionally, we explored the similarities and differences in risk factor patterns across these cancers. These insights contribute to a better understanding of cancer risk profiles and benefit in improving cancer diagnosis and risk monitoring, offering supportive guidance for clinical decision-making.

Acknowledgments

The authors would like to thank the Beth Israel Deaconess Medical Center and the MIT Laboratory for Computational Physiology for making the Medical Information Mart for Intensive Care (MIMIC)–III database available to the research community. The authors would also acknowledge the support from the University of Michigan School of Nursing and the Yale School of Public Health throughout this study.

Data Availability

The datasets analyzed during this study are available on PhysioNet [62].

Abstract

Background: In low- and middle-income countries, cervical cancer remains a leading cause of death and morbidity for women. Early detection and treatment of precancerous lesions are critical in cervical cancer prevention, and colposcopy is a primary diagnostic tool for identifying cervical lesions and guiding biopsies. The transformation zone (TZ) is where a stratified squamous epithelium develops from the metaplasia of simple columnar epithelium and is the most common site of precancerous lesions. However, inexperienced colposcopists may find it challenging to accurately identify the type and location of the TZ during a colposcopy examination.

Objective: This study aims to present an artificial intelligence (AI) method for identifying the TZ to enhance colposcopy examination and evaluate its potential clinical application.

Methods: The study retrospectively collected data from 3616 women who underwent colposcopy at 6 tertiary hospitals in China between 2019 and 2021. A dataset from 4 hospitals was collected for model conduction. An independent dataset was collected from the other 2 geographic hospitals to validate model performance. There is no overlap between the training and validation datasets. Anonymized digital records, including each colposcopy image, baseline clinical characteristics, colposcopic findings, and pathological outcomes, were collected. The classification model was proposed as a lightweight neural network with multiscale feature enhancement capabilities and designed to classify the 3 types of TZ. The pretrained FastSAM model was first implemented to identify the location of the new squamocolumnar junction for segmenting the TZ. Overall accuracy, average precision, and recall were evaluated for the classification and segmentation models. The classification performance on the external validation was assessed by sensitivity and specificity.

Results: The optimal TZ classification model performed with 83.97% classification accuracy on the test set, which achieved average precision of 91.84%, 89.06%, and 95.62% for types 1, 2, and 3, respectively. The recall and mean average precision of the TZ segmentation model were 0.78 and 0.75, respectively. The proposed model demonstrated outstanding performance in predicting 3 types of the TZ, achieving the sensitivity with 95% CIs for TZ1, TZ2, and TZ3 of 0.78 (0.74-0.81), 0.81 (0.78-0.82), and 0.8 (0.74-0.87), respectively, with specificity with 95% CIs of 0.94 (0.92-0.96), 0.83 (0.81-0.86), and 0.91 (0.89-0.92), based on a comprehensive external dataset of 1335 cases from 2 of the 6 hospitals.

Conclusions: Our proposed AI-based identification system classified the type of cervical TZs and delineated their location on multicenter, colposcopic, high-resolution images. The findings of this study have shown its potential to predict TZ types and specific regions accurately. It was developed as a valuable assistant to encourage precise colposcopic examination in clinical practice.

KEYWORDS

artificial intelligence; AI; cervical cancer screening; transformation zone; diagnosis and early treatment; lightweight neural network

Introduction

Cervical cancer remains the fourth most prevalent cancer among women worldwide [1], and it continues to be a leading cause of morbidity and mortality threatening women's health. Since cervical precancerous lesions often progress to invasive cancer over an extended period, early detection is critical for cervical cancer prevention. Colposcopy serves as a crucial component of cervical cancer screening, providing a preliminary diagnosis for patients based on screening results, which then guides subsequent biopsy and treatment. Although it is a fundamental technique that health care providers can easily teach and implement, the strong subjective nature of colposcopy diagnosis makes it difficult for colposcopists with different qualifications to perform standardized diagnoses and make effective clinical decisions [2,3]. Artificial intelligence (AI) diagnostic technology could resolve the disparities in expertise among clinicians and enhance screening efficiency [4].

The transformation zone (TZ) is where a stratified squamous epithelium develops from the metaplasia of simple columnar epithelium and is the most common site of precancerous lesions. More than 90% of cervical cancers develop within the TZ [5], making it a critical region for cervical intraepithelial neoplasia (CIN) diagnosis and early treatment. According to the visibility of the squamocolumnar junction (SCJ), the TZ can be classified into three types: TZ1 (SCJ fully visible), TZ2 (SCJ fully visible under endocervical speculum), and TZ3 (SCJ partially visible or not visible) [6]. Accurately identifying the TZ is crucial for diagnosing and treating cervical precancerous lesions. As the TZ moves into the cervical canal with increasing age, endocervical curettage (ECC) is necessary for biopsy-guided pathology [7]. If TZ types are not classified, the importance of ECC for the canal may be neglected, leading to missed diagnosis of lesions during colposcopic examination. In addition, excision of the entire TZ is a standard treatment for cervical precancerous lesions. For excisional treatment, TZ types determine the length and depth of the cervix to be excised. In destructive treatments, a prerequisite is that the TZ must be either type 1 or type 2. Therefore, the type and location of the TZ are the determinants of treatment choices, and accurately assessing the TZ is essential for guiding more effective biopsies and precise treatment.

However, in underserved population, the skills of colposcopists are generally suboptimal, with colposcopic finding accuracy being significantly lower than desired [8,9]. AI-assisted technology could effectively enhance the competencies of colposcopists in these underserved areas. Current evaluation studies [10,11] have demonstrated that junior or less-experienced colposcopists can detect abnormal cervical lesions more effectively with AI assistance, which indicates its potential to help reduce missed diagnoses. However, the functions of AI cannot be limited. All colposcopic features were the indicators for assessing colposcopist performance. Among them, the accurate identification of TZ types is essential for implementing effective colposcopy diagnostics and treatment procedures, potentially reducing the number of missed diagnoses and unnecessary biopsy procedures. However, current AI-assisted colposcopy systems or developed AI diagnosis models do not include TZ or SCJ detection during model conduction. Therefore, it is essential to integrate important clinical features into AI model training to improve colposcopy diagnosis efficiency.

AI colposcopy diagnostic systems remain challenging to distinguish among benign, CIN1, CIN2, and CIN3+ cases during colposcopy examination [12-14], although they achieved over 80% accuracy in detecting high-grade squamous intraepithelial lesions. This difficulty is attributable to the lack of specificity in the CIN-related acetowhite staining characteristics. Typically, normal cervical features, such as immature squamous metaplasia, congenital TZ, inflammation, and epithelium regeneration, may exhibit mild acetowhite reactions similar to those associated with CIN. This similarity implies that relying solely on acetowhite area features can easily lead to misclassification either for AI or in less experienced colposcopist. In AI model training, standardized annotated images of different acetowhite morphologies or fine-grained lesion descriptions may help with a more precise assessment of acetowhite characteristics [15]. However, current AI-assisted colposcopy research is constrained by the lack of standardized annotated colposcopy images. From a clinical perspective, the colposcopy guidelines issued by the International Federation for Cervical Pathology and Colposcopy (IFCPC) emphasize that CIN-related acetowhite changes are most commonly found in the TZ, and near the new SCJ, with clear demarcation from the surrounding epithelium [6]. Therefore, the TZ region can be used as an indicator to identify lesion areas and can be developed as a learned feature for diagnostic model development, thereby resolving the problem of the lack of annotated colposcopy images. As a result, the multiclassification accuracy of AI-guided colposcopic diagnostic systems may be significantly improved. Therefore, in AI model development, accurately identifying TZ types and the SCJ is a crucial step toward improving AI diagnostic accuracy and guiding biopsies.

In this study, an AI method is developed and validated for the classification and delineation of the TZ. This method not only has the potential to guide clinical colposcopic examinations in resource-limited health care settings but also encourages the advancement of AI-guided digital colposcopic systems. By incorporating all colposcopic findings, such as TZ type and features of both minor and major lesions, AI-guided digital colposcopy could become a mature assistant for universal clinical colposcopy examinations.

Methods

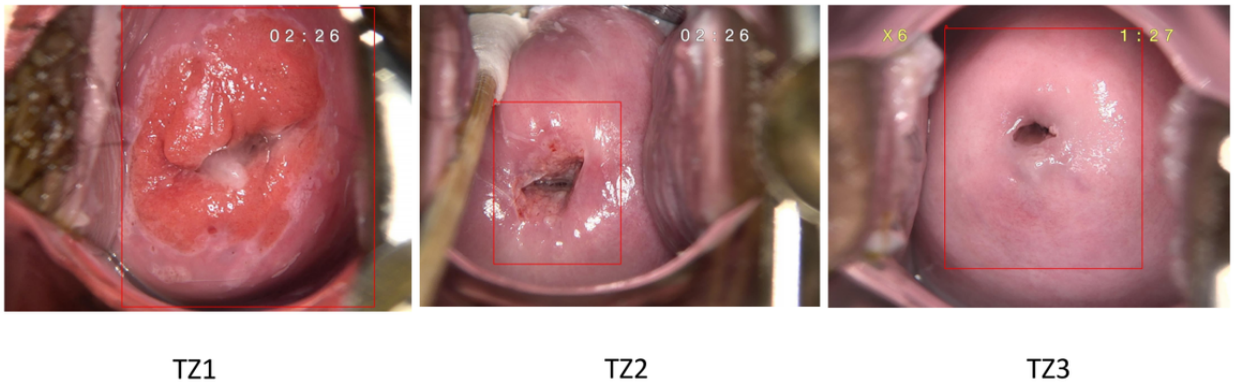
Study Patients

This retrospective study included 3616 women who underwent colposcopy examinations across 6 multicenter hospitals in China between January 2019 and October 2021. These hospitals were

XSL•FO
RenderX

the Gansu Maternity and Child Healthcare Hospital, Second Hospital of Shanxi Medical University, Shenzhen Maternity and Child Healthcare Hospital, Jiangxi Maternity and Child Healthcare Hospital, The Affiliated Hospital of Qingdao University, and Chengdu Women's and Children's Central Hospital. The digital clinical records, including cytology, human papillomavirus infection status, colposcopy findings, and pathological results, were collected. All colposcopy images were captured using digital high-definition video colposcopes (Zonsun Healthcare Co Ltd, Edan Instruments). Colposcopy findings, including adequacy, SCJ visibility, TZ determination, and provisional diagnosis, were qualified by colposcopy experts from tertiary hospitals. The "ground truth" for TZ classification and SCJ visibility in this study was determined by an expert panel following IFCPC guidelines.

The inclusion criteria were as follows: (1) women with complete colposcopy findings and pathological diagnosis, (2) ages between 24 and 65 years, and (3) each record containing at least 5 satisfactory colposcopic images before and after acetic acid staining. The exclusion criteria were (1) all saline solution images (preacetic), since the TZ typically appears after acetic acid staining; (2) poor-quality images, such as overexposed images or those where the cervix was obscured or there was bleeding after the biopsy; (3) inadequacy colposcopic examination; and (4) records with missing TZ types or SCJ visibility. For external validation, an independent dataset was derived from The Affiliated Hospital of Qingdao University and Chengdu Women's and Children's Central Hospital. The training dataset was divided into training and test sets in an 8:2 ratio, with 10% of the training set used for validation during model tuning.



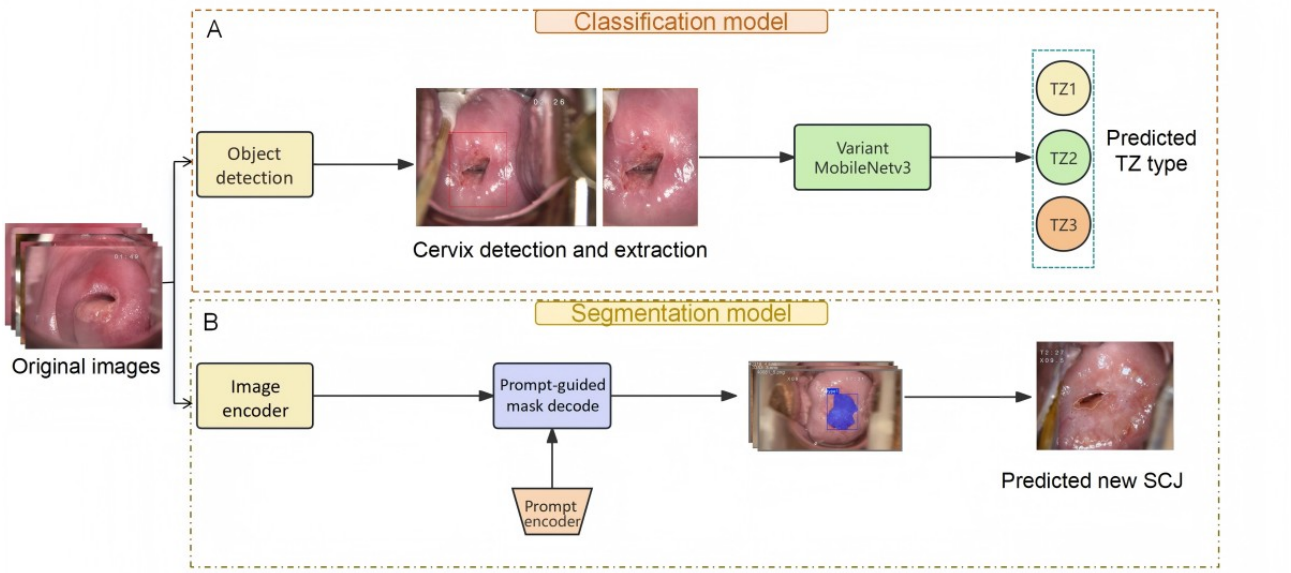
Transformation Zone

The colposcopy procedures adhered to the standard guidelines for *Colposcopy and Treatment of Cervical Precancer* [6]. Time-series images were captured for each case, including 1 original cervix image (saline solution) and at least 4 acetic acid–stained cervix images. The classification of TZ followed guideline criteria. TZ was classified as type 1 when it was entirely located on the ectocervix. In type 2, TZ was partially located within the endocervical canal, but its upper limit could be visualized using auxiliary instruments. Type 3 TZ lies partly or entirely inside the endocervical canal, with its upper limit being partially or completely invisible, even with the aid of auxiliary instruments.

Image Preprocessing

The colposcopy images were captured in high resolution. However, they contained irrelevant objects, such as the endocervical speculum, cotton swabs, or large regions of the vaginal wall, which could interfere with the classification model's ability to extract critical features of the cervix. To address this issue, we used the YOLOv5 network to detect the region of interest. Its single forward pass design enables real-time object detection with high efficiency and precision [16,17]. The integrated cervical region was automatically segmented and examined by a specialist (Figure 1). It divides an image into an S×S grid cell, predicting the bounding box locations and their associated categories. All segmented colposcopy images were resized to 224×224 pixels to align with the input specifications of the model.

Figure 1. Cervix region of interest detection with bounding box examples in representative images. TZ: transformation zone.



Development of the TZ Classification Model

Initially, colposcopy images were input into a detection model to determine the cervical region, which was then preprocessed to enhance feature extraction. These data were then applied to a classification model to determine the types of TZ present (Figure 2A). In the second part of the method, the original images were annotated with new SCJ prompts to guide a general segmentation model in inferring the potential location of the TZ (Figure 2B).

XSL•FO
RenderX

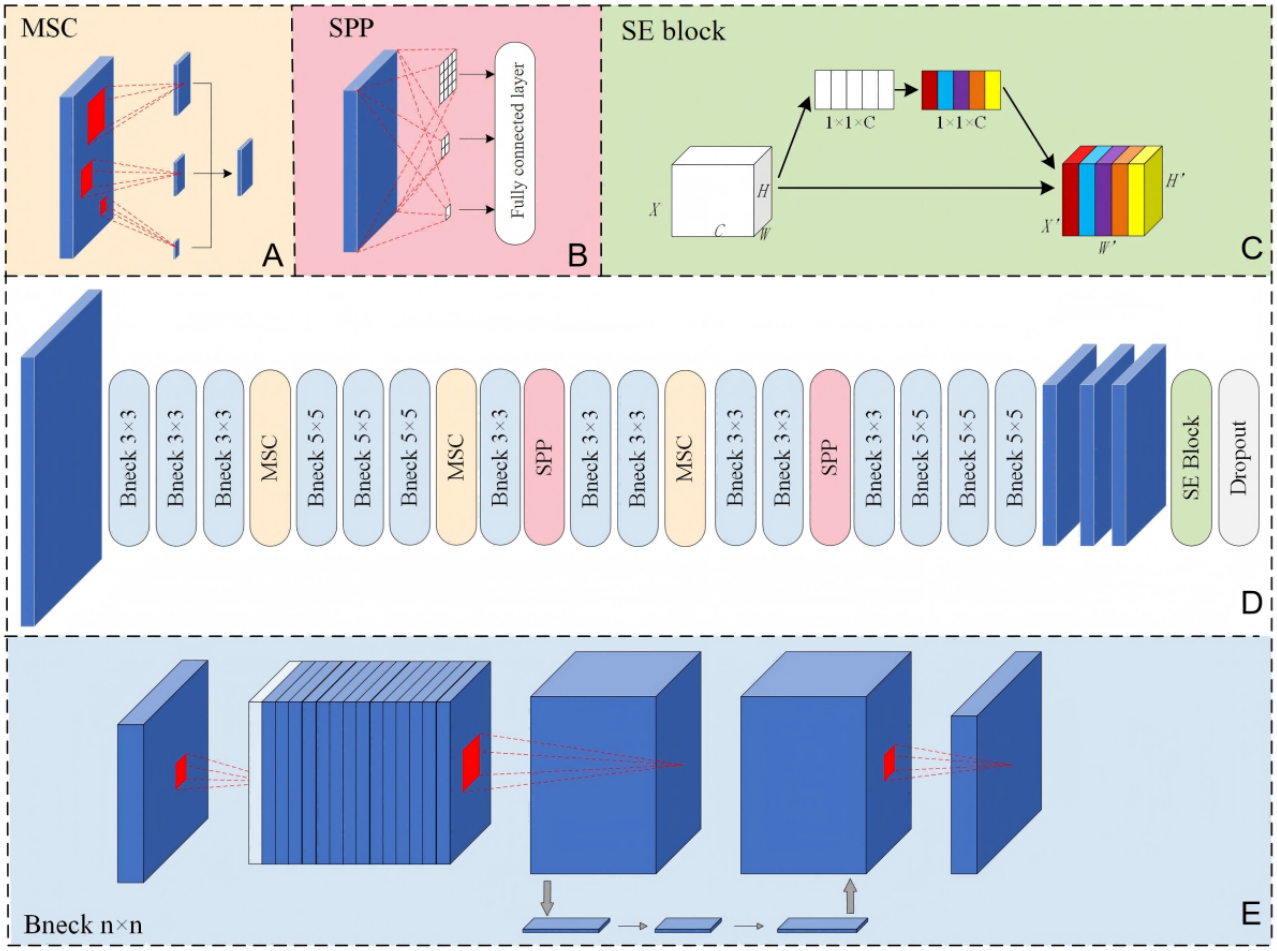


Figure 2. The overall inference process of the TZ identification system consists of two stages: (A) detection and extraction of the entire cervical region from original images, followed by feature extraction using the variant MobileNetV3 and inference TZ1, TZ2, and TZ3 types; and (B) using the original images and images with polygon of the new SCJ as prompts to FastSAM, which then outputs the mask prediction of the out-of-TZ area to infer the new SCJ guidance line. SCJ: squamocolumnar junction; TZ: transformation zone.

We proposed a variant of the MobileNetV3 architecture for classifying TZ, a lightweight convolutional neural network (CNN) specifically designed for efficient operation on portable devices, which was particularly suitable for deployment in resource-limited settings. The overall model structure is presented in Figure 3. Our model retained the depthwise separable convolutions and the HardSwish (H-swish) activation function of MobileNetV3, which reduced computational demand and parameters without compromising accuracy. Multiscale convolution modules have been incorporated into the model to effectively extract features at multiple focal points (Figure 3A), from subtle acetowhite changes in the columnar epithelium to varying TZ-type scopes in the cervix. In addition, we introduced a spatial pyramid pooling module to address features at multiple scales while preserving spatial information in the input images to ensure the richness of feature representation (Figure 3B). The Squeeze-and-Excitation module is a lightweight attention mechanism designed to automatically prioritize the most diagnostically relevant visual patterns within the MobileNetV3 architecture (Figure 3C). In our model, the Squeeze-and-Excitation module was embedded to adjust global feature weights (Figure 3D), enhancing the overall effectiveness of feature extraction. It increased the sensitivity to important features, thereby improving classification performance [18].

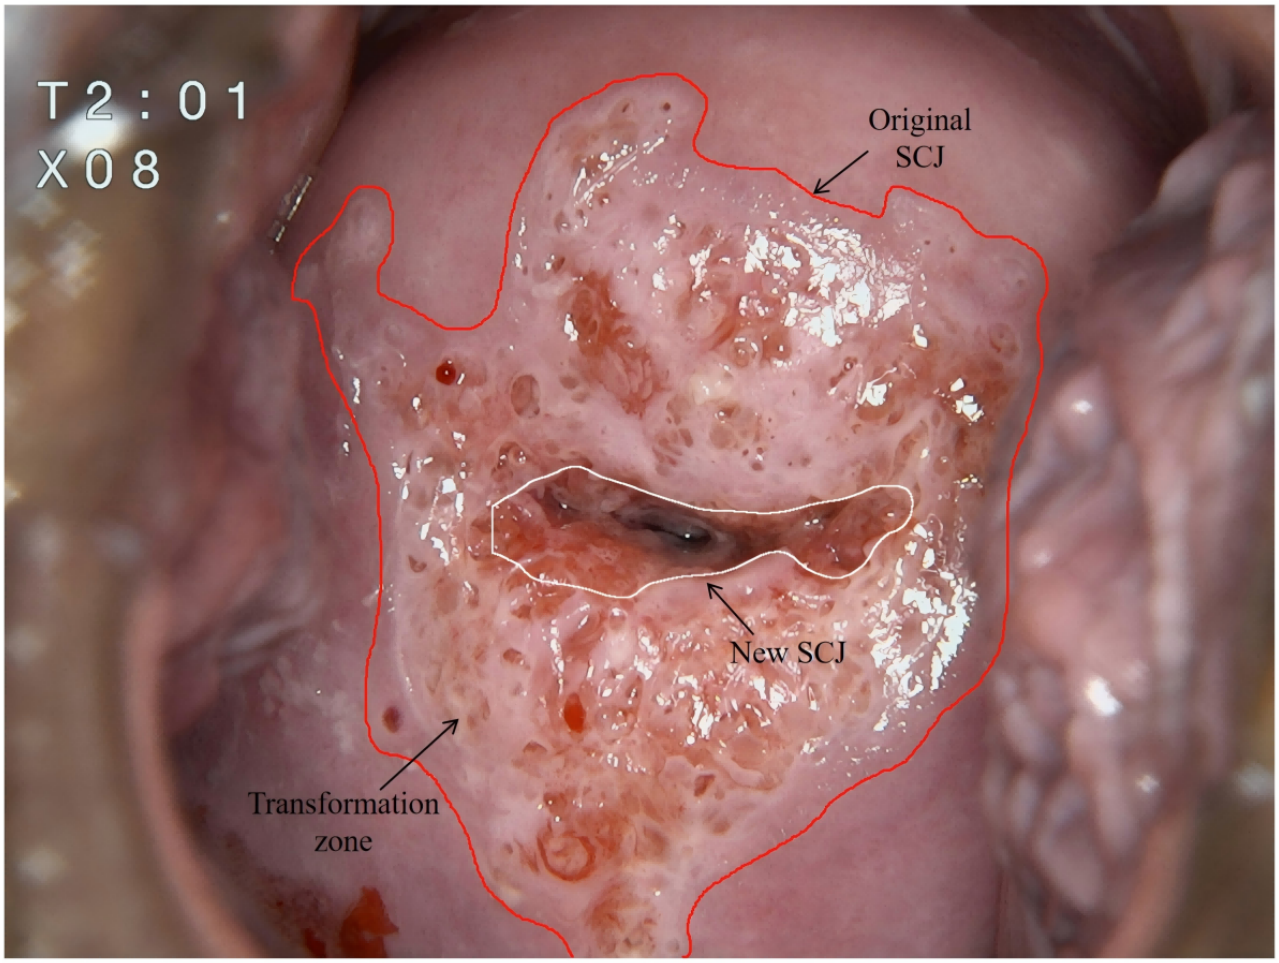
RenderX

Figure 3. The overall architecture of the proposed model: (A) details of the multiscale convolution (MSC) module; (B) details of the Spatial Pyramid Pooling (SPP) module; (C) structure of the Squeeze-and-Excitation (SE) block module; (D) workflow of the model that included detailed layers of the network; and (E) structure of the inverted residuals module.



Development of the TZ Segmentation Model

The FastSAM model was used to segment the TZ from the entire cervix in colposcopy images (Figure 2B). FastSAM was fine-tuned for the specific dataset using a YOLO-based framework [19]. Colposcopic images were resized to 640×640 pixels, and the new SCJ was annotated using LabelMe (MIT CSAIL) [20]. By selectively freezing some of the backbone layers of the model, the deeper layers were fine-tuned to improve adaptation to the specific task, without compromising the extraction of general features. The model's performance was further enhanced by using coarse masks as spatial guides, which allowed the model to focus its attention on the most relevant image regions. The model was trained to delineate the new SCJ, thereby identifying possible TZ areas by this critical boundary. TZ is a dynamic region defined by the area between the original SCJ and the new SCJ. Typically, the original SCJ is considered a virtual line, and identifying the new SCJ is crucial for determining the location of the TZ (Figure 4).

XSL•FO
RenderX

Figure 4. Illustration of the squamocolumnar junction (SCJ) and the transformation zone.

Software and Hardware

The study was performed on a Windows 11 operating system with an NVIDIA GeForce RTX 3080 8GB graphics card. The models were implemented using Python (version 3.6.13; Python Software Foundation) and the PyTorch (Meta AI) Library (version 1.7.1).

Evaluation Metrics

Experiment performance of the cervical TZ classification model was evaluated using accuracy, precision, recall, F_1-score, and average precision, as defined in Equations 1-6.

Where TP, FP, and FN denote the true positive, false positive, and false negative predictions, respectively. $r(k)$ denotes the recall at threshold k. $p(k)$ denotes the precision at threshold k, and n denotes the number of thresholds. AP_i is the average precision for class i, and mAP denotes the mean average precision, where n is the number of classes.

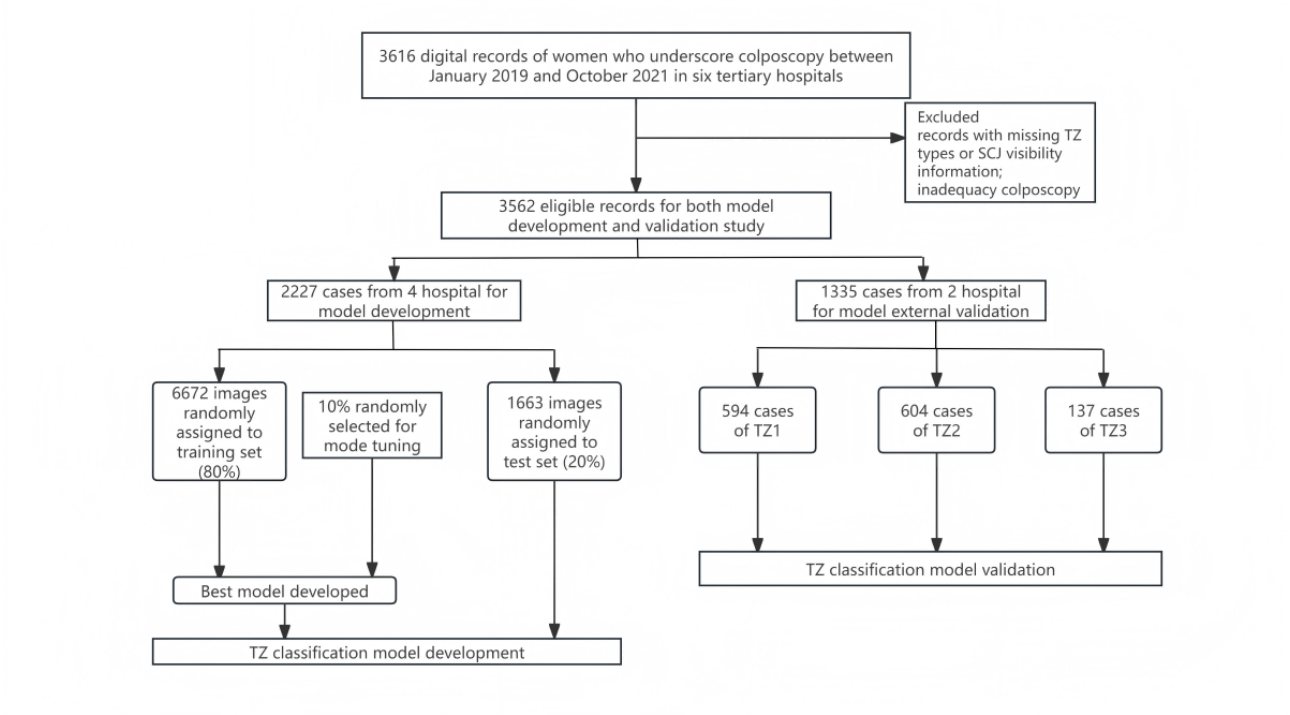
Statistical Analysis

The performance of the classification model was evaluated by comparing it with selected state-of-the-art (SOTA) deep-learning models using metrics such as accuracy, precision, recall, and the area under the precision recall curve, represented by average precision. To evaluate the classification of TZ types, sensitivity, specificity, positive predictive value, and negative predictive value (NPV) were calculated, along with their corresponding 95% CIs. The evaluation metric was defined as the agreement with the expert-provided TZ classification. The demographic characteristics of the study participants were summarized using means and SDs for continuous variables and percentages for categorical variables. A P value of less than .05 (two-sided) was considered statistically significant. Statistical analyses were performed using SPSS (version 27.0; IBM Corp) and Python (version 3.7).

Ethical Considerations

This study was approved by the Institutional Review Board of the Chinese Academy of Medical Sciences and Peking Union Medical College (CAMS and PUMC-IEC-2022-022). Informed consent was not required due to the retrospective nature of the dataset, and all personal information and images were

XSL•FO
RenderX



completely anonymized. We commit that all research data will be used for academic research purposes.

Results

General Information of the Study Dataset

For the classification modeling, 8335 colposcopy images from 4 hospitals were selected for training and evaluation. These images included consisting of 2788 images of TZ1, 2663 images of TZ2, and 2884 images of TZ3. In the external validation study, 1335 cases were selected from 2 hospitals for model inference to predict the TZ types (Figure 5). The demographic characteristics of each participant, including age, colposcopic findings, and the distribution of each TZ type, are provided in Table 1. TZ types were found to be significantly associated with the participants' age group distribution (P<.001). The mean age of all participants at the time of colposcopy was 37.87 (SD 9.99) years, with the mean age of the TZ3 group being 45.04 (SD 11.69) years.

TZ Classification Results

Cervix detection with a bounding box was used for feature engineering. Proper cervix extraction improved classification accuracy. A total of 8335 cervix images were investigated and resized to 224×224 pixels before being input into the classification model. Out of these, 1663 images were used to evaluate the model's performance.

Around 80% of the images were randomly selected as the training set, with the optimal weight parameter model selected during training being used to classify the images in the test set. The validation accuracy of the model gradually improved as the number of epochs increased, as shown in the validation plot (Figure 6). After approximately 100 epochs, both validation accuracy and training loss stabilized, reaching a peak validation accuracy of 83% at the 200th epoch. The validation accuracy fluctuated significantly during the first 25 epochs, it showed a general upward trend, while training loss rapidly decreased, indicating active learning and adjustment of the model. The model reached an optimal balance point and performed well after the 75th epoch when validation accuracy stabilized and training loss continued to decrease but with minimal changes. Overall, the model demonstrated rapid convergence in the early stages of training, with steady performance improvements in the later stages.

Figure 6. Validation accuracy and training loss curve for the proposed classification model.

Our proposed model accurately classified cervical TZ types, as shown in Table 2. The highest classification accuracy of 83.97% and precision of 83.93% were achieved on the test set. For the 3 TZ types, the sensitivity was 84.74% for TZ1, 78.95% for TZ2, and 87.87% for TZ3, while the specificity was 89.99% for TZ1, 91.98% for TZ2, and 94.03% for TZ3. The detailed values for sensitivity, specificity, positive predictive value, and NPV are presented in Table 3. According to the classification performance of TZ types, the sensitivity and NPV for TZ2 were significantly lower.

Table 2. Comparative performance results of the proposed classification model with other state-of-the-art models.

Model	Accuracy (%)	Precision (%)	Recall (%)	F_1-score (%)	mAP[a] (%)
ResNet50	59.22	57.84	56.89	54.66	63.13
VGG16	70.33	69.76	69.21	69.19	74.64

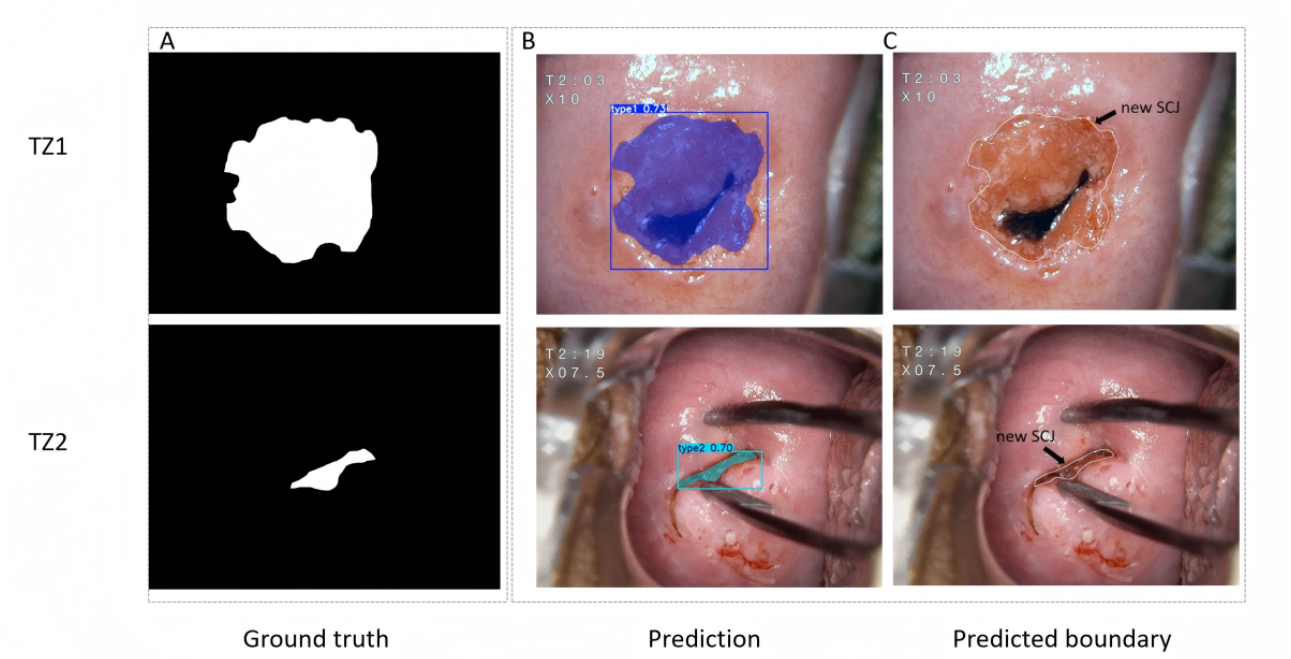
The SOTA deep-learning networks for interpreting colposcopy images were selected to train on our dataset for comparison with our model. Table 2 presents the experimental results of the test set based on various evaluation metrics. The traditional



XSL•FO
RenderX

ResNet50 and Vision Transformer models performed poorly in terms of accuracy and precision, achieving only 59.22% and 57.84%, and 59.46% and 57.64%, respectively. VGG16, with its relatively low-density network structure, performed better than ResNet50 in feature extraction. In addition, we selected 2 lightweight networks for comparison, EfficientNet and ShuffleNet, with higher accuracy of 62.06% and 74.47%. The proposed model achieved the highest accuracy of 83.97% among SOTA models.

TZ Segmentation Result

To enhance AI's clinical guidance, we used a pretrained FastSAM model to segment the TZ region by visualizing the new SCJ. A portion of the training data was used to annotate the new SCJ (Figure 7A), excluding TZ3, as the new SCJ is located in the endocervix. The segmentation model predicted the negative foreground region indicating the area outside the target TZ region (Figure 7B). The region boundary of the mask prediction was the predicted new SCJ (Figure 7C). In the test set, the overall recall and mAP50 (mean average precision at 50% Intersection over Union) of predicted mask were 0.78 and 0.75, respectively.

Figure 7. The segmentation model inference process. (A) Ground truth of the polygonal new SCJ outline. (B) Predictive segmentation of the out-of-TZ area. (C) Representative prediction of the new SCJ guidance line. SCJ: squamocolumnar junction; TZ: transformation zone.

Validation Results

An independent dataset of 1335 cases was used to evaluate the generalization of the TZ classification model, distributed as 594 cases of TZ1, 604 cases of TZ2, and 137 cases of TZ3. The overall classification accuracy was 79.33%. The model's predicted sensitivity for TZ1, TZ2, and TZ3 was 77.3% (95% CI 73.9%-80.6%), 81.1 (95% CI 78.0%-82.3%), and 80.3% (95% CI 73.7%-86.9%), respectively, while the specificity was 94.2% (95% CI 92.4%-95.8%), 83.3% (95% CI 80.6%-85.9%), and 90.7% (95% CI 89.1%-92.3%). The classification performance is presented in Figure 8 and Table 4.

Discussion

Principal Findings

In this study, we proposed a classification and identification model that facilitates clinical colposcopy examinations of cervical TZ. Our AI model achieved an accuracy of 79.33% in the task of classifying the three types of TZ in the external dataset. The sensitivity of TZ3 was 80.3%, and the specificity was 90.7%, which were satisfactory. TZ3 could be accurately differentiated, which further decreased the chance of missed diagnoses of high-grade lesions [21], and it was valuable for guiding ECC and recommending appropriate treatments. The AI model had increased sensitivity on TZ2 and lower sensitivity on TZ1 compared to the performance on the test set, which might be attributed to the similarity between TZ1 and TZ2. According to the standard terminology of the IFCPC, TZ1 and TZ2 were both visible either with or without the assistance of an endocervical speculum [22]. TZ2 was nearly entirely visible in some cases, while the SCJ was only visible at the endocervical canal's border. Therefore, it was difficult to differentiate it from TZ1, which frequently required expert evaluation in strict accordance with established guidelines. In clinical practice, the treatment management for TZ1 and TZ2 is generally similar [6]. Our AI model demonstrated noninferior performance in classifying them and could be used to assist less experienced or inexperienced colposcopists in the colposcopic examination process. The overall model accuracy from the validation study was similar to the performance during model training, indicating that it is capable of generalizing fairly well.

Comparison With Other Studies

In terms of AI techniques, we proposed a method based on the variant MobileNetV3 architecture for cervical TZ classification and FastSAM for segmenting TZ in colposcopy. Currently, only a few deep learning–based models have been developed to classify cervical TZ from colposcopy images. Dash et al [23] conducted a TZ segmentation and classification model based on colposcopy images from the IARC image bank. Similarly, Cao et al [24] developed a high-performance, deep learning model based on retrospective image data collected from one hospital [24]. Comparatively, our method was based on a multicenter study with a more diverse dataset of colposcopy images. While this diversity added to the challenge of feature extraction, the classification model showed better accuracy. Second, the proposed segmentation model could precisely annotate the new SCJ and indicate the approximate location of TZ, which could greatly assist junior colposcopists in selecting biopsy sites. Effective biopsy prioritization focused on the most severe lesions, particularly those within the TZ. Compared with the previous study [23], our method delineated a new SCJ rather than the original SCJ, which can provide more effective assistance and insights for colposcopic clinical examination and treatment. Furthermore, conducted external validation for the TZ classification model for the first time, and our model demonstrated strong stability and generalization performance.

XSL•FO
RenderX

Clinical Implications

In resource-limited settings, colposcopists demonstrated significantly lower clinical skills and performance than those observed in our study. The results of a study evaluating the colposcopic abilities of colposcopists in underserved Chinese communities indicated that colposcopists had a mere 22% accuracy specifically for TZ3 [8]. Similarly, in another study, colposcopists' clinical diagnostic abilities were assessed before and after intensive training [9]. It was found that junior colposcopists had only 49.1% accuracy in classifying TZs. Despite the notable improvement, their accuracy remained below optimal levels at 68.6% following training. In addition, a comparable study conducted in Europe demonstrated that junior colposcopists were only able to detect TZs with a 55% accuracy rate [25]. According to these findings, colposcopists at less-experienced levels generally exhibited inadequate colposcopic performance. However, AI might offer a promising solution to enhance colposcopic capabilities and clinical decision-making confidence. Compared to these studies, our TZ classification model demonstrated strong performance with a high accuracy of 83.97% in the test set and achieved much higher sensitivity in predicting three TZ types in the validation study. Based on the results of previous studies, our model was more effective at stand-alone classification than that of junior colposcopists. Therefore, the method presented in this study accurately identifies TZ in colposcopy images, providing a valuable reference for colposcopists when making clinical decisions. The findings from this study supported the potential of the proposed AI-based TZ identification method as a promising adjunct tool for colposcopic examinations, particularly when integrated with AI colposcopic diagnostic systems and digital colposcopes. Dynamic digital imaging with AI assistance enhances the objectivity of colposcopic examinations and might address the diagnostic subjectivity of less experienced colposcopists. When AI-guided digital colposcopists are deployed in resource-limited health care settings, colposcopists will be able to receive intuitive and accessible guidance on clinical features from AI during the colposcopic examination in real time, supporting less-experienced colposcopists in improving their overall colposcopy skills. Combining AI results with colposcopist assessments helps reduce diagnostic bias, improve colposcopic examination capability, and narrow the gap with resource-rich areas. It addresses the minimization of missed diagnoses, the facilitation of early detection of lesions, the reduction of the risk of CIN progression, and the reduction of the burden of cervical cancer [26]. The application of AI will be integral to improving the quality of colposcopy services in low-resource settings.

The development and application research of AI-guided colposcopy models has emphasized their auxiliary value in clinical practice [14,27]. With the advent of innovations in AI algorithms, these models rely predominantly on mainstream CNNs coupled with transfer learning, as a method of unsupervised learning for image feature learning [28,29]. In some AI models, object detection is used as a metric for identifying lesion areas; however, it remains limited to binary classification tasks. Nevertheless, the multiclassification of normal cervix, low-grade squamous intraepithelial lesion, and high-grade squamous intraepithelial lesion plus poses significant challenges to these models. A clinical perspective suggested that acetowhite changes within TZ have a higher likelihood of association with CIN lesions than those outside of TZ. While the lesion extends across the new SCJ, a biopsy should be taken within the TZ or at the new SCJ. Therefore, by incorporating the TZ-type information as a weight in the model, the AI could be able to perform a more effective feature engineering process within the TZ. It is anticipated that the AI model will markedly enhance the capability of lesion detection, thus eliminating the current limitation in which precise identification is confined to CIN2+ lesions. Our proposed AI system delineated the new SCJ on high-resolution colposcopy images, and it enabled the approximate location of the TZ to be visualized more intuitively, thereby guiding more effective colposcopy examination and biopsy procedures.

For applying AI techniques in limited-resource settings, we proposed a model based on the MobileNetV3 architecture for cervical TZ classification in colposcopy images. Since Google introduced MobileNet in 2017 [30] as a lightweight CNN architecture, it has gained significant attention for its efficiency and accuracy. A lightweight AI model is more energy efficient and requires significantly fewer computational resources than a large-scale AI model, aligning with sustainable AI practices. It has been designed to operate efficiently on battery-operated devices, making it especially suitable for deployment in remote regions with limited power availability and internet access. By minimizing the reliance on high-cost hardware and extensive cloud infrastructure, lightweight AI models enable resource optimization in low-resource settings and facilitate equitable access to AI. Our AI model achieved efficient computation and robust classification performance on portable devices and can be applied actively in a variety of clinical settings to validate its generalization ability. A further economic evaluation is required to support the decision to adopt novel technologies in screening strategies.

Limitations and Future Directions

There are several limitations to this study. First, the scale of the dataset we included was limited, which restricted the ability to support training deeper or more complex deep neural networks. However, the quality and standardization of image acquisition were assured, and the appropriate network depth was chosen to maximize feature extraction. It is necessary to obtain more high-quality colposcopy images with endocervix expansion by auxiliary instruments per case to train more complex networks that can extract additional features and potentially improve classification accuracy in TZ2 and TZ3. To address the suboptimal performance in TZ2 classification, expanding the dataset for TZ2 in future studies could enable the model to capture more distinct texture features that differentiate it from TZ1 and TZ3. The model could be further enhanced by applying edge detection techniques in regions where it is difficult to distinguish TZ2 from TZ3 and to highlight subtle morphological changes at the new SCJ. Second, the external validation was limited to evaluating the AI results alone. Further research is needed to assess the impact of AI-aided colposcopists in the classification of TZ. A prospective clinical trial is further needed

XSL•FO
RenderX

to investigate whether the method can be applied to real-world colposcopy clinics. In addition, although we collected the validation datasets from two different hospitals, the scale of the external validation dataset is relatively limited, particularly when it comes to representing clinical scenarios that involve different colposcope vendors and lighting conditions. Future studies will focus on expanding both the size and scope of the dataset, incorporating data from more regions for more comprehensive validation. Furthermore, transfer learning or domain adaptation techniques may be used to improve the model's robustness and adaptability to various imaging conditions. Finally, the TZ classification lacks an absolute subjective gold standard but is guided by colposcopic examination criteria and expert consensus. However, the colposcopy expert panel from tertiary hospitals conducted the "ground truth" categories for this study in accordance with established guidelines from IFCPC. In light of the subjectivity inherent in TZ classification, using only single-image modality data for model development is limited. Model optimization in the future may implement multimodal learning, which incorporates image data with associated clinical factors (eg, age, menstrual status, gravidity, and parity) to reduce the subjectivity of the model and enhance TZ feature discrimination. Furthermore, the construction of a knowledge graph based on existing consensus and colposcopic examination guidelines will help the model adhere to various rules or logic during the learning process.

Conclusion

In this study, an accurate AI-based method was developed and evaluated for automatically identifying cervical TZ using colposcopy images. The proposed method was the first application of a lightweight CNN for cervical feature extraction and applied a general segmentation model for TZ delineation among multicenter images, achieving commendable classification accuracy on TZ. The proposed approach has the potential to adapt to various colposcopy clinical environments and improve AI-guided colposcopy practice.

Acknowledgments

We acknowledge Haiyan Hu (Shenzhen Maternity and Child Healthcare Hospital), Zhilian Wang (Second Hospital of Shanxi Medical University), Jinfeng Liu (Gansu Maternity and Child Healthcare Hospital), and Jun Lei (Jiangxi Maternity and Child Healthcare Hospital) for assisting with colposcopy image collection and manual labeling. We thank Ms Qianling Dai (Chengdu Women's and Children's Central Hospital), and Ms Haiyan Hu for quality control. We also thank Ms Qianling Dai and Ms Mingyang Chen (Chinese Academy of Medical Sciences and Peking Union Medical College) for their comments on the original manuscript. Abstract

Background: Cervical cancer is a common cause of death among women globally, particularly in Africa. Each year, an average of 7093 women in Nigeria die from cervical cancer. Clinical practice guidelines developed by the Society of Obstetrics and Gynecology of Nigeria (SOGON) aim to prevent cervical cancer. However, the extent of their adoption among gynecologists remains unclear.

Objective: This study aimed to assess Nigerian gynecologists' awareness, understanding, and incorporation of the SOGON clinical practice guidelines for cervical cancer prevention in their clinical practices.

Methods: A convergent parallel mixed methods design was used. Quantitative data were collected via a web-based and in-person survey distributed to gynecologists attending the 57th SOGON Annual General Meeting in Kano, Nigeria (November 2023). A total of 105 gynecologists completed the survey (response rate: 80%). Key informant interviews (n=12) were conducted to provide qualitative insights. Quantitative data were analyzed using descriptive and inferential statistics, including logistic regression (P<.05). Thematic analysis was applied to qualitative data.

Results: Among the 105 respondents (mean age 50, SD 8.3 y and mean postresidency practice 12, SD 9.4 y), 98 (93.3%) reported awareness of the SOGON guidelines, and 74 (70.5%) endorsed their importance for cervical cancer prevention. However, only 58.1% (61/105) of the respondents reported integrating the guidelines into routine clinical practice. Barriers to implementation included limited training (71/105, 67.6%), resource constraints (64/105, 60.9%), and lack of institutional support (57/105, 54.3%). Qualitative data reinforced the need for more tailored guidelines for high-risk populations and rural settings. In addition, 70.5% (74/105) of the respondents advocated for a participatory guideline review process to ensure relevance and feasibility.

Conclusions: While awareness of the SOGON guidelines is high, their integration into clinical practice remains suboptimal due to systemic barriers. Strengthening training programs, improving access to resources, and enhancing institutional support are critical to increasing guideline adoption and advancing cervical cancer prevention efforts in Nigeria.

KEYWORDS

cervical cancer prevention; clinical practice guidelines; gynecologists; implementation science; Nigeria

Introduction

Background

Globally, cervical cancer is the fourth most common cause of cancer-related death among women, with approximately half a million new cases and one-third of a million deaths annually [1]. Cervical cancer accounts for approximately 80% of global cervical cancer–related deaths [2,3]. In Africa, cervical cancer is either the leading or second leading cause of cancer-related deaths among women [4]. Despite being one of the few cancers that are 100% preventable and treatable if detected early, approximately 200,000 new cases and 80,000 deaths occur annually in sub-Saharan Africa (SSA) [4].

The risk of cervical cancer mortality is particularly high in SSA compared to other regions, such as Europe. The International Agency for Research on Cancer reports an age-standardized mortality rate of 18.9 per 100,000 women in SSA, compared to 3.4 per 100,000 women in Western Europe [5-7]. This disparity results from limited access to screening, vaccination, and treatment in SSA [8]. Many women in SSA do not have access to regular cervical cancer screening, leading to late-stage diagnosis and poor treatment outcomes [9-11]. In addition, vaccination rates against human papillomavirus (HPV), the primary cause of cervical cancer, are substantially lower in SSA compared to Europe [8,12].

In Nigeria, cervical cancer remains a substantial public health challenge due to the absence of structured screening programs, insufficient public awareness of preventive measures, and systemic health care barriers [13,14]. It is the second most prevalent malignancy among women aged between 15 and 44 years, with 13,676 new cases and 7093 deaths recorded in 2023 [15], corresponding to an age-standardized incidence rate of 18.4 per 100,000 and death rate of 3.2 per 100,000 [15-17]. Approximately 60.9 million women aged ≥15 years in Nigeria are at risk of developing cervical cancer unless proactive measures are taken [15,18]. However, these figures may underestimate the true burden due to underreporting, inadequate cancer surveillance systems, and limited data collection infrastructure [19,20]. Furthermore, cervical cancer disproportionately affects women during their economically productive years, compounding the socioeconomic impact and perpetuating cycles of poverty [21,22].

Globally, there is a growing emphasis on eliminating cervical cancer, particularly in low and middle-income countries [8,18]. The World Health Organization global strategy aims to achieve the "90–70–90" targets by 2030: vaccinating 90% of girls against the HPV, screening 70% of women by the age of 35 and 45 years, and ensuring that 90% of women diagnosed with precancerous conditions or cervical cancer receive treatment [18]. Meeting these targets in low and middle-income countries, including Nigeria, could reduce new cervical cancer cases by 97% (74 million cases) and prevent 62 million deaths by 2120 [23]. However, achieving these goals in Nigeria will require a robust health systems response, strong political commitment, and the effective implementation of evidence-based interventions [17,21].

Clinical practice guidelines are systematically developed to aid health care providers and patients in making informed decisions for specific clinical scenarios [24]. They offer evidence-based frameworks for best practices and carry legal and medical significance. However, their adoption is influenced by several factors, including awareness, perceived relevance, and systemic challenges [25-27]. In Nigeria, health care providers, particularly gynecologists, at the forefront of cervical cancer prevention, face unique challenges, such as navigating infrastructural deficits, addressing sociocultural stigmas, and managing limited resources [28]. These barriers highlight the need for targeted strategies to bridge the gap between guideline development and implementation.

To address this critical issue, the Society of Obstetrics and Gynecology of Nigeria (SOGON) has developed clinical practice guidelines aimed at cervical cancer prevention [29]. These guidelines provide evidence-based recommendations for primary and secondary prevention, including public health education [29]. Despite their potential to significantly reduce cervical cancer incidence and mortality, the extent to which these guidelines have been implemented remains poorly understood. Structural barriers, including inadequate health care infrastructure, limited provider training, and weak dissemination mechanisms, hinder their adoption. In addition, cultural perceptions, economic constraints, and low prioritization of women's health further complicate the effective integration of these guidelines into routine clinical practice [10,11,30].

Study Objective

This study applies implementation science principles to explore the perspectives of Nigerian gynecologists using the SOGON clinical practice guidelines. Unlike traditional approaches that prioritize patient outcomes, this study focuses on health care providers' experiences, aiming to address the "know-do" gap—the discrepancy between established guidelines and actual clinical practices. By addressing this gap, the study provides critical insights into how the guidelines can be effectively implemented within Nigeria's complex health care landscape, shaped by cultural, socioeconomic, and infrastructural challenges.

Methods

Study Design

This study used a convergent parallel mixed methods design. In this study design, quantitative and qualitative data were collected simultaneously, analyzed separately, and then merged to draw a comprehensive conclusion. The quantitative approach assessed the level of understanding, awareness, and application

XSL•FO
RenderX

of the SOGON clinical practice guidelines. The qualitative component provided in-depth insights into the experiences, perceptions, and recommendations of gynecologists regarding implementing the SOGON clinical practice guidelines for preventing cervical cancer.

Study Setting

The study was conducted during the SOGON 57th Annual General Meeting and Scientific Conference in Kano, Nigeria, from November 20 to 24, 2023, at the Bristol Palace Hotel. The theme of the conference was "the tragedy of maternal deaths in Nigeria: our collective responsibility."

Study Population

The study population was practicing gynecologists within Nigeria who attended the SOGON 57th Annual General Meeting and Scientific Conference, Kano.

Eligibility Criteria

Eligible participants were qualified gynecologists with valid medical degrees and professional certifications that authorize them to practice in Nigeria. It was necessary for them to be actively engaged in practice in public or private health care settings, such as hospitals, clinics, or private practices, and to be located within the geographical boundaries of Nigeria during the study.

Gynecologists who were not actively practicing, such as those who were retired, those who were on extended leave, or those who had transitioned to nonclinical roles, were excluded to ensure that the data collected were directly relevant to the present clinical environment and standards. Individuals lacking completion of their medical degree or necessary gynecological training or practicing without a valid license were also excluded from maintaining professional standard benchmarks in the study. Health care professionals who were not specialized in gynecology, including general practitioners, nurses, and midwives, were excluded because the study specifically targeted implementing SOGON guidelines among gynecologists. Gynecologists unwilling to provide informed consent or participate in the survey or interview process were excluded. Finally, gynecologists of Nigerian origin practicing abroad were omitted, as the study focused on the adoption of SOGON guidelines within health care settings in Nigeria.

Sample Size Determination

As the proportion of gynecologists aware of the SOGON guidelines is unknown, a conservative estimate of p=0.5 was used because it provides the maximum sample size—a standard CI level of 95%, which gives a z score of 1.96 [31]. A margin of error (e), the acceptable error, was set at 5% (0.05), as in many social science studies:

- n=sample size
- N=population size (total number of attendees at the conference)
- p=estimated proportion of the attribute in the population (usually set at 0.5 for maximum sample size)
- e=margin of error (acceptable error rate)

Therefore, a sample size of approximately 110 gynecologists was required for the study.

The qualitative component of this study involved 12 purposively selected participants for key informant interviews (KIIs). These participants were chosen based on their extensive experience or unique perspectives on the implementation of SOGON guidelines. Extensive experience was defined as having at least 10 years of clinical practice as a gynecologist or serving in leadership roles, such as heads of departments or members of guideline review committees, within their institutions or professional organizations such as SOGON. These individuals were considered to possess in-depth knowledge and expertise in the application of the guidelines across various clinical settings. Unique perspectives were sought from individuals working in underserved or rural areas, where distinctive challenges in implementing guidelines are often encountered. In addition, participants involved in educational or advocacy roles related to cervical cancer prevention were included to provide insights into the dissemination and training processes for the guidelines.

The selection process took place during the SOGON 57th Annual General Meeting, where potential participants were identified through professional networks, conference attendee lists, and peer recommendations. Invitations were extended to ensure representation from diverse geographic regions and practice settings, capturing a broad spectrum of experiences relevant to the study's objectives.

The sample size of 12 participants was guided by the principle of thematic saturation, a widely recognized concept in qualitative research [32]. Saturation occurs when no new significant themes or insights emerge from additional data collection, indicating that the sample size sufficiently captures the diversity of perspectives needed to address the research objectives [33,34]. This point was reached during the iterative process of data collection and analysis, where the responses from the 12 interviews provided comprehensive insights into the challenges and facilitators of implementing SOGON guidelines.

Data Collection Instruments

The data collection instruments for this study were adapted from validated scales and designed to measure the attitudes of gynecologists toward adopting the evidence-based practice (EBP), precisely the SOGON guidelines for cervical cancer screening. These adaptations were based on established scales and reviews from previous studies, such as the Evidence-Based Practice Attitude Scale [35] and the insights from the barriers of clinical guideline use among physicians [36]. The instruments were modified to assess the adoption barriers of the SOGON guidelines among Nigerian gynecologists and underwent expert review to ensure content validity.

Quantitative Data Collection

Quantitative data were collected using a structured web-based survey divided into 3 sections (Multimedia Appendix 1). The study tool exhibited a robust internal consistency, as evidenced by an overall Cronbach α score of 0.890.

XSL•FO
RenderX

Section A: Sociodemographic Information

This section gathered basic demographic and professional information from the respondents, including age in years, gender, race or ethnicity, annual household income, board certification (year), number of years of postresidency practice, average number of patients seen on a typical day, and characterization of clinical practice (urban, suburban, or rural).

Section B: Awareness and Understanding of the SOGON Guidelines

The respondents were asked to indicate their level of agreement with statements designed to assess their awareness and understanding of the SOGON guidelines for cervical cancer screening. This session contained 8 items, and responses were measured on a Likert scale, which ranged from "strongly agree" to "strongly disagree." The Cronbach α score for section B was 0.734.

Section C: Incorporation of the SOGON Guidelines Into Clinical Practice

This 8-item section evaluated the extent to which the respondents integrated the SOGON guidelines into their clinical practice. A Likert scale was used to measure agreement levels with statements reflecting attitudes toward adopting new guidelines and practices. The Cronbach α score for section C was 0.932. The final part of this 7-item section includes hypothetical scenarios to understand the potential influences on the likelihood of adopting the SOGON guidelines, which focus on the role of training, a mandate from authorities, peer influence, and personal competence in the adoption process. The Cronbach α score for this final section was 0.867.

Qualitative Data Collection

The qualitative data collection was conducted using a semistructured interview guide to explore gynecologists' experiences and perceptions concerning implementing the SOGON guidelines. It contextualized and enriched the quantitative findings, providing deeper insight into practitioners' attitudes, challenges, and barriers. The interview had 2 sections: section A—challenges and barriers in implementing the guidelines and section B—recommendations for improving uptake. These were open-ended questions crafted to solicit detailed narratives encapsulating personal experiences, systemic obstacles, and practical suggestions for enhancing guideline adoption.

Data Collection Procedure

Quantitative Phase

A self-administered web-based survey tool (Google Forms) was used to distribute the questionnaire (Multimedia Appendix 1). The survey tool was disseminated during the SOGON 57th Annual General Meeting and Scientific Conference to the gynecologists in attendance.

Before initiating the survey, participants were presented with an informed consent form. Only those who provided consent were allowed to proceed to complete the survey. The survey was structured to be intuitive and efficient, aiming to optimize both response rates and the quality of collected data.

To facilitate extensive participation, a comprehensive distribution approach was used. Initially, participants present at the conference were approached directly, and upon obtaining their consent, they were given access to the web-based survey link. In addition, the survey link was distributed through the conference attendees' WhatsApp group, encouraging participation. Finally, the survey link was also shared in the SOGON WhatsApp group, specifically prompting members who had attended the conference but had not yet completed the survey to fill out the survey.

Qualitative Phase

The qualitative phase of this study involved 12 purposively selected KIIs conducted during the SOGON 57th Annual General Meeting and Scientific Conference. To ensure a rigorous and systematic approach to data collection, 2 trained research assistants, with prior experience in qualitative research methods and interview facilitation, conducted the interviews. Before data collection, the research assistants underwent a structured training session to align their understanding of the study objectives, ethical considerations, and interview techniques, ensuring consistency in the interview process.

Participants were contacted in advance to schedule interviews at their convenience, allowing for flexible scheduling to accommodate their professional commitments. Before each interview, participants provided written informed consent, including permission for audio recording to ensure accurate data capture. The research assistants reassured participants that all recordings would remain strictly confidential and used exclusively for research purposes. Each interview was assigned a unique identifier to maintain participant anonymity.

Interviews were conducted in a quiet and private setting within the conference venue to foster open and candid discussions. During the interviews, the research assistants took field notes, capturing nonverbal cues and contextual insights to complement the audio recordings. Immediately after each interview, postinterview reflections were documented to enhance the depth of analysis and ensure comprehensive data triangulation.

Data Analysis

Quantitative Data Analysis

Data management and statistical analysis were performed using SPSS (version 27; IBM Corp). The variables were appropriately coded for analysis, with sociodemographic factors such as age, gender, and years of practice considered as independent variables and the extent of SOGON guideline integration into clinical practice as the dependent variable. Means and SDs were reported for continuous independent variables such as age and years of practice. Categorical independent variables such as gender and board certification were described using frequencies and percentages. The dependent variable was summarized using frequencies and percentages across different levels of agreement or adoption.

The questions in each section of the study were specifically designed to evaluate participants' awareness, practices, and attitudes using a Likert scale. To assess the internal consistency of these scales, we calculated Cronbach α for each section. The

XSL•FO
RenderX

results demonstrated strong reliability, with Cronbach α values of 0.846 for awareness, 0.849 for attitudes, and 0.811 for practices.

On the basis of the evidence of intercorrelation among the items, we grouped the Likert scale questions into a cohesive survey scale and calculated the mean score for these items [37]. Our analysis used the weighted mean as a benchmark: when the mean score was greater than or equal to the weighted mean, it indicated adequacy in the measured items among the participants. Conversely, a mean score below the weighted mean suggested inadequacy in the items assessed.

Logistic regression analysis was performed to identify predictors of guideline uptake, with the dependent variable representing the likelihood of guideline integration. Each independent variable's contribution to the model was assessed, and odds ratios (ORs) were calculated to measure the strength of the association. A significance level (α) of .05 was set for all statistical tests, indicating that results with a *P* value <.05 were considered statistically significant.

Qualitative Data Analysis

The qualitative data analysis was conducted by 3 members of the research team (FTA, ORA, and OMO) and 2 qualitative research experts with experience in implementation science and health policy research. The qualitative data analysis was conducted using a thematic analysis approach. This approach was used to identify, analyze, and report patterns (themes) within data because it provided a flexible approach that can be applied to diverse research questions and highlight similarities and differences across a dataset.

Each audio recording from the in-depth interviews was transcribed verbatim. Transcriptions were double-checked against the recordings to ensure accuracy, capturing nonverbal cues when necessary. NVivo software (Lumivero) was used to organize codes and associate them with text segments. After the initial coding, themes were developed by collating codes and gathering all data relevant to each theme to identify patterned responses or meanings. The themes were reviewed in relation to the coded extracts and the entire dataset. They were then refined to form coherent and distinct patterns. A clear definition and name for each theme was developed, capturing the essence of each theme and what aspect of the data it represents. The final stage involved the selection of vivid and compelling extract examples, analyzing the extracted data, and relating the analysis to the research question and literature. The study detailed each theme, including how themes support, contradict, or develop existing knowledge.

Discrepant cases and nonconfirming evidence were discussed in the narrative to acknowledge the complexity and diversity of the data.

Triangulation and Integration of Data

This study used a convergent parallel mixed methods approach, collecting quantitative and qualitative data simultaneously but analyzing them independently to maintain the integrity of each method. Integration occurred during the interpretation phase, enabling the quantitative findings to provide breadth and generalizability, while qualitative data offered depth and contextual insights. The integration process involved comparing quantitative results, such as awareness levels and predictors of guideline adoption, with qualitative themes that explored systemic barriers such as resource constraints and training deficits.

This triangulation facilitated a comprehensive understanding by identifying areas of convergence, divergence, and complementarity. Both data types consistently showed high awareness but moderate implementation, highlighting a gap between knowledge and practice. Qualitative data explained this gap, revealing resistance due to reliance on clinical judgment and contextual challenges. The combined analysis strengthened the study's conclusions, ensuring a nuanced understanding of SOGON guideline implementation and aligning with best practices in mixed methods research to address the complexities of health systems.

Ethical Considerations

Before the study commenced, ethics approval was sought and obtained from the National Health Research Ethics Committee (approval number NHREC/01/01/2007).

Participants were provided detailed information about the study's purpose, procedures, potential risks, and benefits. All data collected were treated with strict confidentiality. Participants were informed that they could request a summary of the study findings after the study's completion. No financial compensation was provided, but participants received refreshments and conference-related materials.

Results

Overview

A total of 120 eligible participants attended the 57th SOGON Annual General Meeting and Scientific Conference, and 105 gynecologists completed the survey, yielding a response rate of 80%. A total of 105 eligible participants were included in the study. Table 1 presents the sociodemographic characteristics of the respondents. The average age of the respondents was 50 (SD 8) years, with an average of 12 (SD 9.412) years of postresidency practice and 15 (SD 11.73) patients seen daily. The gender distribution showed that 33.3% (35/105) of the respondents were women, while 66.7% (70/105) were men.

[a]MDA: ministries, departments, and agencies.

[b]FMCOG: Fellowship of the Medical College in Obstetrics and Gynecology.

[c]FRCOG: Fellow of the Royal College of Obstetricians and Gynaecologists.

[d]FWACS: Fellowship of the West African College of Surgeons.

[e]RCOG: Royal College of Obstetricians and Gynaecologists.

[f]CSOG: Clinical and Experimental Obstetrics and Gynecology.

[g]WHO: World Health Organization.

[h]ACOG: American College of Obstetricians and Gynecologists.

Regarding the type of practice, the highest proportion of respondents, 56.2% (59/105), worked in public federal teaching hospitals, while the smallest group, 1% (1/105), worked in public ministries, departments, and agencies. This was followed by 15.2% (16/105) of the respondents who worked in public state specialist hospitals, 11.4% (12/105) in public federal medical centers, 9.5% (10/105) in private nonteaching hospitals, and 4.8% (5/105) in public state teaching hospitals, and 1.9% (2/105) of the respondents were self-employed in private practice. The respondents obtained their obstetrics and gynecology fellowship in different years, with the largest group, 26.7% (28/105), obtaining their fellowship between 2016 and 2020.

Most respondents (81/105, 77.1%) practiced in urban areas, while 19% (20/105) practiced in semiurban areas and 3.9% (4/105) in rural areas. The respondents followed different cervical cancer prevention guidelines. The most commonly followed guidelines, which were followed by 40% (42/105) of the respondents, included a combination of World Health Organization, American College of Obstetricians and Gynecologists, and Royal College of Obstetricians and Gynaecologists.

There was a diverse distribution of participants across Nigeria, with higher concentrations in major urban centers—20.9% (22/105) in Lagos and 14.3% (15/105) in Abuja. The broad geographic distribution of respondents ensured comprehensive representation, strengthening the study's ability to capture diverse perspectives from different regions and cultural contexts across the country.

Awareness of the SOGON Guidelines

Most of the respondents (98/105, 93.3%) were aware of the SOGON cervical cancer prevention guidelines. The respondents who were aware of the SOGON guidelines indicated their level of agreement with statements designed to assess their awareness and understanding of the SOGON guidelines for cervical cancer screening.

The analysis of participants' awareness and understanding of the SOGON clinical practice guidelines for cervical cancer prevention demonstrates a generally high level of awareness, with a weighted mean score of 4.24 (SD 0.833) serving as the benchmark for evaluating adequacy across all assessment items.

Participants exhibited strong awareness of key strategies for prevention of cervical cancer, as evidenced by a mean score of 4.63 (SD 0.686). They also demonstrated an understanding of the need for definitive confirmation following positive screening results, with a mean score of 4.26 (SD 0.959). These findings suggest that most participants had a robust grasp of the critical elements of the guidelines.

Awareness of patient eligibility for screening with a mean score of 4.32 (SD 0.830) and the recommended frequency for screening with a mean score of 4.27 (SD 0.949) were slightly above the weighted mean, reflecting a satisfactory but not exceptional level of understanding.

Some challenges emerged in the practical application of the guidelines. Participants' familiarity with implementing SOGON recommendations in clinical practice scored a mean of 4.06 (SD 0.858), while their ability to differentiate SOGON-advised screening methods from other screening tests scored 3.76 (SD 0.856), falling below the weighted mean. These scores highlight areas where additional training or practical tools might be required to bridge the gap between theoretical understanding and practical execution.

Knowledge about assessing patient eligibility according to the guidelines was slightly below the benchmark, with a mean score of 4.10 (SD 0.891). Although this indicates reasonable understanding, enhancing training in this area could further improve participants' competence (Table 2).

XSL•FO
RenderX

Table 2. Awareness and understanding of the Society of Obstetrics and Gynecology of Nigeria (SOGON) guidelines for cervical cancer prevention.

Assessment scale	Score, mean (SD)
"I am aware that SOGON cervical cancer guidelines recommend specific strategies for cervical cancer prevention among women and girls."	4.63 (0.686)
"I understand that women with positive screening results based on SOGON cervical cancer prevention guidelines need to undergo definitive confirmation before treatment."	4.26 (0.959)
"I am aware that positive screening results based on SOGON prevention guidelines do not mean patients have cervical cancer."	4.54 (0.638)
"I am aware of which patients are eligible for screening based on recommendations by SOGON cervical cancer prevention guidelines."	4.32 (0.830)
"I am aware of the recommended frequency of screening by SOGON cervical cancer prevention guidelines for eligible women."	4.27 (0.949)
"I am familiar with how the recommendation of the SOGON cervical cancer prevention guidelines for screening methods are applied in clinical practice."	4.06 (0.858)
"I can differentiate between the SOGON-advised cervical cancer screening method and other cervical screening tests."	3.76 (0.856)
"I am knowledgeable about how to assess patients eligible for screening according to SOGON guidelines."	4.10 (0.891)
Weighted mean	4.24 (0.833)

The evaluation of professionals' incorporation of the SOGON clinical guidelines into practice provides valuable insights into their attitudes and behaviors. The weighted mean score of 3.40 (SD 1.075) serves as a benchmark for understanding overall alignment with the guidelines, with higher scores indicating stronger agreement and adherence and lower scores highlighting potential areas of resistance or reliance on alternative approaches. Participants demonstrated a strong willingness to adopt evidence-based guidelines, as reflected by a high mean score of 4.60 (SD 0.690) for receptiveness to research-backed practices. Similarly, a mean score of 4.15 (SD 0.869) indicates a positive attitude toward adapting to new guidelines, even when these differ from established practices. These scores, well above the weighted mean, emphasize the professionals' recognition of the importance of evidence-based approaches in clinical decision-making. While participants generally valued the guidelines, the mean score of 3.32 (SD 1.410) suggests that many professionals perceive a misalignment between guidelines and the realities of clinical practice. The results indicate a tendency to prioritize personal experience and clinical judgment over formal guidelines, with scores for statements such as "My clinical judgment often takes precedence over academic or formal guidelines" (mean 2.69, SD 1.389) and "Relying on my clinical experience is often more crucial than strictly following a guideline" (mean 2.22, SD 1.374) falling significantly below the weighted mean. These findings point to a preference for individualized decision-making, particularly in complex or unique patient cases. In addition, hesitancy to strictly follow structured guidelines is further reflected with a low mean score of 1.87 (SD 1.177). This suggests that rigid adherence may be seen as impractical or unsuitable in many clinical scenarios, emphasizing the need for guidelines that accommodate flexibility. The mean score of 4.04 (SD 1.012) for integrating new guidelines into practice is slightly above the weighted mean, indicating that while participants strive to incorporate guidelines, there is room for improvement. Therefore, the weighted mean of 3.40 (SD 1.075) represents a moderate overall level of integration, with significant variability across specific aspects of guideline adoption (Table 3).

Table 3. Evaluation of the extent to which you incorporate the Society of Obstetrics and Gynecology of Nigeria (SOGON) guidelines into your clinical practice.

Assessment scale	Score, mean (SD)
"I often integrate new guidelines or practices, such as the SOGON guidelines to enhance patient care"	4.04 (1.012)
"My clinical judgment, based on experience, often takes precedence over academic or formal guidelines"	2.69 (1.389)
"I am receptive to implementing guidelines or practices that are backed by research, like the SOGON guidelines"	4.60 (0.690)
"Guidelines derived from research, such as the SOGON guidelines, may not always align with clinical realities"	3.32 (1.410)
"Relying on my clinical experience is often more crucial than strictly following a guideline"	2.22 (1.374)
"I am hesitant to adhere to any structured guideline in my practice strictly"	1.87 (1.177)
"I am willing to adapt to new guidelines, even if they differ significantly from my usual practices"	4.15 (0.869)
Weighted mean	3.40 (1.075)

Table 4 shows an overall perception of adopting new guidelines and practices, as indicated by the weighted mean score of 4.45 (SD 0.782). This benchmark highlights participants' positive attitudes toward integrating EBPs into their clinical routines. Participants showed the highest agreement with statements regarding aligning new guidelines with their clinical intuition (mean 4.69, SD 0.640) and understanding of effective practice (mean 4.70, SD 0.484). These scores, well above the weighted

XSL•FO
RenderX

mean, suggest that professionals are most likely to adopt guidelines that resonate with their personal judgment and established practices. While slightly lower than the weighted mean, the score for adoption driven by supervising authority mandates (mean 4.12, SD 0.978) indicates moderate influence from hierarchical directives. However, compliance with broader regulatory requirements (mean 4.39, SD 0.860) and state or national mandates (mean 4.32, SD 0.826) scored closer to the weighted mean, reflecting professionals' general willingness to adhere to standardized practices when required. The mean score of 4.32 (SD 0.904) for colleagues' adoption and feedback suggests that peer practices significantly shape attitudes toward new guidelines. This highlights the importance of collaborative environments and peer networks in fostering guideline adoption. A high mean score of 4.60 (SD 0.780) indicates that participants felt well trained and competent in applying new guidelines. This score, significantly above the weighted mean, underscores the critical role of professional development and training in enhancing confidence and facilitating the integration of EBPs.

Table 4. Attitudes toward adopting new guidelines and practices.

Assessment scale	Score, mean (SD)
"It aligned well with your clinical intuition."	4.69 (0.640)
"It resonated with your understanding of effective practice."	4.70 (0.484)
"Your supervising authority mandated it."	4.12 (0.978)
"The regulatory body required it."	4.39 (0.860)
"It was a state or national mandate."	4.32 (0.826)
"Many of your colleagues adopted it and provided positive feedback."	4.32 (0.904)
"You felt sufficiently trained and competent in its application."	4.60 (0.780)
Weighted mean	4.45 (0.782)

Table 5 shows that participants with more than 1 fellowship and a high awareness level significantly impact the adoption of SOGON clinical practice guidelines for cervical cancer prevention. The findings from the adjusted model showed that participants with more than 1 fellowship were 4 times more likely to integrate the SOGON clinical practice guidelines (OR 4.200, 95% CI 1.369-12.888). Similarly, those with a high awareness level were 9 times more likely to influence the incorporation of the SOGON clinical practice guidelines into practice (OR 9.610, 95% CI 3.146-29.357).

Table 5. Factors affecting the incorporation of the Society of Obstetrics and Gynecology of Nigeria (SOGON) guidelines into practice.

Variables and category	Crude OR[a] (95% CI)	*P* value	Adjusted OR (95% CI)	*P* value
Fellowships				
1	Reference	—[b]	Reference	—
>1	3.462 (1.354-8.849)	.01[c]	4.200 (1.369-12.888)	.01[c]
SOGON awareness				
No	Reference	—	Reference	—

Low	Reference	—	Reference	—
High	8.719 (3.104-24.488)	<.001[d]	9.610 (3.146-29.357)	<.001[c]

[a]OR: odds ratio.

[b]Not applicable.

[c]Statistically significant at $P<.05$

[d]Statistically significant at $P<.05$

The qualitative analysis revealed that while most gynecologists knew the SOGON guidelines, there were notable challenges in fully integrating them into clinical practice. Participants shared diverse experiences related to their application of the SOGON clinical practice guidelines, with key themes including practical difficulties in implementation, the need for additional training, and the impact of institutional support on adherence to the guidelines (Textbox 1). The findings provide a comprehensive understanding of the factors influencing guideline adoption and offer recommendations for improving the effectiveness of the SOGON clinical practice guidelines in clinical practice.

Theme 1: Specificity and Relevance

This theme explores the challenges and perceptions of gynecologists regarding the implementation of the SOGON clinical practice guidelines, focusing on their applicability to the unique needs of their patients and specificity for high-risk groups. The responses reveal diverse perspectives, underscoring the importance of aligning guidelines with local and specific patient contexts.

Subtheme 1.1: Applicability to Patient Needs

Gynecologists shared their experiences on how well the SOGON guidelines meet the diverse needs of their patients, particularly those in underserved areas. The responses highlight a perceived gap in the guidelines' relevance for these populations and suggest a need for tailored approaches.

While the guidelines provide a broad framework, there is a consensus among respondents that they lack flexibility for rural and socioeconomically disadvantaged populations, necessitating frequent updates and training for practitioners:

> *The SOGON guidelines are comprehensive but not always a perfect fit for the unique needs of my patients in rural areas. There is a lot that needs to be done for the rural communities. I have colleagues who have not been able to do much in their communities; there is a need for regular training and updates on the SOGON guidelines. Some challenges are also socioeconomic conditions, for which I believe there is a need for more tailored approaches than the guidelines provided.* [Participant 009]

Subtheme 1.2: Specificity for High-Risk Groups

Gynecologists emphasized the importance of adapting the guidelines for high-risk groups, such as women with a family history of cervical cancer or those living with HIV.

Participants identified a critical need for more detailed and tailored guidance when managing high-risk populations. They suggested that additional specificity would enhance clinical decision-making and improve patient outcomes:

> *I appreciate the guidelines, but there is a need for more specificity, especially when dealing with high-risk groups. We need to do more.* [Participant 001]

> *For certain cases, like high-risk patients, having more detailed guidance would enhance our practices.* [Participant 002]

Theme 2: Accessibility

Successful implementation of clinical practice guidelines depends on their accessibility and ease of comprehension for health care providers. This theme addresses gynecologists' experiences with accessing and understanding the SOGON guidelines.

XSL•FO
RenderX

Subtheme 2.1: Availability

Participants reflected on the availability of the guidelines, acknowledging it as a positive first step but expressing concerns about awareness among practitioners.

While availability is essential, there is a clear indication that more needs to be done to raise awareness, particularly among new residents and rural health care workers, to ensure widespread adoption:

> *The guidelines are available, which is a good starting point for adherence across practitioners.* [Participant 004]

> *Accessing the guidelines are crucial; it is the first step in ensuring everyone can follow the best practices. However, I will tell you that some of us are unaware that such guidelines exist, especially for new residents. Then I ask myself, what are we doing then? I believe there is a need to do more awareness even during a Conference like this, though the guidelines are available.* [Participant 002]

Subtheme 2.2: Ease of Understanding

Gynecologists discussed the need for user-friendly formats to facilitate the quick and easy application of guidelines in their busy clinical settings.

The data suggest that while the guidelines are present, their practical utility is limited by their complexity. The respondents advocated for simplified formats, such as pictorial aids and ongoing training, to enhance comprehension and adherence:

> *The guidelines are there, but they are not always easy to digest quickly during busy days. I suggest we have them in pictorial formats for ease of understanding. Also, regular training and workshops will make it easier to understand.* [Participant 001]

> *To enhance adherence, we need more user-friendly formats, especially during hectic clinic hours. I am sure you understand what I am talking about. I see more than 10 patients a day aside from administrative positions and other things I need to do. A conference like this, which is some days off work, could be a good platform to revisit the guidelines, if possible not only the SOGON but other guidelines.* [Participant 005]

Theme 3: Training and Capacity Building

Training is crucial for empowering gynecologists to effectively implement clinical practice guidelines. This theme reflects their experiences and needs regarding training on the SOGON guidelines.

Theme 3.1: Experiences With Training

The respondents acknowledged the benefits of past training but emphasized the need for continuous, focused sessions on the guidelines.

There is a recognition that training efforts have been beneficial but insufficient. The participants expressed the need for more structured and regular training opportunities to stay updated with best practices:

> *I've had some training, but there is always room for more focused sessions on SOGON guidelines. This is very important to get this right.* [Participant 009]

> *Training has been helpful, but it needs to be ongoing to keep up with updates and best practices. Why not have a pre-conference training for this ongoing conference? This is very important.* [Participant 007]

Subtheme 3.2: Additional Training Needs

The respondents highlighted specific areas where additional training would enhance their ability to implement the guidelines effectively.

The feedback showed that participants are eager for deeper, targeted training, particularly on complex aspects of the guidelines that require further explanation:

> *Identifying specific areas where additional training is needed can significantly enhance our ability to implement guidelines effectively.* [Participant 009]

> *There is a need for more support, especially in areas where the guidelines require a deeper understanding. There is a need for additional and regular training.* [Participant 011]

Theme 4: Institutional Support and Resources

Gynecologists operate within health care systems that either facilitate or hinder guideline implementation. This theme examines the influence of institutional support on adherence to clinical practice guidelines.

The data reveal that institutional backing is a significant determinant of successful implementation. The gynecologists expressed that without adequate support, adherence remains challenging, thus affecting patient care quality:

> *Without institutional support, adherence to guidelines becomes challenging, directly affecting patient care. In my workplace, it is difficult to convince my boss to adopt the guidelines.* [Participant 012]

> *Instances where our institution provided crucial support stand out as successful implementations of the guidelines. I can tell you that support is key, and I am a witness in my formal workplace.* [Participant 011]

Theme 5: Patient Education and Awareness (Subtheme 5.1: Role in Guideline Implementation)

The gynecologists recognize that cervical cancer prevention extends beyond clinical practice, requiring active patient education to ensure guideline adherence.

The respondents described how educating patients plays a critical role in implementing guidelines successfully.

The feedback underscores the need for a collaborative approach between practitioners and patients. Educating patients not only helps in adherence but also empowers them to take proactive steps for their health:

XSL•FO
RenderX

> *Educating patients is integral to successful implementation; it is a partnership between practitioners and those we serve.* [Participant 009]
>
> *Our approach to patient education significantly influences how well the guidelines are understood and followed.* [Participant 008]

Theme 6: Feedback and Improvement

This theme discusses the importance of structured feedback mechanisms in improving and updating the SOGON guidelines.

Theme 6.1: Feedback Provision

The gynecologists emphasized the value of providing feedback as a means to refine the guidelines based on practical experiences.

The responses indicate a strong desire for a more systematic process where practitioners can share their experiences and insights to contribute to continuous improvement.

Some respondents stated the following:

> *Providing feedback is essential; it is a way to contribute to improving the guidelines.* [Participant 012]
>
> *There is a need for a structured process where practitioners can easily provide feedback on their experiences.* [Participant 009]

Theme 6.2: Participatory Guideline Review

Furthermore, 70% (74/105) of the participants advocated for a participatory approach in the guideline review process, ensuring their experiences inform updates.

The gynecologists' input suggests that a participatory model would enhance trust and ownership among practitioners, leading to more effective guideline implementation.

Some of the respondents said the following:

> *Making the guideline review more participatory ensures that practitioners' insights are considered in updates.* [Participant 008]
>
> *We want to be part of the process, contributing our experiences to refine the guidelines effectively.* [Participant 007]
>
> *It is not that I do not trust the SOGON guidelines; just to inform you, it was not even mentioned during my years of residence. However, being in a scientific profession, I think we want whatever decision or guideline taken to be backed up by "We are doing this because it is safer. It is safest for the patients, and this is the evidence," rather than "We are doing this," without explaining because you might think: Oh, you are doing this. After all, SOGON says it works.* [Participant 009]

Theme 7: Comparison With Other Guidelines (Theme 7.1: Reference to Other Guidelines)

This theme highlights how gynecologists compare the SOGON guidelines with other standards to provide holistic care.

The participants discussed their practice of consulting various guidelines to ensure comprehensive patient care.

Comparing guidelines appears to be a common strategy among gynecologists to incorporate best practices from multiple sources, suggesting that the SOGON guidelines could benefit from integrating insights from other frameworks.

The gynecologists pointed out the following:

> *Sometimes, we refer to other guidelines; it is essential to consider a holistic approach to patient care.* [Participant 002]
>
> *Comparing guidelines helps us understand where SOGON stands and how to integrate the best practices.* [Participant 001]

Theme 8: Guideline Implementation Successes (Theme 8.1: Positive Experiences)

This theme focuses on successful instances of guideline implementation and the factors that contributed to these outcomes.

The gynecologists shared successful strategies they have used, highlighting the importance of collaboration and adaptability.

The success stories showed that with the right support and approach, effective implementation is achievable. Such examples serve as learning opportunities for other practitioners:

> *Sharing our successes allows us to learn from each other and replicate effective strategies.* [Participant 003]
>
> *Factors contributing to successful implementations are valuable lessons for the entire community.* [Participant 006]

Discussion

Overview

This study was motivated by the introduction of SOGON clinical practice guidelines aimed at enhancing cervical cancer prevention in Nigeria. Despite the availability of these guidelines, data on their adoption by gynecologists remain limited. Understanding the awareness, implementation, and barriers to guideline adherence is critical for improving cervical cancer prevention practices.

Principal Findings

This study used a convergent parallel mixed methods design to evaluate the awareness, understanding, and application of the SOGON guidelines among Nigerian gynecologists. Quantitative data from surveys quantified awareness levels (98/105, 93.3%) and practice distribution (81/105, 77.1% urban), while qualitative data from KIIs provided contextual insights into barriers, such as limited training and institutional support. Integration occurred at the interpretation stage, where quantitative findings, such as the significant association between awareness and guideline adoption (OR 9.610, 95% CI 3.146-29.357), were enriched by qualitative narratives emphasizing professional development needs and rural-urban disparities. This approach revealed systemic and contextual

XSL•FO
RenderX

challenges, including resistance to strict adherence due to overreliance on clinical judgment. These findings align with existing literature, highlighting the importance of combining quantitative and qualitative methods to address the complexities of clinical guideline implementation [38,39].

The high levels of awareness and understanding demonstrated by gynecologists align with EBPs aimed at optimizing patient care [18,40]. Participants knew the need for confirmatory diagnostics following positive screening results, minimizing unnecessary interventions and patient anxiety [29,41]. However, the moderate alignment of clinical practice with the guidelines reflects ongoing challenges in bridging the gap between knowledge and implementation. Global studies similarly highlight that gaps in practical application are often due to insufficient training and limited resources, underscoring the critical role of continuing education in strengthening guideline adoption [38,42,43].

Integrating the SOGON guidelines into clinical practice revealed moderate alignment with the recommendations. The positive perception of adopting new guidelines indicates that health care professionals are generally open to embracing EBPs [42]. This finding aligns with the findings from the study by Lehane et al [39], who highlighted that educational programs and associated curricula are pivotal in shaping health care professionals' knowledge, skills, and attitudes, influencing the quality of care delivered. Such programs provide the foundational support necessary to bridge the gap between guidelines and their practical application [39,44]. Despite this positive outlook, the study identified a reliance on clinical judgment over formal guidelines and a hesitancy to adhere strictly to structured recommendations. This underscores the complex interplay between clinical expertise and guideline adherence in real-world settings, where health care providers often navigate patient-specific needs and systemic constraints. Achieving a balance between respecting clinical judgment and prioritizing evidence-based guidelines is critical to optimizing patient outcomes [44,45]. A systematic review has categorized 3 critical strategies for enhancing skills in EBPs: multifaceted educational approaches that incorporate mentoring and tutoring, single educational strategies, and multifaceted approaches using the 5 fundamental steps of EBPs. These strategies have demonstrated effectiveness in improving health care professionals' ability to integrate evidence-based guidelines into routine practice, emphasizing the importance of targeted training initiatives to strengthen guideline adoption [39,46].

The study findings highlight that Nigerian gynecologists positively embrace new guidelines, even when these differ significantly from their established practices. This openness reflects a commitment to continuous learning and improving patient care, aligning with fostering a culture of lifelong learning and professional development within health care systems [44,47]. This perspective is consistent with evidence from prior studies, which emphasize that adopting new guidelines impacts far beyond their immediate content, shaping broader attitudes and behaviors in clinical practice [26,27,39,48].

The results provide valuable insights into the factors influencing gynecologists' perceptions and adoption of new guidelines. The participants demonstrated strong agreement regarding the importance and efficacy of adopting guidelines, particularly when these align with their clinical intuition and understanding of effective practice. This finding underscores the role of clinical expertise and professional judgment, which health care providers often rely upon to navigate complex and diverse clinical scenarios. Global studies have observed similar trends, where clinical decision-making is frequently informed by a combination of evidence-based guidelines and contextual knowledge of patient needs [11,21,49]. The study also highlights the importance of involving clinicians in the guideline development process to ensure that recommendations resonate with their practical realities. Guidelines tailored to incorporate clinicians' perspectives are more likely to be adopted as they address theoretical best practices and the day-to-day challenges faced in diverse clinical settings. This finding aligns with the literature emphasizing the need for participatory approaches in guideline development to enhance relevance and feasibility [38]. Interestingly, the study revealed that while regulatory requirements and mandates promote adherence, they are not the primary drivers of guideline adoption. The relatively lower mean score associated with the influence of supervisory mandates indicates that clinicians are more motivated by the intrinsic value of guidelines and their alignment with clinical judgment rather than top-down enforcement. Nonetheless, the participants demonstrated high compliance with requirements from regulatory bodies and national policies, underscoring the importance of oversight mechanisms in ensuring standardized practices and maintaining quality of care. Similar findings in the literature highlight the complementary role of regulatory frameworks in reinforcing the integration of EBPs [50-53].

The study highlights the significant role of peer support and professional networks in shaping participants' perceptions and adoption of new guidelines. The influence of colleagues' adoption and feedback was key in promoting guideline adherence and knowledge sharing among Nigerian gynecologists [48]. Collaboration and peer learning opportunities facilitate the exchange of best practices, fostering a culture of continuous improvement within health care organizations. These findings are consistent with prior studies, demonstrating that strong professional networks and peer endorsements enhance the credibility and acceptability of EBPs [38,54]. Participants' confidence and self-efficacy in applying the SOGON guidelines were closely linked to their perception of being well trained and competent. This underscores the importance of ongoing training and professional development initiatives in ensuring health care professionals' proficiency in delivering evidence-based care. Research consistently shows that well-designed training programs improve clinicians' confidence and ability to implement clinical guidelines, particularly when they incorporate hands-on practice and tailored content to address specific needs [9,55].

The study also provides insights into factors influencing the adoption of the SOGON guidelines. A notable finding was the significant impact of educational background and awareness levels on guideline integration. Gynecologists with more than 1 fellowship were significantly more likely to adopt the guidelines than those with only 1 fellowship, emphasizing the

XSL•FO
RenderX

value of advanced training and specialization in enhancing knowledge and skills. This finding aligns with global evidence that advanced professional development improves clinicians' ability to interpret and apply EBPs in diverse clinical settings [44,45]. Furthermore, the study revealed that gynecologists with high awareness of the SOGON guidelines were 9 times more likely to use them in their practice than those with lower awareness levels. This highlights the critical role of knowledge dissemination and awareness campaigns in promoting guideline adherence and standardizing clinical practices. Prior studies have similarly demonstrated that targeted educational initiatives, such as workshops and seminars, significantly improve guideline uptake by addressing knowledge gaps and enhancing familiarity with the guidelines [47,56]. These findings have important implications for clinical practice and professional development strategies in Nigerian health care. To facilitate the widespread adoption of EBPs, health care organizations and policy makers should prioritize educational programs and awareness campaigns focused on improving health care professionals' knowledge of the SOGON guidelines. This could include integrating guideline training into residency programs, hosting regular workshops, and developing accessible learning materials tailored to clinicians' needs. In addition, encouraging continued professional development and advanced training opportunities will further enhance health care professionals' capacity to effectively integrate guidelines into their practice, ultimately improving patient outcomes [47,57].

This study provides valuable insights into gynecologists' experiences and perceptions regarding implementing the SOGON guidelines for cervical cancer prevention. While participants acknowledged the comprehensiveness of the guidelines, many highlighted the need for greater tailoring to address the unique needs of rural and high-risk patient populations. These findings align with existing literature emphasizing the importance of context-specific adaptations to clinical guidelines to ensure their relevance and practicality in diverse health care settings [25,38].

Accessibility emerged as a critical factor influencing adherence to guidelines. Although participants recognized that the guidelines were available, concerns about their awareness, comprehensibility, and ease of use were frequently raised, particularly during busy clinical hours. Participants recommended improving accessibility through user-friendly formats, such as simplified language, visual aids, and digital tools. These suggestions are consistent with prior research, demonstrating that clear, visually engaging materials and practical demonstrations significantly improve guideline uptake among health care providers [39,58]. In addition, regular training sessions were emphasized as essential for promoting guideline adherence and enhancing gynecologists' knowledge and skills in cervical cancer prevention. Continuous education opportunities keep health care providers updated on the latest EBPs and foster a culture of lifelong learning and professional growth [52,59-61].

Participants also emphasized the role of institutional support in facilitating guideline adherence. Successful implementation of the SOGON guidelines was often associated with robust institutional backing, including resource allocation, leadership support, and infrastructure enhancements. This finding underscores the critical role of organizational commitment in promoting EBPs. Supporting evidence from global studies highlights that health care institutions prioritizing guideline integration through dedicated resources and consistent leadership achieve higher compliance rates among health care providers [52,53]. For instance, a study in Germany demonstrated that institutions fostering an environment of quality improvement, supported by strong leadership and infrastructure, significantly enhanced guideline adherence [48,62].

Hung et al [52] investigated the role of organizational culture in influencing guideline adherence within primary care settings. Their findings demonstrated that institutions fostering a culture of continual quality improvement and consistent support and training for health care providers were significantly more effective in implementing clinical guidelines [52]. These insights reinforce the critical role of organizational commitment and institutional support in facilitating guideline integration. The participants in this study similarly highlighted the importance of institutional backing, emphasizing that robust infrastructure, leadership support, and ongoing training were essential for fostering adherence to the SOGON guidelines.

Patient education emerged as another key factor in the effective implementation of guidelines. Participants emphasized the necessity of health care practitioners educating patients and adopting a collaborative approach to care. They also advocated feedback mechanisms, calling for participatory guideline review processes to ensure continual improvement. These findings align with existing research, which shows that health care providers who actively involve patients in their care, offer clear and comprehensible information about treatment options, and encourage shared decision-making are more likely to adhere to clinical guidelines [63]. Studies have further demonstrated that health care institutions incorporating feedback from health care providers and patients into guideline review processes achieve better adherence and improved quality of care delivery [64,65]. This underscores the importance of stakeholder involvement in guideline development and refinement, ensuring that the guidelines remain relevant, practical, and patient centered.

The participants emphasized the importance of practitioners' experiences and insights in effectively refining and updating the guidelines. The study findings show that the participants acknowledged the utility of comparing guidelines to understand best practices and ensure a holistic approach to patient care. Reference to other guidelines was perceived as valuable in guiding decision-making and practice. These findings echo evidence from prior studies that demonstrate how clinical guidelines can enhance the quality of clinical decisions by providing explicit recommendations, supporting clinicians who are uncertain about how to proceed, and addressing inconsistencies in care delivery. Guidelines grounded in rigorous scientific evidence identify beneficial interventions and highlight those lacking strong support, warning clinicians against ineffective, harmful, or wasteful practices [25,39,48]. Such evidence-based guidelines foster critical appraisal among clinicians and strengthen the consistency and appropriateness of care.

XSL•FO
RenderX

Recommendations

On the basis of the study findings, several recommendations can enhance the implementation of SOGON guidelines and improve cervical cancer prevention among Nigerian gynecologists. Comprehensive training programs should be developed to address gynecologists' specific needs, including guideline updates, practical implementation strategies, and clinical decision-making processes. Regular workshops, seminars, and webinars should support ongoing professional development and ensure health care providers remain updated on EBCs. Integrating SOGON guideline training into residency programs for obstetrics and gynecology will expose trainees to EBCs early, fostering a solid foundation for guideline adherence. In addition, advocacy for institutional, regional, and national policy support is critical. Efforts should focus on establishing policies that mandate guideline adherence, allocating resources for training, and incentivizing compliance to ensure widespread and effective adoption.

Strengths and Limitations

The study's strengths include its mixed methods approach, which combined broad quantitative data with detailed qualitative insights for a comprehensive understanding. This study is among the first to examine the adoption of cervical cancer prevention guidelines among Nigerian gynecologists. In addition, including participants from the 57th SOGON Annual General Meeting provided access to a diverse and representative group of experts in Nigeria. Despite these strengths, the study has several limitations when interpreting the findings. First, the focus on gynecologists excludes other health care professionals involved in cervical cancer prevention, such as nurses or primary care providers, limiting the generalizability of the findings. Second, while participants were selected from diverse regions, the sample size was small and may not fully represent the experiences of gynecologists in rural or underserved areas, where guideline implementation challenges may differ significantly. Third, the reliance on self-reported data introduces potential bias, as participants may overestimate adherence or underreport barriers to align with perceived expectations. Fourth, the study's cross-sectional design prevents establishing causal relationships between factors influencing guideline adoption and their outcomes. Finally, the resource and institutional challenges reported by respondents may not fully reflect the experiences of gynecologists across different regions, given the variability in health care infrastructure and support systems within Nigeria.

Conclusions

This study sheds light on Nigerian gynecologists' perceptions of the SOGON guidelines for cervical cancer prevention, revealing overall positive awareness and understanding. The findings underscore the importance of guideline adherence in promoting EBPs and ensuring optimal patient care. While areas for improvement exist, such as enhancing the use of the guidelines in clinical practice, the willingness of health care professionals to adopt new guidelines indicates a commitment to continuous improvement in patient care delivery. Recommendations stemming from this study emphasize the need for comprehensive training programs tailored to gynecologists, ongoing professional development initiatives, and policy support to prioritize guideline integration.

Data Availability

The data supporting the findings of this study are available from the corresponding author upon reasonable request. All data generated or analyzed during the study are included in this published paper and its supplementary materials.

Authors' Contributions

OCE and JII conceptualized the study, supervised the research process, and contributed to the overall study design and manuscript preparation. FTA, IKL, and ORA led the data collection process, ensuring adherence to ethical guidelines, and contributed to manuscript writing and revisions. ORA and FTA were responsible for data analysis, using both quantitative and qualitative methods, and contributed to the interpretation of results. FTA, IKL, CO-J, and OMO facilitated participant recruitment, managed ethics approvals, and contributed to the Discussion and Conclusion sections. CO-J provided technical expertise in methodology, particularly in qualitative research, and reviewed the manuscript for intellectual content. FTA, IKL, GUE, and ORA assisted in drafting the Introduction section and literature review, ensuring that the study was well grounded in existing research. GUE, CO-J, JDT, and JII contributed to the manuscript revision process, ensuring coherence and consistency in writing, and provided critical feedback on the findings. JDT was involved in manuscript editing, formatting, and finalizing the references. JII and OCE reviewed the manuscript for accuracy, contributed to the Discussion section, and ensured alignment with journal submission guidelines. All authors read and approved the final manuscript.

Abstract

Background: Cancer is a leading cause of death worldwide. Early detection through screening, diagnosis, and effective management can reduce cancer mortality. Risk assessment is crucial for improving outcomes by identifying high-risk individuals based on family history, genetics, lifestyle, and environment. Such targeted screening enhances accuracy and resource efficiency. However, the complex nature of oncology data—which includes clinical observations, lab results, radiology images, treatment regimens, and genetic information—presents significant challenges for data interoperability and exchange.

Objective: This study proposes an oncology data model (ODM) based on the Fast Healthcare Interoperability Resources (FHIR) standard to facilitate the capturing, sharing, and processing of oncology data across various cancer care stages. We particularly focused on screening and risk assessment for 5 cancers: breast, cervical, esophageal, lung, and oral, within the Meghalaya Fourth Industrial Revolution for Sustainable Transformation Cancer Care pilot project in India.

Methods: The ODM incorporates data elements from a cancer patient's journey across 5 phases: encounter, risk assessment, clinical investigation, treatment, and outcome. Essential oncology data elements were modeled using the Health Level 7 FHIR Revision 4 standard. Custom FHIR profiles were developed for cancer-specific use cases, with terminology mapped to Systematized Nomenclature of Medicine–Clinical Terms, Logical Observation Identifiers Names and Codes, and the *International Classification of Diseases, 10th Revision*. The implementation guide (IG) was created using FHIR Shorthand, SUSHI Unshortens Short Hand Inputs, and the Health Level 7 IG Publisher. Technical and clinical validation and a stakeholder usability assessment were conducted using a demonstration tool designed for implementer training and adoption.

Results: The data model enhances interoperability across the cancer care continuum, from screening to treatment. The resulting IG includes 25 oncology-specific resource profiles and 50 standardized terminology value sets that support both semantic and syntactic interoperability. Central to the model are the FHIR Questionnaire and QuestionnaireResponse resources, customized for structured data collection in clinical and community settings, supporting cancer screening workflows. Technical validation yielded FHIR conformance and terminology binding, while clinical validation by oncologists and public health experts confirmed the usability and relevance of 5 screening questionnaires. The demonstration tool promoted stakeholder engagement and practical evaluation of the FHIR profiles.

Conclusions: The FHIR-based ODM offers a unified framework for structured, interoperable cancer data exchange from screening to after treatment. This study marks the first comprehensive Indian initiative to apply FHIR standards for oncology screening and risk assessment. Integrating with national digital health systems, like the Ayushman Bharat Digital Mission, can ensure consistent data sharing across screening programs, hospitals, and registries. Future work will focus on real-world model deployment, evaluation in multiple districts, expanding to treatment and survivorship data, and promoting national adoption to inform cancer policy, research, and precision oncology efforts.

Introduction

Despite advances in treatment and early detection, the global cancer burden continues to rise due to factors such as population growth, aging, lifestyle changes, and environmental influences. Millions of new cancer cases and deaths occur each year, with lung, breast, colorectal, and prostate cancers being the most prevalent [1]. In India, cancer is a significant contributor to the burden of noncommunicable diseases, leading to substantial out-of-pocket expenditures for patients. In 2022, India recorded more than 1.46 million new cancer cases, resulting in a crude incidence rate of 100.4 per 100,000 individuals [2-4]. In the state of Meghalaya, India, there is a high prevalence of oral and esophageal cancers, primarily due to lifestyle factors, such as tobacco and betel nut consumption. The region's unique sociocultural practices significantly contribute to these patterns. Access to cancer care facilities is limited, forcing many patients to seek treatment outside the state, which highlights the need for a robust framework for sharing data of patients with cancer to ensure continuity of care [4].

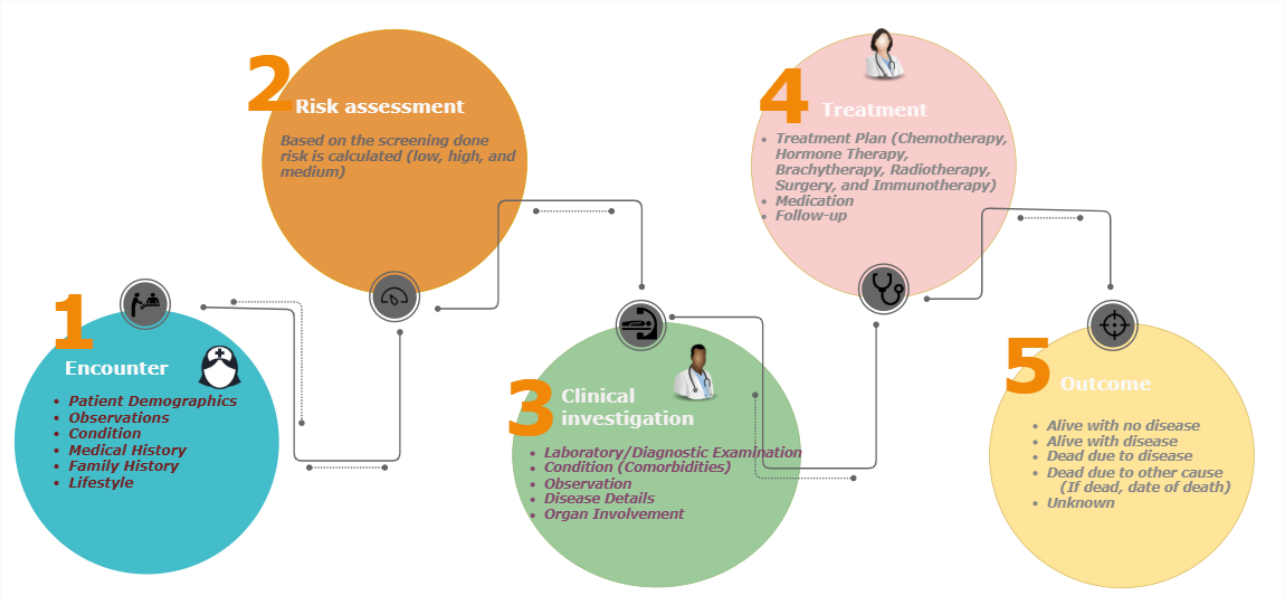
Cancer screening is a vital component of comprehensive cancer control, targeting early detection and timely intervention for cancer management. It offers significant benefits, including improved patient prognosis, reduced treatment costs, and enhanced public health outcomes. Unlike diagnostic procedures that are performed once symptoms appear, cancer screening targets individuals who are asymptomatic, enabling early identification of malignant neoplasm when they are most treatable and manageable. Recognizing this need, the Indian government has launched several targeted screening programs aimed at these prevalent cancers [5-7]. These initiatives strive not only to increase public awareness but also to improve access to screening services across the population [8]. To enhance the effectiveness of these programs, innovative technologies, such as artificial intelligence, machine learning, digital health platforms, mobile screening units, and cost-effective diagnostic methods, are being integrated into the screening process [9-11]. In addition, novel biomarkers specifically tailored to the Indian demographic are being explored to improve accuracy and facilitate early cancer detection. These efforts are being implemented through collaborative models involving central and state governments, nonprofit organizations, and private health care providers.

Cancer data are sourced from various platforms, such as screening systems, electronic health records, laboratory systems, imaging systems, and cancer registries. The lack of uniform data formats and protocols across these federated platforms results in incompatible data that are challenging to integrate, leading to delays in integration [12]. Incomplete data integration limits the effectiveness of clinical decision support systems, which rely on comprehensive data to provide actionable insights. Addressing these data interoperability issues requires concerted efforts [13,14]. Implementing standardized formats and protocols can greatly enhance the quality and efficiency of cancer screening, diagnosis, and treatment globally. The World Economic Forum (WEF), through the Center for the Fourth Industrial Revolution in India, has designed the Fourth Industrial Revolution for Sustainable Transformation (FIRST) in the health care sector. This strategy seeks to align all the stakeholders in the health care ecosystem and address critical challenges across 18 themes along 3 streams: prevention and early detection, curative care, and governance by using Fourth Industrial Revolution technologies. Cancer is the first theme that the FIRST Health portfolio will address, and the initiative has been named FIRST Cancer Care (FCC). The need for the development of an oncology data model (ODM) for interoperability and integration among screening applications, cancer health systems, diagnostic systems, cancer registries, and reporting platforms has emerged from the FCC report published by WEF [15].

The Fast Healthcare Interoperability Resources (FHIR) standard, developed by Health Level 7 (HL7) International, aims to standardize the representation and exchange of health care information [16]. FHIR's compatibility with multiple data formats facilitates its implementation in diverse technological contexts. Using a flexible and robust framework such as FHIR in cancer data modeling aligns with the global and national efforts to harmonize health care data and improve clinical outcomes [17,18]. FHIR has been used in electronic health record data exchange, cancer survivor data sharing, and cancer clinical trials in multiple studies [19-22]. One notable initiative in oncology using the FHIR standard is the Minimal Common Oncology Data Elements (mCODE) to develop and maintain standard computable oncology data formats. mCODE is developed by HL7 Accelerator CodeX, a collaborative community that uses the FHIR standard to accelerate cancer data interoperability. However, mCODE only focuses on observations, conditions, status, stages, body structures (tumor), and genomic report, primarily during and after cancer diagnosis, with more than 37 profiles [23].

The Ministry of Health and Family Welfare, India, has adopted FHIR R4 as a base standard for data exchange under its Ayushman Bharat Digital Mission (ABDM), in which health systems connect through the ABDM Health Information Exchange for sharing the patient's health records [14,24,25]. The FCC program pilot is implemented in the East Khasi Hills district of Meghalaya state in India. The FCC pilot project in Meghalaya concentrated on enhancing cancer screening awareness and conducting comprehensive screening in the East Khasi Hills district [26,27]. This focused approach aimed to bridge awareness gaps and ensure early detection and intervention at the community level. The execution of the project involved multiple project implementation partners working on a public-private cooperation model through a consortium, including the National Health Mission (NHM) Meghalaya as monitoring agency, Apollo Telemedicine Networking Foundation as field implementation and deployment, the National Programme for Prevention and Control of Non-Communicable Diseases as advisory, the WEF as coordination agency, and the Centre for Development of Advanced Computing as data model development agency. This paper particularly focuses on the design and development of the ODM, specifically oncology data modeling used for cancer screening using the FHIR framework [27-29]. ODM FHIR profiles and ValueSets were developed by adopting and mapping to existing ABDM profiles to support data interoperability and

XSL•FO
RenderX



ease integration with other health systems in the country. ODM is the central component for interoperability between various cancer care applications.

Methods

Overview

The ODM is defined by considering the patient journey in cancer detection and treatment in 5 key phases, as illustrated in Figure 1.

Figure 1. Patient journey.

Encounter

This is an initial phase involving the collection of patient information, including demographics, present conditions, medical history, family history, lifestyle, and test observations. Encounters may occur through screening programs, routine checkups, or incidental findings.

Risk Assessment

Risk assessment is performed based on the data collected during an encounter to classify the patient's cancer risk as low, medium, or high. This step guides further investigation and care.

Clinical Investigation

Clinical investigation includes diagnostic examinations, clinical tests, and investigations aimed at confirming a cancer diagnosis. Data generated in this phase may be fragmented due to the complex nature of cancer care. For unconfirmed diagnoses, follow-up with routine monitoring is advised. A confirmed diagnosis moves the patient to treatment planning.

Treatment

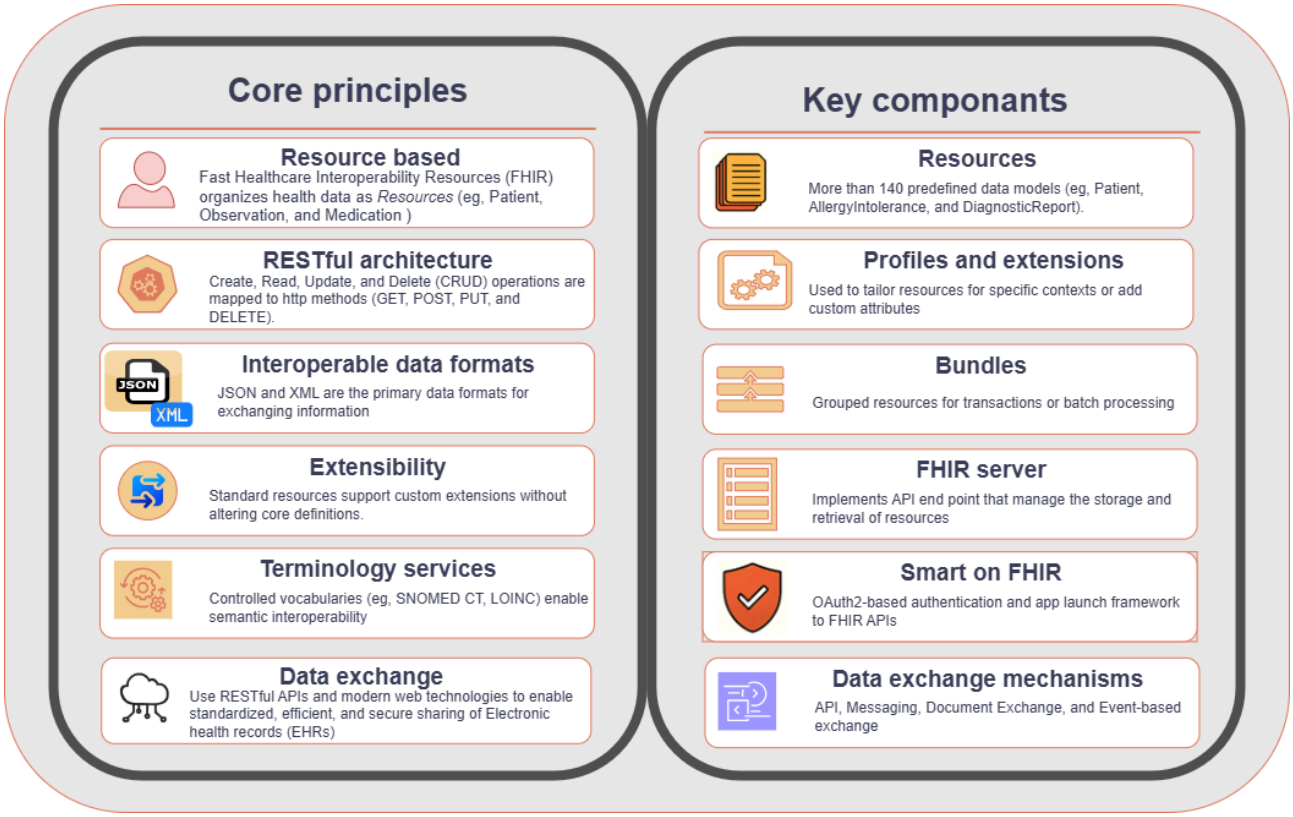
Upon confirmation of cancer, a tailored treatment plan is developed based on the diagnosis. Treatment options include chemotherapy, hormone therapy, radiotherapy, surgery, immunotherapy, and follow-up care. These options are determined by factors such as disease stage, individual health, and specific cancer characteristics.

Outcome

The outcomes are assessed after the treatment. Possible outcomes include being alive without disease, alive with disease, deceased due to cancer, deceased due to another cause, or unknown status.

This structured journey emphasizes continuous data capture and a multidisciplinary approach to ensure comprehensive care for patients with cancer.

FHIR Overview



FHIR is a modern health data exchange framework developed by HL7 International to enhance health care data interoperability. It adopts contemporary web technologies, particularly RESTful interfaces [30]. RESTful interfaces, also known as RESTful application programming interfaces (APIs), are a type of API that adheres to the architectural style of Representational State Transfer. The FHIR framework is structured around the modular components that represent various health care entities such as patients, medications, conditions, and observations, called *resources*, making it both human readable and implementable [31]. Its modular design is instrumental in managing complex datasets, such as datasets used in cancer research and treatment, including screening, genetic information, clinical trials, and treatment histories [32,33]. The normative status of FHIR R4 has enabled its use in many national health programs and health systems [19]. FHIR also enables customizing and extending the resources for a particular use case. These customizations are called profiles and extensions. A profile specifies additional rules and constraints on a base FHIR resource, such as making certain data elements mandatory, defining specific data types, or restricting allowed values for a field [34]. This framework aims to simplify data exchange and improve the usability of health care information systems through various exchange mechanisms and bundling

XSL•FO
RenderX

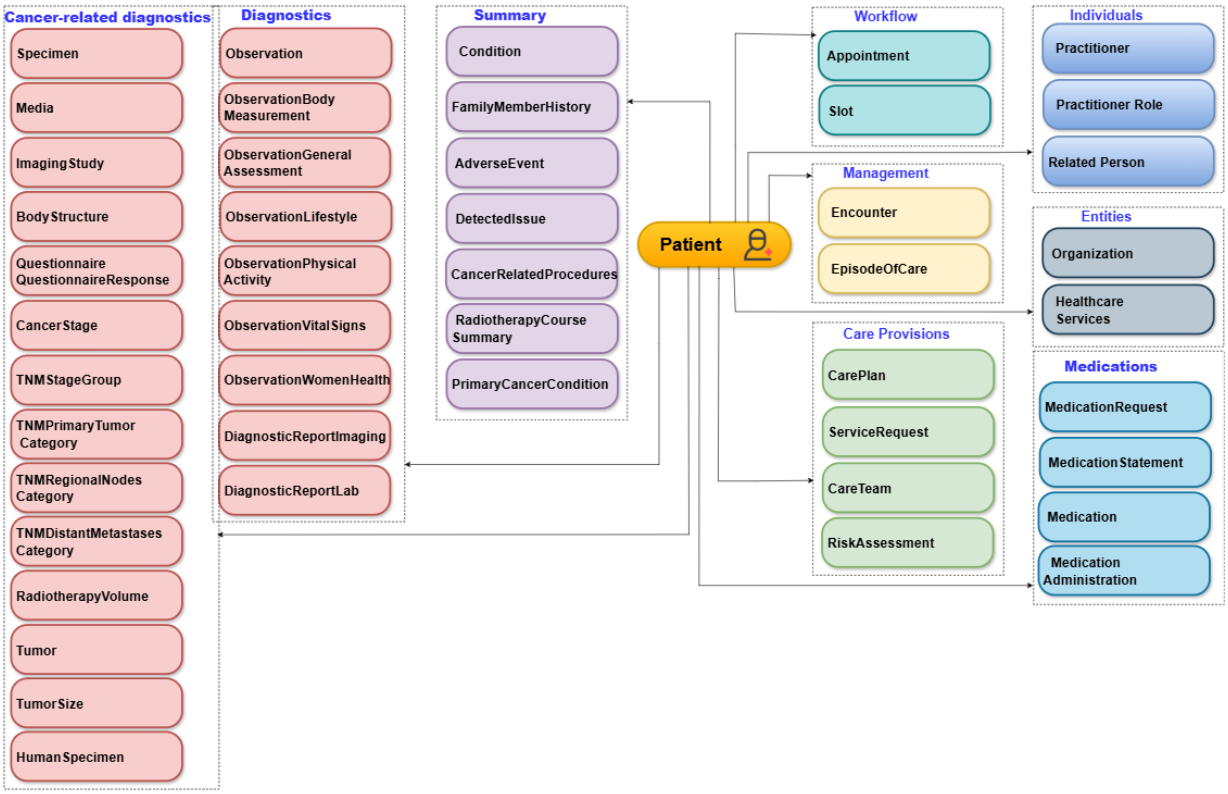
methods. Figure 2 shows the core principles, components, and data exchange mechanisms supported by the framework.

The FHIR standard provides a framework for the seamless exchange of health care information electronically using modern web technologies, such as RESTful APIs and multiple data formats, including JSON, XML, and RDF. This standardized approach enables interoperability between health care systems for data sharing across platforms and devices. The core strength of FHIR lies in its fundamental building blocks—resources. Each resource is an entity that represents a specific type of health data. These modular units are designed for clarity and ease of data handling, enabling developers to create applications that seamlessly exchange and use these data [35]. For instance, patient demographics are recorded in the Patient resource, medical observations in the Observation resource, and family history in the FamilyMemberHistory resource.

Figure 2. Fast Healthcare Interoperability Resources (FHIR) technical overview. API: application programming interface; CRUD: basic operations performed on the data: create, read, update, and delete; EHR: electronic health record; LOINC: Logical Observation Identifiers Names and Codes; OAuth2: open authorization protocol version 2.0; SNOMED CT: Systematized Nomenclature of Medicine–Clinical Terms.

Development of Standard ODM

The lack of standardization in health care data leads to various organizations using diverse formats and systems for data collection and storage. This diversity can create challenges in sharing and integrating data across institutions, which may affect effective communication, collaboration, and the overall quality of patient care. A unified data model offers a compelling solution to this challenge. To tackle these challenges, leveraging emerging technologies is essential.



The FCC report, developed by stakeholders from various sectors, outlines a strategy for transforming cancer care. The Meg Can Care—Meghalaya Cancer Care program, the first of its kind state initiative in India, aims to enhance detection and treatment adherence using emerging technologies through public-private cooperation. These technologies, including smart screening devices, screening applications, and electronic medical records and hospital management information system solutions, must interoperate with each other for data exchange and continued patient care. By establishing standardized data capture processes, such a model would ensure consistency and compatibility across institutions. This, in turn, would facilitate seamless data sharing, leading to several key benefits. Enhanced communication and collaboration among health care providers would lead to more informed decision-making and, ultimately, better patient care. Standardized data would enable researchers to conduct large-scale studies more efficiently, leading to advancements in cancer prevention, diagnosis, and treatment. A unified data model would foster a more collaborative approach to cancer management across various health care providers, facilitating a more comprehensive approach to prevention, diagnosis, and treatment. The implementation of a standardized data model would extend beyond streamlining data exchange. Capturing data through targeted questions during cancer screenings provides a wealth of critical insights into various patient aspects, including demographics, present medical conditions, lifestyle choices, and family history. These details can be structured using specific FHIR resources, facilitating standardized data capture.

Figure 3 provides an overview of various classes referred to in the ODM. Different resources are used to create profiles for cancer-specific data throughout the phases of a patient's cancer

XSL•FO
RenderX

journey. Generic resource classes, such as patient, condition, medication, and outpatient department note, are directly derived as is or with additional customizations to accommodate cancer-specific data from ABDM.

Figure 3. Oncology data model.

FHIR Profiles for ODM

Overview

The ODM aims to capture, represent, and exchange oncology-related data in a consistent format across health care systems. To achieve syntactic as well as semantic interoperability, ODM development involved 4 stages: data modeling, FHIR profiles development, terminology mapping, and FHIR implementation guide (IG) development.

Data Modeling

This foundational stage involves identifying the essential oncology data elements, data structures, and use cases and modeling these data structures in alignment with FHIR's resource-based framework. It also entails identifying the basic resources and requirements of advanced or derivative resources for cancer-related data. A thorough analysis of clinical workflows and data sources in oncology care helped identify the essential data elements and their relationships. The selection of data elements occurred through a systematic and iterative process. This involved an in-depth review and analysis of Apollo Telemedicine Networking Foundation Cancer Screening and National Programme for Prevention and Control of Non-Communicable Diseases applications (mobile or tablet and portal) [28,36], community-based assessment checklist forms [37], and noncommunicable disease operational guidelines [38], followed by the preparation of the comprehensive reference documents.

FHIR Profile Development

Once core resources are identified, FHIR profiles are developed to tailor these resources to oncology-specific needs. Profiles specialize existing resources to capture additional data elements that are unique to oncology. For instance, a CancerDiagnosis profile might extend the *Condition* resource to capture specific details about cancer types and stages [39].

Terminology Mapping

Terminology mapping ensures semantic interoperability in oncology data. The data elements and value sets received from the existing state health programs and survey forms are mapped to standardized terminologies, including Systematized Nomenclature of Medicine–Clinical Terms (SNOMED CT), Logical Observation Identifiers Names and Codes (LOINC), and *International Classification of Diseases, 10th Revision*. A total of 50 standard terminology value sets were developed for precise data representation and mapped to the relevant codable data elements in FHIR resources. All the observation values were fully mapped with the terminology bindings [40].

FHIR IG Overview

The FHIR IG provides a detailed set of specifications and guidelines to address specific health care scenarios or use cases [41]. It ensures consistent implementation, interoperability, and compliance with established data-sharing frameworks. The FHIR IG is hosted in Meg Can Care for adoption and integration [42].

XSL•FO
RenderX

The FHIR IG and profiles for ODM are developed based on FHIR R4 and refer to ABDM profiles using the following tools:

- FHIR Shorthand (FSH) is a specially designed language for defining the content of the HL7 FHIR IG. It is designed to be simple and compact and, along with SUSHI Unshortens Short Hand Inputs (SUSHI), can be used to produce FHIR profiles, extensions, and IGs [43].
- SUSHI is an FSH compiler. SUSHI converts FSH language to FHIR artifacts. SUSHI can run in stand-alone mode or as part of the HL7 IG Publisher [44].
- FHIR Validator is a Java command-line tool to validate FHIR profile instances [45]. The definitions of the profiles were created based on the FHIR specification in FHIR (version R4 4.0.1).
- FHIR IG Publisher is a tool to generate, validate, and publish FHIR IGs. It produces a static website for the guide, which can be hosted on web servers [46].

Ethical Considerations

The research reported in this manuscript does not involve human participants or animal subjects; ethical approval was not applicable.

Results

A structured set of standardized FHIR profiles was developed to support the representation and exchange of oncology-related data, with a focus on enhancing syntactic and semantic interoperability across the cancer care continuum. The implementation effort culminated in the publication of a dedicated FHIR IG. The guide comprises 25 distinct resource profiles tailored to cancer screening, assessment, and treatment workflows. In addition to the resource profiles, a total of 50 standardized terminology value sets were curated to ensure consistency in data capture and coding. These value sets facilitated alignment with recognized terminologies and ontologies, supporting uniform interpretation and reuse of data across systems. This work aimed to minimize the use of extensions by reusing existing data elements from the base standard. However, based on the requirements, 7 extensions related to radiotherapy were developed and used in a controlled manner to ensure flexibility without compromising interoperability. Furthermore, to facilitate training and stakeholder engagement and promote adoption of the ODM, a demonstration application was developed. This application served as a practical tool to showcase the implementation of the FHIR profiles, enabling hands-on exploration and feedback from end users and decision-makers.

Key resources used in oncology data modeling were the FHIR Questionnaire and QuestionnaireResponse resources. Custom profiles were developed for both, reflecting the critical role of cancer screening in early detection and care coordination. These profiles were specifically designed to support the interoperable collection of structured oncology data from clinical environments and community-based digital health platforms. The Questionnaire profile includes 2 mandatory elements: the title and its intended purpose. The profile necessitates the inclusion of at least 1 item within the questionnaire. The data mapping process involves creating an instance of the questionnaire profile populated with actual information.

The cancer screening questionnaires included 21 questions for breast cancer, 20 questions for cervical cancer, 18 questions for esophageal cancer, 20 questions for lung cancer, and 19 questions for oral cancer. These questions were collated from stakeholder applications and validated by practitioners in NHM Meghalaya. Implementers can assign weights to the responses to define cancer risk, which can then support further treatment planning and analysis. On the basis of the Questionnaire profile, 5 separate instances were created for all 5 types of cancers. These instances were developed based on inputs from the existing cancer programs in the state and through multiple stakeholder consultations, including oncology specialists at NHM Meghalaya. The instance of the Questionnaire resource with the standard question set to calculate the risk score for breast cancer is shown in Figure 4. A similar standard questionnaire set was created for cervical, esophageal, lung, and oral cancers.

Each question in the questionnaire is associated with the *LinkId* element to uniquely identify the question. The *Text* element stores the text of a question. The *Cardinality* defines whether the mentioned question must be answered or not, and *Type* shows the data type of the expected answer. The QuestionnaireResponse profile facilitates the capture of diverse answers, with the values in Boolean, numerical data, paragraph-length text entries, single-choice selections, and multiple-choice selections. Responses are stored within a designated QuestionnaireResponse profile instance. The LinkId element value assigned to each question enables the mapping between individual responses and their corresponding questions within the template. Figure 5 illustrates the QuestionnaireResponse Profile instance for breast cancer. Similarly, a few more data instances generated out of the ODM profiles are shown in Figure 6. Data captured from screening examinations for cancers served as the core input for risk assessments to evaluate the likelihood of cancer development. The FHIR RiskAssessment profile was adopted for the result representation. This profile covers patient information, condition, observations, diagnostic reports, documents from the ABDM FHIR profiles, and the *Prediction* element to capture the assessment's result. The prediction can be expressed either in textual form or via a standardized terminology code, such as SNOMED CT.

Technical validation focused on assessing syntactic correctness, conformance to FHIR specifications, and interoperability performance of the ODM. The validation process was carried out using the HL7 FHIR Validator and the HL7 Application Programming Interface–FHIR Java command-line tool for all 25 oncology-specific FHIR resource profiles and 50 value sets. All the resource instances passed syntactic validation against the ODM IG with a successful mapping of coded data elements to SNOMED CT; LOINC; or *International Classification of Diseases, 10th Revision* concepts, confirming strong semantic alignment. The clinical validation was designed to ensure clinical completeness, usability, and relevance of the data elements and screening workflows. The 5 cancer-specific screening questionnaires were reviewed by domain experts,

XSL•FO
RenderX

including oncologists, public health specialists, and field implementers from the Meghalaya Cancer Care Program. Stakeholder engagement and usability assessments were conducted using the demonstration tool to evaluate readiness for implementation within the FCC ecosystem.

Discussion

The larger scope of ODM is to establish a unified information model that integrates seamlessly with all cancer care applications, including screening, diagnosis, treatment, postoperative care, and the cancer registry. This integrated approach helps in enhancing the comprehensiveness and utility of the data for effective disease surveillance, policymaking, and research.

The profiles and the questionnaire template developed as part of the project have been developed, and efforts were undertaken to ensure the template is tailored to the specific demographic characteristics and needs. We have incorporated a mechanism for periodic revision and updates of the questionnaire template. This revision process is crucial for capturing accurate and detailed screening information, enabling the model to address changes in demographic profiles, emerging challenges, and evolving needs. Currently, the ODM is under review and in the integration stage, and it requires thorough consultation with domain experts as well as validation from all relevant stakeholders. To the best of our knowledge, this initiative represents the first comprehensive work in India to develop and implement an ODM for cancer screening and implement Questionnaire and Questionnaire Response resources using international standards, such as FHIR, SNOMED CT [47], LOINC [48], and TNM staging—a classification system for malignancy [49]. This positions the ODM as an early initiative in oncology informatics.

Development of ODM required a continuous harmonization among diverse stakeholders to ensure consensus on the essential oncology data elements. Despite encouraging validation outcomes, several challenges were identified during development and evaluation. FHIR standard literacy among the stakeholders was one of the key challenges, which was resolved through a series of internal workshops on the standard, FHIR resources, value sets, and use of the IG, and so on. Future adoption may also be constrained by limited familiarity with FHIR standards among health IT implementers. The current testing remains limited to simulated data instances. A real-world validation using live screening data in the next phase of the project will provide more insights and strengthen the ODM conformance. The existing electronic medical records and registries are not yet FHIR enabled and require bridging mechanisms for interoperability.

The ODM's (although originally developed for the Meg Can Care project) use of international standards facilitates its adoption by implementers globally. National-level adoption can be beneficial to address the challenges of data collection and coding [50]. However, such a larger adoption requires harmonization of these datasets to standardized terminologies. In addition, national-level adoption requires a live implementation showcase at the district and state levels, central endorsement, and inclusion under the ABDM framework for its scalability and consistent data sharing across screening programs, hospitals, and registries. The ODM offers a framework for integrating cancer screening programs, cancer hospitals, and cancer registries into an interoperable cancer network. By leveraging FHIR's RESTful APIs, the model can support efficient data exchange and seamless integration with health care systems. Future work shall focus on real-world deployment and model evaluation in multiple districts; expansion to treatment and survivorship data; and national adoption to inform cancer policy, research, and precision oncology efforts. This expansion would offer broader benefits to researchers and the cancer care community. While similar models exist in regions such as mCODE, a globally harmonized

XSL•FO
RenderX

framework could address oncology data requirements across diverse health care systems, fostering international collaboration and advancing cancer research and care worldwide.

Acknowledgments

This work was carried out under the Meghalaya Cancer Care project funded by the National Health Mission, Meghalaya, India. The authors additionally acknowledge that JMIR Publications provided article processing fee (APF) support for the publication of this work. The authors would like to acknowledge Gaur Sunder, scientist F, HPC-Medical and Bioinformatics Applications Group, for his continuous support and guidance and thank the institution for the opportunity to contribute to this body of knowledge. The authors would also like to acknowledge J Satyanarayana, chief advisor, the Center for the Fourth Industrial Revolution India, World Economic Forum, for his valuable inputs during the development of the oncology data model.

Abstract

Background: Breast cancer is the most common cancer among women and a leading cause of mortality in Europe. Early detection through screening reduces mortality, yet participation in mammography-based programs remains suboptimal due to discomfort, radiation exposure, and accessibility issues. Thermography, particularly when driven by artificial intelligence (AI), is being explored as a noninvasive, radiation-free alternative. However, its acceptance, reliability, and impact on the screening experience remain underexplored.

Objective: This study aimed to explore women's perceptions of AI-enhanced thermography (ThermoBreast) as an alternative to mammography. It aims to identify barriers and motivators related to breast cancer screening and assess how ThermoBreast might improve the screening experience.

Methods: A mixed methods approach was adopted, combining an online survey with follow-up focus groups. The survey captured women's knowledge, attitudes, and experiences related to breast cancer screening and was used to recruit participants for qualitative exploration. After the focus groups, the survey was relaunched to include additional respondents. Quantitative data were analyzed using SPSS (IBM Corp), and qualitative data were analyzed in MAXQDA (VERBI software). Findings from both strands were synthesized to redesign the breast cancer screening journey.

Results: A total of 228 valid survey responses were analyzed. Of 228, 154 women (68%) had previously undergone mammography, while 74 (32%) had not. The most reported motivators were belief in prevention (69/154, 45%), invitations from screening programs (68/154, 44%), and doctor recommendations (45/154, 29%). Among nonscreeners, key barriers included no recommendation from a doctor (39/74, 53%), absence of symptoms (27/74, 36%), and perceived age ineligibility (17/74, 23%). Pain, long appointment waits, and fear of radiation were also mentioned. In total, 18 women (mean age 45.3 years, SD 13.6) participated in 6 focus groups. Participants emphasized the importance of respectful and empathetic interactions with medical staff, clear communication, and emotional comfort—factors they perceived as more influential than the screening technology itself. ThermoBreast was positively received for being contactless, radiation-free, and potentially more comfortable. Participants described it as "less traumatic," "easier," and "a game changer." However, concerns were raised regarding its novelty, lack of clinical validation, and data privacy. Some participants expressed the need for human oversight in AI-supported procedures and requested more information on how AI is used. Based on these insights, an updated screening journey was developed, highlighting improvements in preparation, appointment booking, privacy, and communication of results.

Conclusions: While AI-driven thermography shows promise as a noninvasive, user-friendly alternative to mammography, its adoption depends on trust, clinical validation, and effective communication from health care professionals. It may expand screening access for populations underserved by mammography, such as younger and immobile women, but does not eliminate all participation barriers. Long-term studies and direct comparisons between mammography and thermography are needed to assess diagnostic accuracy, patient experience, and their impact on screening participation and outcomes.

Introduction

Background

Breast cancer remains the most common type of cancer and the leading cause of death among European women [1]. In 2022, it was responsible for nearly one-third of all new cancer cases among women in 27 European countries [2]. Early cancer detection through screening is a key part of a cancer prevention strategy [3]. Screening programs are therefore developed to establish guidelines prioritizing who should be invited based on age and risk factors [4]. These guidelines consider cost-effectiveness and balance the trade-off between the harms of overdiagnosis and the reduction of mortality due to early detection [5].

Despite free access to cancer screening programs in many European countries, this offer is not taken up by all women among the target population [6]. The decision to attend screening is influenced by a mix of habitual, practical, and emotional factors, including past health care experiences, logistical barriers, and fear of pain or radiation [7]. Awareness, trust in health care professionals, and social support are important motivators, while lack of information, low perceived risk, and discomfort serve as common barriers [8-10].

Concerns about discomfort and radiation exposure associated with mammography are one of the major barriers [11], leading to an ongoing search for alternative screening technologies. This study explores the potential of thermography as a new screening method by examining the barriers in current breast cancer screening, gathering women's perceptions of thermography, and identifying ways to improve the screening journey to encourage higher participation.

Current Screening Techniques and Their Limitations

Several breast cancer methods are currently available. The most commonly used is mammography, with digital breast tomosynthesis (DBT) emerging as a new diagnostic tool [12]. Second, breast ultrasound has also progressed beyond its initial role in differentiating cysts versus solid masses [13]. Third, breast magnetic resonance imaging (MRI) is the standard supplemental screening tool available for both high and intermediate-risk women [14].

Each of these techniques presents advantages and comes with some limitations. Ultrasound is commonly used as a supplemental screening technique for women with dense breasts in whom mammography has a lower sensitivity. However, ultrasound has been criticized for its relatively low specificity, leading to many recalls and biopsies for benign lesions [15]. Breast MRI offers the highest sensitivity for detecting occult cancer, regardless of breast density [14]. Nevertheless, high costs and the limited tolerability and availability of MRI scanners make population-wide screening difficult [16]. Mammography, despite its proven accuracy in detecting early-stage cancers, presents challenges such as radiation exposure, discomfort, and reduced effectiveness in women with dense breast tissue [17-19].

Thermography as an Emerging Alternative

Given the limitations of conventional screening methods, researchers have explored alternative technologies, such as thermography. Thermography is a noninvasive imaging technique that detects heat patterns and blood flow abnormalities, which may indicate malignancy [20]. Unlike mammography, it does not involve radiation exposure or physical compression of the breast, making it a potentially more comfortable and accessible option for screening [17,18,21,22]. Nonetheless, its effectiveness in early-stage cancer detection remains debated due to lower specificity and higher false-positive rates, making it as yet unsuitable to fully replace mammography for early cancer detection [18,19,23].

Advancements in artificial intelligence (AI) have significantly improved thermography's diagnostic potential [24]. AI algorithms can enhance image analysis, detect subtle thermal abnormalities, and improve sensitivity [21-23,25]. Recent studies have shown promising results, suggesting that AI-driven thermography could complement mammography in screening programs [22,23,25]. However, further research is needed to validate its clinical applicability and reliability [18,21,23]. Given the persistent barriers associated with current screening methods and the emerging promise of AI-enhanced thermography, it is essential to understand how potential users perceive this technology. Exploring these perceptions can offer insights into how new screening options may better meet women's needs and expectations.

Goal of the Study and Contribution

This study aims to explore potential gaps in the current screening journey, from the decision to undergo screening through the procedure itself to receiving results, by listening to women's perspectives. In doing so, we aim to identify key barriers, improve the user experience, and assess whether AI-driven thermography can serve as a more accessible and less intimidating alternative.

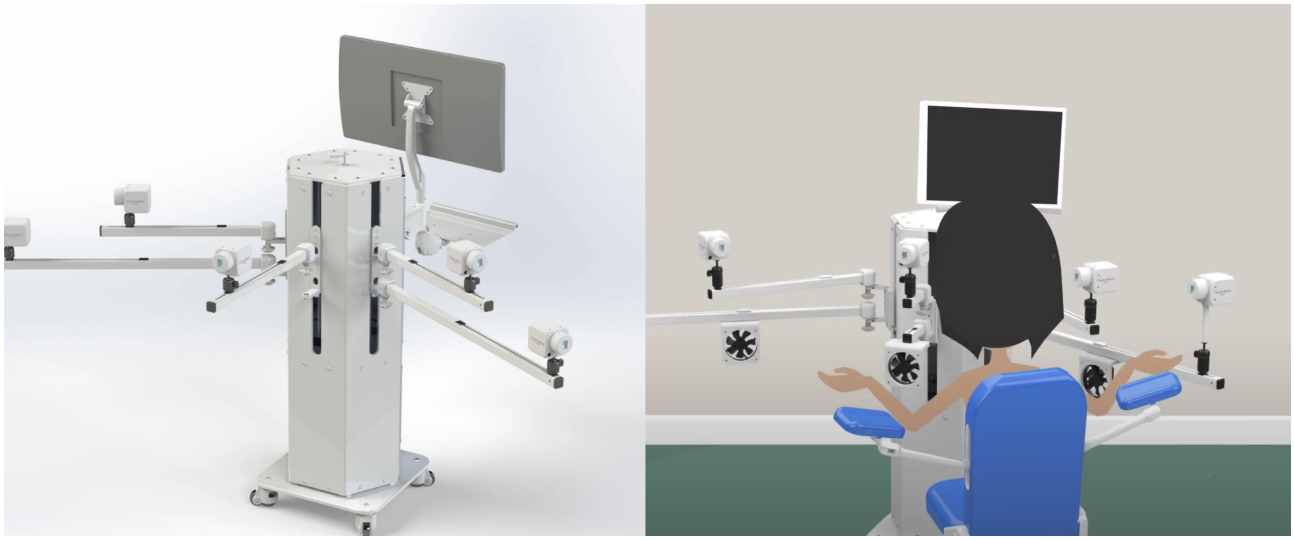
Several studies have explored the experiences of women in breast cancer screening. For example, Ciria-Suarez et al [26] have mapped the breast cancer patient journey, highlighting areas where patient experience can be improved. Other studies, such as those by MacKinnon et al [27] and Foerster et al [28] have examined disparities in access to screening and the psychological factors influencing participation. In addition, Kim et al [29] have explored how cultural and linguistic factors influence screening participation among Korean women in Australia, demonstrating that specific barriers exist for different population groups. This focus on minorities can also be found in Racine and Andsoy's study [30]. While these studies provide valuable insights, they primarily focus on the broader health care journey and mammography experiences.

Our study differs by specifically examining the user experience of AI-driven thermography. While previous research on thermography has concentrated on technical aspects and diagnostic accuracy [17], our work focuses on screeners' perceptions, trust, and acceptance of this novel screening method. By incorporating feedback on the ThermoBreast procedure, we aim to understand how this approach could

XSL•FO
RenderX

address barriers associated with traditional mammography and improve breast cancer screening accessibility.

Methods



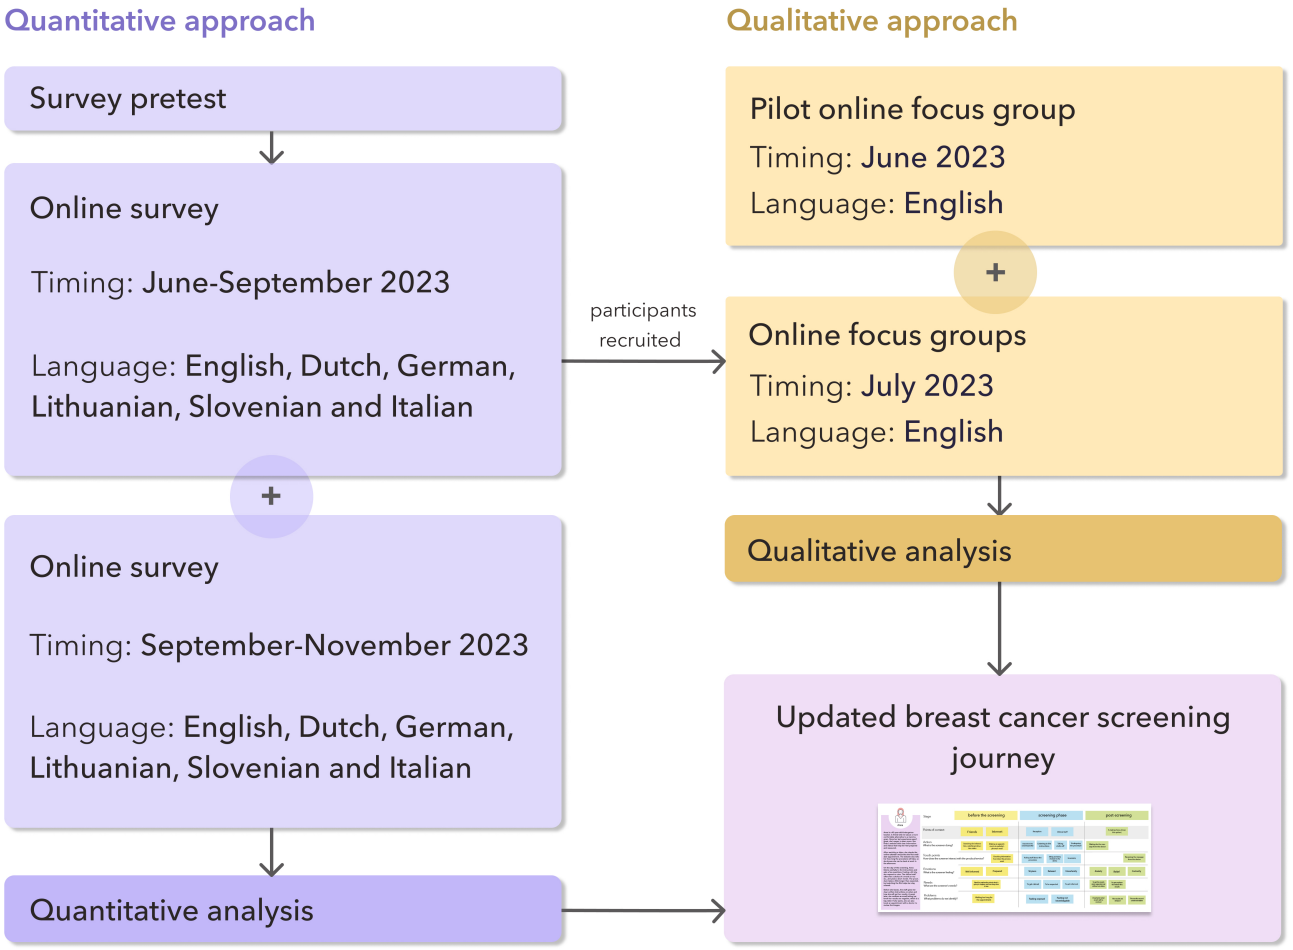
Study Context: ThermoBreast Project

This study was conducted as part of the EU-funded ThermoBreast project, which aims to develop an advanced thermography device as a more comfortable, accessible, and potentially equally precise alternative to mammography [31]. At the start of the project, an animated video [32] was created to illustrate the ThermoBreast procedure. This visual aid was used to explore women's screening preferences and to inform strategies for increasing participation in breast cancer screening programs.

The AI-based thermography system (Figure 1) featured in the video was still in preparation for clinical trials at the time of the study and had not yet been approved. It combines medical thermography, using highly sensitive infrared cameras capable of detecting temperature differences as small as 0.02°C, with an AI model that analyzes dynamic thermal patterns to detect vascular abnormalities associated with malignancy [31].

During the procedure, the participant sits in a chair with armrests and opens their arms while cameras scan the chest and underarm regions. The process is entirely contact-free and takes approximately 12 minutes. Due to its noninvasive and inclusive design, which does not impose age or breast size restrictions, the technology has the potential to address key limitations of mammography, especially for individuals for whom the procedure is not recommended or who view it negatively.

Figure 1. ThermoBreast screening device as shown in the animated video.



Study Design and Overview

To gain both broad insights into and in-depth feedback on the ThermoBreast procedure, we adopted a mixed method approach combining an online survey with follow-up focus groups. The survey served a dual purpose: collecting initial quantitative data and recruiting participants for the focus groups. After the focus groups were completed, the survey was relaunched to gather additional responses from new participants. The study timeline is presented in Figure 2. Insights from both methods were used to update and visually map the breast cancer screening journey.

XSL•FO
RenderX

Figure 2. Study design overview.

Eligibility Criteria

To participate in the survey, respondents had to be female, at least 18 years old, and understand one of the following languages: English, Dutch, German, Lithuanian, Slovenian, or Italian. For the focus groups, participants were required to understand English to enable cross-European participation and ensure a diversity of perspectives.

Questionnaire Development

The questionnaire was developed by authors [KSK and AJ] based on previous studies [8,9,33] and consisted of 24 items. It addressed attitudes, awareness, and knowledge [8,9]; the role of social networks and health care providers [9]; personal and sociocultural factors; and cues to action [33] that influence motivators and barriers to mammography. Sociodemographic questions were also included. To ensure relevance, the questions were discussed in detail with a project partner from a cancer organization (co-author [AC]). The final version was reviewed by other project partners, including medical professionals, who also contributed to the translation process.

The questionnaire included multiple-choice items, open-ended questions, and items rated on a 5-point Likert scale (refer to Multimedia Appendix 1 for the full list of questions). It was pretested internally for timing, clarity, and technical functionality by several project partners and imec-SMIT researchers who were not involved in its development. Based on their feedback, minor adjustments were made. The final version took approximately 10 minutes to complete.

The original questionnaire was developed in English and translated into Dutch, German, Lithuanian, Slovenian, and Italian by project partners. The selected languages reflect the countries represented in the project consortium and the partners' ability to effectively distribute the survey within their local contexts.

Online Survey Recruitment

The survey was distributed through a social media post created by our project partner, Accelopment, which included a direct link to the Qualtrics survey (refer to Multimedia Appendix 2 for the message and post). It was shared across the ThermoBreast project's social media channels, including Facebook, WordPress, and LinkedIn, and was also reposted by project members and partners, such as accelopment and Cancer Patients Europe (CPE). In addition, the link was circulated through an email campaign by CPE partners [AC and JJV] via their newsletter and network, and it was published on both the ThermoBreast and CPE websites.

Given these distribution channels—especially LinkedIn, the ThermoBreast website, and the CPE website—the sample likely skews towards individuals with higher education levels or interests in health-related topics. The CPE website, in particular, reaches out to cancer survivors and patients. Therefore, the

XSL•FO
RenderX

sample should be regarded as a convenience sample, influenced by the nature of these dissemination contexts.

Online Survey Data Collection

Data collection was carried out using the online platform Qualtrics (Silver Lake), which automatically recorded responses. Questions were adapted dynamically based on participants' indicated experience with breast cancer screening: some were shown only to women with previous experience, others only to those without. Participants were provided with the option to review and revise their responses using the Back button. The survey was open from 26 June to November 7, 2023. Preliminary results were analyzed in early September. After the focus groups held in July, the question about optional participation was removed. The survey was accessible without a password, and no direct contact with potential participants occurred beforehand. Participation required agreement to informed consent and compliance with eligibility criteria. Response completeness was monitored automatically by Qualtrics, and IP addresses were collected to identify the number of unique respondents.

Topic Guide Development

The semistructured topic guide (Multimedia Appendix 1) was developed by authors [KSK and AJ] in consultation with the CPE organization and informed by themes from previous literature [29,34] and the animated ThermoBreast video, to ensure all relevant screening-related topics were addressed. Topics included past screening experiences, first impressions of ThermoBreast, perceived comfort, the role of AI and trust in technology, and communication of results. The draft was reviewed with coauthor [AC] and pilot tested in a focus group with 7 female experts in human-computer interaction and digital health from Vrije Universiteit Brussel. This session, moderated by authors [KSK with AP] as note-taker, was used to evaluate group norms (eg, "raise hand" function), platform functionality, and question flow. Based on feedback from this session and feasibility considerations, minor refinements were integrated into the final guide.

Online Focus Groups Recruitment

At the end of the survey, participants could express interest in joining focus groups by providing their contact details and indicating a participation slot. These individuals were later invited via email by the researcher [KSK] by sending them a link to Microsoft Teams and an informed consent form. Experts participating in the pilot focus groups were recruited directly by researchers through their professional network.

Online Focus Group Data Collection

Focus groups were conducted online via Microsoft Teams, each lasting 60 minutes. Sessions were recorded with participants' previous written and verbal consent. A moderator [KSK or AP] led the discussion, while a note-taker [AP or KSK] documented key points.

Statistical Analysis

Descriptive statistics, including frequencies and cross-tabulations, were conducted. Reliability of scale-based questions was assessed using Cronbach α. *t* tests were performed for selected comparisons. All analyses were conducted by KSK using SPSS (version 29.0, IBM Corp). Open-ended responses were extracted, coded in Microsoft Excel, and integrated into the SPSS dataset by KSK. Responses from ineligible participants (eg, incomplete responses, "male" and "other" participants, try-out responses, etc) were excluded from the analysis.

Qualitative Data Analysis

Microsoft Teams auto-generated transcripts were reviewed and edited as needed by researchers [KSK and AP]. Although initially intended as a pilot, the expert focus group provided relevant thematic insights and was included in the final coding and analysis. All names were pseudonymized. Transcripts were coded in MAXQDA 2022 using open, axial, and selective coding [35] by 2 white female researchers [KSK and AP] of European origin. To ensure reflexivity, initial coding was performed independently, followed by discussions to align interpretations and finalize the coding scheme. Final themes were defined, named, and visualized to enhance transparency (Results section).

Revision of Breast Cancer Patient Journey

Themes, selected focus group quotes, and key survey insights were organized on a Miro board and restructured to reflect the stages of the breast cancer screening journey. This material informed the update of a reference journey map from [36], following journey mapping principles [37]. The outline was created in Miro board and finalized in Adobe Illustrator [KSK]. Several personas were drafted based on both qualitative and quantitative data by KSK and AP, and the one most closely aligned with the European screening target group (age 45 - 49 years) [38] was selected for the final visualization and detailed patient journey.

Ethical Considerations

Ethical approval (number 14320023000111) was obtained on June 22, 2023, from the Health Research Ethics Board of University Hospital Brussels (UZ Brussels). All participants received written informed consent forms detailing study purpose, procedures, duration, risks and benefits, right to withdraw, and privacy safeguards. Survey participation required agreement via an "I understand and agree" button. Data were anonymized via the encrypted Qualtrics platform. Email addresses collected for focus group invitations were stored separately and deleted from Microsoft SharePoint after study completion.

Informed consent forms for focus groups were sent to participants by email and returned signed. Sessions were recorded with previous permission and transcribed using Microsoft Teams. Transcripts were checked and corrected against the recordings [KSK and AP], and names were pseudonymized (P=participant and E=expert). No monetary or nonmonetary compensation was provided for participation in either the survey or focus groups.

Results

Focus Group Results

Data Collection and Participants

The online focus groups explored participants' past breast screening experiences, motivations, and perceptions of thermography. The pilot consisted of 1 group with 7 women aged 25 - 48 years (mean 36.7, SD 7.8 years). Two women had experience with screening, and 5 participants were nonscreeners. Out of 101 survey respondents, 24 expressed interest in joining the focus groups and provided their contact information. All interested individuals were contacted; however, only 11 chose to participate. The online focus groups with potential screeners contained data of 11 women aged 25 - 66 years (mean 50.7, SD 13.8 years) who participated in 5 different groups. For more details of the participants, please consult Table 1 below.

Table . List of participants in the online focus groups.

Focus group and participant	Nationality	Age (y)	Breast cancer screening or test experience
Pilot			
E1[a]	Dutch	32	None, but breast cancer in the family
E2	Brazilian	33	Clinical examination; mammography experience heard from her mother
E3	Belgian	48	MRI[b], mammography, ultrasound
E4	Dutch	25	None; experience heard from the family
E5	Dutch	37	None
E6	Belgian	45	None
E7	Belgian	37	None, but breast cancer in the family
1			
P1[c]	Belgian	57	Regular mammography screener, breast cancer in the family
P2	Dutch	49	BC[d] patient; various screening experiences: mammography, ultrasound, tomosynthesis, MRI
2			
P3	US	63	MRI, mammography
3			
P4	Montenegrin	25	*BRCA* gene; ultrasound, MRI
P5	UK	49	BC patient; mammography, MRI, ultrasound
4			
P6	N/A	54	*BRCA* gene; mammography, MRI, ultrasound
P7	Spanish	25	Clinical examination
P8	Dutch	55	*BRCA* gene; mammography
5			
P9	N/A	62	Mammography
P10	Spanish	66	History of BC; regular screener
P11	Irish	53	Mammography

Themes

The coding process resulted in 5 main categories: past experience with screening, before the screening, the screening process, the postscreening phase, and thermography feedback. The past experience category explores women's previous experiences with any type of screening. The screening journey category focuses on factors that could be improved in screening with thermography, based on the video shown and experiences from different breast cancer screening methods. The final category examines opinions on the concept of thermography technology and the use of AI. Refer to Figure 3 for an overview of the coding scheme.

Figure 3. Coding scheme based on the focus groups data.

Past Experience With Screening

Most of the participants did have experience with some kind of screening or a breast-cancer test procedure (such as mammography, MRI, ultrasound, and tomography). Some participants (P2, P5, P6, P9, and P11) shared problems with discomfort and pain during the mammography, described as: "squeezing," "smashing," and "panini experience." A few participants also mentioned their concerns about using x-rays and their willingness to understand why this is needed. More discomfort and "traumatic experience" were assigned to MRI, which was mentioned by 4 participants (E3, P2, P4, and P5). On the other hand, ultrasound was described several times as the most comfortable method. Overall, almost all participants were positive about the idea of screening and found it important.

Before the Screening Phase

Participants' motivations for screening included: a family history of breast cancer or genetic predisposition (P1, P4, P8, E1, and E7), feeling of responsibility ("something I am supposed to do"; P1 and P3). Current patients of breast cancer (P2 and P5) mentioned that once they went through all the screenings, they got used to it and no longer gave it any thought.

Regarding barriers, participants mentioned: not experiencing any problems (P3), not being old enough for mammography (P4), or concerns that their breast size (both too big or too small) would not be ideal for screening (P1). Several participants (P2 and P10) pointed out the long waiting time for the screening appointment. For example, P2: "… So, I felt something about a year ago and then it took six months before I could get a screening."

The Screening Process

Interaction With Clinical Staff

Interaction with staff (technicians who perform the examination, doctors) emerged as a prominent topic of discussion and was perceived as a potential barrier to screening. Most of the participants emphasized the importance of good communication and sufficient explanation, as many of the participants liked the detailed explanation of the procedure in the video. Notably, some participants (P3 and P5) indicated that the quality of interaction and how well they were treated by medical staff is more important for them than the process of screening or test itself.

Participants across multiple focus groups (FG2, FG3, FG4, and FG5) attributed ideal qualities to clinical staff, including being friendly, kind, nice, empathetic, helpful, respectful, and positive. They emphasized the importance of being able to ask questions and get full, comprehensible information. The guidance and explanation before and during the procedure were also positively perceived.

Additional factors that could influence their interaction and level of comfort and trust during screening were the duration of their relationship with the doctor or clinical staff (P3, P5), the gender of the doctor or clinician (P4), and the doctor's or clinical staff's level of experience (P3). In addition, the inconsistency in seeing the same practitioner was noted as a potential factor affecting trust (P5).

Environment

Many participants (E3, P1, P2, P3, P4, P5, and P9) welcomed the idea of possible adjustments according to their needs, such as choice of music or podcast during procedure (P1, P4, and P5), choice of (informative) movie or short film playing on the screen (P2, P3, and P9), possibility to turn the lights on or off (E1) or having the option to wear an additional robe so as to feel less exposed (E1 and E6).

Participant E6 highlighted the importance of inclusivity, suggesting that focus and distraction methods should be adjusted to the individual's needs. Furthermore, E6 recommended creating a less clinical atmosphere, advocating for a spa-like experience with sauna robes for increased comfort.

However, some participants (E6 and E5) expressed concerns that offering too many options might be overwhelming or trigger feelings of shyness during the procedure. Participants with previous screening experience, like P1 and P2, indicated they

XSL•FO
RenderX

did not require extra care and prioritized efficiency over additional amenities.

Regarding exposure and privacy during the screening, some participants (P2, P4, and E6) were comfortable with nudity during the procedure, while others viewed it as a sensitive issue. Suggestions to maintain dignity included providing additional robes, curtains, or private rooms without interruptions from other staff.

Explanation

Most participants emphasized the importance of understanding the procedure's steps and being informed about what occurs during the screening. They stressed the need to comprehend both the process beforehand and the ongoing events while undergoing the procedure. P7 specifically highlighted the significance of using clear and simple language during explanations. Participants 9 and 3 also stressed the value of enabling screeners to ask questions regarding the procedure and ensuring they receive satisfactory responses.

Time Issues

Some participants (P3 and P6) highlighted the importance of minimizing the duration of the procedure. They suggested that patients should be informed about the estimated length of the screening or any potential delays. For instance, participant P6 expressed frustration with the long time it took to receive the results. Participant P2 also pointed out that shorter procedures help alleviate discomfort.

Postscreening Phase

Receiving Results

Preferences for receiving results varied, with some favoring a phone call for positive test results (by positive test result, we mean that cancer was found; P8 and P10), while others preferred email or text message for negative results (P8, P6, and P10). However, the consistency of the communication channel was deemed more crucial (P4 and P5), with a pre-agreed approach followed by doctors when conveying results to reduce stress.

Participants P2, P3, P10, and P11 highlighted the importance of face-to-face explanation and interpretation of results by experts. In addition, P1 and P2 suggested receiving a written summary of the results from the doctor during the meeting, facilitating retention of important information: "It would be nice to get some text you can remember afterwards... so you can tell your family" (P1).

Perception of Thermography

Thermography Positives

In general, the first impression after viewing the video about AI-driven thermography was positive by all participants. They described the procedure as a good idea (P6 and P10), a game changer (P9), they liked the fact that the procedure is noninvasive, there is no breast manipulation, and it seems more comfortable (P2, P3, P4, P5, P8, P7, P9, P10, P11, E1, and E2) than the usual procedures they had already heard about. It was generally perceived as an "easier procedure" (P4 and P8), "better experience" (P11), and "less traumatic" (P4). Several participants (P1, P3, P6, P9, and E6) also mentioned the advantage of not using radiation.

Concerns About Thermography

Various concerns were raised in the focus groups regarding the new technology. One concern is its novelty, with participants expressing the need for clinical evidence to assess its effectiveness and reliability before fully trusting the procedure (P2, P3, P5, P8, P10, P11, and E6). Participants 2 and 3 also pointed out that the novelty of the machine can potentially affect other circumstances, such as the waiting time and the length of the procedure, for instance:

> *Indeed this is one of the concerns that I would have… Is this a very expensive machine? Meaning that the hospital would have only one… Meaning, you'd have a longer waiting list than the current methodology. Um… so this definitely would be a concern like, because it seems to be taking longer, you know…* [P2]

Some participants mentioned that being exposed in front of a camera could also be an issue for some women (P5, E1, E2, E3, E7, and E6). For example:

> *I mean I think any screening device, especially like MRI, is really scary when you first look at it …you know to have these like cameras and then these fans, it might be a little bit overwhelming for some people as well.* [P5]

Participants P2, P4, P5, E3, E5, E6, and E7 expressed a need for more information about data sharing, concretely what data are collected exactly and how is it processed and stored, for example:

> *Even though it's a heat sensor, it will be like a heat based picture of your [breasts]… So, I mean, I know it's for health-related reasons, but it's still a picture of your [breasts] even though it's not like a normal picture.* [E5]

Finally, many participants highlighted a cold temperature during the procedure as a possible problem (P1, P2, P5, P9, P10, P11, E4, and E7). As a possible solution, Participants 1 and 2 suggested showing a countdown of the cold air on the screen.

AI Perception

The use of AI was perceived rather neutrally (P4, P5, P9, and E5) to positively (P1, P2, P3, P6, P8, and P10); however, participants would like to have more information and explanations about how the AI in the thermography works (P2, P3, P4, and P11). Nevertheless, certain prerequisites for trusting thermography with AI were mentioned, such as training on a large data set (P2 and P8) and collaboration with a human expert; doctor (P2, P3, P5, P10, E1, and E4).

Survey Insights Into Mammography: Motivators and Barriers

To complement the qualitative insights focused on thermography, this section summarizes the main survey findings about mammography motivators and barriers. A total of 268 responses were collected. After applying the exclusion criteria described in the methodology, 40 responses were removed. The

XSL•FO
RenderX

final dataset used for analysis consisted of 228 eligible responses. The first part of the data (n=101) was analyzed in early September to produce preliminary results. The remaining responses (n=127) were added later, and the full dataset was analyzed together.

Screening Experience and Demographics

Participants (N=228) were divided based on their experience, screeners (154/228, 68%, mean age 53 years, SD 12) and nonscreeners (74/228, 33%, mean age 36 years, SD 9.7). Most of the participants were European and currently lived in Europe, in the city and had a university degree. For more details about the socioeconomic characteristics, refer to Table 2 and Multimedia Appendix 2.

XSL•FO
RenderX

Table . Socioeconomic characteristics in the online survey.

Socioeconomic characteristics of the sample (N=228)	Responses, n (%)
Origins (European)	
Italy	127 (55.7)
Ireland	27 (11.8)
Lithuania	15 (6.6)
Belgium	13 (5.7)

XSL•FO
RenderX

Awareness and Perceived Importance of Screening

Most women (146/228, 64%) were aware of available breast screening procedures near them. Nearly all participants (223/228, 98%) found breast screening important, which includes those who were not aware of their options. For more details, consult Multimedia Appendix 2.

Sources of Information on Breast Cancer Screening

The most frequent sources of information about breast cancer screening among women who were aware of their options were doctors (122/146, 84%), family and friends (63/146, 43%), and internet (56/146, 38%). For full details, refer to Multimedia Appendix 2.

Impact of Screening Invitations and Reminders

In total, 58% (132/228) of the participants had already received an invitation for breast cancer screening, and 88% of those who received the reminder (116/132) reported that it helped them to make an appointment for the screening, and most respondents (164/228, 72%) agreed that reminders would help them in the future to get a mammogram.

Motivators and Barriers Towards Mammography

Personal values, such as belief in breast cancer prevention, were the main motivators (69/154, 45%), followed by an invitation from a screening program (68/154, 44%), a doctor's recommendation (45/154, 29%) and family history of breast cancer (31/154, 20%; Table 3).

The most frequently chosen reason for nonscreeners was no recommendation from a doctor (39/74, 53%), no warning signals (27/74, 36%) or breast-related problems (21/74, 28%), and not a sufficient age for mammography (17/74, 23%). A total of 21 screeners out of 154 indicated the following barriers: pain during the procedure, the long wait for an appointment, radiation and invasiveness, fear of cancer, not sufficient evidence, high cost, and behavior of medical staff (Table 3). Most screeners did not indicate any physical issues that would prevent them from having mammography. Five respondents out of 154 mentioned specific obstacles, such as the size of their breasts and the inability to move their arm due to a frozen shoulder. Financial barriers were found to be insignificant factors in both groups, together with concerns related to language, cultural misunderstanding, and religious beliefs (consult Table A4 in the Multimedia Appendix 2 for more details). Regarding the procedure itself, mammography was perceived as less comfortable by people with actual experience (refer to Multimedia Appendix 2 for details).

Table . Survey results overview.

Motivators towards mammography (Screeners, n=154)	Responses, n (%)
What were the reasons for undergoing the mammography procedure? (multiple choice)	
I believe in breast cancer prevention	69 (44.8)
I got an invitation/reminder from a screening program	68 (44.2)
It was recommended by my doctor	45 (29.2)
I have/had breast cancer in the family	31 (20.1)
I had some warning signals	19 (12.3)
I have had a problem related to my breast before	13 (8.4)
I was advised to go from family members and/or friends	11 (7.1)
I had a positive experience in my last screening	5 (3.2)
My family members and/or friends go to the screening	5 (3.2)
Other (please specify)	8 (5.2)
Barriers towards mammography (Screeners, n=154)	
Was there anything that discouraged you from the mammography procedure?	
Yes	21 (13.6)
No	133 (86.4)
If yes, please specify what discouraged you? (Screeners, n=21; open question)	
Pain, discomfort	6 (29)
Long wait for the appointment, availability	5 (24)
Radiation	3 (14)
Fear	2 (10)
Not sufficient evidence	2 (10)
Too expensive	1 (5)
Behavior of medical staff	1 (5)
Other	1 (5)
Barriers towards mammography (Nonscreeners, n=74)	
What were the reasons why you did NOT undergo the mammography screening? (Nonscreeners, n=74)	
I did not get any recommendation from my doctor	39 (53)
I did not have any warning signals	27 (36)
I have not had any breast-related problem	21 (28)
I did not get any invitation/reminder	15 (20)
I do not have an overview if the screening is available for me	9 (12)
I was not advised to go from family members and/or friends	5 (7)
Mammography is painful	5 (7)
I do not have time for the mammography	3 (4)
I do not believe in breast cancer prevention	1 (1)
Mammography uses radiation	1 (1)
I do not know anyone with breast cancer	1 (1)
Other	22 (30)
Other reasons for not undergoing mammography (mentioned in the open questions, n=22)

No invitation	1 (5)

Updated Breast Cancer Screening Journey

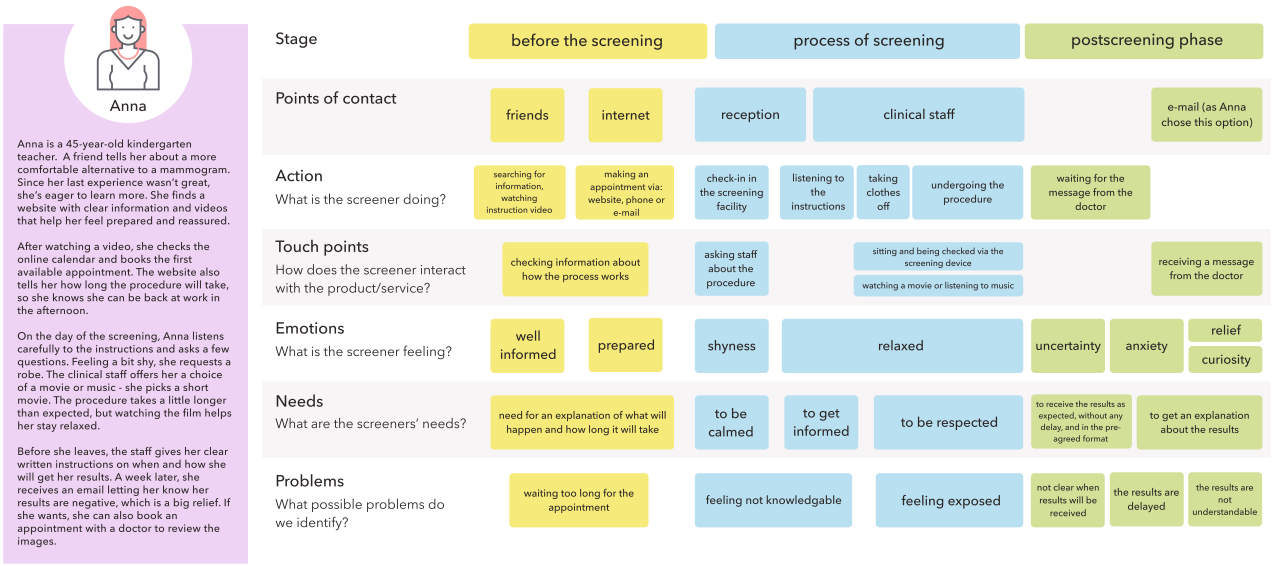
As described in the Methods section, survey and focus group insights were thematically mapped to the breast cancer screening journey using a collaborative Miro board. The updated journey reflects participant preferences and perceived barriers across the screening experience.

The revised journey is centered on a persona, a 45-year-old woman, reflecting the most commonly targeted age group for screening across European programs. Several key improvements were identified:

Before the screening

Participants emphasized the need for better preparation, including clear, accessible information on available screening options. Survey findings indicated that even women who valued screening often lacked awareness of what technologies were accessible to them. Flexibility in appointment scheduling was also considered important, with a preference for multiple booking channels such as online platforms, email, and phone.

Screening experience



Thematic analysis highlighted that empathetic interaction with clinical staff was a key factor influencing comfort and trust during the procedure. Participants valued being treated respectfully and receiving clear explanations throughout the process.

Postscreening phase

Receiving results in a preagreed format and timeframe was seen as essential. Focus group participants stressed the importance of structured communication, including both verbal and written explanations of results.

These user-informed insights were integrated into a revised screening journey visual (Figure 4), intended to guide future patient-centered improvements in breast cancer screening programs.

Figure 4. Proposed screening journey based on the insights from both qualitative and quantitative data.

Discussion

Principal Findings

This study explored women's perception of ThermoBreast technology and their previous experiences with mammography and other breast cancer tests. Our findings suggest that personal values and doctor recommendations strongly influence participation, while discomfort, waiting times, and lack of awareness act as major barriers. Young age was also identified as a barrier, for which thermography could be a potential solution. In addition, while AI-driven thermography was perceived as a promising alternative, concerns about its novelty, accessibility, and reliability were raised. How the screener is treated during the procedure showed to be more important than the technology itself or physical discomfort that screening can bring. Collected insights were brought together to improve current breast cancer screening journeys and inspire future screening programs.

XSL•FO
RenderX

Comparison With Previous Studies

Studies have consistently shown that discomfort is a major deterrent for mammography screening [17-19]. Although this was not prevalent in the survey results, women in the focus groups mentioned experiencing discomfort during the procedure as an important deterrent. Interestingly, our survey results indicate that women who had not yet undergone mammography perceived the procedure as more comfortable compared with those who had already experienced it. However, no significant difference was found.

Beyond physical discomfort, trust in health care providers plays a crucial role in screening participation. Similar to our findings, research by [10] has identified trust in health care providers as a crucial determinant of screening uptake, alongside effective communication [39]. In addition, our study highlights the importance of reminders and doctor recommendations as key motivational factors for screening participation. This aligns with previous research showing that structured reminders and physician encouragement significantly increase adherence to screening programs [40].

Cultural factors have been widely recognized as potential barriers to screening participation, particularly among minority populations. However, in contrast to previous studies that identified cultural, religious, and language barriers as significant obstacles [29,33], our findings did not indicate these as major factors influencing participation. This could be due to the specific demographic composition and the convenience nature of our sample, which may not fully represent minority groups who typically face these barriers. In addition, studies such as those by MacKinnon et al [27] and Foerster et al [28] have examined disparities in access to screening, particularly among underrepresented populations. Future studies should aim to include more diverse and underrepresented populations to ensure equitable and inclusive access to screening programs and emerging screening technologies.

While previous research has primarily examined the technical efficacy of thermography [17], our study uniquely contributes by capturing patient perceptions, concerns, and trust in AI-driven screening. Previous research, such as Ciria-Suarez et al [26], has mapped the breast cancer patient journey, highlighting logistical and emotional barriers to screening participation. Building on this, our study explores perceptions of thermography as an alternative screening method while also shifting the focus from the patient to the screener—an aspect that remains underexplored [27,28].

Finally, while previous research has investigated patient trust in AI-driven diagnostic tools [41], limited studies have specifically examined trust in AI-driven thermography. Our findings indicate that, while women appreciate the noninvasive nature of thermography, concerns persist regarding its reliability and clinical validation. This underscores the need for further research into the usability, accuracy, and integration of AI-driven thermography within existing screening programs.

Limitations

Like other studies, this research has limitations. First, the sample was based on convenience rather than representativeness. The survey primarily served as a recruitment tool, with self-reported responses and no external validation. While we acknowledge that male breast cancer exists, this study focused on women, the majority of affected individuals. Younger women, not part of standard screening programs, were underrepresented despite efforts to include them. Language limitations may have excluded certain EU populations. Participants were mostly highly educated and engaged in breast cancer prevention, potentially narrowing perspectives on screening barriers. In addition, as focus groups were conducted in English, women with lower educational levels were underrepresented. Future research should seek broader inclusion.

Second, focus group insights were based on personal experiences and perceptions. While clinician interaction was a key factor, participants did not always specify health care roles they were referring to. Similarly, it was unclear whether discussed tests were part of initial screening or later diagnostics.

Third, as participants lacked real-life experience with ThermoBreast or other thermography techniques, direct comparison with mammography was not possible. However, insights into the procedure may inform other thermographic methods and contribute to a more user-centered screening approach. The proposed breast cancer screening journey offers valuable considerations for future programs, regardless of the technology used.

Conclusions

AI-driven thermography holds promise as a noninvasive and radiation-free alternative to mammography, but its adoption depends on trust, clinical validation, and effective communication from health care professionals. Understanding the current mammography experience, including its barriers and motivators, provides valuable insights into how screening participation can be improved. Key areas for enhancement include regular screening invitations, efficient appointment scheduling, empathetic interactions with clinical staff, and clear, understandable explanations about the procedure, and structured communication of results.

While thermography could expand screening access for certain groups such as younger and immobile women, it does not eliminate all participation barriers. Some physical limitations, such as frozen shoulder, remain unaddressed. Furthermore, concerns about the reliability and accuracy of thermography highlight the need for further clinical validation. Our findings emphasize that the overall screening experience extends beyond the technology itself, with factors such as the clinical environment and the patient-provider relationship playing a crucial role in screening uptake. Nonetheless, many women welcomed the prospect of a less invasive and more accessible procedure.

Future research should prioritize making screening programs more inclusive, ensuring that underrepresented groups such as individuals with lower educational attainment, disadvantaged socioeconomic backgrounds, men, and younger women are better engaged. Tailoring the breast cancer screening journey to meet their specific needs will be essential for increasing awareness, accessibility, and participation in emerging screening

XSL•FO
RenderX

technologies. Furthermore, more long-term studies on thermography, as well as direct comparisons between mammography and thermography, are needed to fully understand the differences in screening experiences and their impact on participation and outcomes.

Acknowledgments

The authors would like to thank all the women who participated in this research. This manuscript benefited from the use of the large language model ChatGPT to improve clarity, grammar, and coherence. All suggestions were reviewed and edited by the authors. The final version was also proofread by external professional editing services.

Funded by the European Union, views and opinions expressed are, however, those of the author(s) only and do not necessarily reflect those of the European Union or the European Health and Digital Executive Agency (HaDEA). Neither the European Union nor the granting authority can be held responsible for them (grant agreement no. 101096329).

Data Availability

The focus group data are restricted due to privacy concerns stated in the informed consent. The detailed survey results can be found in Multimedia Appendix 2.

Authors' Contributions

KSK contributed to conceptualization, methodology, formal analysis, data curation, writing–original draft, writing–review & editing, and visualization. AP conducted formal analysis and writing–review & editing. AJ managed conceptualization, methodology, supervision, writing–review & editing, project administration, and funding acquisition. AC handled conceptualization, methodology, writing–review & editing, and project administration. JJV contributed to writing–review & editing and project administration. At the time of the study, KSK and AP were employed as researchers at imec-SMIT, Vrije Universiteit Brussel. KSK had been working there since 2021, and AP since 2023. AJ held the position of professor and unit leader at imec-SMIT, Vrije Universiteit Brussel. AC served as Chief Executive Officer at Cancer Patient Europe, while JJV was Director of Research and Patient Engagement at the same organization.

Abstract

Background: Traditional education for patients with cancer faces challenges related to timeliness, accessibility, and a personalized approach. Social media has emerged as a novel platform for delivering cancer-related educational content, garnering growing academic interest. However, a comprehensive assessment of the current research landscape in this domain is lacking.

Objective: This study aimed to identify research hotspots; trace the evolution of social media–based education for patients with cancer; and map the leading journals, institutions, and international collaboration networks in this field.

Methods: A bibliometric and thematic analysis was conducted using tools, such as VOSviewer, Bibliometrix, and CiteSpace, to examine articles indexed in the Web of Science Core Collection from 2011 to 2025. The analysis explored publication trends, author and institutional collaboration networks, keyword co-occurrence, factor analysis, thematic clusters, and the evolution of disciplinary keyword categories.

Results: A total of 119 publications were retrieved. The Journal of Medical Internet Research was the most productive journal in this field, publishing 13 articles (10.9%). The University of Minnesota was the most productive institution, contributing 6 publications (5.0%). The United States accounted for the largest proportion of publications (56/119, 47.1%), with 5 of the top 10 institutions based in the country. The United States also led the international collaboration network. Keyword analysis identified key research hotspots, including platform-specific information dissemination, tailored educational interventions for diverse patient populations, efforts to enhance quality of life, and challenges related to health misinformation. Thematic evolution demonstrated a shift from basic information-seeking behaviors to broader topics such as digital health and health equity, indicating a multidimensional and interdisciplinary research trajectory.

Conclusions: This study represents the first bibliometric analysis of social media–based cancer education, providing actionable insights to inform digital health literacy strategies and advance patient-centered, equitable health care.

(JMIR Cancer 2025;11:e77214) doi:10.2196/77214

KEYWORDS

social media platforms; bibliometric analysis; health literacy enhancement; digital health technology applications; cancer education

Introduction

The World Health Organization (WHO) projects that by 2040, the global incidence of new cancer cases will reach 28.4 million annually [1]. Despite the rising incidence of cancer, significant improvements in early screening, targeted therapies, and immunotherapies over the past 2 decades have notably enhanced the survival rates of patients with cancer. According to 2023 surveillance data, the overall 5-year cancer survival rate in the United States has increased from 49% in 1975 to 68%, while the rate for childhood cancers has surpassed 85% [2]. The cancer care paradigm is shifting from a disease-centered model to a

XSL•FO
RenderX

health management–oriented model, with patient education emerging as a crucial element [3]. However, traditional offline medical education models face significant challenges regarding timeliness, accessibility, and personalization, creating barriers for health education systems [4].

Against this backdrop, the exponential growth of social media presents a transformative opportunity to overcome the limitations of traditional education models for patients with cancer. With over 5 billion global users, social media platforms have emerged as a novel and powerful medium for education for patients with cancer [5]. The intersection of social media and education for patients with cancer represents a rapidly evolving field. Traditionally, patient education has been defined as a planned, systematic, and continuous process through which health care professionals deliver information, skills training, and emotional support to patients and their families or caregivers, enabling them to manage their health conditions and engage in clinical decision-making [6]. In digital environments, however, patient education is often decentralized and informal, with content frequently emerging organically through information exchange among patients, caregivers, and peer communities, rather than being solely initiated by professionals [7]. Social media plays a significant role in patient empowerment, facilitating broader peer-to-peer education through the dissemination of health information [8]. Accordingly, this study expands the concept of education for patients with cancer to encompass any online content, produced by professionals or peers, that aims to enhance cancer-related knowledge, self-management capabilities, or decision-support. By leveraging real-time interactivity, personalized content delivery, and community-based support functions, social media–based cancer education not only provides timely and personalized information but also empowers patients by enhancing health literacy, encouraging active participation in decision-making, and fostering self-management awareness [9]. These elements collectively promote a dynamic balance of medical power between professional institutions and individual patients.

Social media are internet-based platforms that allow users to create and share content, as well as engage in social interactions [10]. They encompass various forms of media, including instant messaging tools, professional knowledge-sharing platforms, interactive platforms, video-sharing sites, and microblogging websites [11,12]. The proportion of patients with cancer obtaining disease-related information through social media has increased from 38% in 2015 to 72% in 2023 [13]. Moreover, the usage rate of social media among patients with cancer is 47% higher than that of the general population [14]. Through online interactive platforms, patients with cancer and their families can access a range of educational services, including the dissemination of disease-related knowledge, support for treatment decision-making, psychological and emotional support, and health behavior interventions [15]. This technology-enabled educational model provides personalized health information and promotes interaction and support among patient groups, transforming patients from mere recipients of treatment to active health managers.

However, the application of social media in education for patients with cancer faces significant risks in the information ecosystem. On major global platforms, such as YouTube, Facebook, and TikTok, a lot of cancer-related content lacks evidence-based support, potentially causing clinical harm [16]. For instance, 12% of posts related to bladder cancer on Pinterest advocate urine therapy [17]. Algorithm-driven recommendation mechanisms further exacerbate information asymmetry through the “echo chamber effect” [18]. Misinformation significantly influences patient decision-making. Commercialization further distorts medical education. Commercialization of health care significantly influences medical students’ ethical stance, with a high proportion agreeing to commercial propositions [19].

Currently, research on social media–based cancer education primarily focuses on enhancing information dissemination [20], technology-driven interventions [21], patient behavior analysis [22], and information quality assessment [23]. These studies are mostly empirical case analyses, emphasizing the application of social media in psychological support, treatment decision-making, and quality of life improvement. However, research in this field is increasingly fragmented, hindering a comprehensive understanding of the current status and developmental trajectory of social media–based education for patients with cancer. This fragmentation results in a lack of systematic insights into the knowledge structure, collaborative networks, and evolutionary pathways of the field. Although systematic reviews have investigated the application of mobile health interventions in education for patients with cancer [24] and the determinants of eHealth literacy among patients with cancer [25], they typically focus on specific interventions or influencing factors, overlooking the broader applications and research progress of social media in education for patients with cancer.

Bibliometric analysis provides a powerful framework for understanding the research landscape. Through a systematic study of academic literature, it clarifies the knowledge structure, emerging themes, collaborative networks, and developmental trajectories of a particular field, thereby offering evidence-based insights for researchers, policy makers, and platform developers. Previous studies have used bibliometrics to investigate the application of knowledge management on Twitter in health promotion [26], the interdisciplinary application of big data in HIV research [27], and the trends in natural language processing in the medical field [28]. However, to our knowledge, no bibliometric studies have specifically targeted social media–based education for patients with cancer.

This study used bibliometric methods to systematically analyze the current research landscape of education for patients with cancer on social media platforms and explore the knowledge structure and developmental trends in this field. By conducting quantitative analyses of publication trends, co-occurrence of high-frequency keywords, thematic clustering, core authors, and institutional collaborative networks, this study aimed to address the following research questions:

1. What are the core journals, institutions, and researchers in the field of social media–based education for patients with cancer?

XSL•FO
RenderX

2. How do different countries and regions collaborate in the field of social media–based education for patients with cancer?
3. What are the main themes and popular research directions in the field of social media–based education for patients with cancer?

By answering these questions, this study aimed to provide a theoretical integration pathway for academia, policy makers, and health care practitioners. It offers evidence-based insights for health policy makers to optimize the allocation of digital health education resources and data support for health care practitioners to design patient education programs tailored to the characteristics of the platform, thereby promoting patient empowerment.

Methods

Data Source and Retrieval Strategy

The Web of Science Core Collection (WoSCC) served as the data source for the present bibliometric and thematic analysis. This database covers peer-reviewed journals indexed in the Science Citation Index Expanded, Social Sciences Citation Index, and Emerging Sources Citation Index, ensuring broad coverage of high-quality interdisciplinary scholarly literature, and is widely used in bibliometric research [29,30].

To ensure a systematic and comprehensive retrieval process, and based on this study's conceptualization of social media and patient education, we developed a search strategy integrating three key conceptual domains: (1) patients with cancer, (2) social media and digital platforms, and (3) patient education and health communication. The search terms in each domain were informed by Medical Subject Headings (MeSH) and frequently used synonyms identified in relevant literature. The retrieval process consisted of 5 steps.

Step 1: Identification of Articles Related to Patients With Cancer

In step 1, the following search query was used (search query #1): TS=("cancer patients" OR "oncology patients" OR "neoplasm patients" OR "cancer survivors" OR "patients with cancer" OR "malignancy patients"). This ensured the inclusion of studies addressing patients with cancer or survivors described using various commonly adopted terms.

Step 2: Identification of Articles Related to Social Media and Online Communities

In step 2, the following search query was used (search query #2): TS=("social media" OR "online platforms" OR "online communities" OR "Twitter" OR "Facebook" OR "Instagram" OR "YouTube" OR "TikTok" OR "LinkedIn" OR "Reddit" OR "WhatsApp" OR "WeChat" OR "Telegram" OR "blogs" OR "microblogs" OR "forums" OR "wikis"). This selection reflected both generic terms and platform-specific keywords, covering a range of functional types as well as regionally representative social media platforms to maximize the comprehensiveness of the search.

Step 3: Identification of Articles Related to Health Education and Communication

In step 3, the following search query was used (search query #3): TS=("patient education" OR "health education" OR "health promotion" OR "health literacy" OR "health coaching" OR "health information" OR "patient engagement" OR "patient empowerment" OR "self-management education" OR "health communication" OR "patient support" OR "cancer education" OR "oncology education" OR "treatment adherence education" OR "symptom management education" OR "survivorship education"). This search covered a broad range of educational strategies and communication approaches relevant to cancer care and survivorship.

Step 4: Combining Queries and Applying Filters

We applied Boolean logic to combine the queries and retrieve articles situated at the intersection of these domains. The retrieval was conducted on March 5, 2025. The final search strategy was as follows: TS=("cancer patients" OR "oncology patients" OR "neoplasm patients" OR "cancer survivors" OR "patients with cancer" OR "malignancy patients") AND TS=("social media" OR "online platforms" OR "online communities" OR "Twitter" OR "Facebook" OR "Instagram" OR "YouTube" OR "TikTok" OR "LinkedIn" OR "Reddit" OR "WhatsApp" OR "WeChat" OR "Telegram" OR "blogs" OR "microblogs" OR "forums" OR "wikis") AND TS=("patient education" OR "health education" OR "health promotion" OR "health literacy" OR "health coaching" OR "health information" OR "patient engagement" OR "patient empowerment" OR "self - management education" OR "health communication" OR "patient support" OR "cancer education" OR "oncology education" OR "treatment adherence education" OR "symptom management education" OR "survivorship education").

Step 5: Refinement of the Results

To ensure information accuracy, a comprehensive data cleaning process was applied. Data were examined, with duplicates removed and erroneous entries corrected to ensure that each sample in the final dataset retained only 1 valid affiliation. To ensure rigor and consistency, the screening process was conducted by 2 independent researchers (ZG and GZ). Any discrepancies between the 2 researchers were resolved by consulting a third researcher (YF). Publications were limited to English-language articles within the thematic scope of this study, while meeting abstracts, editorial materials, proceeding papers, and studies unrelated to the topic were excluded. The literature screening was carried out using both the built-in refinement tools of the WoSCC database and manual review to ensure accuracy.

Data Analysis and Visualization

This study used multisource analysis tools (VOSviewer 1.6.18, Bibliometrix R package 4.0, and CiteSpace 6.4.R2) to conduct multilevel analysis of the filtered literature dataset, covering 3 aspects: data standardization, collaboration network modeling, and research hotspot mining.

The original data exported from the WoSCC database included 2 types of data structures: one was in the plain text file format, which was used for analysis with VOSviewer and CiteSpace,

XSL•FO
RenderX

and the other was in the BibTeX format, which was used for analysis with Bibliometrix. The record content of the exported data included "Full Record and Cited References," which facilitated subsequent analysis.

During data standardization, bibliographic metadata were first standardized using regular expressions, and institution names were normalized via string-matching technology. For instance, different spelling variants of "University of Minnesota" were unified. In addition, different forms of the same keyword, such as "quality-of-life," were merged into "quality of life" to ensure consistency. A keyword supplementation mechanism was established using the Python Pandas library: when author keywords were missing, they were supplemented with Keywords Plus data, and duplicate records were identified and removed through double verification of DOI and title.

Core journals were identified by Bradford Law in Bibliometrix. Journals were ranked in descending order according to the number of relevant articles published. Each zone contains approximately the same number of articles; however, the number of journals included in each successive zone increases geometrically. Among them, the first zone typically consists of a relatively small number of journals that publish the most relevant articles and is regarded as the core set of journals within the research field [31].

The collaboration networks of institutions and countries were generated using VOSviewer, with the normalization method set to LinLog/monotonic, a minimum collaboration frequency of 2, and a clustering resolution of 0.80. The size of the nodes represented the total link strength.

Research hotspot analysis included static and dynamic dimensions. In the static analysis, Bibliometrix generated a keyword tree map (top 50 high-frequency words; clustered by the Ward minimum variance method), theme map (top 200 high-frequency words; walktrap algorithm with step length t=4, minimum cluster frequency per thousand documents was set to 5), and factor analysis map (top 50 high-frequency words; optimal cluster number determined by the elbow method and a silhouette score ≥0.7). Semantic networks were constructed via VOSviewer, which created a keyword clustering map (binary counting; minimum co-occurrence frequency of 2, including 174 keywords). Co-occurrence intensity was calculated based on cosine similarity, and the minimum spanning tree algorithm formed the network topology. Clustering labels were automatically annotated using the association strength algorithm.

In the dynamic evolution analysis, CiteSpace version 6.4.R2 was used to construct a disciplinary category evolution network. The time span was set from 2011 to 2025, with a time slice length of 1 year. Node selection was based on the improved g-index, with the scaling factor k set to 25. The filtering criterion for keywords, terms, or stacked labels was "By Degree," with the threshold set at 2. In the clustering analysis, the log-likelihood ratio algorithm was applied to identify disciplinary clusters, ensuring that the modularity Q value exceeded 0.3 to guarantee the rationality and clarity of the clusters. To preserve the integrity of the original network structure, no pruning operations were applied in the network trimming settings. Finally, the historical evolution trajectories of research topics were presented through the timeline view, revealing the dynamic evolutionary trends of disciplinary development.

Ethical Considerations

This metadata analysis of published work used publicly available data and did not involve human subjects, individual data collection, biomedical interventions, or the use of any sensitive personal information. It is thus exempt from ethical review under national guidelines, and approval from an ethics committee was not required.

Results

Basic Information on the Included Studies

The relevant literature in this field covers the period from 2011 to 2025, involving 63 sources and producing a total of 119 publications, with an annual growth rate of 10.41%. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram is presented in Figure 1. The research involved 784 authors, among whom only 2 were single authors, and 17.65% of the authors were involved in international collaborations. The average number of coauthors per publication was 7. The research included 414 author-provided keywords, with a total of 4953 references cited across the publications. The average age of the publications was 4.52 years, and each publication was cited on average 24.39 times, reflecting the continuity and academic impact of research in this field (Multimedia Appendix 1).

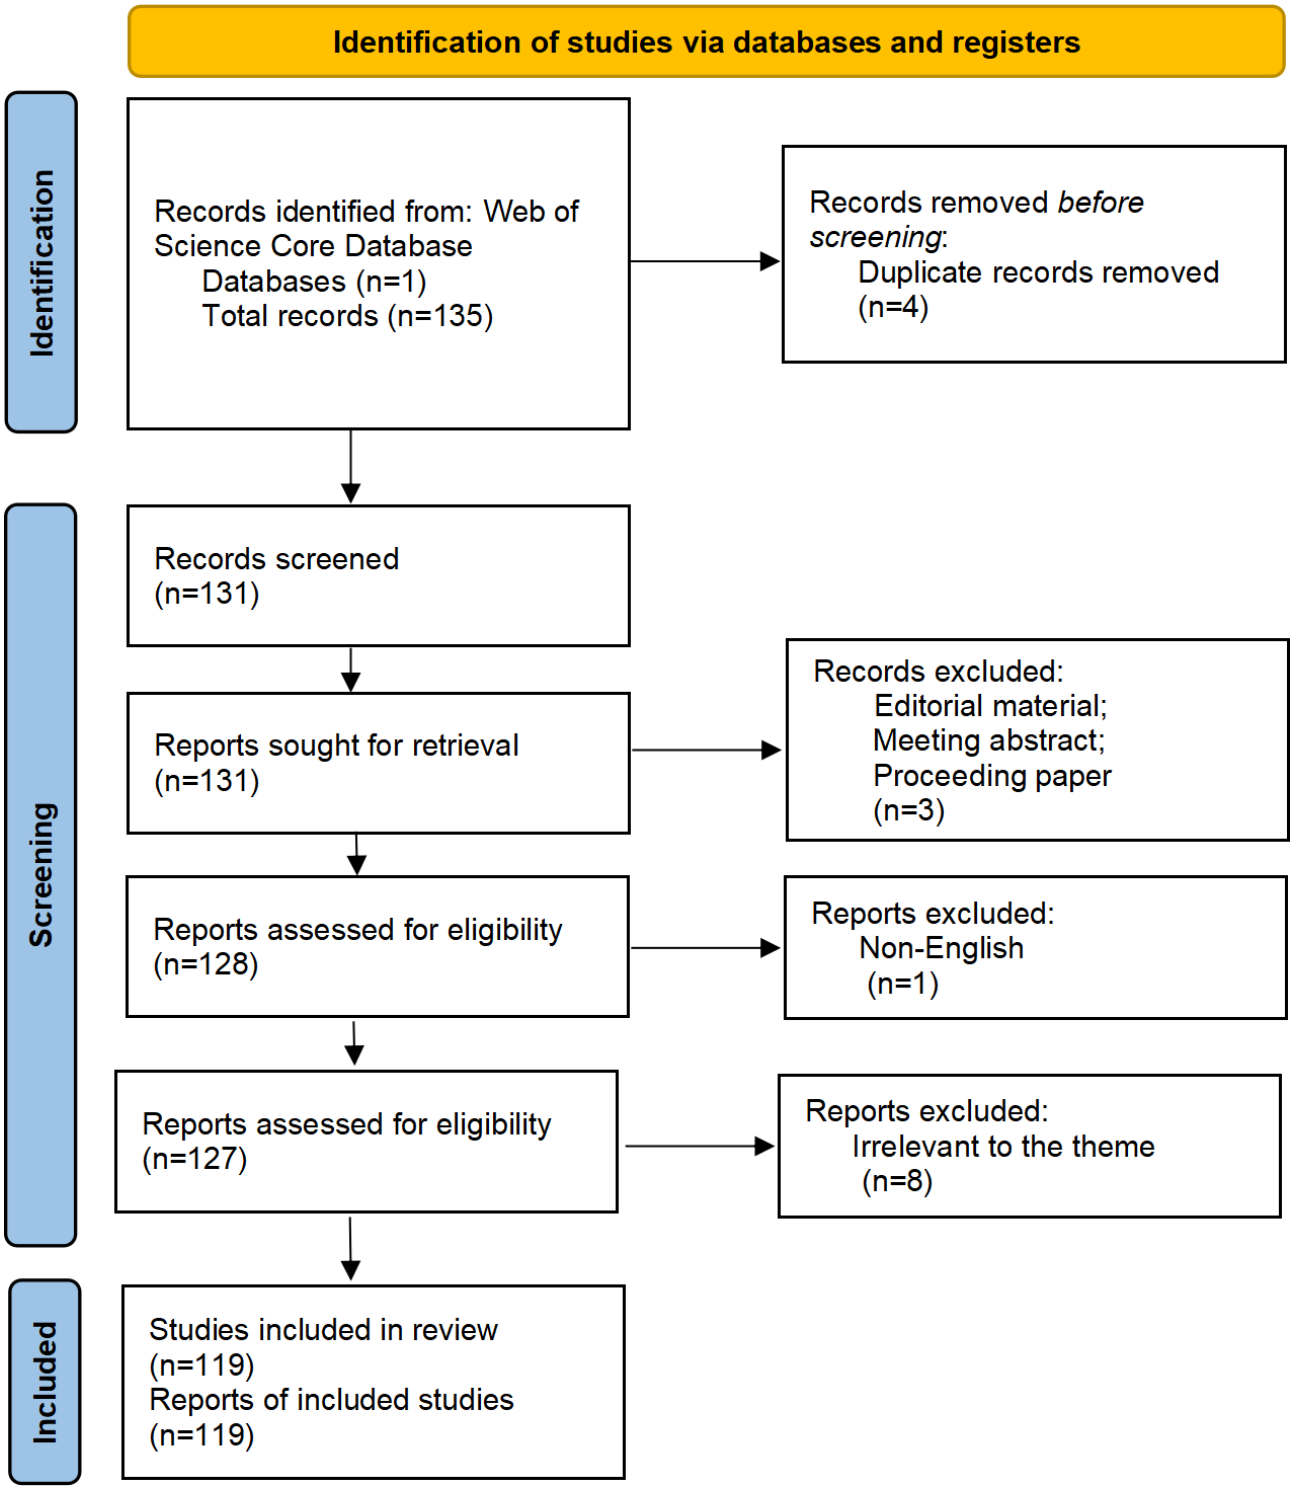
Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



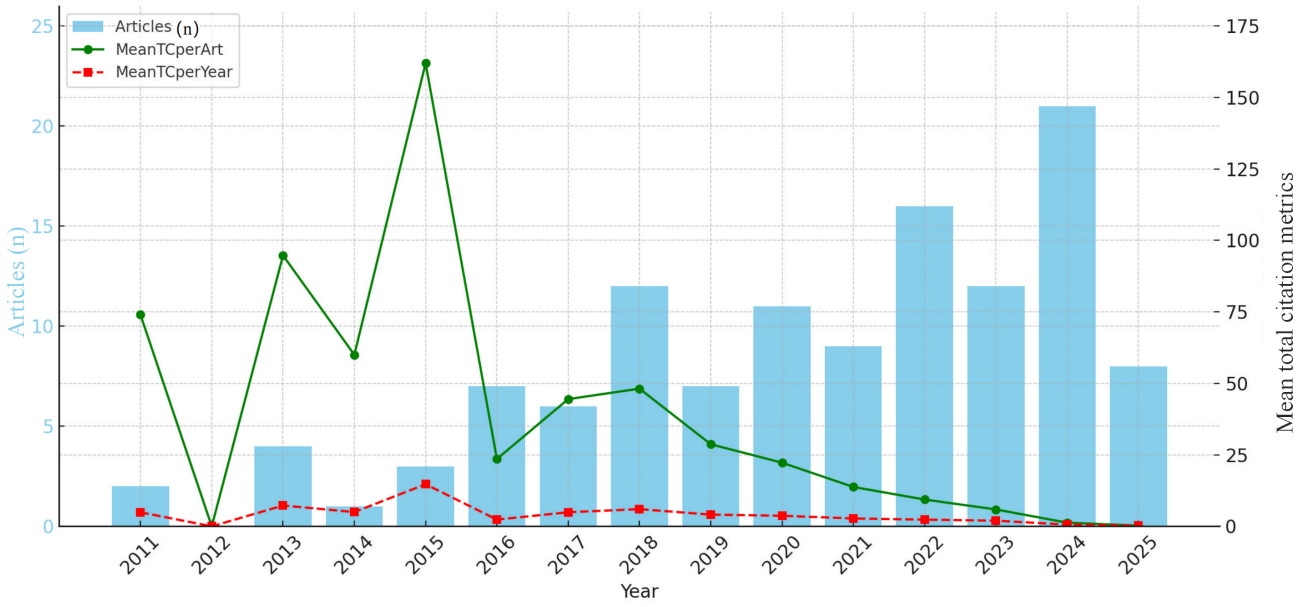


Figure 2 presents the evolution chart of article output and mean total citation metrics. The annual publication output fluctuated but showed an overall upward trend, with slight declines in 2014, 2017, 2019, and 2021. Regarding mean total citation metrics, both mean total citations per article and mean total citations per year displayed a general downward trend.

Analysis of the Most Productive Entities

Table 1 presents the high-output journals, institutions, and authors in the study field. Regarding journals, the Journal of Medical Internet Research led with 13 publications (10.9%), followed by Supportive Care in Cancer with 10 publications (8.4%). The Journal of Cancer Education and the Journal of Cancer Survivorship each had 8 publications (6.7%).

XSL•FO
RenderX

Table . The top 10 journals, institutions, and authors by publication output.

Variable	Articles, n
Journal	
Journal of Medical Internet Research	13
Supportive Care in Cancer	10
Journal of Cancer Education	8
Journal of Cancer Survivorship	8
BMJ Open	4
Cancer Medicine	3
International Journal of Medical Informatics	3
Journal of Adolescent and Young Adult Oncology	3

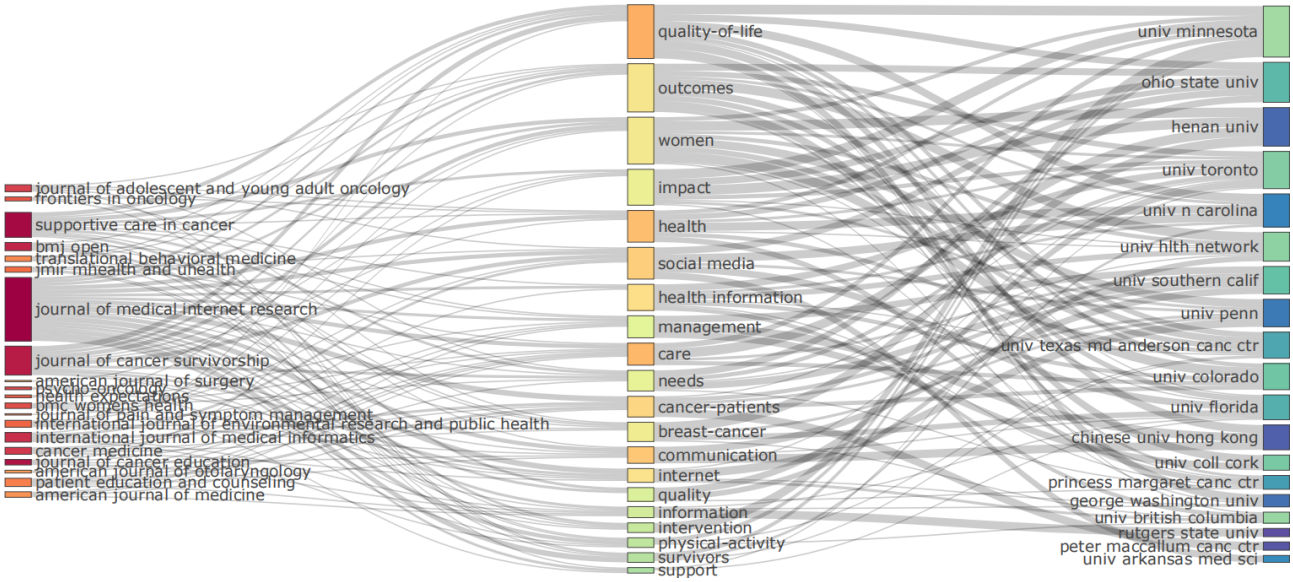
Davoren	2

In terms of institutions, the University of Minnesota had the highest number of publications (6/119, 5.0%). Both the University of British Columbia and the University Health Network were tied for second place, with 3 publications each (2.5%). The majority of these high-output institutions are located in the United States (5 institutions) and Canada (3 institutions), with 1 additional institution in Ireland (University College Cork) and 1 in Spain (Bellvitge Biomedical Research Institute).

In terms of authors, no single author stood out with a significantly higher number of publications. Most authors in the list had published 2 articles (eg, Aggarwal R and Balaratnam K). This indicated a relatively dispersed research community in this field, without a clear core group of high-output authors.



Using Bibliometrix, we identified 4 core journals in the field of social media–based education for patients with cancer. These include the Journal of Medical Internet Research, Supportive Care in Cancer, Journal of Cancer Education, Journal of Cancer Survivorship, and BMJ Open (Multimedia Appendix 2).

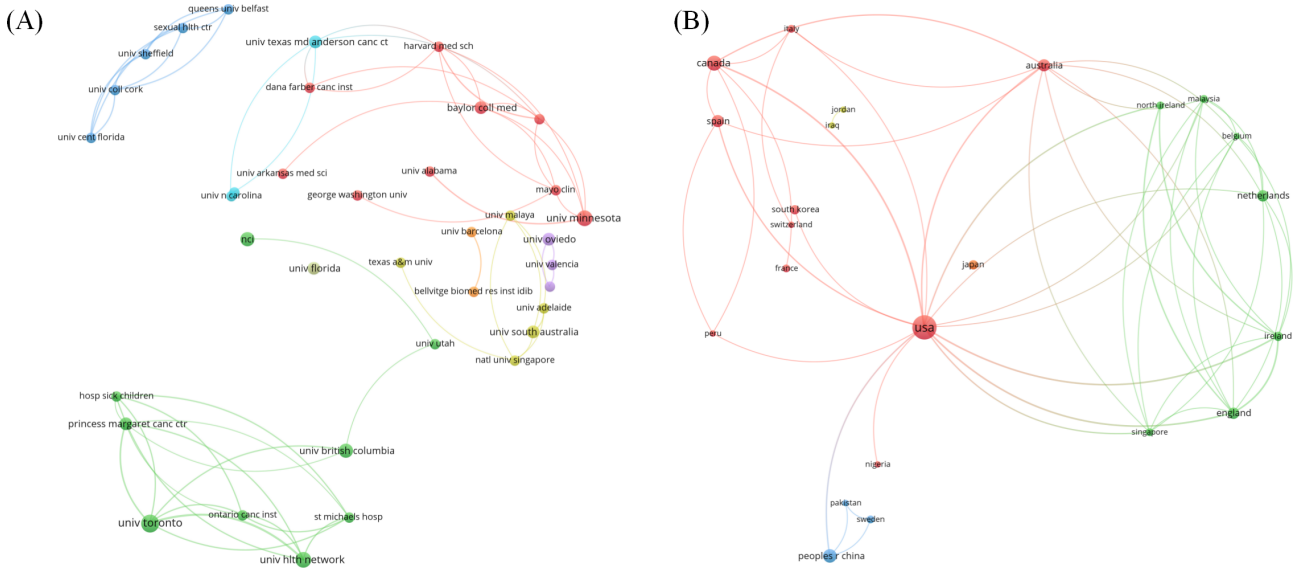
The Sankey diagram (Figure 3) generated by Bibliometrix provides a visual representation of the interconnections among journals, keywords, and institutions, thereby elucidating the

XSL•FO
RenderX

research themes of the most influential journals and institutions in the field of social media–based education for patients with cancer.

Figure 3. Sankey diagram of relationships among journals (left), keywords (center), and institutions (right).

The Journal of Medical Internet Research, the most productive journal in this field, is distinguished by its extensive range of topics. The keywords associated with it included “social media,” “cancer patients,” “health information management,” “communication,” “intervention,” and “quality of life.” These connections underscore its emphasis on the application of social media in education for patients with cancer, with a particular focus on core topics such as patient health information management, communication-based interventions, support system development, and the enhancement of quality of life through social media platforms. The University of Minnesota, a high-output institution in this domain, was linked to keywords such as “quality of life,” “outcomes,” “women,” and “impact.”



Analysis of the Collaboration Network

With regard to the top 10 countries contributing to the field, based on the number of publications among the 119 articles analyzed, the United States had the highest number of publications (56/119, 47.1%), followed by Canada (12/119, 10.1%) and China (10/119, 8.4%). Other contributing countries included Australia and Spain (each 7/119, 5.9%); the United Kingdom and the Netherlands (each 5/119, 4.2%); and Turkey, Japan, and South Korea (each 3/119, 2.5%) (Multimedia Appendix 3).

The collaboration analysis diagrams were generated by VOSviewer. The institution collaboration diagram (Figure 4A) illustrates the cooperative relationships among various institutions, with node size indicating their importance within the network. Overall, the collaboration network exhibited distinct regional characteristics and was primarily led by institutions from North America and Europe.

XSL•FO
RenderX

Figure 4. Collaboration analysis. (A) Institution collaboration. The green cluster is centered around the University of Toronto, and the blue cluster is primarily composed of institutions from Northern Ireland such as Queen's University Belfast and The University of Sheffield. The red cluster includes prominent American institutions like Harvard Medical School and Baylor College of Medicine, while the purple cluster is dominated by Spanish institutions. The colored lines between nodes reveal regional cooperation patterns, with significant collaboration among institutions in the southern United States. (B) Country collaboration. The United States occupies a central and pivotal position in international cooperation.

The national collaboration diagram (Figure 4B) illustrates the cooperative relationships among various countries. The United States was interconnected with multiple countries, including Canada, the Netherlands, and Ireland, through dense collaborative links, thereby steering the core dynamics of international cooperation. Concurrently, countries, such as Spain, Italy, Australia, and Belgium, also exhibited extensive international collaborative networks.

Analysis of Research Hotspots

The keyword tree map generated by Bibliometrix (Figure 5) identifies the 50 most frequent keywords in social media–based education for patients with cancer. Core keywords, such as "quality of life" (20/354, 6%), "care" (15/354, 4%), and "health" (15/354, 4%), were prominent, reflecting a focus on patient well-being. Other high-frequency keywords were related to demographics (eg, "women" [12/354, 3%], "cancer survivors" [4/354, 1%], and "African-American" [3/354, 1%]), health communication (eg, "health information" [15/354, 4%], "communication" [13/354, 4%], and "education" [7/354, 2%]), behavioral support (eg, "exercise" [6/354, 2%], "behavior" [5/354, 1%], and "physical activity" [9/354, 3%]), and psychological metrics (eg, "distress" [5/354, 1%] and "reliability" [5/354, 1%]). These keywords underscore the multidimensional nature of research in this area.

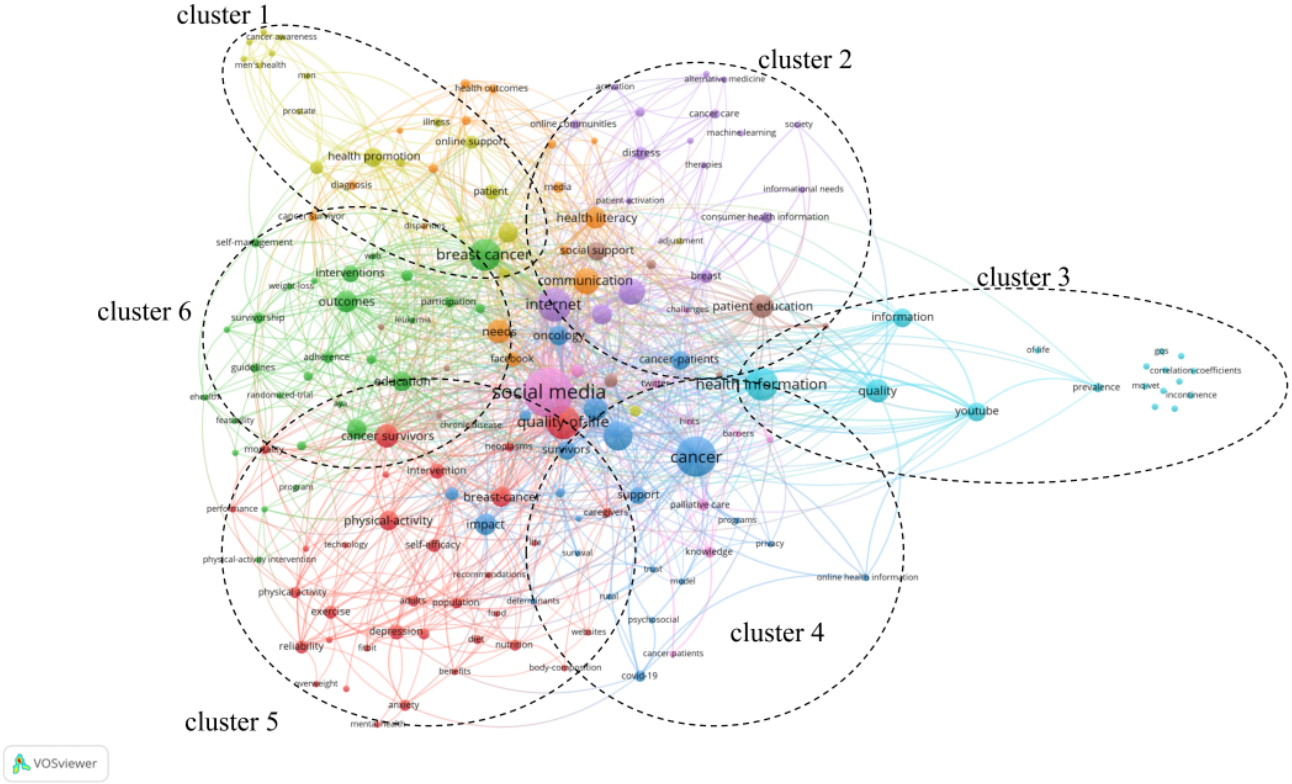


Figure 5. Keyword tree map of social media–based cancer education.

Based on the keyword tree map, a further keyword clustering analysis (Figure 6) was conducted to reveal the strength of co-occurrence relationships among keywords within the literature, generated using VOSviewer. A total of 174 keywords were included. The clustering map categorized the keywords into 6 distinct clusters, each coalescing around a specific thematic focus.

XSL•FO
RenderX

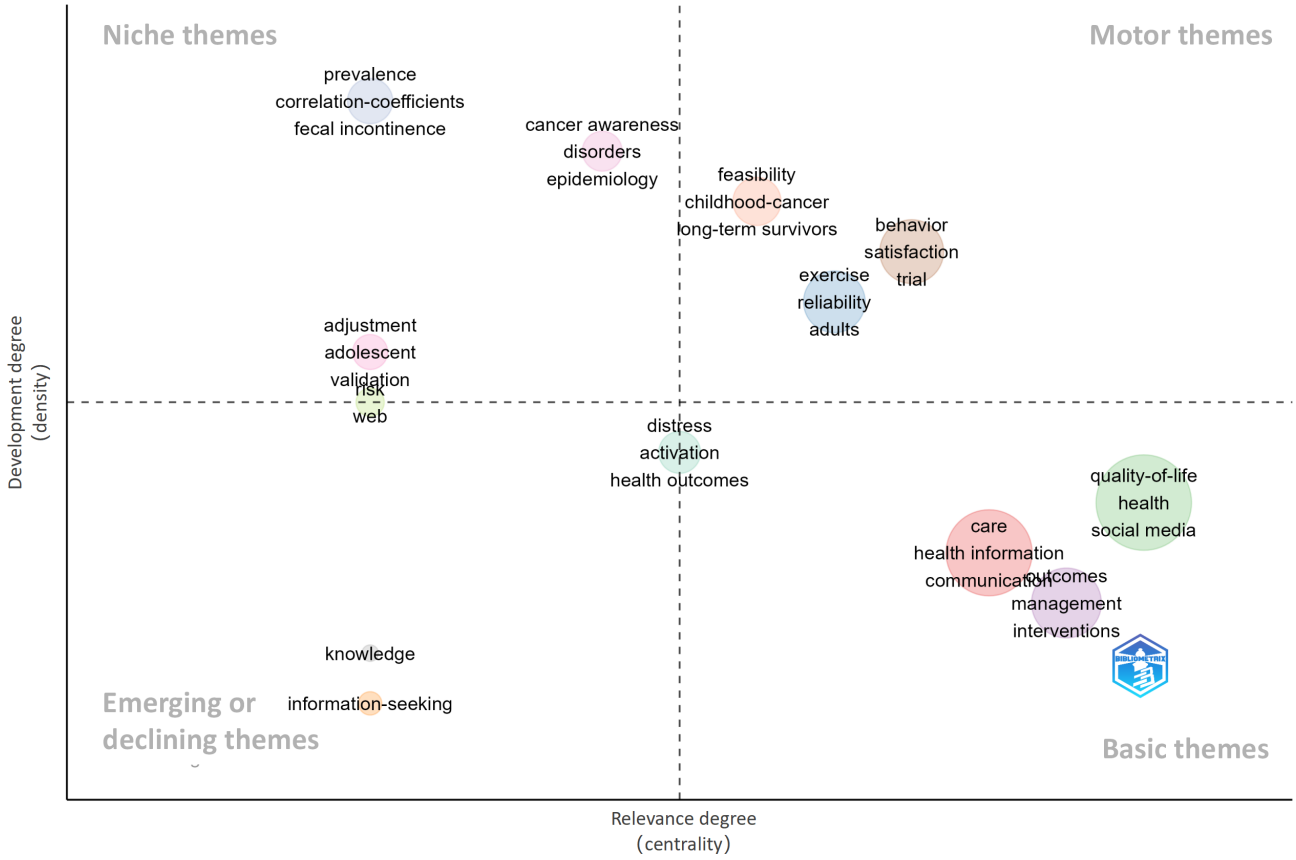
Figure 6. Keyword clustering of social media–based cancer education.

Cluster 1 centered on cancer-related health promotion and men's health issues. Its keywords were "health promotion," "men," "prostate," "cancer awareness," and "diagnosis." The cluster explored cancer prevention strategies and the diagnosis of prostate diseases in men.

Cluster 2 focused on patient experience and health disparities, particularly the role of complementary and alternative medicine in cancer care. Keywords, such as "patient," "health outcomes," "disparities," "alternative medicine," and "complementary," suggested that this cluster centers on understanding variations in health outcomes among different patient populations. Particular emphasis was placed on the influence of cultural and social contexts on treatment effectiveness and the integration of traditional and alternative medicine approaches to improve therapeutic outcomes.

Cluster 3 dealt with cancer information dissemination and online resource use. Its keywords were "information," "internet," "social media," "health information," and "YouTube." It discussed how cancer information spreads via the internet and social media, and how patients access health resources online.

Cluster 4 covered care for patients with cancer and relevant medical technologies. Its keywords were "cancer," "cancer patients," "palliative care," "machine learning," and "surgery." The cluster focused on care for patients with cancer, especially palliative care, and the application of medical technologies like machine learning in cancer treatment, including surgical assistance.



Cluster 5 looked into cancer survivor well-being and lifestyle interventions. Its keywords were "cancer survivors," "quality of life," "physical activity," "mental health," and "nutrition." The cluster assessed how cancer survivors can enhance their quality of life through physical activity and nutrition, and emphasized their mental health care.

Cluster 6 focused on breast cancer research and the support needs of patients throughout the treatment process. Keywords, such as "breast cancer," "communication," "support," "outcomes," and "randomized controlled trial," highlighted a dual emphasis: the use of rigorous methodologies, particularly randomized controlled trials, to evaluate treatment efficacy, and the importance of ensuring comprehensive communication and emotional support for patients during the course of care.

In addition to the keyword clustering analysis, a thematic map (Figure 7) was generated using Bibliometrix to further reveal the structural distribution and development potential of research themes in cancer education on social media platforms. The map had 4 quadrants.

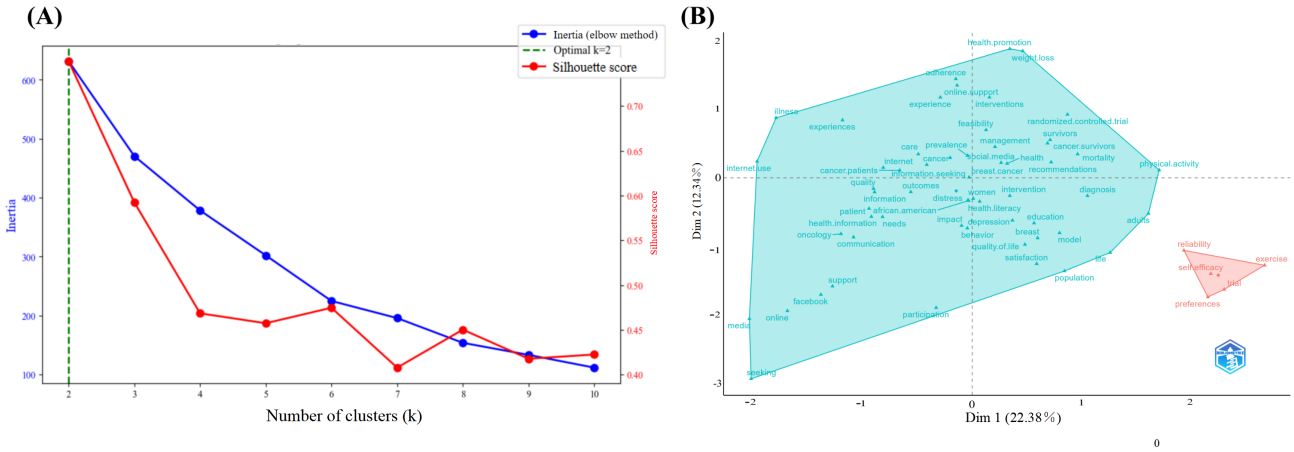
XSL•FO
RenderX

Figure 7. Thematic map of social media–based cancer education. The horizontal axis represents the centrality of a theme in the field (ie, its relevance), while the vertical axis represents the density (ie, the degree of development of the theme). The division into 4 quadrants helps to interpret the position and evolutionary direction of each theme within the field.

The upper-right quadrant had "motor themes" with key themes that were both highly relevant and well developed. Keywords, such as "feasibility," "childhood cancer," "long-term survivors," "behavior," "satisfaction," "trial," and "adults," indicated that current research is focused on the feasibility of clinical interventions, the behavioral management of cancer survivors, and the validation of educational pathways grounded in behavioral theories.

The upper-left quadrant had keywords, such as "prevalence," "epidemiology," "correlation coefficients," "cancer awareness," and "adolescent," which pointed to research centered on specific populations, disease types, or methodological approaches. Although these studies are relatively mature in terms of methods and theoretical frameworks, they have yet to exert a broad influence in the field due to limitations in target populations or research scope.

The lower-right quadrant included keywords, such as "quality of life," "health," "social media," "care," "communication," and "interventions." These represented foundational topics that recur within cancer education, covering aspects of health information dissemination, care management, and quality of life interventions. While these themes are highly relevant to the field, their internal mechanisms still require further theoretical development and empirical exploration, and they remain at a critical stage of transitioning from empirical observations to theoretical frameworks.



The lower-left quadrant had keywords, such as "knowledge" and "information-seeking," which were classified as either emerging or declining themes, indicating that they currently lack methodological support or practical integration.

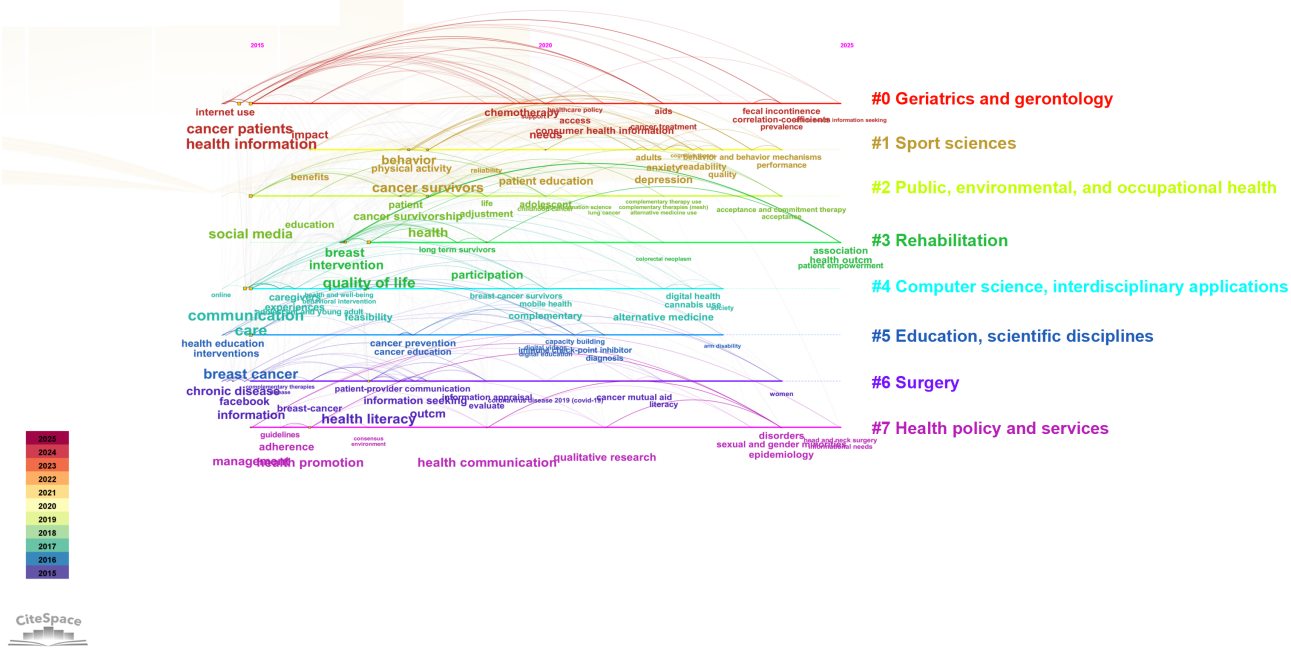
In addition, keywords, such as "distress" and "activation," were positioned near the boundary of the left quadrants, while "risk" and "web" appeared between the upper-left and lower-left quadrants. These "boundary themes" suggest possible areas for interdisciplinary convergence and research integration.

The factor analysis conducted using Bibliometrix further examined the covariation among keywords from the perspective of latent variables, contributing to the extraction of the main research pathways and logical structure [32]. The optimal number of clusters was identified as 2 (Figure 8A). Figure 8B illustrates the specifics of the clustering with red and blue clusters.

XSL•FO
RenderX

Figure 8. Factor analysis of social media–based cancer education. (A) Determination of the optimal number of clusters; (B) Structure map.

The red cluster included keywords, such as “reliability,” “self-efficacy,” “trial,” “exercise,” and “preferences,” emphasizing the validation of short-term interventions through standardized experiments. This represented an individualized intervention pathway guided by medical empiricism.



The blue cluster covered a broader scope, including keywords related to social media and information access, such as “internet use,” “social media,” “facebook,” “information seeking,” and “health information needs.” It also covered keywords related to disease management and quality of life, such as “illness,” “experiences,” “behavior,” “quality of life,” “health promotion,” and “weight loss;” keywords associated with support and interventions, such as “online support,” “interventions,” “education,” and “management;” and keywords related to implementation and management, such as “feasibility,” “management,” “randomized controlled trial,” “diagnosis,” and “physical activity.”

The blue cluster highlighted patient-centered psychosocial support and cultural adaptability, whereas the red cluster focused more on the evidence-based validation of individual behavioral interventions. Together, these clusters represented two distinct directions: (1) the empirical validation pathway of individualized behavioral interventions and (2) the systemic construction of a population health ecosystem.

Figure 9 presents the evolutionary map of keyword disciplinary categories generated by CiteSpace, illustrating the disciplinary domains and temporal distribution of keywords in cancer education research based on social media platforms. The figure demonstrates the evolving trends of keywords related to cancer across various disciplinary fields. Overall, research in cancer education and information dissemination is undergoing a multidimensional transformation, from an early-stage focus on information access and patient education to more integrated concerns, including comprehensive treatment, psychosocial support, digital empowerment, and health equity.

XSL•FO
RenderX

Figure 9. Evolutionary map of keyword disciplinary categories of social media–based cancer education. On the right, 8 disciplinary categories are labeled, while on the left, keywords are color-coded along a timeline, indicating their level of activity during different time periods.

In the early stage, multiple disciplines primarily focused on keywords, such as “health information,” “patient education,” “internet use,” and “communication,” reflecting a strong emphasis on basic information acquisition and health education for patients with cancer. This trend was particularly evident in fields such as “geriatrics and gerontology,” “sport sciences,” and “education, scientific disciplines.”

In the middle stage, research across disciplines began to concentrate on specific treatments and health interventions, as indicated by the frequent appearance of keywords such as “chemotherapy,” “cancer treatment,” “intervention,” and “health care policy.” This shift demonstrates a progression from information dissemination toward clinical pathways, rehabilitation strategies, and health policy development, with particular attention observed in the fields of “public, environmental, and occupational health,” “rehabilitation,” and “surgery,” highlighting concerns regarding treatment accessibility and policy support.

In the later stage, research trends became increasingly diversified and interdisciplinary. On one hand, keywords, such as “digital health” and “capacity building,” illustrated the growing role of “computer science, interdisciplinary applications” and “education, scientific disciplines” in integrating digital technologies with educational platforms. On the other hand, the emergence of keywords, such as “prevalence,” “patient empowerment,” “alternative medicine,” and “sexual and gender minorities,” suggested that cancer education research on social media is expanding toward topics related to individual differences, psychological cognition, and social equity. In particular, within the field of “health policy and services,” increasing attention is being directed toward psychological support and addressing the health needs of vulnerable populations.

In summary, the keyword evolution in cancer education research on social media platforms revealed distinct developmental phases—beginning with information acquisition and patient education, progressing through treatment modalities and behavioral interventions, and evolving into digital support systems and the social governance of health equity. This interdisciplinary and multidimensional evolution reflects not only the advancement of medical technologies but also the growing societal, cultural, and policy-driven demand for comprehensive cancer education and patient support.

Discussion

Basic Information

This study involved the first bibliometric analysis of research on social media–based cancer education, offering a comprehensive overview of the evolution, research distribution, and collaboration patterns in this field. The overall publication volume in this area has shown an upward trend; however, the mean total citations per article has declined each year, reflecting the foundational role of early basic research. The fluctuation in research output may be associated with the iterative development of social media platforms and technologies, as well as the impact of major social events such as the COVID-19 pandemic. Among journals, the Journal of Medical Internet Research has the highest number of publications (Table 1). It is distinguished by its disciplinary foresight, methodological innovation, and international influence, with a particular focus on core topics such as patient health information management, communication-based interventions, support system development, and the enhancement of quality of life through

XSL•FO
RenderX

social media platforms. At the national level, the United States holds a dominant position in this field, which may be related to its state support [33]. Canada also demonstrates significant international influence in this field. Its government has promoted digital health innovation initiatives [34], and its research institutions have formed a clustered research ecosystem, particularly in North America and Europe [35]. Although China ranks third globally in publication volume, it lacks high-output institutions with international influence, reflecting issues of research fragmentation and insufficient internationalization (Figure 4). Other developing countries have relatively low research output in this field. Future efforts should prioritize stronger global resource-sharing and deeper international collaboration.

Research Focuses and Implications

Through a systematic keyword analysis, we identified the most prevalent research themes in social media–based cancer education: platform-specific information dissemination, tailored educational interventions for diverse patient populations, efforts to enhance quality of life, and challenges related to health misinformation. The prominence of these themes indicates that social media plays a multifaceted role in education for patients with cancer.

We identified YouTube, Twitter, and Facebook as the most commonly used platforms for cancer education at present. Cancer education strategies should be tailored to the specific characteristics of each platform. On YouTube, a long-form video platform, health educators can leverage its rich audiovisual capabilities to develop structured learning modules, enabling patients to systematically acquire knowledge about treatment processes and side-effect management [36]. The real-time nature and high interactivity of Twitter make it particularly suitable for the rapid dissemination of evidence-based updates and expert interpretations, thereby facilitating the immediate spread of research findings and clinical guidelines [37]. Facebook's group and mixed-content format is more conducive to building patient communities where experience sharing and emotional support can help enhance treatment adherence and psychological well-being [38]. Furthermore, since Twitter's rebranding to X, the platform's recommendation algorithm has undergone significant adjustments, which may alter its user demographics [39-41]. Future educational strategies must adapt to these changes by integrating strategic content planning and keyword optimization to improve information visibility and intervention effectiveness [42,43].

Keyword analysis highlighted the diversity of patient populations. Male patients tend to seek health support from official sources and are less likely to engage in emotional expression [44,45], and expert-delivered authoritative educational videos and professional consultations can be leveraged to enhance educational effectiveness. In contrast, female patients are more willing to share personal treatment experiences and emotions [46]; therefore, leveraging peer-to-peer exchange and emotional resonance can enhance the effectiveness of educational interventions [47]. Adolescents and young adults tend to prefer interactive and visual forms of education and are more susceptible to the influence of digital opinion leaders [48]. Therefore, short-form video content and dissemination mediated by digital opinion leaders should be used to enhance their engagement, complemented by strengthened online community building [49,50]. Elderly patients typically rely on traditional or official channels for health information and are more receptive to live lectures and voice-based questions and answers [51]. Thus, content should focus on simplicity, clarity, and strong practical applicability, with increased opportunities for face-to-face or synchronous communication. Vulnerable groups, such as African Americans and gender minorities, face barriers in health information access due to trust issues and cultural sensitivity [52,53]. Therefore, educational content should prioritize privacy protection and cultural adaptation [54-56]. Additionally, improving digital literacy among disadvantaged populations, including low-income individuals, rural residents, and the elderly, can help bridge the digital divide [57]. Targeted training, simplifying the complexity of digital applications, and increasing community support [58,59] can effectively close this gap.

Quality of life–focused interventions represent the core of social media–based cancer education. Studies have shown that such interventions can improve patients' treatment adherence, self-management abilities, and psychological well-being [60]. Tools, such as 3D medical animations [61], short-form videos [62], and online courses [63], deliver information on postoperative care, rehabilitation training, psychological adjustment, and nutrition management in visual formats, thereby enhancing patients' comprehension and retention of professional knowledge [64]. Artificial intelligence and big data–driven intelligent recommendation systems further provide personalized guidance on diet, exercise, and psychological support [65], while online consultations offer timely resources to alleviate anxiety and improve intervention outcomes [66]. When designing health content for diverse populations, it is essential to incorporate outcome-oriented feedback mechanisms. These can be implemented through regular surveys [67], online assessments [68], and user-generated satisfaction ratings [69]. Importantly, future research should integrate the authentic voices of patients with cancer as end-users of educational platforms by employing qualitative methods, such as in-depth interviews [70] and focus group discussions [71], to gather their experiences, needs, and suggestions. This approach not only enriches the dimensionality of feedback data, providing deeper and more contextualized insights, but also helps align educational content and delivery formats with patients' actual needs and preferences [72]. Based on these quantitative and qualitative feedback mechanisms, health education platform managers should lead real-time adjustments to educational content and formats, with deep involvement from educational experts and health care professionals. Educational experts are responsible for optimizing content structure and pedagogical methods from an instructional perspective, while health care professionals ensure the scientific validity and accuracy of the content. Through such collaborative efforts, all stakeholders can ensure that educational content and formats are precisely tailored to patient needs, thereby maximizing educational effectiveness and improving patients' quality of life, treatment adherence, and mental health.

XSL•FO
RenderX

It is important to note that the proliferation of false cancer information has become a significant challenge. Unverified alternative therapies, pseudoscientific advice, and distorted medical data (often emotionally provocative) tend to spread more rapidly and widely than evidence-based information [73,74]. Recommendation algorithms exacerbate this issue [75]. Studies indicate that approximately 30% of cancer-related information contains false or misleading elements [76], and patients with lower educational attainment are more susceptible to these effects [77]. The dissemination of misleading information not only delays treatment and undermines trust between patients and health care providers, but also increases patients' psychological burden, making clinical decision-making more complex and uncertain [78]. Addressing this challenge requires multistakeholder collaboration, including enhanced media literacy education [79], encouraged participation of health care professionals in health communication [80], application of natural language processing and machine learning–based intelligent detection tools to identify and flag misleading content in real-time [81,82], and policy-level strengthening of content regulation to effectively curb the spread of misinformation.

Limitations

This study has several limitations. First, relying solely on the WoSCC database may have resulted in the omission of relevant literature from other significant databases, undermining the comprehensiveness of the analysis. Additionally, focusing only on English-language publications overlooked research in other languages, potentially excluding region- or language-specific studies. Second, despite diligent keyword selection, some articles related to potential themes might have been overlooked, limiting the completeness of the analysis. Moreover, the selection of node parameters is relatively subjective. Different researchers may choose varying parameters based on research objectives and interpretations, which can introduce bias into the analysis results. Future research should address these issues by incorporating additional databases, including multilingual literature; integrating qualitative and quantitative approaches; and updating the data range, thereby enhancing the breadth and accuracy of the findings. Additionally, employing multiple parameter validation methods can improve the reliability and comparability of research results.

Conclusions

This bibliometric analysis of 119 articles in the field of social media–based cancer education revealed trends in research output, characteristics of international collaboration, and key research hotspots. The Journal of Medical Internet Research emerged as the leading journal in this field, publishing the highest number of relevant articles. The University of Minnesota was the most productive institution, and the United States was the most productive country, with 5 of the top 10 institutions being based in the United States and international collaborations being led by the United States. Through keyword analysis, this study further identified research development phases and key research focuses in this field. This bibliometric analysis provides direction for future research, helping scholars better understand the evolution and development trends in this area. Future studies should further explore the mechanisms of social media platforms in education for patients with cancer, investigate innovative educational models and technological applications, and better address the diverse needs of patients with cancer to improve their quality of life and health literacy.

Acknowledgments

The authors thank the reviewers and editors for their constructive feedback. During the preparation of this work, the authors used ChatGPT (OpenAI) to improve the readability and language of the manuscript. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the published article. This research was funded by the Center for Genomic and Personalized Medicine, Guangxi Key Laboratory for Genomic and Personalized Medicine, Guangxi Collaborative Innovation Center for Genomic and Personalized Medicine (grant number: GXGPM202303), and Young Scientists Fund of Guangxi Hospital Division of The First Affiliated Hospital, Sun Yat-sen University (grant number: YQ2024008).

Abstract

Background: Generative artificial intelligence (AI) is increasingly used to find information. Providing accurate information is essential to support patients with cancer and their families; however, information returned by generative AIs is sometimes wrong. Returning wrong information is called hallucination. Retrieval-augmented generation (RAG), which supplements large language model (LLM) outputs with relevant external sources, has the potential to reduce hallucinations. Although RAG has been proposed as a promising technique, its real-world performance in public health communication remains underexplored.

Objective: This study aimed to examine cancer information returned by generative AIs with RAG using cancer-specific information sources and general internet searches to determine whether using RAG with reliable information sources reduces the hallucination rates of generative AI chatbots.

Methods: We developed 6 types of chatbots by combining 3 patterns of reference information with 2 versions of LLMs. Thus, GPT-4 and GPT-3.5 chatbots that use cancer information service (CIS) information, Google information, and no reference information (conventional chatbots) were developed. A total of 62 cancer-related questions in Japanese were compiled from public sources. All responses were generated automatically and independently reviewed by 2 experienced clinicians. The reviewers assessed the presence of hallucinations, defined as medically harmful or misinformation. We compared hallucination rates across chatbot types and calculated odds ratios (OR) using generalized linear mixed-effects models. Subgroup analyses were also performed based on whether questions were covered by CIS content.

Results: For the chatbots that used information from CIS, the hallucination rates were 0% for GPT-4 and 6% for GPT-3.5, whereas those for chatbots that used information from Google were 6% and 10% for GPT-4 and GPT-3.5, respectively. For questions on information that is not issued by CIS, the hallucination rates for Google-based chatbots were 19% for GPT-4 and 35% for GPT-3.5. The hallucination rates for conventional chatbots were approximately 40%. Using reference data from Google searches generated more hallucinations than using CIS data, with an OR of 9.4 (95% CI 1.2 - 17.5, $P<.01$); the OR for the conventional chatbot was 16.1 (95% CI 3.7 - 50.0, $P<.001$). While conventional chatbots always generated a response, the RAG-based chatbots sometimes declined to answer when information was lacking. The conventional chatbots responded to all questions, but the response rate decreased (36% to 81%) for RAG-based chatbots. For questions on information not covered by CIS, the CIS chatbots did not respond, while the Google chatbots generated responses in 52% of the cases for GPT-4 and 71% for GPT-3.5.

Conclusions: Using RAG with reliable information sources significantly reduces the hallucination rate of generative AI chatbots and increases the ability to admit lack of information, making them more suitable for general use, where users need to be provided with accurate information.

Introduction

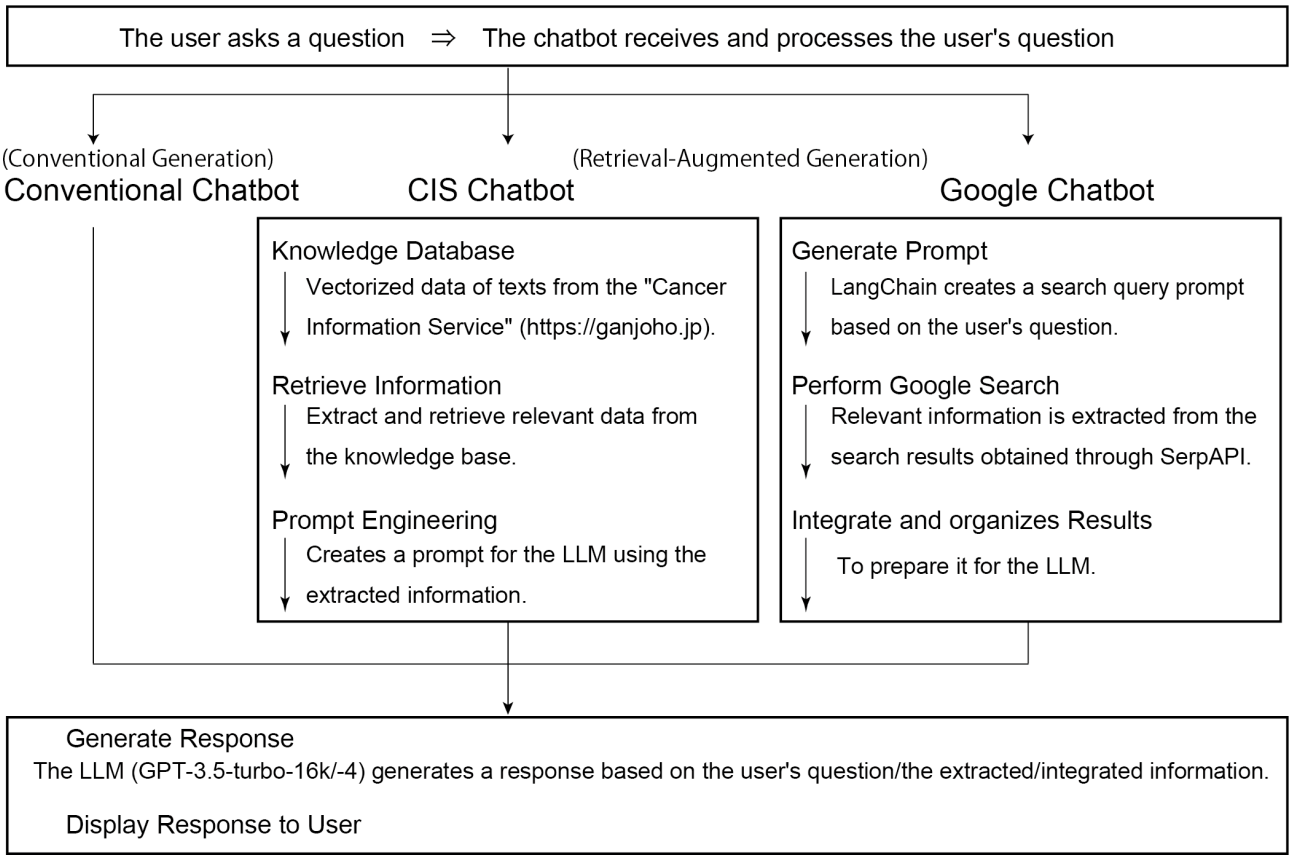
Misinformation on the internet may cause harm to people with cancer, and this needs to be addressed. Currently, most patients with cancer face difficulties in obtaining accurate and reliable information from websites [1-3]. In Japan, many websites and social media platforms contain misinformation, and search engines display results based on access frequency, not accuracy [2,3]. Most patients with cancer do not verify the accuracy of the information owing to their health-related anxious psychological state [4]. Patients who receive complementary and alternative medicine with insufficient evidence have been reported to have poorer prognoses compared with those who receive standard cancer treatment, highlighting the potential impact that access to accurate information can have on cancer outcomes [5]. Now that many patients obtain information about their health from the internet [6-8], there is a pressing need to create a system that enables easy access to accurate medical information. Advances in artificial intelligence (AI) have been applied to medicine to assist in diagnosis [9], particularly in interpreting medical images in areas such as radiology, pathology, gastroenterology, and ophthalmology [10-16]. In information retrieval, generative AI chatbots using natural language processing have been reported to have advantages over traditional search engines [17-21]. Using generative AI chatbots in searching for cancer-related information has the potential to provide patients with easily accessible and understandable health information.

A major issue with generative AI responses is their potential to provide incorrect yet seemingly plausible information, known as hallucination [22,23]. To reduce the rate of hallucinations, a method called retrieval-augmented generation (RAG) has been developed [22,24,25]. RAG combines nonparametric memory (external knowledge bases), specialized databases, and internet information with the training data of large language models (LLMs) [24-26]. This approach provides up-to-date knowledge and generates responses based on relevant evidence, minimizing hallucinations [26]. Therefore, we hypothesized that an AI chatbot with RAG that uses text from the cancer information service (CIS) [27] could provide accurate cancer-related information to the general public and patients. CIS is a reliable cancer information website operated by the National Cancer Center of Japan. The content is developed by medical professionals, including physicians, and is thoroughly reviewed before publication.

This study aims to examine how generative AI chatbots that refer to reliable information respond and explore the potential of AI in providing trustworthy cancer information. We developed a prototype of a generative AI chatbot that uses specific reference information and compared it to a traditional generative AI chatbot that relies only on its pretraining data, without any references. We investigated how RAG can help reduce these hallucinations in LLMs when delivering cancer-related medical information by assessing the characteristics of their responses and hallucination rates.

Methods

Ethical Considerations



This research does not involve human participants who require protection from risks involved in research. Therefore, it does not need a review by an institutional review board, according to the Japanese ethics guidelines for medical research involving human participants [28]. This study was reported in accordance with the TRIPOD (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis)-LLM [29].

Development of Generative AI Chatbots

As useful methods to reduce hallucinations, RAG, fine-tuning, and prompt engineering have been reported [25]. This study adopted RAG, which has the advantage of shorter development time, being simpler and more cost-effective than fine-tuning, and being easier to develop [25]. Additionally, the concept of the developed RAG is considered to be more easily applicable to other areas compared with prompt engineering [24,25]. We developed 6 types of generative AI chatbots by combining 2 versions of LLMs (GPT-4 and GPT-3.5 turbo-16k, referred to as GPT-3.5) with 3 reference information sources using RAG (CIS, Google search, and none) (Figure 1). Accordingly, the resulting chatbot types were as follows: CIS-based chatbots using GPT-4 and GPT-3.5, Google-based chatbots using GPT-4 and GPT-3.5, and conventional chatbots without RAG using only LLM, GPT-4, and GPT-3.5. The CIS chatbot system used CIS as the reference information source. We selected CIS as the RAG information source because its content is highly accurate and user evaluations indicate a sufficiently high overall satisfaction, even when compared with global standards [30]. All web page data from CIS was converted to text using Python for Windows (version 3.12; Python Software Foundation) and processed using the BeautifulSoup library (version 4.12.3), on a per-page basis. The data was then vectorized using text-embedding-ada-002 (OpenAI, Inc, accessed between March 15 and 20, 2024) and stored in a knowledge database (Azure AI Search, Microsoft Corporation, Redmond, WA, USA). To retrieve similar texts in response to user queries, a vector search was conducted using the Best Matching 25 algorithm and the Hierarchical Navigable Small World algorithm. The retrieved text was then processed by passing it to the LLM via RAG with prompt engineering, using an application programming interface (API) (OpenAI, Inc.) to generate responses. The Google chatbots were developed to compare responses generated by chatbots using accurate information sources (CIS) with those generated based on results from traditional search engines. These chatbots generated responses based solely on information retrieved from Google search results. The system used SerpAPI (integrated via LangChain, New York, NY, USA) to execute search queries and obtain relevant search results, including top-ten ranking websites. The conventional chatbots used GPT without any specific references, generating responses through the API. The system environment was developed using Python and Google Colaboratory (Google LLC, Mountain View, CA, USA), with the project development commissioned to Pipon Inc. (Tokyo, Japan).

Figure 1. Overview of 3 artificial intelligence (AI) chatbots. Six types of AI chatbots using retrieval-augmented generation (RAG). In the CIS chatbot system, reference information sources include “Cancer Information Service”, a reliable cancer information website operated by the National Cancer Center. In the Google chatbot system, responses are generated based solely on information retrieved from Google search results. The conventional chatbot uses the generative pretrained transformer without RAG. All generative AI chatbots used GPT-4 and GPT-3.5-turbo-16k. CIS: cancer information service; GPT: generative pretrained transformer; LLM: large language model.

Datasets

The questions were designed with the assumption that they would be used by the general public; thus, they did not cover specialized medical knowledge. Questions related to clinical matters and daily life were selected. One of the authors (SN) collected 80 cancer-related questions from 2 sources—the CIS website and Yahoo! Answers [31], a general opinion-based, community-driven platform provided by Yahoo Japan Corporation that is used to obtain information and resolve inquiries—between May and June 2024. All collected questions were reviewed by the authors. The questions were selected based on the following criteria: information availability, practical relevance to daily life, and simplicity of structure. These questions were generated by converting CIS and Yahoo! Answers content into interrogative forms, such as “What is…?” or “Could you explain…?.” After removing duplicates and integrating similar items, the final set comprised 62 cancer-related questions written in Japanese (Multimedia Appendix 1). Of these, 31 questions were based on information available on the CIS website. The remaining 31 questions addressed topics not covered by the CIS website. These were created by referencing posts on Yahoo! Answers. Questions were formulated by analyzing multiple user-submitted entries to capture common concerns and frequently asked issues among the general public. For each question from Yahoo! Answers, the absence of corresponding information on the CIS website was confirmed before inclusion. Each question was entered as a prompt, including the original full text in Japanese, along with a standardized instruction: "Use the following pieces of context to answer the question. If you don’t know the answer, just say that you don’t know; don’t try to make up an answer.” Only one response was generated per question without regeneration or manual revision. AI chatbot responses to these questions were generated by entering prompts (including the full original text of the questions). All 62 questions were fed into the 6 chatbots, yielding a dataset of 372 entries, and results were recorded in a data spreadsheet and linked to the corresponding questions. Access to all AI chatbots was provided between May and September 2024. For the English version presented in this paper, the responses in the dataset were translated from Japanese using GPT-4o and manually checked for technical terms by the authors. The original Japanese texts are shown in Multimedia Appendix 1.

Data Analysis

All generated responses were reviewed for accuracy and absence of hallucinations by one of the authors with 8 years of work experience at a university hospital, with practical involvement in patient support and medical communication that includes patients with cancer. Any ambiguity was resolved by consulting another author, a physician with more than 20 years of cancer information experience with the National Cancer Center of Japan. Chatbot responses were primarily classified into 5 types (Table 1): “No response,” “No response but provided additional information,” “Unclear response,” “Response containing

XSL•FO
RenderX

hallucinations," and "No issues." Under no response, the chatbot responded, "Unable to respond due to text not containing information," which was categorized as "No response." In contrast, the case where some additional information was provided as "Unable to respond, please consult your doctor or cancer consultation and support center" was categorized as "No response but provided additional information." Some of the responses provided were observed as unclear, including phrases like "It is not clear..." or "It is said to...," which were categorized as "Unclear responses," while others presented unsupported statements, including names that do not exist. Responses that included fictional names or terms, as well as incorrect information—such as nonevidenced answers or errors regarding surgical indications—were categorized as "Responses containing hallucinations." We defined hallucinations as responses that included nonexistent events, names, or terms, and unsubstantiated answers, distinguishing them from unclear responses. It is important to provide accurate information in the medical field; therefore, we defined a hallucination as a response that risks causing medical harm. Even when a response did not explicitly make a statement, if it could potentially cause medical harm, for example, "Consuming a lot of sugar may potentially increase the growth of cancer…," it was classified as a hallucination. Conversely, if the response was unlikely to have significant effects, such as "Exercising while having cancer can be effective if done under proper guidance and the supervision of a physician…," it was classified as an "Unclear response." All other responses were classified as "No issues."

Table . Examples of responses to chatbot queries and classification.

Questions and responses[a]	Classification
Q: "I live in the Kita Ward of Sapporo City. A friend has been diagnosed with bile duct cancer. Which hospital would be recommended for treatment?"	
A: "The provided text does not contain information about hospitals in Kita Ward of Sapporo City." (Generated by Google Chatbot GPT-4, CIS[b] Chatbot GPT-4)	No response
A: "The provided text does not contain information about hospitals in Kita Ward of Sapporo City. However, contacting the 'Cancer Consultation Support Center' may be helpful, as their staff can assist in finding hospitals with experience in treating bile duct cancer." (CIS Chatbot GPT-3.5)	No response but provided additional information
A: "There are hospitals and clinics in Sapporo City, Hokkaido, that specialize in the diagnosis and treatment of bile duct cancer." (Google Chatbot GPT-3.5)	Unclear response
A: "Here are some hospitals in the Sapporo City Kita Ward area that are known to provide treatment for bile duct cancer: • Hokkaido University Hospital • Sapporo Medical University Hospital • Sapporo City Hospital" (nonexistent name) (Conventional Chatbot GPT-4, - 3.5)	Response containing hallucinations
Q: "Can garlic treat cancer?"	
A: "While it is not clear whether garlic is effective in the treatment of cancer, it is said to have potential cancer-preventive effects." (Google Chatbot GPT-3.5)	Unclear response
Q: " Could you tell me which mushroom is most effective against cancer?"	
A: "The mushroom known to be effective against cancer is the Turkey Tail mushroom." (Nonevidence-based information) (Conventional Chatbot GPT-4, Google Chatbot GPT-4, - 3.5)	Response containing hallucinations

[a]The response was given in Japanese and presented in English in the table.

[b]CIS: cancer information service.

The response rate for model output and the hallucination rates of different chatbots were compared using a Fisher exact test, and the subgroup analysis was conducted with questions on and not on the CIS website. To assess the effect of RAG in reducing hallucinations, a generalized linear mixed-effects model (GLMM) assuming a binomial distribution on all datasets was applied. In this model, the reference data (ie, CIS vs conventional/Google) and versions of LLMs (ie, GPT-4 vs GPT-3.5) were included as fixed effects. The model was adjusted for whether the question content was covered on the CIS website, and both the presence of CIS-covered questions and response length were included as random effects. In the process of constructing the model, it was confirmed via Akaike information criterion comparison that these 2 random-effect factors did not significantly influence the model outcome. Odds ratios (OR) for hallucinations associated with the explanatory variables included as fixed effects were estimated using GLMM. Sample size calculations were based on a pilot dataset comprising 1000 simulation runs. The effect size assumed was an OR of 9.54, which was derived from the pilot testing with the preliminary samples of 240. The statistical power was set to β=.8, and α=.05. The calculation showed that we needed a sample size of 372. Although the observed OR was 9.4, a little smaller than the assumed effect size, we had a power of β of

XSL•FO
RenderX

85.6% (95% CI 83.3 - 87.7). In this analysis, the collected categorical data were transformed into dummy variables, and continuous variables were dichotomized with the median for use as categorical data. The normality of the data was assessed using the Shapiro-Wilk test and a normal Q-Q plot. Statistical analyses were conducted using Stata/IC for Windows (version 16.0; StataCorp LP). We used R for Windows (version 4.2.1; R Foundation for Statistical Computing) for the sample size calculation in GLMM (*simr* package) and modeling (*lme4* package). All reported *P* values were 2-sided, and $P<.05$ was considered statistically significant.

Results

Chatbot Response Rates and Patterns

Responses to 372 questions were classified according to the definitions described in the methods section. Of these responses, 116 (31%) were categorized as "No response," with 18 (5%) being "No response but provided additional information." Of the remaining 256 (69%) responses, 35 (10%) were "Unclear response," and 72 (19%) were "Responses containing hallucinations." Furthermore, 149 (40%) of all responses did not contain any issues and were classified as "No issues" (Figure 2).

Figure 2. Categorization of AI chatbot responses to all questions. Chatbot responses were categorized as follows: "No response" for cases where it stated, "Unable to respond due to text not containing information," and "No response but provided additional information" for responses like, "Unable to respond, please consult your doctor or cancer consultation and support center." "Unclear responses" included phrases like, "It is not clear." or "it is said to.," while "Responses containing hallucinations" referred to fictional names, unsupported claims, or incorrect information, such as errors about surgical indications. All other responses were classified as "No issues."

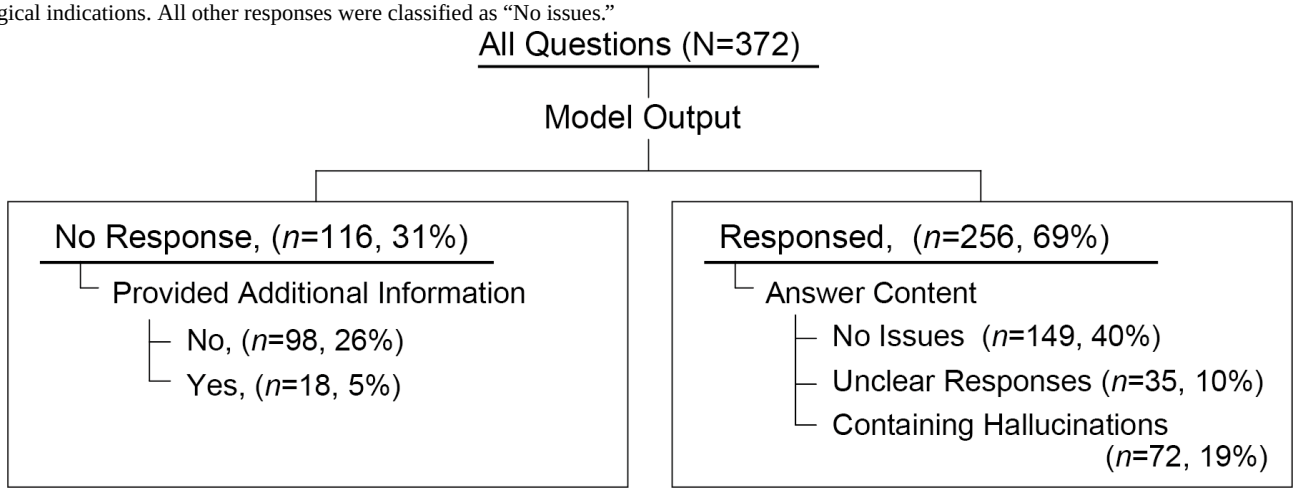

Table 2 shows the proportions of responses/nonresponses to the questions. The response rates varied significantly across the 6 chatbots, ranging from 22 (36%) to 62 (100%) responses out of 62 questions. The chatbots with RAG (ie, CIS chatbot and Google chatbot) had lower response rates than the conventional models. For 31 questions on information on the CIS website, the responses of the CIS chatbots were 22 (71%) for GPT-4 and 30 (97%) for GPT-3.5; however, they correctly returned nonresponse for questions not covered by CIS (0% response). On the other hand, Google chatbots responded to both questions on information covered and not covered by CIS more closely—14 (45%) and 16 (52%) for GPT-4, and 28 (90%) and 22 (71%) for GPT-3.5. The conventional chatbot responded to all questions regardless of the LLM versions.

Table . Response rates to questions by generative artificial intelligence (AI) chatbots for information covered/not covered by the cancer information service (CIS).

AI chatbot /LLM[a, b]	Total (N=62), answered, n (%)	Covered by the CIS (n=31), answered, n (%)	Not covered by the CIS (n=31), answered, n (%)	*P* value[c]
CIS GPT-4	22 (36)	22 (71)	0 (0)	<.001
CIS GPT-3.5	30 (48)	30 (97)	0 (0)	<.001
Google GPT-4	30 (48)	14 (45)	16 (52)	.80
Google GPT-3.5	50 (81)	28 (90)	22 (71)	.11
Conv. GPT-4	62 (100)	31 (100)	31 (100)	>.99
Conv. GPT-3.5	62 (100)	31 (100)	31 (100)	>.99

Chatbot Hallucinations

Table 3 shows the proportions of responses with hallucinations for the six chatbots. AI chatbots with RAG showed fewer hallucinations than conventional chatbots. Chatbots that reference CIS generated the lowest rate of hallucinations. For 31 questions on information on the CIS website, hallucinations seldom occurred: 0 (0%) and 2 (6%) for CIS chatbots and 2 (6%) and 3 (10%) for Google chatbots with GPT-4 and 3.5, respectively. For 31 questions on information not covered by CIS, Google chatbots generated more responses containing hallucinations: 6 (19%) with GPT-4 and 11 (35%) with GPT-3.5. The conventional models generated hallucinations in approximately 40% of their responses. Significant differences in the proportion of responses containing hallucinations were observed between the six types of chatbots (all *Ps*<.001).

Table . Rate of responses containing hallucinations (defined as text containing fictitious names, nonexistent terms, or incorrect information) by generative artificial intelligence (AI) chatbots for questions about information covered/not covered by the Cancer Information Service (CIS).

AI Chatbot /LLM[a, b]	Total (N=62), occurrence, n (%)[c]	Covered by the CIS (n=31), occurrence, n (%)[c]	Not covered by the CIS (n=31), occurrence, n (%)[c]
CIS GPT-4	0 (0)	0 (0)	N/A[d]
CIS GPT-3.5	2 (3)	2 (6)	N/A
Google GPT-4	8 (13)	2 (6)	6 (19)
Google GPT-3.5	14 (23)	3 (10)	11 (35)

[d]Not applicable due to no response.

Factors Associated With the Generation of Hallucinations

In bivariate analysis based on 256 questions that received responses (Figure 2), hallucinations differed significantly in their rate of occurrence depending on the RAG reference data (Table 4): the lowest rate was observed in the CIS chatbot, with hallucinations occurring in 2 (2%), followed by the Google chatbot with 22 (18%) and conventional chatbot with 48 (39%) (*P*<.001). The occurrence of hallucinations was not related to the content of questions being covered or not covered by CIS, output length, and versions of LLM (All, *P*≥.05). In multivariate analysis, adjusting for other factors, models with RAG reference data from Google search results were more likely to generate hallucinations compared with those with RAG reference data from CIS, with an OR of 9.4 (95% CI 1.2 - 17.5; *P*<.01). Similarly, conventional GPTs had an OR of 16.1 (95% CI 3.7 - 50.0; *P*<.001) compared to those with RAG reference data from CIS. Differences in LLM versions did not contribute to hallucination generation.

Discussion

Principal Findings

We focused on reducing misinformation by avoiding hallucinations. By testing generative AI chatbots with RAG on different referencing datasets, our study showed that incorporating reliable cancer information significantly reduced the occurrence of hallucinations compared with using conventional GPT models or Google searches as reference sources. Conversely, when no reference information was available, the system correctly returned no response.

Comparison to Prior Work

In this study, nonparametric memory LLMs (CIS Chatbot/Google chatbot) had fewer hallucinations than the parametric memory LLM (conventional chatbot) (2% - 18% vs39%, *P*<.001, Table 4). This highlights the importance of the quality of nonparametric knowledge sources, as indicated by the Google chatbot with the odds of hallucination 9.4 (95% CI 1.2 - 17.5, *P*<.01) times as large as that of the CIS chatbot (Table 4). Many websites that provide information on cancer treatment have a higher proportion of harmful information compared with those offering reliable information in Japanese [2,3]. In this study, the responses by the Google chatbot to information that lacks evidence (not covered by CIS) and its higher incidence of hallucinations compared with those of the CIS chatbot suggest that misinformation or evidence-lacking information existed within the reference sources. Since LLMs generate responses based on reference information without assessing the accuracy of that information, the accuracy of the RAG information source is crucial for providing accurate information. The use of AI chatbots on various cancers has been reported, including head and neck cancer [32], prostate cancer [33], liver cancer [34], kidney cancer [35], breast cancer [36,37], lung cancer [20], colon cancer, pancreatic cancer [38], cervical cancer [39], as well as topics like cancer treatment [13,40], ophthalmic information [11,41,42], and cardiovascular disease

XSL•FO
RenderX

prevention [43]. In these studies, RAG was not used. In situations where the definitions and extent of hallucinations are not clearly established, AI chatbots generally lack expertise and accuracy, despite containing hallucinations and significant gaps in information [15,44]. Clinical acceptability can be influenced by many factors, including social expectations of the AI, the extent of damage the potential inaccuracy can cause, and the support system to check and correct hallucinations. Additionally, previous studies in which national medical licensing examination questions were answered by a chatbot have reported that the accuracy of AI responses varies depending on the complexity of the questions [45]. The potential influence of clinical informatics and cancer-related topics, which could be more prone to hallucinations compared with other clinical, medical, and health informatics topics, could not be thoroughly examined in this study. The RAG-AI chatbot could enable the bridging of these gaps if it obtains accurate information. Overall, our findings support that in RAG-based systems, the reliability of reference information plays a key role in reducing hallucination generation.

Generally, questions from patients with cancer span a wide range of topics and are not limited to evidence-based content [46]. In this study, a trade-off was observed between the hallucination rate and response rate across different types of chatbots. The conventional chatbot responded to all inquiries, the RAG chatbot, especially with CIS reference, exhibited an increased rate of unanswered questions (100% vs 36 - 81%, P<.001, Table 2). Not providing misinformation suggests that developing RAG-AI chatbots has the potential to prevent patients from being harmed by misinformation. We need to consider how such systems should address responses that lack scientific evidence during their development for general use. Conversely, we observed that the CIS chatbot at times did not respond to questions about information that existed in the CIS references. Cases in which the chatbot does not respond despite the presence of relevant information in the reference data represent a technical challenge that must be addressed. These problems may have been caused by errors in data retrieval by the LLM or by vectorization or structuring in the knowledge database [22]. However, these could be minimized through LLM fine-tuning and prompt engineering [22]. When developing RAG-AI chatbots, information from reliable data sources can be used to explain the reasons for lack of evidence or to issue warnings by combining a scenario-based chatbot with standardized responses [47]. Further, the AI chatbot search style used in this study could display only relevant content according to the user query and has the added benefit of simplifying the information retrieval process, improving efficiency, and saving time [15].

Limitations

This study has several limitations. First, the evaluated LLMs were limited to GPT-3.5-turbo-16k and GPT-4. AI advances are rapid, and as of 2025, many new capable versions, such as GPT-4.5 [48], Gemini 2.0 Pro [49], and Claude 3.7 Sonnet [50] have been developed. While there were no statistically significant differences in hallucination rates between the LLM versions, each LLM has its own characteristics, and there may be models better suited for RAG-AI chatbots. Second, we did not verify the accuracy of the data referenced by the RAG of the Google chatbot. Because the Google chatbot references the Google search results, the information referenced by the Google chatbot naturally included treatments not approved by the Japanese regulatory authorities and did not exclude sites that made exaggerated claims without relevant clinical evidence. A report showed that advertisements constitute 10% of the information accessed in search results in Japan [3]. In the future, analyzing the relationship between the original reference data and the generated responses could provide insights into the hallucination generation process. Third, all questions and responses were conducted in Japanese. Reports indicate that GPT-4 has improved capabilities for languages other than English compared with GPT-3.5 [51]. However, since we did not compare responses in English, some hallucinations may have been caused by simple errors in translation into Japanese. Nonetheless, the results indicate that RAG, using accurate information sources, can generate high-quality responses even in languages other than English. Fourth, in this study, a wide range of CIs were observed in the multivariate model (eg, conventional GPT OR 16.1, 95% CI 3.7 - 50.0). This may reflect that the sample size was relatively small. A model excluding the length of the generated text and quality of the questions showed that the Akaike information criterion remained almost unchanged compared with the final model. Investigating a larger sample size in the future may lead to more robust results. Finally, having a single reviewer for response classification may have introduced some misclassification bias. Of the 76 detected hallucinations, 51 clearly contained factually incorrect information, such as nonexistent events, names, or terms. These errors were objectively confirmed by cross-checking with the CIS website and medical guidelines. The remaining 25 cases included statements presented with certainty despite lacking medical evidence, raising concerns about their reliability. These cases were reviewed by a physician with extensive experience in cancer information to ensure the validity of the assessments. Accordingly, it is reasonable to assume that the risk of misjudgment associated with single-reviewer classification was minimal within the scope of this study.

Future Directions

The development of RAG-AI chatbots such as the CIS chatbot in this study, which is linked to highly reliable information, like medical guidelines and scientific papers, has the potential to address these issues. Such systems have the potential to bridge the current gaps in accessing medical information for patients with cancer and their families.

Conclusions

This study demonstrates that using RAG to incorporate accurate medical information into generative AI chatbots can reduce hallucinations. We believe that the results of this study are encouraging. Advances in both generative AI technology and better information sources can generate optimal responses for topics that lack scientific evidence while preventing hallucinations due to inferior data use, enabling accurate information provision by AI chatbots.

Abstract

Background: Asian American patients have reported unique needs and barriers related to cancer care. While patient navigation can facilitate care coordination and help address barriers to care, in-person navigation is time and resource intensive. Virtual patient navigation can extend the benefits of patient navigation to more patients, especially those with non-English language needs.

Objective: This study aimed to develop, implement, and test an online portal providing virtual navigation, including access to resources in English, Chinese, and Vietnamese, for Asian American patients with newly diagnosed colorectal, lung, or liver cancer.

Methods: The online portal was built on a secure, cloud-based platform. We recruited adults aged 21 years or older with a recent diagnosis of stage I-IV colorectal, lung, or liver cancer; who identified as Asian American; spoke English, Cantonese, Mandarin, or Vietnamese; and resided in the Greater San Francisco Bay Area, California. Participants were assigned a language-concordant navigator who assessed their needs and provided tailored resources and support over 6 months through the online portal. Participants completed baseline, 3-month, 6-month, and user experience surveys. We report descriptive statistics on sociodemographic characteristics, quality of life (Functional Assessment of Cancer Therapy–General [FACT-G]), and user experiences. We used generalized estimating equations (GEE) to analyze repeated measures of quality of life.

Results: The online portal included (1) a public-facing landing page, (2) a navigator interface, and (3) a participant interface, which were all available in English, Chinese, and Vietnamese. Among 51 participants, 47 (92%) and 49 (96%) completed the 3- and 6-month surveys, respectively. The mean age was 58 (SD 13) years, with 37 (73%) men, 33 (65%) speaking English, and 20 (39%) having less than a college education. Twenty-six participants (51%) had colorectal cancer, 21 (41%) had lung cancer, and 4 (8%) had liver cancer. The average total FACT-G score was 73.0 (SD 17) at baseline, 73.2 (SD 17) at 3 months, and 75.1 (SD 19) at 6 months. In GEE models, participants reported an increase in emotional well-being at 6 months compared to baseline (coefficient 0.99, 95% CI 0.01 - 1.97). Among the 47 participants who completed the user experience survey, some reported issues with registering and logging into the portal, but 44 (94%) reported that the program was culturally appropriate, 35 (74%) found calls from the navigators helpful, and 35 (74%) would recommend the program to others.

Conclusions: This multilingual virtual patient navigation program for Asian American patients with cancer was deemed culturally appropriate and helpful in our pilot study. Emotional well-being improved among users of the portal. Some participants reported technical challenges, but most were satisfied with the program. Language-concordant virtual patient navigation and online supportive care tools can extend the reach and benefits of patient navigation.

Introduction

Patient navigation is a patient-centered health care delivery strategy that aims to help patients and their families identify and overcome health care barriers [1]. Patient navigation is an effective intervention for improving access to care, facilitating coordination of care, and increasing rates of preventive cancer screening, particularly for underserved patients [1]. Importantly, patient navigation can also help address linguistic and cultural barriers that contribute to disparities in health care access and outcomes [2]. Recognizing the critical role of social drivers of health, patient navigation can provide patients with guidance and support to address barriers related to finances, transportation, housing, food access, mental health, and language [3-6]. Navigators can also provide logistical guidance in navigating the complex health care system, especially for diseases such as cancer that can involve multiple health care providers [7,8]. However, patient navigation programs are human resource–intensive and can be confined by geography or the health care system. As a result, they are not easily scalable or inclusive of broader patient populations.

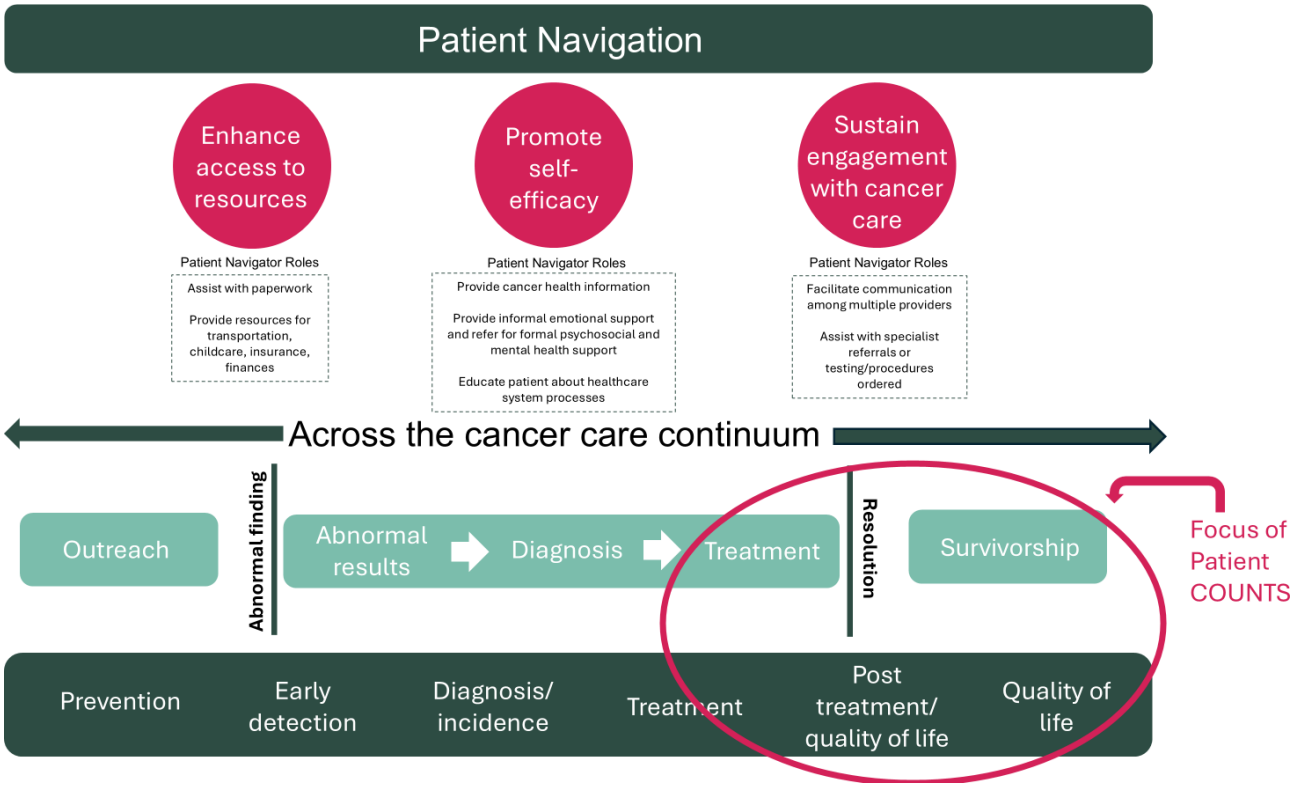
Cancer is the leading cause of death among Asian American adults [9]. Asian American patients with cancer have reported barriers to care, including communication challenges and language discordance with their health care team, limited information about cancer diagnosis and treatment, and difficulty in navigating the health care system [10-12]. They have also reported unmet needs related to their physical health, psychosocial stress, finances, and overall quality of life [13]. Virtual patient navigation and online supportive care tools have the potential to extend the benefits of patient navigation to a wider audience, particularly those with non-English language preferences, who face increased barriers to obtaining care and accessing resources [14-16]. Such tools can also help address the complex medical, emotional, social, and logistical needs of patients with cancer, thereby improving quality of life, physical and emotional functioning, and reducing symptom distress [17-21].

Patient Cancer OUtreach, Navigation, Technology, and Support (COUNTS) is a pilot program designed to provide resources and support to Asian American patients with cancer and their caregivers through virtual navigation from a language-concordant patient navigator and an online portal. In the first phase, we designed, implemented, and pilot-tested an in-person patient navigation intervention, which was reported previously [22]. We refined the patient navigation program based on feedback from the in-person pilot test for the virtual navigation phase of our study. Here, we describe the design and development of an online portal to facilitate patient navigation. We then pilot-tested this online portal among participants and navigators in English, Chinese, and Vietnamese and reported on the usability. Our focus is to demonstrate how this novel approach can showcase the scalability of a language-concordant, virtual patient navigation model and improve the quality of life among Asian American patients with newly diagnosed colorectal, lung, or liver cancer.

Methods

Patient COUNTS Portal Design and Development

A Patient Advisory Council (PAC) was convened to guide the development and implementation of Patient COUNTS. The PAC consisted of 15 Asian American members who were patients with cancer and/or survivors, caregivers, community leaders, academic partners, and cancer clinicians. The PAC met every 2 months starting in September 2018 through June 2022.



We adapted frameworks by McKenney et al [23] on patient navigator roles as well as Freeman and Rodriguez [24] on patient navigation across the health care continuum for the intervention (Figure 1). The roles of our patient navigators included helping participants enhance access to care, promote self-efficacy, and sustain engagement with care. The study team worked with the UCSF School of Medicine Technology Services (SOM Tech) to develop an online portal to facilitate virtual patient navigation for Asian American patients with cancer, with these patient navigator roles in mind.

The online patient portal was built in Salesforce, a secure, Health Insurance Portability and Accountability Act (HIPAA)–compliant, cloud-based platform, and project management was handled in Jira (Atlassian Corporation). The portal was developed using an iterative and collaborative process over two 5-month build periods. Upon completion of each of the 2 builds, the SOM Tech team met with the study team to conduct usability testing and user training, particularly for the patient navigators. Finally, the team worked closely with SOM Tech, the PAC, and the Shanti Project (a community-based organization that provides navigation to patients with cancer in San Francisco) to ensure the online portal was user-friendly, culturally relevant, and linguistically accurate. Feedback on the portal was gathered during focus groups and PAC meetings at multiple points during development. Modifications to the portal were made based on priority and budget. All elements of the portal were available in English, Chinese, and Vietnamese; translation and back-translation for the portal were conducted by multilingual staff.

The study team worked with the Shanti Project to develop a database of trusted local, tailored resources related to health care access, financial and legal issues, social and emotional support, transportation, food and nutrition, cancer information, housing, and other issues. The database was integrated into the navigator interface of the online portal so that navigators could identify appropriate resources to share with participants based on the needs reported by participants. Over the course of the study, navigators also added new resources to the database based on new needs identified by participants.

Figure 1. Patient navigation across the cancer care continuum framework (adapted from McKenney et al [23] and Freeman and Rodriguez [24]).

Online Portal Implementation, Testing, and Evaluation: Participant Population and Recruitment

The implementation and testing of virtual patient navigation via the online portal for Patient COUNTS occurred from October 2020 to May 2022. Adult patients with recently diagnosed cancers within the previous 6 months were identified using an early-case ascertainment process from the Greater Bay Area Cancer Registry, a population-based cancer registry that covers 9 counties (Alameda, Contra Costa, Marin, Monterey, San Benito, Santa Clara, Santa Cruz, San Francisco, and San Mateo) in California. After receiving lists of newly diagnosed patients with cancer from the Greater Bay Area Cancer Registry, letters were sent to the physician on record to ensure that there was no medical contraindication for study participation. If there were no responses from the physician after 14 days, an invitation letter with an opt-out option was sent to the potential participant. After another 14 days, recruiters called potential participants who did not respond to the invitation letter to assess interest and eligibility. Additional recruitment approaches included informing health care providers and community organizations about the study and distributing flyers.

The eligibility criteria were: adults aged 21 years or older; self-identified as Asian American; spoke English, Cantonese, Mandarin, or Vietnamese; had stage I-IV colon, rectum, lung, or liver cancer; diagnosed in one of 9 Greater Bay Area counties; were currently receiving treatment or planning to receive treatment; and were willing to stay in the study for 6 months. Participants were excluded if they were unable to provide consent because of a medical or psychological condition or if they had already completed treatment at the time of enrollment.

Our initial goal was to enroll 50 participants in this pilot virtual patient navigation study, based on the feasibility of the available patient pool, numbers needed to assess portal effectiveness, and resource availability. We screened participants for eligibility until we reached our target sample size.

Virtual Patient Navigation Intervention

Potential study participants accessed an eligibility screener by entering a unique code that was included in a mailed invitation letter. Upon entering their code and completing the eligibility screener, eligible participants were directed to an electronic consent form and online registration. Once registered as a study participant, participants were assigned a language-concordant patient navigator. After ensuring eligibility and obtaining consent, patient navigators connected with participants through the portal.

Navigators received training through the Shanti Project as well as supervision by study team members with expertise in issues related to Asian American patients with cancer [22]. We leveraged the pillars of our patient navigation framework to ensure the roles played by our patient navigators met the unique needs of our participants. The needs assessment survey was conducted through the online portal, where navigators assessed logistical, psychosocial, and financial needs. Based on the needs reported by each participant during their 6 months enrolled in our program, patient navigators provided logistical and emotional support. The assigned patient navigator aimed to enhance access to care by providing tailored resources to the participant through the participant's individualized resource page on the online portal (eg, local financial and legal resources, information on where to obtain durable medical equipment, or transportation assistance). Participants could also peruse the database of local resources that our team curated on the general

XSL•FO
RenderX

resource page of the online portal, which was available to all participants. Navigators promoted self-efficacy by providing emotional support or referring participants to formal psychosocial support. They also provided cancer-related health information relevant to the questions asked by participants. Finally, patient navigators encouraged sustained engagement with care by helping to schedule appointments or facilitating communication with care teams, including interpreting for patients during clinic appointments if requested.

Throughout the program, patient navigators connected with participants through the online portal, text messages, phone calls, or WeChat (Tencent Holdings Ltd), a smartphone app popular among Chinese-speaking participants. The use of multiple modes of communication ensured that navigators could reach participants using a preferred method, enhancing the overall user experience and engagement. The frequency and timing of navigator-participant interactions were tailored to the needs of each participant.

Navigators conducted baseline, 3-, and 6-month in-language surveys. These surveys could be conducted through the online portal, but were also available by phone or mail, depending on the participant's preference.

Survey Administration

The baseline survey and the follow-up surveys at 3 and 6 months included questions about sociodemographic characteristics; cancer type, stage, and treatment; and quality of life. Participants were also asked about needs related to patient navigation or cancer support, including financial issues, transportation or housing concerns, symptom management related to cancer or treatment side effects, mental health needs, or assistance related to language issues.

Participants who completed the 6-month program were invited to complete a user experience survey, which evaluated participants' experiences and satisfaction with the program. If family members assisted participants with the online portal, they were also invited to complete a user experience survey. The user experience survey was administered by a trained multilingual project staff member in participants' preferred language (English, Cantonese, Mandarin, or Vietnamese) who was not the participant's assigned navigator and who had limited contact with the participant.

Based on participants' preferences, all surveys (baseline, 3-month, 6-month, and user experience) were conducted online through the portal, by phone, or via mail.

Study Measures and Variables

Sociodemographic characteristics were obtained from the baseline survey, including age, sex, highest level of education, marital status, annual household income, health insurance status, nativity, language preference, and English language fluency. Information on cancer type, stage, and treatment (including surgery, chemotherapy, or radiation) was self-reported on the baseline survey or was obtained from the cancer registry (if applicable).

We evaluated whether participants completed standard-of-care treatment based on their cancer type and stage. Standard-of-care treatment was defined from guidelines from the National Cancer Institute and reviewed by an oncologist on the team (Multimedia Appendix 1).

We used the Functional Assessment of Cancer Therapy–General (FACT-G) to assess quality of life through the baseline and both follow-up surveys. The FACT-G includes four subscales assessing (1) physical well-being, (2) social well-being, (3) emotional well-being, and (4) functional well-being. The instrument has a total of 27 items, each with a 5-point rating scale (0=not at all, 1=a little bit, 2=somewhat, 3=quite a bit, and 4=very much). For the FACT-G subscale domains in the study sample, Cronbach α values ranged from 0.72 to 0.79, suggesting acceptable internal consistency across subscales.

For this study, subscale scores were computed as the prorated sum of the item responses for that subscale as long as more than 50% of the questions comprising the subscale were answered. Prorating replaces missing values with the mean of the completed items for that subscale and is an acceptable method of imputing missing data in the FACT-G instrument [25].

The FACT-G total score was calculated as the sum of the 4 subscale scores, as long as at least 22 of the 27 items (80%) were answered; total FACT-G scores ranged from 0 to 108. Higher scores represent a better quality of life. However, due to an error in the English version of the question "I feel close to my friends," we removed this item when calculating the social score for all participants. Therefore, the maximum total score for the FACT-G in our study was 104.

We defined clinically meaningful change as a 2-point change in a subscale domain or a 4-point change in the total FACT-G score [26].

Data Analysis

Survey data were managed using Research Electronic Data Capture (REDCap; Paul A Harris; [27]), Qualtrics (Qualtrics^{XM}), and Salesforce (Salesforce, Inc) electronic data capture tools. For survey responses, we report descriptive statistics on sociodemographic characteristics, quality of life, and user experiences. We used generalized estimating equations (GEEs) to analyze repeated measures of quality of life for total FACT-G and each subscale domain (physical well-being, social well-being, emotional well-being, and functional well-being) separately; no covariates were included in the GEE models. Stata (version 16.0; StataCorp LLC) was used to analyze the data.

Ethical Considerations

The study was registered with the National Institutes of Health Clinical Trials Registry (NCT03867916). The University of California, San Francisco, Institutional Review Board (18 - 25820) and the state of California Committee for the Protection of Human Subjects approved this study (2019 - 176-UC San Francisco). All consent and study materials were available in English, Chinese, and Vietnamese. Consent was obtained by phone or online in the participant's preferred language. For interested participants who deferred to family members, we obtained verbal consent from the participant to allow us to speak to their family member. Participants were

XSL•FO
RenderX

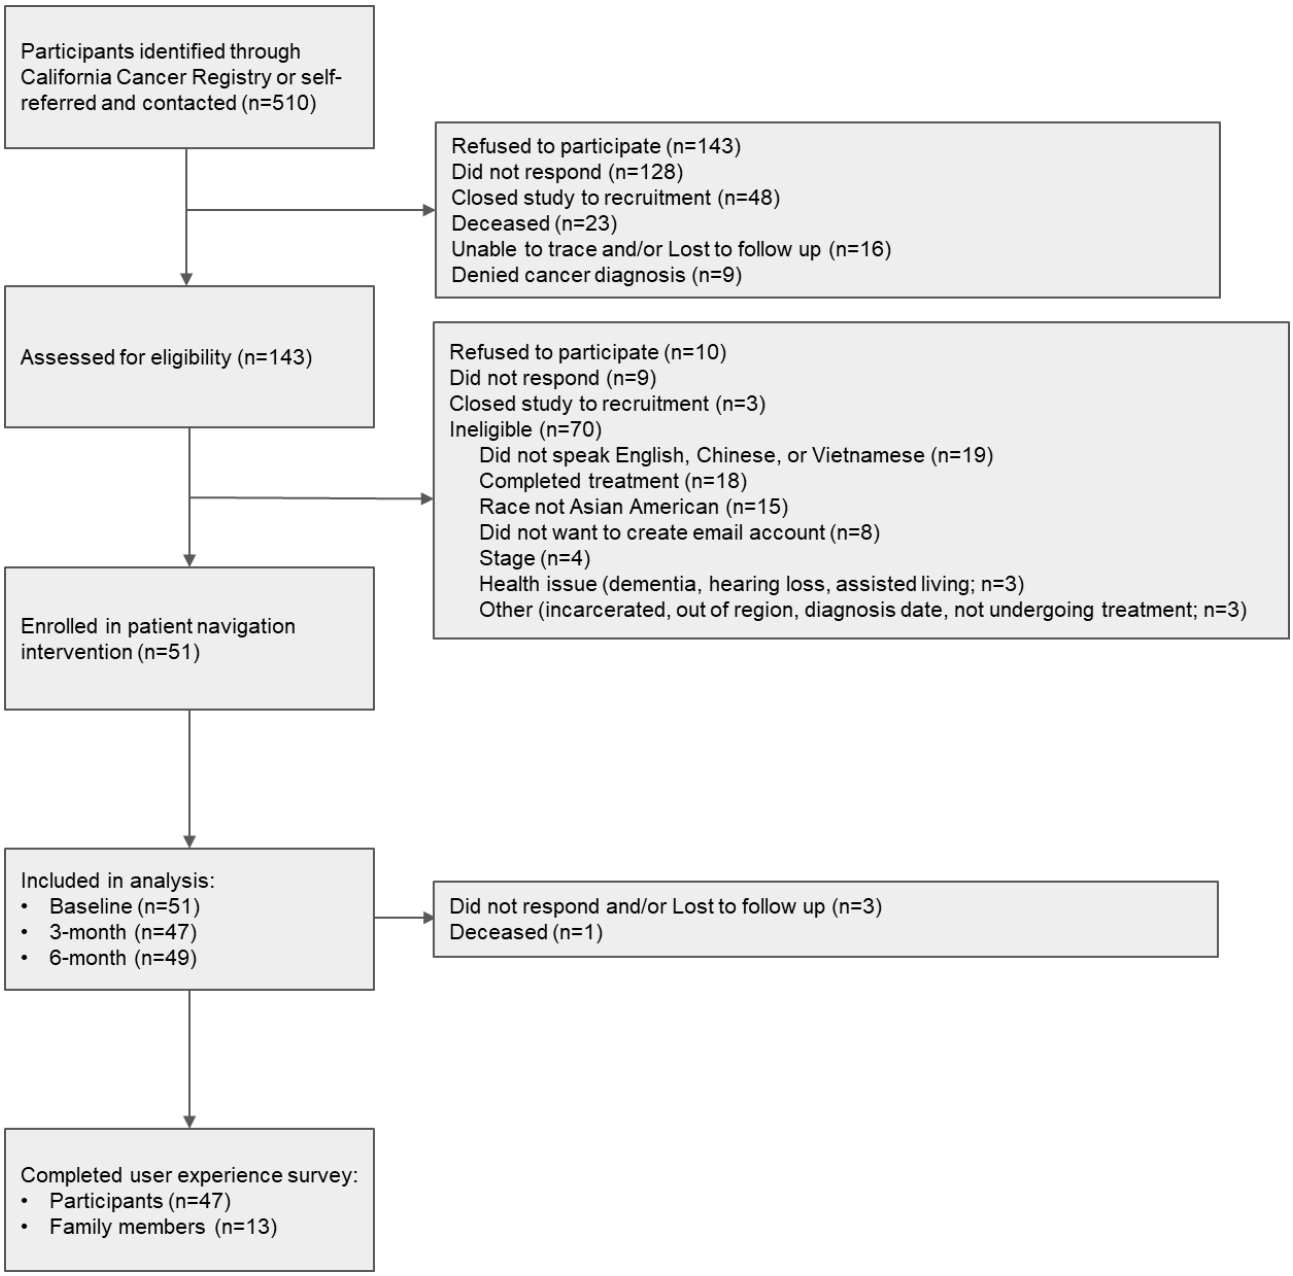
assigned a study-specific ID number. All surveys were deidentified; only deidentified data were shared among the research team during the analysis phase. Data were stored behind the Department of Epidemiology and Biostatistics firewall on a password-protected server that was accessible only by the research team. Participants were provided a gift card of US $25 for completing each of the baseline, 3-month, 6-month, and user experience surveys (up to US $100 total).

Results

Portal Development

The online portal was built in 2 phases. During the first build (May to September 2019), the team built the infrastructure in Salesforce Health Cloud, integrated Qualtrics for data collection, built a participant interface for eligibility screening, consent, and enrollment, translated the website, developed notifications and reporting, and conducted user acceptability testing. The team received feedback from the PAC to improve the usability of the online portal, including increasing font size for readability and more clearly differentiating between how to contact the navigator for program or resource questions versus how to contact the study team for concerns about the study. Based on user feedback, the needs assessment was reordered to be completed before the rest of the survey. In addition, the resources provided to participants on the participant interface of the online platform were reorganized to prioritize relevance and language. During the second build (January to March 2020), the team worked to improve the navigator experience, created follow-up surveys, improved the participant interface on the online portal, translated the portal into Vietnamese, and made other improvements based on the feedback provided during PAC sessions and user acceptability testing.

Ultimately, the online portal included three main components: (1) a public-facing landing page, (2) a navigator interface, and (3) a participant interface. The landing page provided background information about the study, video testimonials from patients and caregivers, biographies of the patient navigators, and the study's contact information. Patient navigators used the online portal for eligibility screening, obtaining consent, and administering the surveys. They also used the online portal to contact patients, assess needs, and provide resources relevant to those needs. On the participant interface, participants could log in to the online portal and either access the personalized resources provided by navigators or explore all the resources available in the database. The contact information for their assigned patient navigator was available on the online portal. The entire online portal was available in English, Chinese, and Vietnamese. During the study, 51 participants, 16 caregivers, and 4 patient navigators used the online portal.



The study team collated an extensive database of 167 local resources to provide to participants in the following domains: (1) affordable medical and dental care, as well as alternative medicine services; (2) financial, transportation, legal, or housing needs; (3) activities for patients with cancer and survivors; (4) caregiver resources for both children and adults; (5) information about side effects of treatment, as well as organizations that provided cosmetic and durable medical equipment to help mitigate some of those side effects; (6) mental health services, including individual counseling and support groups; and (7) local food resources.

Online Portal Testing and Evaluation: Participant Recruitment and Baseline Characteristics

Of 510 potential participants with newly diagnosed colorectal, lung, or liver cancer who were identified for potential eligibility, including 1 participant who self-referred, 143 (28%) refused, 128 (25%) did not respond, 23 (5%) were deceased, 16 (3%) were lost to follow-up, and 9 (2%) denied having a cancer diagnosis (Figure 1). In addition, 48 were sent letters, but did not receive follow-up phone calls for enrollment due to the study's closure to recruitment. Among the remaining 143 participants who were assessed for eligibility, 10 (7%) refused, 9 (6%) did not respond, and 3 (2%) were not fully followed up on due to the study closing to recruitment; 70 (49%) were ineligible due to not speaking English, Chinese, or Vietnamese; having already completed treatment; not identifying as Asian American; or not wanting to create an email account (Figure 2). In total, 51 participants completed the baseline survey and were enrolled in the intervention, 47 (92%) completed the 3-month follow-up survey, and 49 (96%) completed the 6-month follow-up survey. Forty-seven (92%) participants completed surveys online, and 3 (8%) participants completed surveys over the phone. Navigators and participants mostly connected through phone calls (51 participants; range 1 - 27 calls) and emails (36 participants; range 1 - 10 emails). Navigators only messaged 2 participants (range 1 - 5 messages) through the online portal.

XSL•FO
RenderX

Figure 2. Flow diagram for participants in the Patient Cancer OUtreach, Navigation, Technology, and Support (COUNTS) pilot virtual patient navigation program.

For the 51 participants, the average age was 58 years (SD 13), 37 (73%) were male, and 43 (84%) were married or living with a partner (Table 1). Twenty (39%) participants had less than a college education, and 15 (29%) had a household annual income of US ≤$50,000. Participants in this study largely relied on Medicare and Medi-Cal for health insurance (34/51, 66%) (Table 1). Twenty-seven (53%) participants were born in China or Hong Kong, 5 (10%) in Vietnam, and 12 (24%) in other countries outside of the United States (including India, the Philippines, Japan, Indonesia, Laos, Malaysia, Pakistan, and Taiwan). Thirty-three (65%) participants reported their preferred languages as English, 16 (31%) preferred Cantonese, and 2 (4%) preferred Vietnamese (Table 1).

Characteristic	Participants
Cancer treatment status (at baseline)[a], n (%)	
Had surgery	36 (71)
Started chemotherapy	29 (57)
Started radiation	16 (31)
Not planning on having treatment	1 (2)
Completed standard-of-care treatment[f]	34 (83)

[a]Not mutually exclusive categories.

[b]Other place of birth includes India, Philippines, Japan, Indonesia, Laos, Malaysia, Pakistan, and Taiwan.

[c]Defined as speaking English "not well" or "not at all."

[d]Defined as needing help with reading instructions, pamphlets, or other written material from doctor or pharmacy "sometimes," "often," or "always."

[e]Redacted for cell size n≤11 if data from cancer registry.

[f]Defined from guidelines from the National Cancer Institute and reviewed by an oncologist on the study team.

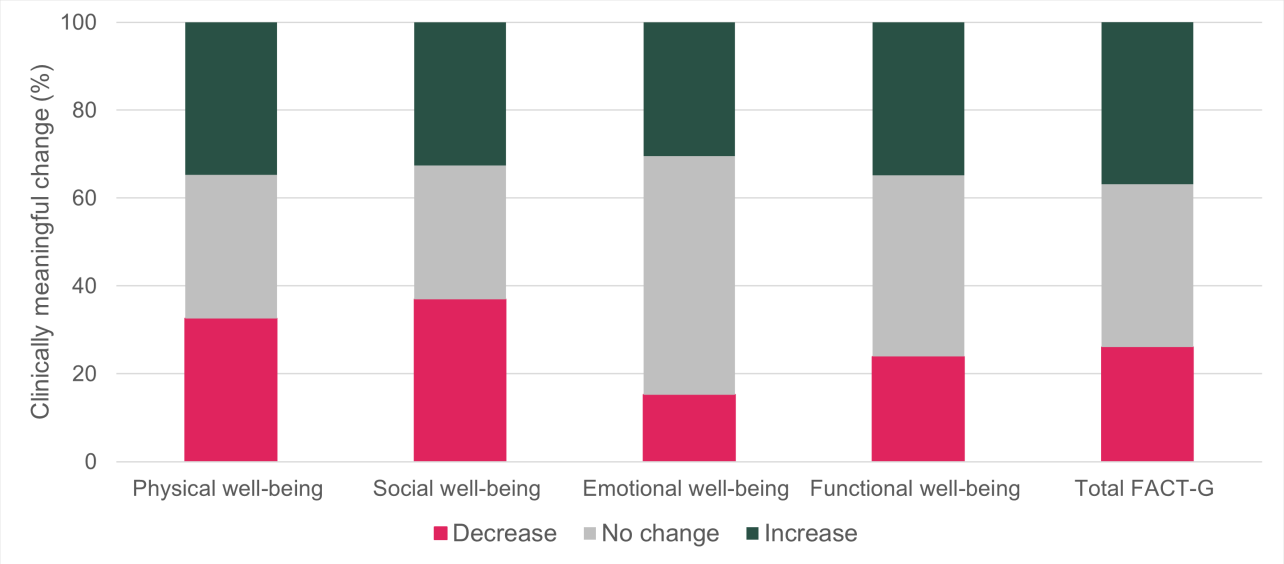
Twenty-six (51%) participants had colorectal cancer, 21 (41%) had lung cancer, and 4 (8%) had liver cancer. Twenty-three participants (55%) had stage I or II cancer. Most participants had started cancer treatment at baseline, with 36 (71%) having undergone surgery, 29 (57%) having started chemotherapy, and 16 (31%) having started radiation (Table 1). Among participants who received treatment during the study period, 34 (83%) completed standard-of-care treatment. The remaining participants had partially completed recommended treatment, but it is unknown if treatment was fully completed, as we did not follow them past the 6-month timeframe of the study.

Participant Quality of Life: FACT-G Scores

Among all participants who completed baseline, 3-, and 6-month surveys, the average FACT-G score was 73.0 (SD 17.0), 73.2 (SD 17.2), and 75.1 (SD 19.1), respectively (Table 2).

Table . Functional Assessment of Cancer Therapy–General (FACT-G) scores at baseline, 3-month, and 6-month surveys for Patient Cancer OUtreach, Navigation, Technology, and Support (COUNTS) participants.

FACT-G domain[a]	Baseline (n=49), mean (SD)	3 months, (n=45), mean (SD)	6 months (n=46), mean (SD)
Physical well-being	20.9 (5.9)	21.7 (5.5)	21.7 (6.4)
Social well-being	16.8 (5.5)	16.4 (5.1)	17.0 (4.9)
Emotional well-being	18.1 (4.3)	18.3 (4.2)	19.1 (4.2)
Functional well-being	17.1 (6.7)	16.7 (6.4)	17.3 (7.5)
Total FACT-G[b] score	73.0 (17.0)	73.2 (17.2)	75.1 (19.1)



[a]Includes participants who completed both baseline and 6-month surveys and answered at least half of each of the subscales. Answers to the statement "I feel close to my friends" were dropped from all participants in the analysis, given an incorrect transcription in English. Therefore, the total FACT-G score for our study was out of a total of 104 points (compared to the usual 108 total points), and the social well-being subscale domain had a maximum of 24 points; the subscale domains for physical, emotional, and functional well-being remained the same (maximum 28 points each).

[b]FACT-G: Functional Assessment of Cancer Therapy–General.

Sixteen (35%) participants had a clinically meaningful increase in physical well-being, 15 (33%) in social well-being, 14 (30%) in emotional well-being, 16 (35%) in functional well-being, and 17 (37%) in total FACT-G scores (Figure 3).

XSL•FO
RenderX

Figure 3. Clinically meaningful changes in Functional Assessment of Cancer Therapy–General (FACT-G) total and subscale scores from baseline to 6-month survey for Patient Cancer OUtreach, Navigation, Technology, and Support (COUNTS) participants.

Among participants who completed baseline and 6-month surveys, clinically meaningful change was defined as a 2-point change in the subscale domain or a 4-point change in total FACT-G score.

In our GEE model, only emotional well-being had a clinically meaningful increase at 6 months compared to baseline (coefficient 0.99, 95% CI 0.01 - 1.97; Table 3).

Table . Generalized estimating equation (GEE) models analyzing repeated Functional Assessment of Cancer Therapy–General (FACT-G) total and subscale scores at 3 months and 6 months compared to baseline.

FACT-G[a] domain[b]	3 months, coefficient (95% CI)	6 months, coefficient (95% CI)
Physical well-being score	0.70 (−0.67 to 2.06)	0.52 (−0.83 to 1.87)
Social well-being score	−0.55 (−1.94 to 0.84)	0.06 (−1.32 to 1.45)
Emotional well-being score	0.25 (−0.73 to 1.24)	*0.99 (0.01 to 1.97)* [c]
Functional well-being score	−0.50 (−2.00 to 1.00)	0.17 (−1.33 to 1.66)
Total FACT-G score	−0.09 (−3.72 to 3.54)	1.74 (−1.86 to 5.34)

[a]FACT-G: Functional Assessment of Cancer Therapy–General.

[b]No covariates were included in the GEE models.

[c]Italicized values indicate statistically significant at $P<.05$.

User Experience

The user experience survey was completed by 47 participants and 13 family members, representing 48 unique participants. Of 47 participants who completed the user experience survey, 44 (94%) reported that the program was culturally appropriate (“good,” “very good,” or “excellent”). In addition, 35 (74%) reported that calls from the navigator were helpful, and 37 (78%) said that navigators understood their concerns. Participants reported that the most useful features of the online portal were the needs assessment, videos describing cancer experiences among Asian American patients, and resources being available online. However, 21 (45%) participants had difficulty with the technical aspects of the portal, with 15 (32%) reporting they got help from family members to use the portal. Most participants who reported difficulty with the portal reported issues related to registering and logging in to the platform, including not knowing how to enter the code provided to them (for eligibility screening). Nevertheless, 36 (77%) participants thought the online portal was useful, 39 (83%) participants were satisfied with the overall program, and 35 (74%) participants would recommend the program to others. Among the 40 participants who received resources from a navigator, 33 (83%) said that the resources provided were helpful.

Of 13 family members who participated in the user experience survey, 9 (85%) thought calls from the navigator were helpful, and 12 (92%) said that navigators understood their concerns. Furthermore, all 13 (100%) family members thought the program was culturally appropriate (“good,” “very good,” or “excellent”). In contrast, only 4 (31%) thought the portal was useful. Overall, 9 (69%) family members were satisfied with the program, and 10 (77%) would recommend the program.

Discussion

Principal Findings

To our knowledge, this is the first study to develop and test a virtual patient navigation program that leveraged an online platform in multiple languages to provide support and resources

XSL•FO
RenderX

to Asian American patients undergoing cancer treatment. We found that developing a virtual online patient navigation portal was technologically challenging yet feasible and successfully achieved our goal of assessing the needs of Asian American patients with cancer and connecting them with relevant resources and support. Participants reported a clinically meaningful increase in emotional quality of life between baseline and 6 months.

Comparison to Previous Literature

Language assistance was one of the highest reported needs among participants from both phases (in-person and virtual) of Patient COUNTS [10,11]. Language discordance between patients and their clinical care teams has been associated with difficulty communicating with providers, challenges in accessing medical services, worse health status, and decreased patient satisfaction [28-32]. Building the online portal in English, Vietnamese, and Chinese and providing language-concordant patient navigation filled a critical gap in improving cancer care for Asian American patients with non-English language preference and those with limited English proficiency. In the first phase of Patient COUNTS (in-person patient navigation), 88% of participants had a non-English preferred language, and 75% reported having limited English proficiency (defined as participants who reported speaking English “not at all” or “not well”) [33]. In developing the online portal, a critical component was ensuring that the entire interface was available in Chinese, Vietnamese, and English so that participants were able to engage with the portal regardless of their language preference. In this second phase of the program, which focused on virtual patient navigation, 35% reported a non-English language preference and 41% reported limited English proficiency, which is more representative of the level of English proficiency of Asian Americans in the general US population: one-third of the Asian American population reports speaking English less than “very well” [34]. Individuals with limited English proficiency and limited health literacy also face increased challenges with digital health literacy [34]. In our study, 45% reported challenges in using the portal. Most (80%) participants who described difficulties with the portal reported issues with registering and logging in to the platform, which required an email address. Five participants reported a lack of familiarity with computer technology or challenges in navigating the portal itself. This suggests that improvements can be made to enhance the usability of our online portal and reduce barriers among populations who historically have faced increased barriers to using such online tools. Despite these challenges, the majority of participants (77%) reported that they found the online portal helpful. While our first study showed that in-person patient navigation was more attractive to participants with a non-English language preference or limited English proficiency, this study demonstrated that virtual language- and culturally concordant navigation via an online portal can effectively support a diverse sample of Asian American participants with cancer undergoing treatment.

Ensuring that patients have access to linguistically and culturally sensitive resources, particularly during vulnerable times such as with a new cancer diagnosis and while undergoing cancer treatment, is essential to improving patient satisfaction and outcomes, especially in underserved populations. Overall, the Patient COUNTS program was well received by participants and their caregivers, with high satisfaction rates. This was similar to our in-person pilot as well as other in-person cancer-related patient navigation programs [35-37]. The majority of participants found the Patient COUNTS portal useful and would recommend it to others. More participants in the in-person patient navigation program reported that their patient navigator understood their health concerns (80%), compared to about half of the participants who completed the virtual navigation. This highlights the importance of the human connection in patient navigation that contributes to patient satisfaction with the program. In particular, this is true among family members of participants, most of whom found the patient navigators to be helpful, but only one-third thought the online portal was useful. Our study found that emotional well-being improved at 6 months compared to baseline; it is possible that our patient navigators were able to contribute to participants’ emotional well-being by providing support in addition to tailored resources for our participants. About 75% of participants in our study felt that calls from their navigator were helpful and that navigators understood their concerns. In future iterations, the online portal could also include resources for family members and caregivers of participants, as many of them assist participants in accessing and navigating the health care system.

Strengths and Limitations

Our study had several limitations. First, the study included participants recruited from the Greater San Francisco Bay Area who spoke English, Chinese, or Vietnamese; were recently diagnosed with colorectal, lung, or liver cancer; and were undergoing or planning to undergo treatment; thus, the findings may not be generalizable to other populations or geographies. However, we focused on this population to build upon previous work that found a need for navigation to address local disparities in cancer-related care. Second, longer-term experience with the portal and its impact on quality of life in a larger follow-up study would help validate the usefulness of the portal. Third, many participants reported challenges with registering and logging into the online portal. It is possible that negative first experiences with the portal may have discouraged participants from using it. To help mitigate this, patient navigators were able to walk participants through the process of registering and logging in. Fourth, while we informally asked patient navigators about their experience with the training, online portal, and intervention, future studies should obtain more formal feedback from patient navigators to help us understand the usability of the online portal and better inform future improvements. Fifth, given our small sample size, we may have lacked adequate power to detect changes in quality of life in GEE analyses; our GEE analyses were also unadjusted for potential confounders. Yet, we were able to demonstrate the feasibility of a linguistically concordant and culturally appropriate virtual patient navigation program. Finally, a lack of curated and up-to-date culturally and linguistically appropriate resources meant that our team and navigators had to manually research and confirm helpful resources for the patients.

XSL•FO
RenderX

Lessons Learned

Our team learned several important lessons from designing, building, and implementing Patient COUNTS: (1) participants value human connection, (2) registration should be simple, (3) resources are difficult to keep up to date, and (4) building technology-enabled tools is costly. We believe that the primary reason our virtual intervention was well received was that our navigators were able to connect with participants, listen to them, and respond to their needs with a culturally sensitive and linguistically concordant approach. With respect to issues related to registration and logging in, we recommend that future tools use phone numbers with 2-factor identification for registration and login to eliminate the use of email and passwords. In addition, partnering with organizations that have regularly updated nationwide databases can address challenges with resources becoming outdated. Finally, using existing, industry-standard tools such as REDCap [27] for conducting eligibility screening and participant surveys can allow teams to spend limited financial, time, and personnel resources on the intervention rather than building these research components internally. We have incorporated these lessons into our current expansion of Patient COUNTS to racially and ethnically diverse patients with breast cancer who speak English, Spanish, or Chinese.

Conclusion

In summary, an online portal providing virtual patient navigation to Asian American patients with cancer was challenging, yet feasible, acceptable, and helped provide linguistically and culturally sensitive support and resources. To our knowledge, this is the first virtual patient navigation program offered in multiple languages for Asian American patients undergoing cancer treatment. While improvements to the underlying platform can be made to improve the experience for participants, their caregivers, and navigators, virtual patient navigation has a high potential to reach more patients, improve health outcomes, and reduce health disparities in underserved populations.

Data Availability

The datasets generated or analyzed during this study are not publicly available in a repository due to participant privacy, but may be made available from the corresponding author on reasonable request.

Authors' Contributions

TN, SG, JT, and SSM made substantial contributions to the conception and design of the study. SSM, DO, and LA led the design and development of the online portal. MK, LA, DO, CW, HB, JC, and KW prepared study materials, recruited participants, and collected data. CW, BH, and JC provided patient navigation. JNC, JT, and SSM made substantial contributions to data analyses. JNC, DO, SSM, and KW led the writing.

Conflicts of Interest

None declared.

Abstract

Background: Plain language summaries (PLSs) of Cochrane systematic reviews are a simple format for presenting medical information to the lay public. This is particularly important in oncology, where patients have a more active role in decision-making. However, current PLS formats often exceed the readability requirements for the general population. There is still a lack of cost-effective and more automated solutions to this problem.

Objective: This study assessed whether a large language model (eg, ChatGPT) can improve the readability and linguistic characteristics of Cochrane PLSs about oncology interventions, without changing evidence synthesis conclusions.

Methods: The dataset included 275 scientific abstracts and corresponding PLSs of Cochrane systematic reviews about oncology interventions. ChatGPT-4 was tasked to make each scientific abstract into a PLS using 3 prompts as follows: (1) rewrite this scientific abstract into a PLS to achieve a Simple Measure of Gobbledygook (SMOG) index of 6, (2) rewrite the PLS from prompt 1 so it is more emotional, and (3) rewrite this scientific abstract so it is easier to read and more appropriate for the lay audience. ChatGPT-generated PLSs were analyzed for word count, level of readability (SMOG index), and linguistic characteristics using Linguistic Inquiry and Word Count (LIWC) software and compared with the original PLSs. Two independent assessors reviewed the conclusiveness categories of ChatGPT-generated PLSs and compared them with original abstracts to evaluate consistency. The conclusion of each abstract about the efficacy and safety of the intervention was categorized as conclusive (positive/negative/equal), inconclusive, or unclear. Group comparisons were conducted using the Friedman nonparametric test.

Results: ChatGPT-generated PLSs using the first prompt (SMOG index 6) were the shortest and easiest to read, with a median SMOG score of 8.2 (95% CI 8 - 8.4), compared with the original PLSs (median SMOG score 13.1, 95% CI 12.9 - 13.4). These PLSs had a median word count of 240 (95% CI 232 - 248) compared with the original PLSs' median word count of 364 (95% CI 339 - 388). The second prompt (emotional tone) generated PLSs with a median SMOG score of 11.4 (95% CI 11.1 - 12), again lower than the original PLSs. PLSs produced with the third prompt (write simpler and easier) had a median SMOG score of 8.7 (95% CI 8.4 - 8.8). ChatGPT-generated PLSs across all prompts demonstrated reduced analytical tone and increased authenticity, clout, and emotional tone compared with the original PLSs. Importantly, the conclusiveness categorization of the original abstracts was unchanged in the ChatGPT-generated PLSs.

Conclusions: ChatGPT can be a valuable tool in simplifying PLSs as medically related formats for lay audiences. More research is needed, including oversight mechanisms to ensure that the information is accurate, reliable, and culturally relevant for different audiences.

KEYWORDS

health literacy; patient education; health communication; ChatGPT; neoplasms; Cochrane; oncology; plain language; medical information; decision-making; large language model; artificial intelligence; AI

Introduction

The significance of health literacy has been well established through numerous studies [1,2], demonstrating its importance not only for individual health care [3] but also within the public health system [4,5]. Various organizations, including the Center for Disease Control and Prevention and the National Institute of Health, have underscored the importance of using plain language in health communication to enhance understanding

XSL•FO
RenderX

of medical conditions and patients' engagement [6,7]. Health literacy is particularly important in oncology, where the advancement in cancer treatment beyond traditional methods has positioned patients and their families even more in the center of making care decisions [8]. Upon receiving a cancer diagnosis, patients often turn to various sources for more information, such as the internet, forums, social support groups, and literature [9,10]. Enhancing patients' understanding of their conditions has been shown to positively impact patient adherence and clinical outcomes in various chronic disease models by influencing patient behavior [11-13], whereas patients' struggle to understand complex medical information can adversely affect their adherence to medical advice [14]. However, nearly half of cancer patients struggle to understand the information about their treatment options from scientific literature [15]. Even though the official recommendation of the American Medical Association is that health information should be written at the reading level of the sixth grade in the US education system [16], the complexity of web-based cancer information often exceeds the reading and comprehension abilities of an average person, failing to meet the necessary standards for readability and understandability of health information [17].

To address the gap between the complexity of scientific evidence and the public, many organizations, including Cochrane, dedicate a lot of effort to enhancing the quality of health information available to the public [18]. Cochrane Database of Systematic Reviews is recognized as a highly reliable source for evaluating the effectiveness of health interventions [19]. Cochrane systematic reviews provide both a scientific abstract for professionals and a plain language summary (PLS) for the lay public [20]. Studies have consistently demonstrated that PLSs, which are authored by the same researchers who write the corresponding scientific abstracts, tend to exhibit readability levels that exceed those recommended for health information intended for a general audience [20-24]. In our previous study, we found that Cochrane PLSs for oncology interventions not only required a reading proficiency well above the average public level but also used language that lacked engagement, potentially reducing the reader's interest [21]. Additionally, the PLSs frequently contained ambiguous or insufficiently clear conclusions regarding the efficacy of the interventions assessed in the systematic review [21]. This lack of clarity can leave readers, especially patients and nonspecialists, uncertain about treatment benefits or outcomes, thus diminishing the utility of these summaries in supporting informed health decisions. In addition, we have to bear in mind that the language people use plays a vital role in processing and interpreting information in text, as well as in shaping psychological responses to information and influencing whether the reader will perceive the content as more relatable [25,26]. Given the significant challenges associated with the readability and clarity of PLSs, it is important to explore innovative solutions that can enhance the communication of health information to the lay public.

Artificial intelligence (AI) tools recently emerged as a tool to help generate textual outputs relevant to health care, with the potential to revolutionize the medical sector [27,28]. A standout example of AI in action is the Chat Generative Pretrained Transformer (ChatGPT), a chatbot that operates on the Generative Pretrained Transformer technology [29]. This technology is a type of large language model (LLM) with over 175 billion parameters, capable of understanding and generating text that mimics human conversation [30]. ChatGPT has been trained on a wide variety of internet content, such as books, articles, and websites [31,32]. Its fine-tuning process includes reinforcement learning from human feedback, enhancing its ability to grasp complex user intents and respond accurately to a wide array of tasks, including those related to medical inquiries [30,33]. The deployment of natural language processing models like ChatGPT in the health care field promises to significantly improve access to medical information for both professionals and patients [29,34,35].

Recognizing the challenge posed by the low readability of PLSs authored by researchers for Cochrane systematic reviews, particularly in the context of oncology interventions, we sought to investigate the potential of using AI LLMs, specifically ChatGPT as one of the most accessible tools today, to create PLSs that are more relatable to the public. Cochrane reviews are renowned for their rigorous methodologies and comprehensive analyses; however, this complexity often results in PLSs that may be difficult for a lay audience to understand [20,21]. By using ChatGPT, we aimed to improve the readability and the linguistic characteristics of these summaries, so that they effectively communicate critical findings, methodologies, and implications in a manner that is clear and engaging for nonexpert audiences.

Methods

Study Design and Data Sources

In this study, we analyzed the readability, linguistic characteristics, and conclusiveness of the PLSs generated by ChatGPT from corresponding scientific abstracts of Cochrane systematic reviews of oncology interventions. We then compared them to the readability and linguistic characteristics of the original PLSs, as well as with the conclusiveness of the corresponding scientific abstracts. The dataset included 275 PLSs and corresponding scientific abstracts of Cochrane systematic reviews about oncology interventions up to February 2019 from our previous study [21]. In that study, we assessed the language characteristics of PLSs of Cochrane systematic reviews of oncology interventions in comparison with corresponding Cochrane scientific abstracts. We used this dataset as it included the scientific abstracts for which the conclusiveness of the efficacy of interventions was already assessed, so that we could compare the conclusiveness of the AI-generated PLS with that of the original scientific abstracts from which it was created. Cochrane systematic reviews included in the dataset addressed came from Cochrane review groups focused solely on oncology: Breast Cancer; Childhood Cancer; Colorectal Cancer; Gynaecological, Neurooncology, and Orphan Cancer; Haematological Malignancies; and Lung Cancer. These groups served as representatives of different clinical cancer types. Systematic reviews that did not address intervention studies were excluded. Summaries from the dataset have been analyzed in terms of their Simple Measure of Gobbledygook (SMOG) index, linguistic characteristics (word

XSL•FO
RenderX

count and percentage of words related to different emotions), and the category of conclusiveness [21]. The full dataset is publicly accessible via the Open Science Framework [36].

We used the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist for reporting the results of this study.

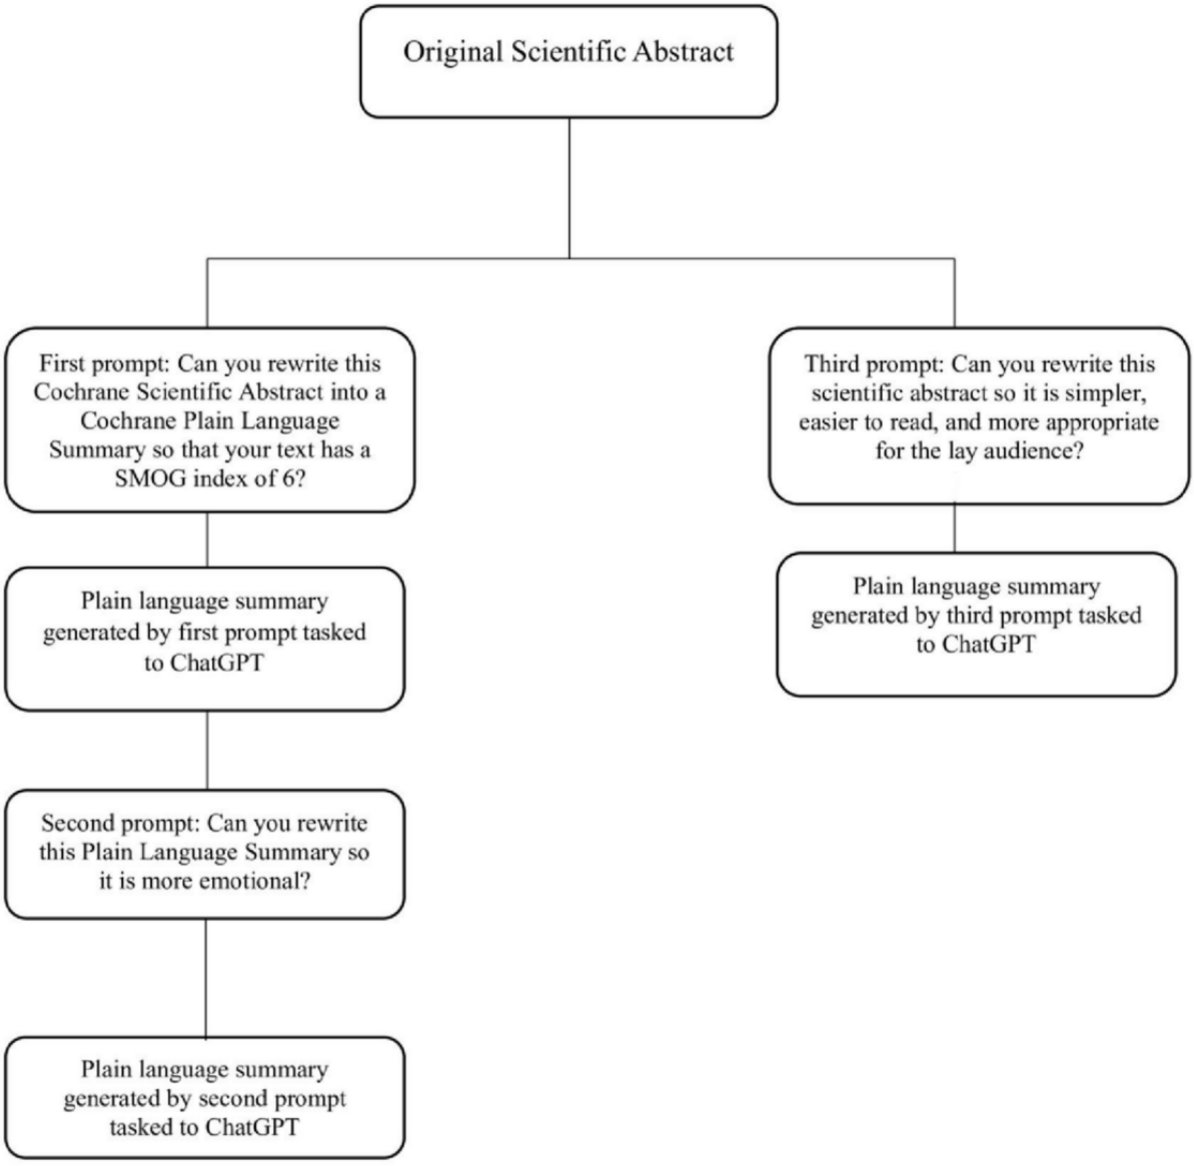
Generation of PLSs by ChatGPT

We used a subscription chatbot, ChatGPT (version 4; Open AI) [37]. At the moment of our research, training data for ChatGPT included information up to April 2023.

We formed 3 prompts, and an author (JŠP) asked ChatGPT each prompt for each PLS separately. Before asking these questions, we asked ChatGPT to explain what a SMOG index is. ChatGPT correctly described the readability measure, its formula, and the interpretation of results, confirming that ChatGPT was adequately familiar with the SMOG index. We then used the following prompts (Figure 1):

1. Can you rewrite this Cochrane Scientific Abstract into a Cochrane Plain Language Summary so that your text has a SMOG index of 6?
2. Can you rewrite this Plain Language Summary so it is more emotional?
3. Can you rewrite this scientific abstract so it is simpler, easier to read, and more appropriate for the lay audience?

In the first prompt, we asked ChatGPT to rewrite the scientific abstract into PLS with a SMOG index of 6, because the official recommendation of the American Medical Association and National Health Institute is that the health information should be written at the reading level of the sixth grade in the US education system [16,38].



For the second prompt, we continued the conversation with ChatGPT that started in the first prompt. Since we found in our previous study that PLSs had language that was more emotional compared with the corresponding scientific abstracts and that PLSs that have a higher percentage of emotional tone have better readability [21], we used the PLS that was provided to ChatGPT in first prompt and asked ChatGPT to rewrite it again so that is more emotional, so this prompt was included to assess if adding emotional resonance could enhance reader engagement and relatability.

In prompt 3, similar to prompt 1, we asked ChatGPT to simplify the scientific abstract, but without defining the SMOG index. This prompt was designed to explore if using simpler language alone (without a specified readability index) would yield results with improved accessibility while retaining the essential information and nuance necessary for an accurate understanding of oncology topics. When tasking this prompt, we started a new chat with ChatGPT, so that it did not rely on the previous answer.

After that, for each PLS provided by ChatGPT, we measured its readability, expressed as SMOG index, and the following linguistic characteristics: word count and percentage of words related to authenticity, clout, emotional, and analytic tone. We analyzed only the first answers generated by ChatGPT for each of the 3 prompts and did not ask ChatGPT to revise the texts again. To be sure that the content of the PLS provided the same facts as the corresponding scientific abstract, we also checked the conclusiveness of each generated PLS, that is, checked whether there was any difference with the original conclusiveness category for the scientific abstract, determined in our previous study [21]. Multimedia Appendix 1 contains a supplementary table with examples of prompts.

XSL•FO
RenderX

Figure 1. Generation of Cochrane plain language summaries by ChatGPT. SMOG: Simple Measure of Gobbledygook.

SMOG Index

The readability of summary formats in English was assessed using the SMOG index [39]. SMOG index assesses the readability of certain content by counting polysyllabic words and the result is presented as the number of years of education required to understand a given text [39]. It is considered to be suitable for health information due to its consistent results, higher expected comprehension levels, application of recent validation criteria for estimating reading grade levels, and ease of use [39]. SMOG index for PLSs in English was calculated using a web-based tool "WebFX Readability Test Tool" [40]. The tool's reliability and accessibility made it a suitable choice for evaluating the readability of PLSs in our study. Regarding SMOG index interpretation, the official recommendation of the American Medical Association and National Health Institute is that health information should be written at the reading level of the sixth grade in the US education system [16,38].

Linguistic Characteristics

PLSs generated by ChatGPT were analyzed regarding their linguistic characteristics, using the Linguistic Inquiry and Word Count (LIWC) [41], a software tool designed to analyze a given text by comparing each word to its predefined dictionary. The tool categorizes text words into 4 main variables: analytical, clout, authenticity, and emotionality shared in the tone of the text, expressed as the percentage of words from the text in a particular category. The analytical thinking category is based on recognizing words associated with logic or connecting concepts and putting them into a relationship. Greater use of words related to analytical thinking is related to cognitive complexity and abstract thinking [26]. Clout speech is a variable that refers to the use of terms that denote self-confidence, leadership, or social status. A higher proportion of such words suggests that the author speaks from a position of expertise and certainty in what is stated, and a lower proportion suggests a style of presenting information that is humbler [42]. Authenticity is determined by the percentage of words related to personality,

XSL•FO
RenderX

such as the use of personal nouns in the first person (“I”, “my”, and “mine”), present tense, and relative adverbs (near, now). The use of these words is connected to writing that is more personal and honest [43]. Emotional share relates to how positive the tone is according to the words used. A score of 100 in emotional tone would mean the tone is maximally positive, while a score of 50 means an even balance of positive and negative emotion words [44].

Conclusiveness

The category of conclusiveness for each ChatGPT-generated PLS was analyzed by JŠP and checked by IB. Data extraction spreadsheet was tested by 2 authors (JŠP and IB). One author extracted the data, and the other one independently reviewed the data in a 10% random sample of PLSs and corresponding scientific abstracts. Then, it was checked whether the entry in the table was correct. Interobserver agreement was high (κ range 0.80 to 1.00, 95% CI 0.84 - 1.00). We resolved the differences in rating through the discussion with a third author (AM) before full data extraction.

The conclusiveness of statements about efficacy and safety was categorized into 3 categories [45]:

1. Conclusive: positive conclusive (there was moderate- or high-quality evidence indicating the effectiveness or safety of the intervention; ie, the drug was proven effective/safe); negative conclusive (there was moderate- or high-quality evidence indicating that the intervention is ineffective or harmful, or authors advised against the intervention/comparison or it is not recommended); or equal conclusive (the interventions analyzed were equally effective and safe).
2. Inconclusive: positive inconclusive (there was evidence suggesting effectiveness or safety, but it is of low quality or inconclusive, and the authors suggest that more research is needed); negative inconclusive (there was evidence of ineffectiveness or harm (evidence demonstrating that there was no effect or that the intervention was not safe) or authors urged against the intervention or comparison, or it is not recommended; however, the evidence is of low quality or inconclusive, or authors state that more research is needed); or equal inconclusive (the interventions appeared to be similarly effective and safe, but the evidence was of lower quality or inconclusive, and the authors suggest that more research is needed).
3. Unclear: no evidence (there was no evidence as the search did not retrieve any randomized controlled trials, ie, empty reviews); no opinion (the authors did not offer any opinion or judgment); and unclear (the authors did not give a clear conclusion or state that the more research is required).

Based on these criteria, we defined a category of conclusiveness for each of the derived PLS, and then the category of conclusiveness was compared with those from the original scientific abstracts to check whether they match and give the same conclusion about the effectiveness or safety of the intervention [21].

Statistical Analysis

Descriptive Statistics

The data on readability, word count, and linguistic characteristics were assessed as numeric variables. As the data deviated from normal distribution, the results were presented as medians and 95% CI and were presented on original PLS and across 3 prompt groups. The data on conclusiveness was assessed as frequencies and was presented on a bar chart across 3 different prompt groups.

Group Comparison

The results from the analysis of ChatGPT-generated PLSs were compared with the already published data for the original PLSs and scientific abstracts [21]. Since all versions were derived from the same PLS, the results were treated as within the subjects’ group under different conditions. Since the within-subjects ANOVA was not appropriate due to the deviations in the normality of data distribution, the comparison between groups was made using the Friedman nonparametric test for repeated measures, as nonparametric alternative and post hoc testing was made using the Conover post hoc test, since it is one of the recommended methods.

Statistical Software

Analyses were made using JASP (v.0.18.1.0; Jasp Team 2023) and R (v4.3.3; R core team, 2024) [46].

Ethical Considerations

The authors did not require ethical approval as the study is based solely on publicly available summaries of Cochrane systematic reviews. The research does not involve human participants or the use of animals. This is in accordance with the ethical code of the University of Split School of Medicine (April 2009).

Results

Overview

We generated a total of 275 PLSs for each of the 3 ChatGPT prompts. On average, all of them had statistically fewer words than the original PLSs (Table 1).

XSL•FO

Table . Comparison of linguistic characteristics (median, 95% CI) between different plain language summary (PLS) groups.

Variable	Original[a], median (95% CI)	ChatGPT prompt, median (95% CI)			*P* value[b]
		First prompt: write from scientific abstract at SMOG[c] index 6	Second prompt: make PLS from first prompt more emotional	Third prompt: write simpler PLS from original PLS	
Word count	364 (339 - 388)	240 (232 - 248)	285 (278 - 292)	273 (266 - 278)	<.001
SMOG index[d]	13.1 (12.9 - 13.4)	8.2 (8.0 - 8.4)	11.4 (11.1 - 12)	8.7 (8.4 - 8.8)	<.001
Linguistic characteristics[e]					
Analytical tone	95.5 (95.0 - 95.8)	55.9 (53.6 - 57.9)[f]	85.7 (84.0 - 86.7)	60.9 (57.7 - 63.1)	<.001
Clout	50.0 (47.7 - 51.8)	67.2 (64.9 - 70.9)[f]	80.3 (77.8 - 83.6)	70.5 (68.0 - 72.8)	<.001
Authenticity	28.6 (26.2 - 31.3)	50.5 (47.0 - 53.5)[f]	38.0 (34.8 - 40.1)	49.4 (45.8 - 54.2)	<.001
Emotional tone	22.1 (18.5 - 26.2)	54.8 (51.3 - 58.7)[f,g]	63.9 (58.6 - 69.6)[f]	54.4 (51.9 - 56.4)	<.001

[a]The results for the original PLSs are from the previous study [21].

[b]Friedman nonparametric test. All post hoc differences were statistically significant except those labeled with symbols in superscript.

[c]SMOG: Simple Measure of Gobbledygook.

[d]Readability was measured as a SMOG index [39]. Higher scores indicated lower readability.

[e]Linguistic characteristics of the text were measured using dictionary-based text word categorizations by the Linguistic Inquiry and Word Count (LIWC) [26]. The variables are presented as the percentage of words from the text in a particular category.

[f]Not different from prompt 3.

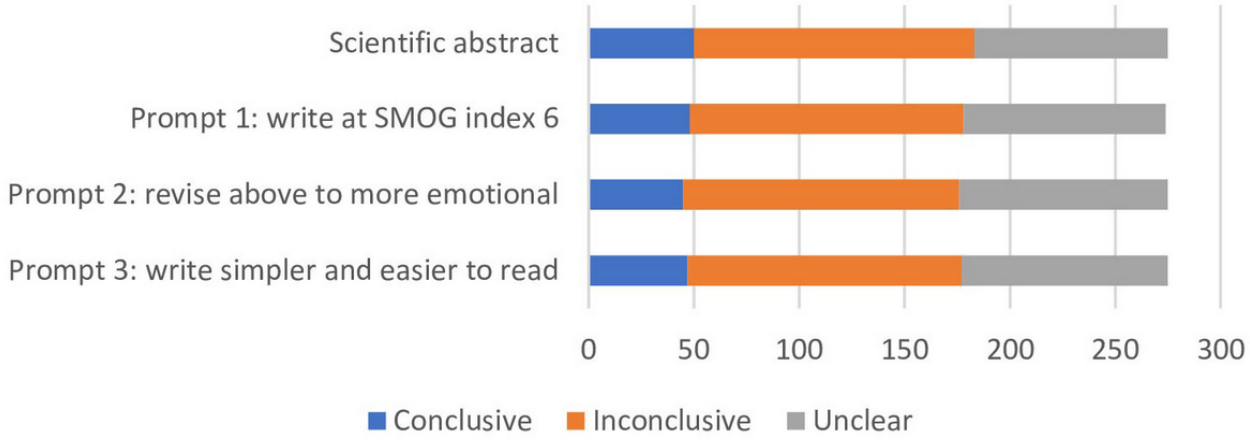
[g]Not different from prompt 2.

SMOG Index and Linguistic Characteristics

PLSs generated by the first prompt (write at SMOG index 6) were the easiest to read, with the median SMOG index of 8.2 (95% CI 8 - 8.4), and the shortest. Regarding linguistic characteristics, these PLSs had less analytical tone and more authenticity, clout, and emotional tone when compared with the original PLSs written by authors (Table 1).

PLSs generated by the second prompt (make prompt 1 more emotional), had a median SMOG index of 11.4 (95% CI 11.1 - 12). Those PLSs also had more analytical tone and clout compared with the PLSs generated by the first prompt, but no difference in the emotional tone. They also used fewer words related to authenticity than the PLSs generated by the first prompt (Table 1).

PLSs generated by the third prompt (write simpler PLS from original) had a median SMOG index of 8.7 (95% CI 8.4 - 8.8). Linguistic characteristics did not differ from the PLSs generated by the first prompt, but they had a less analytical and more authentic tone than the PLSs generated by the second prompt (Table 1).



Across the 3 GPT prompts, the results were consistent, without major outliers.

Conclusiveness

The category of conclusiveness of all 3 ChatGPT-generated PLSs did not differ from that of the original scientific abstract (Figure 2).

XSL•FO
RenderX

Figure 2. Distribution of plain language summaries according to the conclusiveness of the efficiency of interventions described in the systematic reviews across 4 different groups of writing prompts. SMOG: Simple Measure of Gobbledygook.

Discussion

Principal Findings

Our study investigated the potential of using an LLM-ChatGPT, to generate more readable and engaging PLSs for Cochrane systematic reviews in oncology. The results demonstrate that ChatGPT-generated PLSs were shorter and easier to read, as illustrated by the SMOG indices across different prompts. Across all prompts, ChatGPT-generated PLSs exhibited a decrease in analytical tone while showing higher levels of authenticity, clout, and emotional tone compared with the original PLSs. Notably, the categorization of conclusiveness in the original abstracts remained consistent in the ChatGPT-generated PLSs.

Specifically, PLSs created by the first prompt (targeting a SMOG index of 6) achieved the lowest SMOG index and the highest readability among the 3 approaches we used. The median SMOG index of the PLSs generated through prompt 1, while higher than the targeted level of 6, was still significantly lower than that of the original PLSs authored by researchers (median SMOG index 13.1).

The second prompt, which aimed to make the summaries contain text with more emotionally positive content, resulted in an increase in SMOG index and a notable shift toward analytical and clout tones, indicating that the addition of emotional language might inadvertently increase linguistic complexity. This observation is crucial because previous studies have shown that emotional resonance can improve reader engagement and comprehension [21], yet it must be balanced with readability to avoid overcomplicating the content.

The third prompt again managed to improve the readability of the summaries. Despite differences in readability and tone, the conclusiveness about the efficacy of the intervention in ChatGPT-generated PLSs remained consistent with that of the original scientific abstracts. This consistency is encouraging, as it suggests that ChatGPT can maintain the integrity of the original scientific conclusions while rephrasing content for a lay audience.

PLSs generated by ChatGPT had language characteristics more suitable for the lay population than the original PLSs from the published Cochrane systematic reviews [21]. They had fewer words and better readability—from the median of 8.2 to 11.2 compared with the original 13.1 SMOG index, bringing it closer to the recommended sixth-grade reading level for the health information intended for the lay public [16]. However, it is not clear whether we can expect at all for PLSs from oncology to be at the recommended reading level, as it is not sometimes possible to replace complex scientific expressions or names of the drugs (eg, trastuzumab-deruxtecan) without altering the meaning and jeopardizing the translation of the information to the reader in the correct way.

Regarding the linguistic content of the PLSs [16,42-44], those generated by ChatGPT had lower content with an analytical tone, meaning that they did not relate so much to abstract thinking or cognitive complexity as the original PLSs. They also had a higher positive emotional tone (a score over 50 for all ChatGPT-generated PLSs) than the original PLSs, which had a predominantly negative emotional tone (median of 22 out of maximum 100). ChatGPT-generated PLSs also had higher clout, meaning that the information came from the position of expertise and certainty, and they used more personal nouns, present tense, and relative adverbs, increasing authenticity tone, that is, making it more personal and honest. In this way, ChatGPT-generated PLSs could influence the subjective experience of people and their engagement in the given text when they process the information in the PLSs with respect to their opinion about the truthfulness of the information or their confidence in the information [25]. These cognitive processes are very important in reacting to health information, as it has been shown that patients adhere more to advice from doctors that contains more positive emotions [47].

Comparison to Prior Studies

ChatGPT-generated PLSs were closer in their characteristics to the press releases of Cochrane systematic reviews, written by professional writers. A study of Cochrane systematic reviews that had an official press release showed that these press releases were written in a more conversational and emotional language than the scientific abstracts or PLSs in different languages,

XSL•FO
RenderX

making them more engaging [22]. ChatGPT-generated PLSs had similar qualities, without losing the conclusiveness of the message, making them more suitable for health evidence translation to the patients and the general public.

Strength and Limitations

Regarding the strengths of the study, this study is among the first to evaluate the use of AI for generating PLSs in oncology, focusing on readability, linguistic characteristics, and consistency with original scientific conclusions. The use of multiple prompts provided a nuanced understanding of how prompt design influences AI-generated content.

These results must be considered in light of several limitations. First, we used PLSs from a single source, the Cochrane Library, and these PLSs were written by different authors. However, summaries from the Cochrane Library have the same format of presenting health information and specific guidance for writing PLSs [48], making them comparable. Second, we analyzed the PLSs in English only since it was the only common language for the summaries in oncology systematic reviews. The focus on English ensured uniformity in linguistic analysis, avoiding inconsistencies in translation processes. Third, a notable limitation of this study is that it required ChatGPT to generate PLSs from scientific abstracts and not from the complete texts of Cochrane systematic reviews. Typically, PLSs are derived from the full content of the reviews [48], which provides a more thorough understanding of the study's findings, methodologies, and contextual factors. Reliance only on scientific abstracts may lead to PLSs lacking depth and detail. Fourth, ChatGPT-4 was developed using a diverse dataset of publicly available information spanning multiple domains and at the time of our study, its information is limited to publicly available sources up to 2021 [49]. OpenAI does not specify the exact content of medical information included or the precise time frame of the dataset [49]. We used ChatGPT-4, the subscription version (unlike its predecessor ChatGPT-3.5), the most advanced and widely available version of ChatGPT during the study period, ensuring access to its latest capabilities, but it is available only to people willing to pay a monthly subscription. For the second prompt in our study, we relied on the answers from ChatGPT provided in the first prompt. For all 3 prompts, we did not ask the system to further rephrase the text but analyzed only the first output. Different AI models vary in training, algorithms, and capabilities, making the use and results of one model not universally applicable to others [50]. We did not use other AI tools such as Microsoft Bing AI, Bard, Jasper, or ChatSonic, which could have given different results. Microsoft Bing AI can only process up to 2000 characters [51], which is not suitable for summaries. Bard was not available in Croatia at the time of conducting the study [52], and Jasper and ChatSonic offered only paid subscriptions for which we did not have sufficient resources [53,54]. Additionally, we did not use specialized AI tools designed specifically for creating PLS, such as Sorcero's solution [55] or Putnam Associates' generative AI approach for PLSs [56]. Our decision not to use these specialized tools stemmed from a focus on general AI models that are more accessible to a wider range of users and our intent to evaluate the performance of widely available, nonspecialized AI for PLS generation. Fifth, it has to be kept in mind that, while our study assessed linguistic characteristics such as clout, analytical tone, authenticity, and emotional tone, it is equally important to consider the cultural and emotional sensitivities of the target audience [57]. AI models like ChatGPT-4 are trained on extensive datasets that may not fully capture the nuances of various cultural backgrounds. Consequently, the generated PLSs might lack the cultural relevance or sensitivity necessary to effectively communicate with all segments of the lay public. Further research should include PLSs from multiple sources to assess the generalizability of AI-generated PLSs across diverse formats and writing styles and explore the potential of AI tools in generating PLSs in languages other than English, to support Cochrane efforts to provide health information in 20 different languages [58].

Future Directions

What conclusions and recommendations can be drawn from our study? Our study is one of the first tests of AI language tools in creating health information from complex health evidence synthesis that is suitable for the lay public. The real-world implementation of medical AI interventions generally lacks high-quality evidence, as a recent systematic review identified 65 randomized controlled trials evaluating AI interventions, but only 7 with chatbots as an intervention [59]. We do not think that, at the current level of development, ChatGPT can replace evidence synthesis in real time, as it does not get updates in real time [60] and there is a potential for bias in the training data, which can result in biased or inaccurate responses [61]. In addition, text generated from the training data can have several other issues besides bias, such as plagiarism [62], lack of context, as well as underestimation of novelties in medicine that are important but may be less represented in web sources [63].

On the other hand, ChatGPT and other generative AI tools may be useful in ensuring the quality and appropriateness of the summary information for health evidence synthesis, such as Cochrane systematic reviews. Although Cochrane has clear guidance on writing PLSs [48], the evidence shows that they are not adequately implemented and published PLSs are not at the desired level of clarity and quality [64]. It seems that the authors of Cochrane systematic reviews have difficulties in translating their results into a language that is suitable for the lay public. This affects not only the usefulness of the PLSs but also their translations into a number of languages, where it is not clear whether there is a further loss to the clarity and understandability of the message to the lay public [22]. Readability metrics like the SMOG index provide an indication of text complexity but do not guarantee comprehension by the intended audience. This gap highlights the need for future research to evaluate the effectiveness of AI-generated PLSs in real-world settings and to determine their actual understandability among diverse patient populations.

Conclusions

Having all that in mind, ChatGPT may be a valuable tool in helping create content designed for the lay public. Cochrane should further explore the use of ChatGPT in generating PLSs, either as a tool for the authors or as an independent, systemic tool to generate high-quality, high-fidelity PLSs, also ensuring

XSL•FO
RenderX

that the main message of health information is unchanged and accurate.

Acknowledgments

This study was funded by the Croatian Science Foundation ("Professionalism in Health - Decision making in practice and research, ProDeM") under grant agreement number IP-2019-04-4882. The funder had no role in the design of this study, its execution, analyses, interpretation of the data, or decision to submit results.

Data Availability

The full summarized data generated or analyzed during this study are included in this published article and its supplementary information files. The datasets extraction sheets generated or analyzed during this study are available in the Open Science Framework repository [36].

Authors' Contributions

AM gave the idea for the study, and all authors contributed to the study plan. JŠP collected the data. IB analyzed the data and interpreted the results. JŠP wrote the first draft of the manuscript, and all authors critically revised the manuscript. All authors agreed to the version submitted for publication and take responsibility for the accountability of the study.

Conflicts of Interest

The authors declare no conflicts of interest, except for their membership in Cochrane.

Abstract

Background: Patients frequently resort to the internet to access information about cancer. However, these websites often lack content accuracy and readability. Recently, ChatGPT, an artificial intelligence–powered chatbot, has signified a potential paradigm shift in how patients with cancer can access vast amounts of medical information, including insights into radiotherapy. However, the quality of the information provided by ChatGPT remains unclear. This is particularly significant given the general public's limited knowledge of this treatment and concerns about its possible side effects. Furthermore, evaluating the quality of responses is crucial, as misinformation can foster a false sense of knowledge and security, lead to noncompliance, and result in delays in receiving appropriate treatment.

Objective: This study aims to evaluate the quality and reliability of ChatGPT's responses to common patient queries about radiotherapy, comparing the performance of ChatGPT's two versions: GPT-3.5 and GPT-4.

Methods: We selected 40 commonly asked radiotherapy questions and entered the queries in both versions of ChatGPT. Response quality and reliability were evaluated by 16 radiotherapy experts using the General Quality Score (GQS), a 5-point Likert scale, with the median GQS determined based on the experts' ratings. Consistency and similarity of responses were assessed using the cosine similarity score, which ranges from 0 (complete dissimilarity) to 1 (complete similarity). Readability was analyzed using the Flesch Reading Ease Score, ranging from 0 to 100, and the Flesch-Kincaid Grade Level, reflecting the average number of years of education required for comprehension. Statistical analyses were performed using the Mann-Whitney test and effect size, with results deemed significant at a 5% level (P=.05). To assess agreement between experts, Krippendorff α and Fleiss κ were used.

Results: GPT-4 demonstrated superior performance, with a higher GQS and a lower number of scores of 1 and 2, compared to GPT-3.5. The Mann-Whitney test revealed statistically significant differences in some questions, with GPT-4 generally receiving higher ratings. The median (IQR) cosine similarity score indicated substantial similarity (0.81, IQR 0.05) and consistency in the responses of both versions (GPT-3.5: 0.85, IQR 0.04; GPT-4: 0.83, IQR 0.04). Readability scores for both versions were considered college level, with GPT-4 scoring slightly better in the Flesch Reading Ease Score (34.61) and Flesch-Kincaid Grade Level (12.32) compared to GPT-3.5 (32.98 and 13.32, respectively). Responses by both versions were deemed challenging for the general public.

Conclusions: Both GPT-3.5 and GPT-4 demonstrated having the capability to address radiotherapy concepts, with GPT-4 showing superior performance. However, both models present readability challenges for the general population. Although ChatGPT demonstrates potential as a valuable resource for addressing common patient queries related to radiotherapy, it is imperative to acknowledge its limitations, including the risks of misinformation and readability issues. In addition, its implementation should be supported by strategies to enhance accessibility and readability.

Introduction

In an increasingly digitized society, patients frequently resort to the internet to access information about cancer [1-3]. However, despite being one of the most favored informational modalities, websites often require more content accuracy and better readability [1].

Recently, artificial intelligence (AI)–powered chatbots such as ChatGPT have signified a potential paradigm shift in how patients with cancer can access a vast amount of medical information [1,3,4]. The rise of these AI platforms, accessible to the general public, has escalated notably since OpenAI released version 3.5 of ChatGPT (GPT-3.5) on November 30, 2022 [4-13], which amassed over 1 billion users in March 2023 [4].

ChatGPT, a large language model (LLM) [6,14-17], uses natural language processing to offer varied responses to the same query considering the context of the conversation and individual user preferences [18]. Through text-to-text communication, ChatGPT can engage with humans [12] and aims to deliver responses resembling human interactions [6,14,18]. This model has undergone extensive training on a diverse corpus of text data encompassing a broad spectrum of sources, including books, scholarly articles, and web pages, enabling it to effectively comprehend and respond to natural language queries across a broad range of topics [19,20]. Moreover, the model's performance is enhanced through reinforcement learning from human feedback, which enables it to produce more coherent and contextually relevant responses [21]. Additionally, ChatGPT can compose emails, essays, and medical reports, as well as solve problems and provide clarification [10,13,22,23].

On March 14, 2023, OpenAI announced the release ChatGPT-4 (GPT-4), which became available through a subscription-based model [9,12,16]. This new version demonstrated outstanding performance across numerous academic and professional benchmarks, providing more refined and varied responses than GPT-3.5 [24].

In this context, ChatGPT has emerged as a contender for traditional search engines, such as Google, because of its capacity to filter vast quantities of data and provide easily comprehensible responses [4,6]. Consequently, ChatGPT is a potentially reliable source of medical information to both the public and patients with cancer, and it is capable of offering insights regarding radiotherapy [4,25]. This is particularly significant given the general public's limited knowledge of this treatment [15,26] and concerns regarding its possible side effects [27].

Radiotherapy is a well-established treatment that delivers targeted ionizing radiation with precision with the aim of destroying cancer cells while minimizing damage to healthy tissues. Approximately half of all patients diagnosed with cancer undergo radiotherapy as a part of their care. Advances in radiotherapy have increased its complexity, requiring greater preparation and support for patients who may face physical and psychological challenges [28]. Considering that approximately 80% of patients have limited knowledge regarding radiotherapy and associated expectations regarding treatment, many have significant misconceptions. These commonly include concerns about radiation burns or the possibility of becoming radioactive as a result of the treatment [29,30]. Such misunderstandings, coupled with the unfamiliarity of radiotherapy for most patients and the inherent invisibility of the treatment, further complicate their ability to fully comprehend the process [31,32]. Therefore, providing clear and accessible information is essential for reducing patients' fear of treatment [31]. Previous studies have explored radiotherapy educational resources, such as videos, and tested group education in radiotherapy settings. However, these studies did not specifically address individual patient education and support needs at key time points [33]. Alternatively, written documentation has proven effective for patients who may feel overwhelmed by excessive verbal information, as it allows them to process the material at their own pace and share it with family and friends [34]. Therefore, ChatGPT offers a convenient and accessible method for patients to obtain written information and support [19].

Given that patient education is particularly crucial for patients with cancer because of the complexity of their treatment pathways [20], providing them with comprehensive information about radiotherapy at appropriate stages may enhance adherence to the treatment plan, because inadequate information can lead to increased uncertainty, unnecessary anxiety, and distress among patients and their families [27,35,36]. Additionally, poorly informed patients are likely to be dissatisfied with their care, have difficulty coping [35], and have many follow-up questions regarding the treatment process. Moreover, patients with cancer often feel uncomfortable discussing their body image and sexual health with their clinicians. Consequently, patient communication with ChatGPT may lower these barriers [36].

However, given that ChatGPT was not explicitly trained for oncology-related inquiries, the quality of the information it provides remains unverified [7,14,36]. Evaluating the quality of responses is crucial, as misinformation can foster a false sense of knowledge and security, lead to noncompliance, and result in delays in receiving appropriate treatment [4,14,15]. Nevertheless, various limitations of ChatGPT have been identified. It has been observed to fall below the expected educational level [4], as health-related materials intended for patient consumption are typically recommended to have a reading level equivalent to fifth and sixth grades [4,37]. Furthermore, the training data for GPT-3.5 are outdated, limited to the information available up until September 2021, and lack access to newer knowledge beyond that date [5,38,39]. To address this constraint, GPT-4 introduces a novel feature that allows the use of external plug-ins [25]. However, this new version is available exclusively through paid subscription [9,12,16]. Additionally, ChatGPT tends to provide unreliable or inaccurate information, potentially generating incorrect or misleading responses [14,16]. This issue often arises from the dependence of models on their training data, which may not always be up-to-date or fully comprehensive [40].

To date, limited research has been conducted on the application of language models in the medical domain and the effectiveness of ChatGPT in patient education remains indeterminate [14].

XSL•FO
RenderX

Although the literature addressing ChatGPT's capabilities has proliferated in recent months, there remains a lack of data regarding the quality and reliability of the responses it provides [11,18]. This gap underscores the necessity for more comprehensive studies to evaluate the performance of language models, including ChatGPT, in the medical context. Ensuring that these models are equipped with the most current and comprehensive data is essential for their effective application in radiotherapy health care.

This study aimed to evaluate the quality and reliability of ChatGPT responses to common patient queries regarding radiotherapy to ascertain its potential as a reliable source of patient information. Additionally, it aimed to compare the performance of GPT-3.5 with GPT-4 in generating responses to the same radiotherapy queries.

Methods

Prompt Generation

To determine the most common patient queries regarding radiotherapy, an assessment was conducted using articles that addressed topics related to the most relevant patient concerns. These served as the foundation for the development of 128 questions, 90 of which were derived from the studies by Halkett et al [27,35,41] and Zeguers et al [32], whereas the remaining 38 were sourced from the National Cancer Institute [42]. The questions were then organized into a table to facilitate the identification of duplicates and the selection of the most pertinent ones. There were 36 questions identified as duplicates, and 43 were deemed specific to certain pathologies or specialized treatments, leaving a total of 49 questions. Four authors (AG, CM, MC-R, and MC) excluded 9 additional questions upon agreement, resulting in a final set of 40 queries to be input into ChatGPT. This exclusion aimed to ensure that the responses could be applied to all patients receiving radiotherapy, thereby reflecting their primary concerns and doubts. The questions were intentionally phrased in the first person to mirror the way patients might typically frame their queries when interacting with ChatGPT [43] and were structured to address the informational needs of patients at various stages of radiotherapy [27]. The final set of questions was categorized into three dimensions: general information (n=14), planning and treatment (n=16), and side effects (n=10) (Textbox 1). These dimensions were selected based on previous studies [27,31,32,44], which assessed the most critical information needs for patients receiving radiotherapy, and they were further chosen to evaluate the strengths and limitations of responses across various topics in radiotherapy.

XSL•FO
RenderX

Textbox 1. Common patient queries regarding radiotherapy by dimension inserted in ChatGPT.

General information

1. Why is radiotherapy recommended?
2. What does radiotherapy involve?
3. When should radiotherapy and chemotherapy be combined?
4. What's the cost of radiotherapy treatment?
5. Who will be providing my radiotherapy treatment?
6. How does the radiotherapy treatment machine work?
7. What impact will radiotherapy treatment have on my life?
8. What impact will radiotherapy treatment have on my health in the future?
9. During the period of radiotherapy, will I have to follow a particular diet?
10. Will radiotherapy make me radioactive?
11. What does radiotherapy do to healthy cells?
12. How long does radiotherapy take to work?
13. Can I be cured of my disease through radiotherapy treatments?
14. What will happen after the radiotherapy treatment is finished?

Planning and treatment

1. Can I maintain my daily routine and activities during radiotherapy?
2. Can I keep working while undergoing radiotherapy treatments?
3. Are complementary medicines recommended while undergoing radiotherapy treatments?
4. What's the planning appointment in radiotherapy and what does it involve?
5. Why is computed tomography (CT) planning necessary in radiotherapy?
6. Why are tattoos useful in radiotherapy CT planning?
7. What happens on the first day of radiotherapy treatment?
8. Will the radiotherapy treatment schedule be adjusted to my availability?
9. What am I expected to do during the radiotherapy treatment?
10. Does the radiotherapy machine make noise?
11. How close is the radiotherapy treatment machine going to get?
12. What happens during radiotherapy treatment?
13. Is there a possibility of experiencing pain due to the radiotherapy treatment?
14. How long does a radiotherapy session last?
15. What should I wear for radiotherapy treatment?
16. Will there be follow-up after the end of radiotherapy treatments?

Side effects

1. What are the side effects of radiotherapy?
2. What skin care should I have during and after radiotherapy?
3. Am I going to feel tired after the radiotherapy treatments?
4. What hygiene care should be taken after radiotherapy treatments?
5. Which steps should be taken to reduce radiotherapy side effects?
6. Will the radiotherapy treatment be interrupted if I experience adverse side effects?
7. Who can I go to if the radiotherapy side effects become too burdensome?
8. Will radiotherapy affect my fertility?
9. Will radiotherapy cause hair loss?
10. Will radiotherapy cause permanent damage?

RenderX

Data Collection

Responses were collected from ChatGPT between April 6, 2024 and April 9, 2024. Each question was queried on both versions of ChatGPT in English. Each query was entered separately using the "New Chat" function, acknowledging that ChatGPT considers the context of the conversation, which can influence responses. Therefore, the memory retention option was disabled when the questions were introduced into ChatGPT to ensure independence of the responses. The queries were then regenerated in each version of ChatGPT, and both responses were documented to analyze consistency.

Various methods were then used, as described in later sections, to assess the quality and reliability of the response content, response consistency, response readability, and similarity between responses from GPT-3.5 and GPT-4.

Outcomes

Quality and Reliability

To evaluate the quality and reliability of the information provided by ChatGPT, we used a 5-point Likert scale, known as the General Quality Score (GQS), which has been used in previous studies [14,45]. The assessment criteria included accuracy, lay-language use, information flow, usefulness, and empathy. The 5-point Likert scale was defined as follows: (1) inaccurate information, poorly organized text, missing important details, and not helpful for patients; (2) limited accuracy, some relevant information is present, but still not easily understandable for patients; (3) adequately accurate information and some important details are explained in plain language; (4) accurate information, well-organized text, and most relevant details are presented in a patient-friendly manner; and (5) extremely accurate information, well-structured text, and all relevant details are presented in a compassionate and patient-friendly manner [14].

The median GQS was calculated by averaging the ratings provided by 16 independent radiotherapy experts with substantial experience in managing oncology patients undergoing radiotherapy. The experts were randomly assigned to evaluate either GPT-3.5 or GPT-4, assuring that each expert evaluated only the responses from one of ChatGPT's versions to reduce potential bias during the evaluation process, thereby decreasing the likelihood of altering assessments and enhancing their credibility [46]. All the experts received detailed instructions on the evaluation guidelines to promote a uniform understanding of the assessment process. Furthermore, the responses from ChatGPT were provided to the experts in paper format, and their evaluation was conducted in real time without internet access and without knowledge of which version the responses corresponded to, thereby ensuring a blinding effect. Moreover, the authors (CM and MC-R) who analyzed the obtained results were unaware of the identity of the radiotherapy experts.

Consistency and Similarity

The consistency and similarity of the responses were evaluated using the cosine similarity score. This method involves transforming the text information provided by ChatGPT into vectors, then calculating the cosine of the angle between the two vectors, indicating how similar the responses are to each other. Scores were calculated using an online tool. The cosine similarity score ranges from 0 to 1, where a score of 0 indicates complete dissimilarity between the texts, and a score of 1 indicates complete similarity [14,36].

To assess the similarity between the responses generated by GPT-3.5 and GPT-4, the initial responses to the same question provided by both versions were inserted into the web-based tool to determine the cosine similarity score between them.

The consistency of the responses generated by ChatGPT was assessed by entering the same question into both versions and calculating the cosine similarity score between the two responses to the same question. By regenerating the same question, we aim to assess whether ChatGPT can provide consistent information or if its responses vary widely.

Readability

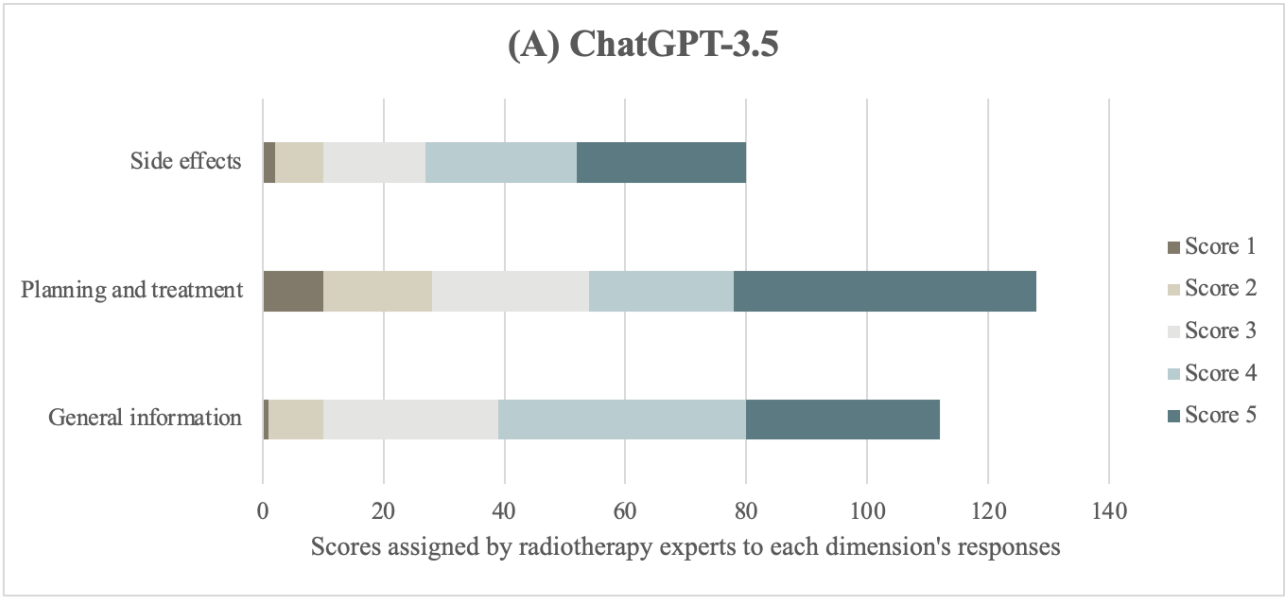
To evaluate readability, responses from both versions were assessed using a web-based Flesch Reading Ease Score (FRES) calculator. This calculator determined the responses' readability using two different indices: the FRES and the Flesch-Kincaid Grade Level (FKGL). These readability tests use mathematical formulas that consider factors such as sentence length and word count. The FRES is a numerical score ranging from 0 to 100, with higher numbers indicating better readability, meaning the content is easier to read and understand [8,47,48] and corresponds to a lower grade level [4,47,48] (Multimedia Appendix 1). The FKGL score indicates the average number of years of education needed to comprehend a text, with lower scores suggesting better readability [8,47,48] and correlating to the equivalent school level [4,47] (Multimedia Appendix 2).

Statistical Analysis

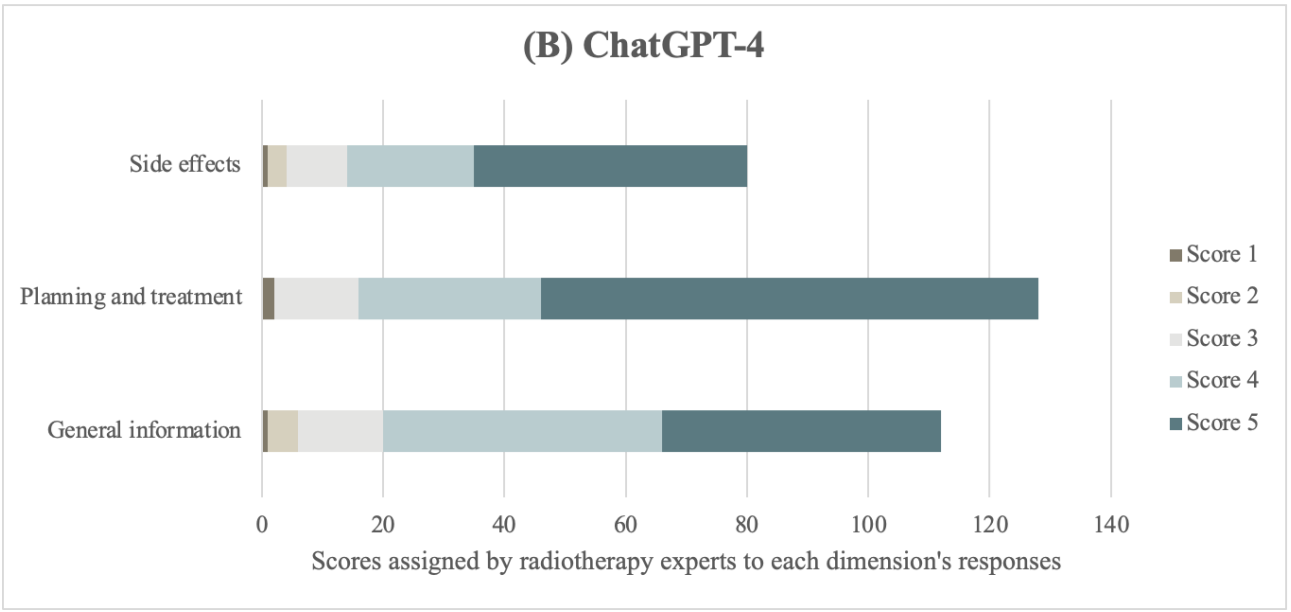
The data were analyzed using SPSS statistical software (version 29.0; IBM Corp). The results were considered statistically significant at the 5% level (P=.05). Exploratory data analysis was carried out using frequency analysis (n, %) for categorical variables and median and interquartile range (IQR = $Q_3 - Q_1$) for continuous variables. To test the normality of the data, the Shapiro-Wilk test was used. The Mann-Whitney test (since the normality assumption was not verified) and effect size were used to compare the evaluations between the 2 versions of ChatGPT. To analyze the question evaluations, scores were calculated for each question, considering the 8 experts assigned to each version. Krippendorff α and Fleiss κ were used to assess the agreement between experts. For this analysis, the experts' assessments were considered for all questions in each dimension in each version of ChatGPT.

Ethical Considerations

This study did not qualify as human subjects research due to the lack of patient involvement and identifying data for the health professionals involved; therefore, it was deemed exempt from institutional review board approval. Additionally, the use of ChatGPT, a public platform accessible to all, meant no permission was required to use the information generated in this study.



XSL•FO
RenderX



Results

Quality and Reliability

GPT-3.5 received primarily midrange scores, with most evaluations at levels 3 (n=72) and 4 (n=90), indicating generally accurate and comprehensible responses. Notably, many responses had the highest rating of 5 (n=110), providing extremely accurate and well-structured information. However, they also received low scores of 1 (n=13) and 2 (n=35), suggesting inaccurate or limited information, respectively. Conversely, GPT-4 received the highest score of 5 (n=173), indicating a superior ability to provide accurate and well-structured information. A significant number of responses were assigned a score of 4 (n=97), while a smaller proportion received a score of 3 (n=38), demonstrating that it consistently provided responses that were accurate, well-organized, and accessible to patients. Remarkably, GPT-4 exhibited a lower number of low scores of 1 (n=4) and 2 (n=8) than GPT-3.5. The score breakdown by the question dimension is shown in Figure 1.

Figure 1. Number of scores assigned by radiotherapy experts to the total number of responses in each dimension from (**A**) ChatGPT-3.5 and (**B**) ChatGPT-4. The Likert scale was defined as follows: score 1=inaccurate information; score 2=limited accuracy; score 3=adequately accurate information; score 4=accurate information; and score 5=extremely accurate information.

Considering the general information dimension, statistically significant differences were detected between the 2 versions of ChatGPT regarding questions 3 (P=.03, effect size=0.6) and 10 (P=.04, effect size=0.5). Regarding planning and treatment, statistically significant differences were detected for questions 5 (P=.046, effect size=0.5), 7 (P=.002, effect size=0.8), 9

XSL•FO
RenderX

(*P*=.003, effect size=0.7), and 11 (*P*=.02, effect size=0.6). Finally, regarding side effects, statistically significant differences were detected for question 9 (*P*=.04, effect size=0.5). In either situation, GPT-4 showed higher ratings (Table 1). The high effect size values revealed a weak overlap in the response distributions between the 2 versions of ChatGPT. However, in the results of the comparison of the evaluation of the 2 versions of ChatGPT, for the other questions, the effect size was low, revealing overlapping distributions of responses, which is why no statistically significant differences were detected. It can also be seen that, although not significant, version 4 of ChatGPT presents higher evaluation scores.

Based on the analysis of Krippendorff α and Fleiss κ coefficients across the 3 dimensions (general information; planning and treatment; and side effects), the results indicated a low level of agreement in the classification of questions for both GPT-3.5 and GPT-4. This trend of weak agreement was consistent across the overall set of queries in Multimedia Appendix 3.

Consistency and Similarity

Regarding similarity and consistency, a cosine similarity score ranging from 0 to 1 was calculated, as previously described. Concerning similarity, the median (IQR) cosine similarity between GPT-3.5 and GPT-4 responses was 0.81 (IQR 0.05), indicating a reasonably good similarity between the 2 versions of ChatGPT. Notably, question 11 in the planning and treatment

XSL•FO
RenderX

dimension exhibited the lowest similarity, with a value of 0.68. With respect to consistency, the cosine similarity median (IQR) for GPT-3.5 and GPT-4 responses were 0.85 (IQR 0.04) and 0.83 (IQR 0.04), respectively. In both versions, consistency was demonstrated to be good or very good, with values ranging between 0.74 and 0.92.

Readability

The word count, sentence count, FRES, and FKGL score for both versions are summarized in Table 2. A relevant disparity was observed in the median (IQR) word count between GPT-3.5 and GPT-4 (299.00, IQR 176.5 versus 344.50, IQR 74.75). Additionally, the sentence count was higher in GPT-4 compared to GPT-3.5 (20.00, IQR 10.5 versus 18.00, IQR 17).

[a]Please refer to Table 1 for the full questions.

[b]FRES: Flesch Reading Ease Score.

[c]FKGL: Flesch-Kincaid Grade Level.

The FRES median (IQR) for GPT-3.5 and GPT-4 responses were 32.98 (15.59) and 34.61 (16.07), respectively. This indicates that the responses generated by the two versions were considered college-level and difficult to read. The FKGL median (IQR) for GPT-3.5 and GPT-4 responses were 13.32 (3.79) and 12.32 (3.32), respectively. This suggests that at least 13 years of education (college-level) are required to understand the responses generated by GPT-3.5, whereas the responses from GPT-4 require at least of 12 years of education (college-level) for comprehension.

Discussion

Principal Findings

The power and utility of AI platforms in health care, such as ChatGPT, are rapidly evolving and improving and have the potential to significantly improve patient education [5,49]. This study sought to assess the quality and reliability of ChatGPT responses to common patient queries regarding radiotherapy with the aim of determining its potential as a reliable source of information for patients. We also aimed to compare the performances of GPT-3.5 and GPT-4 in generating responses to the same radiotherapy-related queries.

Although most responses were correct or close to correct, upon comparing the accuracy of responses between GPT-4 and GPT-3.5 in the 3 dimensions, it became evident that GPT-4 consistently offered improved elucidation of specific concepts relevant to radiotherapy treatment. In question 10 of the general information dimension, GPT-4 specifically delineated that patients are nonradioactive and may safely interact with others posttreatment (“You can safely be around others, including children and pregnant women, without any risk of exposing them to radiation”). However, this aspect was not as clearly articulated in GPT-3.5, which failed to mention that patients may come into contact with others after treatment. Additionally, within the side effects dimension, in questions 2 and 3, GPT-4 emphasized that the intended creams to use throughout radiotherapy treatment should only be those recommended by the health care provider (“Apply a fragrance-free moisturizer recommended by your healthcare provider”) and specified strategies to mitigate fatigue, a treatment-related side effect. However, this advice was not as detailed in the responses from GPT-3.5. Within the planning and treatment dimensions, GPT-3.5 demonstrated a propensity to diverge from directly addressing the queried issue in certain responses in contrast to GPT-4. In question 7, the response did not describe the first day of treatment but rather outlined the entire course of the patient’s radiotherapy. Question 11 failed to specify the distance between the equipment and the patient, a detail that was thoroughly addressed by GPT-4. In response to question 12, GPT-3.5 did not describe what occurs during treatment, instead reiterating the patient’s overall course. This indicates that GPT-3.5 exhibits reduced accuracy when responding to queries related to planning and treatment, as Valentini et al demonstrated [50].

However, in GPT-4’s response to the 13th planning and treatment question, specific information was inaccurately presented as it erroneously stated that radiotherapy induces direct pain (“Direct Pain from Treatment Site: Radiotherapy can cause localized pain at the site of treatment”). This error may have occurred because not all web-based sources are reliable, and because the model is trained on a diverse array of internet texts, it may incorporate biased or outdated information. Consequently, misinformation regarding cancer continues to pose a significant concern in online communication, which could result in responses or recommendations that do not consider the most current, evidence-based medical practices [21].

Moreover, there were a few occasions in both versions in which a lack of information was demonstrated. For instance, in question 7 of the side effects dimension, neither version mentioned that radiation therapists, who are team members that assist the patient daily throughout their treatment [31], could serve as advisers for patients experiencing severe side effects.

In summary, both GPT-3.5 and GPT-4 demonstrated the ability to address concepts related to radiotherapy. However, GPT-4 provided more targeted and detailed responses, thereby exhibiting superior performance compared to GPT-3.5, as corroborated by several studies [9,24,25,43,47]. The reduced number of scores of 1 and 2 assigned by radiotherapy experts to GPT-4 responses indicated a substantial improvement in response quality and reliability.

Comparison With Prior Work

In most responses, ChatGPT used a typical structure characterized by a succinct introductory paragraph, followed by 5 or 6 bullet points delineating the responses, culminating in a short concluding paragraph. Additionally, in a fair number of responses generated by GPT-3.5 (n=25) and GPT-4 (n=28), a statement was included advising that the information provided should always be discussed with health care providers, consistent with prior studies [43,51,52]. This recommendation is significant because the use of ChatGPT in health care must be carefully

XSL•FO
RenderX

monitored and should not be viewed as a substitute for human judgment. Its performance, safety, and associated risks require thorough evaluation by experts before integration into mainstream practice [53]. Moreover, it is essential that the model be trained on a substantial dataset validated by experts. This rigorous validation process could enhance the reliability and trustworthiness of ChatGPT responses, ultimately benefiting patient care [54].

The cosine similarity score indicated a reasonably substantial similarity and consistency, and while subtle changes in sentence structure were noted, most answers remained consistent, implying accuracy [3].

A key feature influencing consistency is the temperature parameter, a value ranging from 0 to 2, which adjusts the randomness of each subsequent word in the chat output. A value of 0 results in minimal variability, whereas values approaching 1 introduce greater randomness and creativity into the responses. Creativity is a powerful tool in communication, as it simplifies complex concepts, fosters critical thinking, and enhances the accessibility of intricate information, making it especially valuable for developing patient education materials. However, using ChatGPT with high creativity settings in clinical contexts may present challenges. By lowering the creativity level, we ensure that the summarized information remains faithful to the training data, thereby prioritizing accuracy and reliability over creative expression. Although this feature is not currently available for modification in ChatGPT, it may be included in future iterations of the tool's web interface [55].

Therefore, ensuring high reliability in ChatGPT's outputs is essential for users to trust its data-driven conclusions. Although advances in ChatGPT's performance can be attributed to key developments in its underlying technology, it is crucial that patients approach the information provided by AI tools such as ChatGPT with caution [56]. This is especially important given that ChatGPT does not disclose the bibliography used to generate responses [7,21,22]. This issue was observed during our study, as the bibliography was not disclosed in either version, indicating ChatGPT's inability to inform users of the contentious nature of certain information [7,10,21,22]. This lack of transparency is particularly significant, given the ethical concerns that arise regarding its application in patient care. Its implementation may lead to unintended or undesirable issues such as risks of bias and transparency, challenges related to interpretability, and generation of inaccurate content, all of which can have serious negative consequences for patient health [53].

Moreover, patient accessibility to AI technology varies significantly according to socioeconomic status, education, age, and geography. Individuals in higher socioeconomic groups or urban areas have better access to the necessary infrastructure, whereas those in lower socioeconomic conditions or rural regions face significant barriers. The effective use of AI also requires digital literacy and computational skills, making the understanding of technology crucial [57]. Although AI can revolutionize education and research, GPT-4 may widen the gap between the wealthy and poor [58]. Conversely, the free availability of GPT-3.5 helps reduce socioeconomic inequalities in cancer treatment by providing fast medical information to all, regardless of financial circumstances [21].

Concerning readability, all responses were considered more difficult to read than the sixth grade reading level recommended for patient consumption, a concern highlighted in prior studies [4,37]. This finding suggests that although the content was predominantly accurate, it was presented at a level too advanced for the public, particularly for individuals with lower health literacy [37,59]. Health literacy, defined as a patient's ability to read and understand health care information and make effective decisions, is crucial for quality patient engagement in health care options. An important aspect of health literacy is readability, which measures the ease with which text can be read and understood and is particularly relevant in radiotherapy due to the complexity of the field and its evolving nature. Patients with lower health literacy may have limited knowledge of radiotherapy; struggle to understand their conditions, treatments, and potential side effects; and often confuse different treatment modalities [60]. Owing to the heightened challenges faced by these patients, this bears particular significance [36].

Various studies have been conducted to assess ChatGPT's ability to enhance readability and simplify responses [36,61-63], considering that, when providing patient education in a written form, it is important to ensure that it is tailored to the reading level of the target population [62]. To address this issue, it was suggested that direct prompts such as "Explain this to me like I am in fifth grade" could assist in generating simplified responses [36,61-63]. This indicates the potential of ChatGPT to tailor responses to varying literacy levels and customize them based on an individual's educational background [61].

Strengths and Limitations

This investigation revealed that both GPT-3.5 and GPT-4 demonstrated proficiency in addressing radiotherapy-related concepts, with GPT-4 exhibiting notably higher performance. Although GPT-4 achieved marginally better readability scores, the content generated by both models remains complex for a general audience. Therefore, their use should be complemented by strategies to improve their accessibility and readability. Moreover, ChatGPT holds significant potential in promoting health behavior changes among patients with cancer by enhancing health literacy and supporting the self-management of radiotherapy-related conditions [64]. However, ChatGPT's responses must be validated by experts before they are integrated into a health care system to serve as a reliable source of information [53,54]. Therefore, ChatGPT shows promise in providing clinical guidance, suggesting treatment options, and serving as a valuable resource for medical education, facilitating a more effective shared decision-making process [6,47,59,65]. Hence, it can potentially serve as an alternative to current web-based resources [36].

This study had some limitations. First, the formulation and phrasing of queries in both versions may have influenced the performance of ChatGPT. Second, the queries were exclusively written in English, which restricted the responses to a single language. Third, although the total number of questions was comparable to other studies [1,8,11,18,47,50], the optimal number of queries needed to effectively evaluate the model

XSL•FO
RenderX

remains undetermined, and the sample may not capture the full diversity of patient concerns about radiotherapy. Fourth, the scoring process inherently involves subjectivity, particularly with the GQS, as different raters may interpret and prioritize quality aspects differently. Fifth, the potential bias introduced by using a 5-point Likert scale may lead to a central tendency bias, as respondents tend to avoid extreme options and cluster their answers around the midpoint, which can limit the granularity of the evaluations and distort the data [66,67]. Sixth, this study was conducted within a specific time frame (April 2024), and ChatGPT is expected to improve continuously over time. Repeating this study at a later time could improve response quality.

Another limitation of our study was the limitations of ChatGPT itself. First, it should be noted that the information provided by GPT-3.5 is available only up to September 2021. Second, GPT-4 has a limited number of questions that can be posed within a specific time frame and it is exclusively accessible through paid subscriptions, potentially constraining the public's access to more accurate information. Finally, ChatGPT is one of the many AI models available, making it uncertain whether the responses obtained represent the general characteristics of all LLMs.

Future Directions

Further research is essential to fully comprehend ChatGPT's role in patient education, including comparative studies with other AI models or traditional information sources, to better contextualize the findings. Additionally, future work should incorporate patient feedback into their understanding and satisfaction, providing valuable insights into the effectiveness of ChatGPT as an educational tool in real-world settings.

Conclusions

Both GPT-3.5 and GPT-4 demonstrated the ability to address concepts related to radiotherapy, with GPT-4 exhibiting superior performance. Although GPT-4 achieved slightly better readability scores, the content produced by both versions remains challenging for the general public. This highlights the need for caution regarding potential misinformation and readability. Furthermore, the paid subscription model for GPT-4 could exacerbate existing health care disparities by limiting access to certain patient populations. Despite these limitations, ChatGPT shows promise as a valuable tool for addressing common patient queries regarding radiotherapy. However, its use should be complemented by strategies to improve accessibility and readability.

Acknowledgments

This work received Portuguese national funding from FCT – Fundação para a Ciência e a Tecnologia, IP, through the Research Center for Psychological Science of the Faculty of Psychology, University of Lisbon (UID/04527). The funding source was not involved in the study design, analyses, or interpretation of the data; writing of the report; or decision to submit the paper for publication. The authors used AI to assist in rephrasing sentences and enhancing their clarity and effectiveness. After using the tool, the authors reviewed and edited the content as necessary and take full responsibility for the final publication.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

AG and MC contributed to the conceptualization, methodology, writing/review and editing, supervision, and project administration. CM and MC-R were responsible for the conceptualization, methodology, investigation, resources, data curation, and writing the original draft. EC conducted the statistical analysis. All authors approved the final version of the manuscript and had full responsibility for the decision to submit for publication.

Abstract

Background: Large language models (LLMs) such as ChatGPT (OpenAI) are increasingly discussed as potential tools for patient education in health care. In radiation oncology, where patients are often confronted with complex medical terminology and complex treatment plans, LLMs may support patient understanding and promote more active participation in care. However, the readability, accuracy, completeness, and overall acceptance of LLM-generated medical content remain underexplored.

Objective: This study aims to evaluate the potential of ChatGPT-4 as a supplementary tool for patient education in the context of lung cancer radiotherapy by assessing the readability, content quality, and perceived usefulness of artificial intelligence–generated responses from both clinician and patient perspectives.

Methods: A total of 8 frequently asked questions about radiotherapy for lung cancer were developed based on clinical experience from a team of clinicians specialized in lung cancer treatment at a university hospital. The questions were submitted individually to ChatGPT-4o (version as of July 2024) using the prompt: "I am a lung cancer patient looking for answers to the following questions." Responses were evaluated using three approaches: (1) a readability analysis applying the Modified Flesch Reading Ease (FRE) formula for German and the 4th Vienna Formula (WSTF); (2) a multicenter expert evaluation by 6 multidisciplinary clinicians (radiation oncologists, medical oncologists, and thoracic surgeons) specialized in lung cancer treatment using a 5-point Likert scale to assess relevance, correctness, and completeness; and (3) a patient evaluation during the first follow-up appointment after radiotherapy, assessing comprehensibility, accuracy, relevance, trustworthiness, and willingness to use ChatGPT for future medical questions.

Results: Readability analysis classified most responses as "very difficult to read" (university level) or "difficult to read" (upper secondary school), likely due to the use of medical language and long sentence structures. Clinician assessments yielded high scores for relevance (mean 4.5, SD 0.52) and correctness (mean 4.3, SD 0.65), but completeness received slightly lower ratings (mean 3.9, SD 0.59). A total of 30 patients rated the responses positively for clarity (mean 4.4, SD 0.61) and relevance (mean 4.3, SD 0.64), but lower for trustworthiness (mean 3.8, SD 0.68) and usability (mean 3.7, SD 0.73). No harmful misinformation was identified in the responses.

Conclusions: ChatGPT-4 shows promise as a supplementary tool for patient education in radiation oncology. While patients and clinicians appreciated the clarity and relevance of the information, limitations in completeness, trust, and readability highlight the need for clinician oversight and further optimization of LLM-generated content. Future developments should focus on improving accessibility, integrating real-time readability adaptation, and establishing standardized evaluation frameworks to ensure safe and effective clinical use.

Introduction

Artificial intelligence (AI) has made remarkable progress in recent years, with models like ChatGPT, launched by OpenAI in November 2022, emerging as critical tools in natural language processing. Built on the GPT architecture, ChatGPT has evolved from GPT-1 (2018) to GPT-4o (May 2024), with each iteration improving accuracy, contextual understanding, and versatility, particularly in generating human-like texts. In addition to ChatGPT, other notable large language models (LLMs) include Google's Bard, which excels in generating creative content and integrating real-time data, Meta's LLAMA, tailored for research and noncommercial applications, and Anthropic's Claude, which prioritizes safety and ethical AI interactions.

ChatGPT, in its current form, offers notable advantages in the medical field, especially in patient education and communication [1,2]. It can provide clear explanations of complex medical concepts, answer patient queries, and assist clinicians in creating educational materials [3,4]. ChatGPT is a powerful tool for enhancing patient understanding and engagement in treatment plans, leveraging its ability to process and generate text from vast datasets.

In health care, ChatGPT has found diverse applications [5]. It is particularly effective for patient education, simplifying complex medical jargon into accessible language and offering support beyond clinical hours. Patients often have follow-up questions about treatment processes, side effects, safety, and treatment design and delivery [6].

These queries can significantly increase staff workload, potentially exacerbating physician burnout and negatively affecting care quality [7]. LLM chatbots like ChatGPT offer a promising solution to mitigate this burden by answering routine patient inquiries and reducing the workload on health care professionals. Furthermore, its ability to simulate conversations enables interactive patient education, improving comprehension and fostering a more informed and empowered patient community [4,8,9].

However, ChatGPT has limitations. It lacks critical thinking and contextual judgment, which can lead to misinformation or factually inaccurate responses, commonly referred to as "hallucinations" [10,11]. Other concerns include the risk of providing incorrect medical information, breaches of patient privacy, generating falsified documents or images, overdependence on AI in medical education, and reinforcing existing biases [12]. In addition, the current version relies on data up to 2021, limiting its ability to provide up-to-date medical information [13].

Lung cancer, one of the most prevalent cancers and the leading cause of cancer-related deaths worldwide, presents a significant need for patient education [14]. Given the critical implications of this diagnosis with its complex treatment modalities, such as radiotherapy, patients often seek comprehensive, reliable, and easily accessible information online [15].

This study aims to evaluate the educational capabilities and limitations of GPT-4 for patients undergoing radiotherapy for lung cancer. This includes a clinician-led evaluation of response relevance, accuracy, and completeness and a patient-led review of its performance in providing educational content. In addition, a readability analysis was conducted to assess the accessibility of the responses generated.

Methods

Overview

We, a team from the Department of Radiation Oncology at University Hospital Ludwig-Maximilians-University, Munich, Germany, designed 8 questions about radiotherapy for lung cancer. These questions were developed by collecting input from clinicians primarily involved in lung cancer treatment at our department, asking them which questions they frequently encounter during consultations. To ensure a representative selection, 4 experienced physicians from our lung cancer core team were interviewed. The questions covered general information about lung cancer, treatment options, radiotherapy, side effects, quality of life, preparations before treatment, and follow-up care. The questions were presented to GPT-4o (version as of July 2024) via OpenAI's web interface, using the prompt: "I am a lung cancer patient looking for answers to the following questions." Textbox 1 displays the questions and ChatGPT's responses. The questions and answers were originally in German and translated for this publication. To ensure consistency, each question was posed to ChatGPT 5 times using the same prompt. Each question was presented individually using a standardized prompt structure, without engaging the model in an ongoing conversation or allowing follow-up questions or AI-generated additional prompts. This approach ensured that each response was independent and comparable across multiple trials. The responses were reviewed for variations in content and length by the primary researcher, and no substantial differences were identified.

Textbox 1. Questions and responses from ChatGPT-4o.

Q1: What is lung cancer?

ChatGPT: Lung carcinoma, also known as lung cancer, is a malignant neoplasm in the lung tissue. It develops when cells in the lungs grow uncontrollably and form tumors. There are 2 main types of lung cancer:

- Non-small cell lung carcinoma (NSCLC): This is the most common type and accounts for about 85% of cases. It includes various subtypes such as adenocarcinoma, squamous cell carcinoma, and large cell carcinoma.
- Small cell lung carcinoma (SCLC): This type is more aggressive and grows faster than non-small cell lung carcinoma. It is less common and accounts for about 15% of cases.

The main causes of lung cancer are tobacco smoking, inhalation of second-hand smoke, environmental and workplace exposure to certain pollutants, and genetic factors. Symptoms can include chronic cough, chest pain, weight loss, and shortness of breath. Diagnosis is usually made by imaging (eg, X-ray, CT scan) and biopsies. Treatment may include surgery, radiotherapy, chemotherapy, and targeted therapies, depending on the type and stage of the cancer.

Q2: How can lung cancer be treated?

ChatGPT: The treatment of lung cancer depends on the type (non-small cell or small cell) and the stage of the disease:

- Surgery: removal of the tumor and surrounding lung tissue, often for early stages of non-small cell lung cancer.
- Radiotherapy: High-energy radiation destroys cancer cells, which is useful for inoperable tumors or for follow-up treatment.
- Chemotherapy: Drug treatment to kill or inhibit the growth of cancer cells, used before or after surgery and in advanced stages.
- Targeted therapy: Drugs that attack specific molecular targets on cancer cells, particularly effective for certain genetic mutations.
- Immunotherapy: Stimulates the immune system to fight cancer cells, especially in advanced non-small cell lung cancer.
- Palliative therapy: Alleviates symptoms and improves quality of life in advanced cancer.

Treatment is often customized and may include a combination of these methods.

Q3: What are the advantages of radiotherapy over other treatment options?

ChatGPT: Radiotherapy offers several advantages in the treatment of lung cancer:

- Targeted treatment: precise radiation attacks the tumor directly, sparing the surrounding healthy tissue.
- Noninvasive: No surgical intervention is required, which is ideal for patients who cannot undergo surgery.
- Complementary to other therapies: Effective in combination with chemotherapy to improve outcomes.
- Applicability for inoperability: Useful for tumors that cannot be surgically removed.
- Pain relief: Relieves symptoms and improves quality of life in advanced cancer.
- Preservation of organ function: Preserves lung function better than complete removal of a lung section.
- Outpatient treatment: Often available as an outpatient therapy, minimizing hospitalization.

These benefits make radiotherapy a valuable treatment option for various stages of lung cancer.

Q4: How is radiotherapy carried out for lung cancer?

ChatGPT: Radiotherapy for lung cancer is carried out in several stages:

- Planning: Imaging techniques such as CT or MRI create detailed images of the tumor. A radiotherapist plans the exact dose and position of the radiation.
- Simulation: The patient is placed on a couch in the treatment position, often with special cushions or masks for stabilization. Markings on the skin or special tattoos help with precise alignment.
- Treatment: The actual radiotherapy takes place over several sessions (fractions), typically daily over several weeks. High-energy beams are directed at the tumor from different angles to achieve maximum effect and spare healthy tissue.
- Monitoring: regular reviews and imaging during the treatment phase to adjust therapy and monitor progress.

The treatment is painless and is performed on an outpatient basis, with each session lasting only a few minutes.

Q5: What are the possible side effects of radiotherapy for lung cancer?

ChatGPT: Radiotherapy for lung cancer can have several side effects, depending on the radiation dose and the area treated:

Acute side effects:

- Fatigue: frequent feeling of exhaustion.
- Skin reactions: Redness, irritation, or dryness in the irradiated area. Cough and breathing difficulties: Intensification of existing symptoms.

XSL•FO
RenderX

Late side effects:

- Scarring in the lungs can lead to long-term breathing problems. Pneumonia: Radiation pneumonitis is an inflammation of the lung tissue.
- Esophagitis: Inflammation and pain in the esophagus, making swallowing difficult.

Rare side effects:

- Heart problems: With radiation near the heart.
- Secondary tumors: Increased risk of other types of cancer in the irradiated area.

Side effects vary from person to person and can be mitigated by supportive measures and medication. Close monitoring by the treatment team helps to identify and treat side effects at an early stage.

Q6: What precautions or preparations are necessary before the radiation treatment?

ChatGPT: Several precautions and preparations are necessary before radiotherapy for lung cancer:

- Consultation and planning: a detailed consultation with the radiotherapist to discuss the treatment plan, possible side effects, and the expected course.
- Detailed imaging (CT and MRI) for precise localization of the tumor.
- Medical preparation: review and adjustment of current medications, as some may affect the radiation effect.
- Assessment of general health and lung function tests.
- Physical preparation: Making markings or tattoos on the skin for exact alignment during radiation.
- Possibly the creation of custom-made splints or masks to stabilize the treatment position.
- Nutrition and lifestyle advice: Advice on nutrition to strengthen the body.
- Advice to stop smoking and avoid alcohol to promote healing.
- Psychological support: access to counseling and support to manage anxiety and stress before treatment.

These preparations help to make the treatment more effective and safer.

Q7: How does radiation affect the patient's quality of life during and after treatment?

ChatGPT: Radiotherapy can affect the patient's quality of life in various ways, both during and after treatment:

During treatment:

- Fatigue: Frequent fatigue may limit daily activities.
- Skin reactions: Redness and irritation may cause discomfort.
- Breathing problems and coughing: Exacerbation of existing symptoms that interfere with everyday life.

After treatment:

- Recovery phase: Fatigue may last a few weeks, and return to normality often takes longer.
- Long-term effects: Scarring and radiation pneumonitis can cause breathing difficulties.
- Emotional distress: Fear of relapse and coping with physical changes.

Positive effects:

- Symptom relief: reduction of tumor pain and improvement in breathing can increase quality of life.
- Cancer control: Effective tumor control or reduction increases well-being and confidence.

Close cooperation with the medical team, supportive measures, and a healthy lifestyle help to improve quality of life during and after radiotherapy.

Q8: What follow-up care is required after radiotherapy for lung cancer?

ChatGPT: After radiotherapy for lung cancer, careful aftercare is crucial. This includes regular check-ups to monitor the response to treatment and detect possible relapses at an early stage. These usually include imaging such as CT or PET scans, blood tests, and lung function tests. It is also important to monitor and treat side effects of radiotherapy, such as pneumonia (radiation pneumonitis) or pulmonary fibrosis. Rehabilitation measures can help to improve lung function and increase quality of life. Psychosocial support is also an essential part of aftercare to provide emotional support for patients and their families.

Evaluation of Readability

A readability analysis was conducted using the Modified Flesch Reading Ease (FRE) Formula for German. A well-established readability metric for the English language is the FRE scale [16]. The FRE measures the readability of a text in terms of its average sentence length (ASL) and the average number of syllables per word (ASW). It relies on the fact that short words or sentences are usually easier to understand than longer ones. For this analysis, we have used the modified FRE for the German language by Toni Amstad [17]: FRE (German)=180−ASL−(58.5×ASW).

Also, the 4th Vienna Formula (WSTF) was used. Unlike the FRE, the Vienna Formula (WSTF) has not been adapted for the German language. Instead, it is based on the work of Bamberger and Vanacek [18], who analyzed German textual material. They derived at least 5 versions of the Vienna Formula for prose and nonfiction texts. Typically, the fourth WSTF is used for text analysis. This metric is also based on average sentence length (ASL) and the proportion of words with three or more syllables (mean word syllables [MS]): WSTF=0.2656 × ASL +0.2744 × MS−1.6939.

The readability analysis and score calculation was performed using Python (version 3.8; Python Software Foundation) and its text processing libraries, such as nltk for sentence and word tokenization and a custom syllabification function for the German language. The FRE score was computed directly based on the modified formula for German. The WSTF score was calculated using the 4th Vienna Formula.

While the FRE and WSTF do not directly map to standard grade levels in the German language, readability categories were approximated to estimated educational levels to provide a practical interpretation of the required comprehension level. This approach allows for a more intuitive understanding of the readability of ChatGPT-generated responses in the context of patient education (see Table 1 for details).

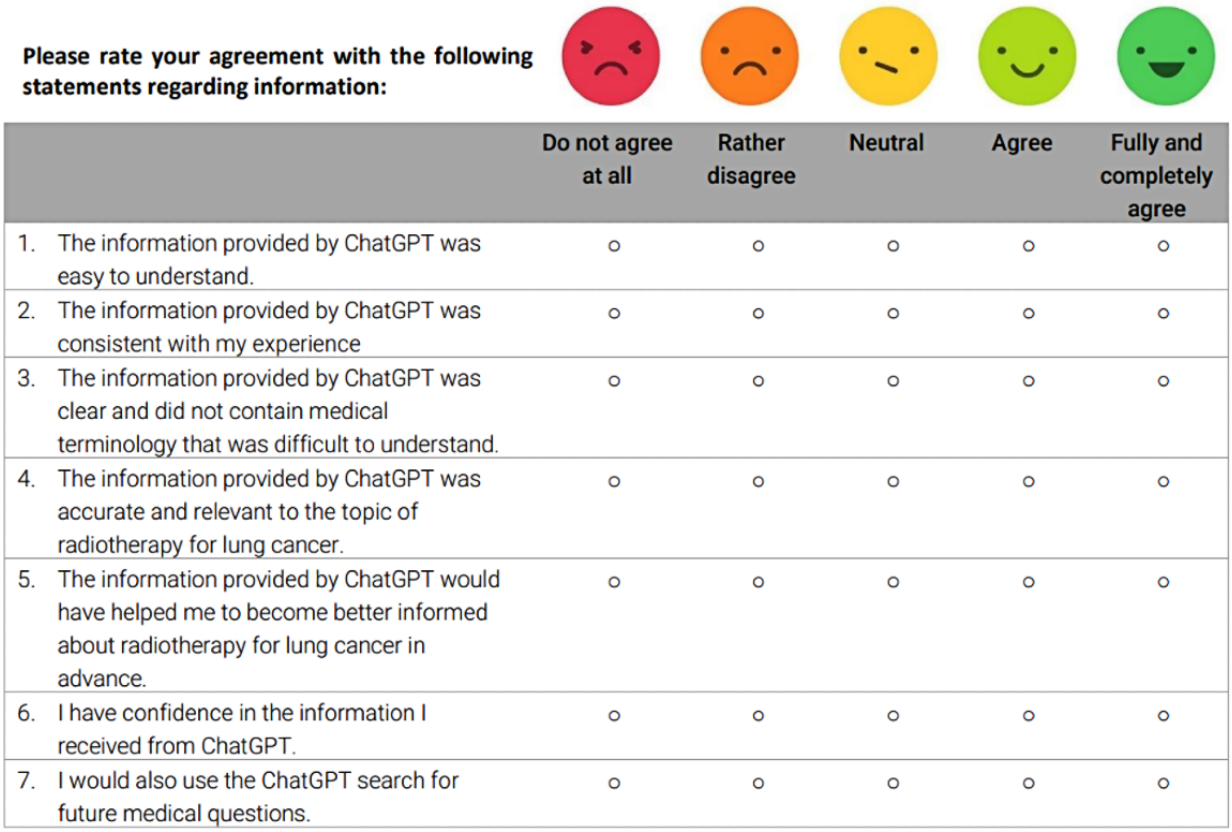
Table . Interpretation of readability scores with estimated educational level: Modified Flesch Reading Ease (FRE) for German and 4th Vienna Formula (WSTF).

Description	FRE[a]	WSTF[b]	Estimated educational level (approximate)
Very difficult to read	0 - 29	>14	University level
Difficult to read	30 - 49	13 - 14	Upper secondary (Grade 10-12/13)
Fairly difficult to read	50 - 59	10 - 13	Lower secondary (Grade 7 - 10)
Average readability	60 - 69	8 - 10	Upper middle school (Grade 6)
Fairly easy to read	70 - 79	7 - 8	Lower middle school (Grade 5)
Easy to read	80 - 89	5 - 7	Upper elementary (Grade 4)
Very easy to read	90 - 100	4 - 5	Lower elementary (Grade 1 - 3)

[a]FRE: Modified Flesch Reading Ease.

[b]WSTF: 4th Vienna Formula.

Clinician Evaluation



Following the readability analysis, the 8 responses were independently evaluated by 6 clinicians experienced in lung cancer treatment, including 2 radiation oncologists, 2 medical oncologists, and 2 thoracic surgeons, all with 5 - 12 years of experience working in specialized lung cancer centers with a university teaching function. This multidisciplinary approach ensured a comprehensive evaluation from different medical perspectives while remaining focused on lung cancer treatment. Clinicians received an information sheet outlining the study's procedures and objectives. The question-answer pairs and evaluation sheet were provided in electronic form. Evaluators had no time limit to complete the assessment, scoring each response for relevance, correctness, and completeness using an ordinal 5-point Likert scale, with 1 indicating disagreement and 5 indicating complete agreement with the statements that the responses were relevant, correct, and complete, respectively. Respondents were also allowed to add additional comments to their evaluations.

Patient Evaluation

Finally, the question-answer pairs were presented to patients with lung cancer during their first follow-up appointment after completing radiotherapy. Patients were invited to participate in a study evaluating an LLM for patient education. They received an information sheet outlining the study's procedures and goals and were asked to sign a data security statement and provide informed consent before participation. After consenting, patients were given the question-answer pairs on paper sheets and had as much time as needed to complete the evaluation. The evaluation was based on 7 statements to assess ChatGPT's performance in terms of comprehensibility, accuracy, relevance, and trustworthiness using a 5-point Likert scale (1=strongly disagree to 5=strongly agree; see Figure 1). In addition, they were asked whether the information made them feel better informed and if they would consider using ChatGPT for future medical questions. Patient responses from the paper forms were manually entered into Microsoft Office Excel (version 2410) by the primary researcher for further processing and analysis.

XSL•FO
RenderX

Figure 1. Example of a 5-point Likert scale presented to patients to rate ChatGPT's responses.

Please rate your agreement with the following statements regarding information:

	Do not agree at all	Rather disagree	Neutral	Agree	Fully and completely agree
1. The information provided by ChatGPT was easy to understand.	o	o	o	o	o
2. The information provided by ChatGPT was consistent with my experience	o	o	o	o	o
3. The information provided by ChatGPT was clear and did not contain medical terminology that was difficult to understand.	o	o	o	o	o
4. The information provided by ChatGPT was accurate and relevant to the topic of radiotherapy for lung cancer.	o	o	o	o	o
5. The information provided by ChatGPT would have helped me to become better informed about radiotherapy for lung cancer in advance.	o	o	o	o	o
6. I have confidence in the information I received from ChatGPT.	o	o	o	o	o
7. I would also use the ChatGPT search for future medical questions.	o	o	o	o	o

Ethical Considerations

The local Ethics Committee of Ludwig-Maximilians-University Munich (LMU) approved the study protocol in August 2023 (approval 23 - 0742). The study was conducted in accordance with the Declaration of Helsinki, and all patients provided signed written consent to participate. To ensure privacy and confidentiality, all collected data were anonymized before analysis and no personal identifiable information was stored or shared. Data were handled in compliance with institutional and national data protection regulations. Participants did not receive any financial or material compensation for their participation in the study.

Statistical Analysis

Data are reported using descriptive statistics, including median, mean, and SD. Statistical analyses were performed using Microsoft Office Excel (version 2410). Figures were generated using Python (version 3.8) with the Matplotlib library. Data extracted from tables was structured in Pandas DataFrames for analysis and plotting.

Results

Evaluation of Readability

Table 1 shows the interpretation of readability scores with an estimated educational level. The FRE scores ranged from 6.3 to 42.3, with a mean of 23.4 (SD 11.2), classifying most responses as "very difficult to read" (University level). Similarly, the WSTF scores ranged from 10.6 to 16.8, with a mean of 13.8 (SD 2.1). Most responses were in the "very difficult to read" category, with some being "difficult" (upper secondary, grade 10-12/13) or "fairly difficult" (lower secondary, grade 7 - 10; see Table 2).

XSL•FO

Clinician Evaluation

Table 3 presents the evaluation of ChatGPT's responses by 6 clinicians experienced in treating lung cancer: 2 radiation oncologists, 2 medical oncologists, and 2 thoracic surgeons.

The mean scores for relevance ranged from 3.7, SD 0.94 (responses 2 [treatment] and 3 [advantages of radiotherapy]) to 4.3, SD 0.75 (response 8 [follow-up]). Correctness scores varied between 3.5, SD 0.50 (response 7 [quality of life]) and 4.3, SD 0.75 (response 8 [follow-up]). Completeness ratings ranged from 3.5, SD 0.50 (responses 2 [treatment], 5 [side effects], and 7 [quality of life]) to 4.2, SD 0.69 (response 8 [follow up]). Overall, responses showed variability in performance, with relevance and correctness achieving higher mean scores than completeness. Notably, response 8 (follow-up) scored the highest across all 3 dimensions (relevance: 4.3, SD 0.75; correctness: 4.3, SD 0.75; and completeness: 4.2, SD 0.69), while response 7 (quality of life) scored the lowest for correctness (3.5, SD 0.50).

A thoracic surgeon commented that ChatGPT did not discuss chances of treatment success and recurrence rates. A medical oncologist commented that the role of multidisciplinary tumor boards should have been mentioned. A radiation oncologist commented that there was no differentiation between radiotherapy modalities.

Completeness	4.2 (0.69)	0 (0)	0 (0)	1 (17)	3 (50)	2 (33)

Patient Evaluation

The responses generated by ChatGPT were evaluated by 30 consecutive patients who underwent radiation therapy for lung cancer between June 2024 and October 2024 at the University Hospital LMU Munich during their first follow-up examination 6 weeks after treatment completion. The median age of the 19 male and 11 female patients was 66 years (48 - 87 years). A total of 26 of those patients had non-small cell lung cancer (NSCLC), while 4 patients had small cell lung cancer (SCLC). In addition, 12 patients received concomitant chemotherapy, and 10 patients received stereotactic body radiotherapy (SBRT). A total of 5 patients were treated using magnetic resonance-guided radiotherapy (MRgRT).

Results of the patient evaluation are summarized in Table 4. The highest-rated statement was "The information provided by ChatGPT was easy to understand," with a mean score of 4.4 (SD 0.61), where 94% of patients rated it as "agree" or "strongly agree." Similarly, the statement "The information provided by ChatGPT was accurate and relevant to radiotherapy for lung

XSL•FO
RenderX

cancer" received a high mean score of 4.2 (SD 0.83), with 87% of patients rating it positively. The statement "The information provided by ChatGPT was consistent with my experience" achieved a mean score of 4.1 (SD 0.63), reflecting alignment with patient expectations. Similarly, the statement "The information provided by ChatGPT was clear and did not contain medical terminology that was difficult to understand" received a mean score of 4.1 (SD 0.81), with 80% of patients giving positive feedback. This highlights ChatGPT's strength in delivering accessible and jargon-free information.

In contrast, statements related to usability and trustworthiness received slightly lower ratings. "The information provided by ChatGPT would have helped me to become better informed about radiotherapy for lung cancer in advance" and "I would also use ChatGPT for future medical questions" both scored a mean of 3.9 (SD 0.94). In addition, the statement "I have confidence in the information I received from ChatGPT" scored 4.0 (SD 0.84).

Table . Patient's ratings of statements 1 - 7. Scores are based on a 5-point Likert scale, where 1 represents the lowest and 5 the highest score (1=strongly disagree, 5=strongly agree).

Statement	Mean (SD)	Ratings on likert scale, n (%)				
		1	2	3	4	5
The information provided by ChatGPT was easy to understand.	4.4 (0.61)	0 (0)	0 (0)	2 (7)	14 (47)	14 (47)
The information provided by ChatGPT was consistent with my experience.	4.1 (0.63)	0 (0)	0 (0)	5 (17)	18 (60)	7 (23)
The information provided by ChatGPT was clear and did not contain medical terminology that was difficult to understand.	4.1 (0.81)	0 (0)	1 (3)	5 (17)	13 (43)	11 (37)
The information provided by ChatGPT was accurate and relevant to the topic of radiotherapy for lung cancer.	4.2 (0.83)	0 (0)	2 (7)	2 (7)	14 (47)	12 (40)
The information provided by ChatGPT would have helped me to become better informed about radiotherapy for lung cancer in advance.	3.9 (0.94)	0 (0)	3 (10)	6 (20)	12 (40)	9 (30)
I have confidence in the information I received from ChatGPT.	4.0 (0.84)	0 (0)	1 (3)	8 (27)	12 (40)	9 (30)
I would also use the ChatGPT search for future medical questions.	3.9 (0.94)	0 (0)	3 (10)	6 (20)	12 (40)	9 (30)

Discussion

Principal Findings

Providing accessible and understandable information is a key component of patient-centered care, particularly in oncology. Research has shown that patients with cancer often seek information from sources other than their health care providers, with the internet serving as a primary resource [19]. However, existing online resources frequently fail to address patients' specific questions, especially in radiation oncology and often exceed recommended complexity levels [20,21]. Against this background, our study explores the potential of the most widely used and broadly adopted LLM, ChatGPT [22], making it a relevant and practical model for evaluating real-world applications in patient communication and education in lung cancer radiotherapy.

This study evaluated the benefits and risks of using ChatGPT to educate patients undergoing radiotherapy for lung cancer. The analysis included a multifaceted evaluation of ChatGPT-generated content, including readability assessment, clinician evaluation, and patient feedback. The main findings indicate that while ChatGPT's responses are often technically complex and rated as "difficult to read" based on objective readability measures (FRE and WSTF), patients still perceived the information as clear and understandable. Clinicians rated the responses positively for relevance and correctness but noted some limitations in completeness.

Comparison With Previous Work

The readability analysis of ChatGPT's responses revealed that the FRE and WSTF scores classified most responses as "very difficult to read" or "difficult to read," which may limit accessibility, particularly for individuals with lower health literacy. The low readability scores are primarily due to the extensive use of complex medical terminology and long sentence structures, which increase the calculated ASL and ASW values, thereby reducing readability. While the FRE and WSTF scores do not have direct grade-level equivalents in German, texts classified as "very difficult to read" or "difficult to read," typically require upper secondary education or higher for full comprehension. In addition, the complexity of the prompt can influence the readability of responses, as more detailed inquiries

XSL•FO
RenderX

tend to generate longer, more technical answers, which may further reduce readability. These findings are consistent with previous studies in other medical domains, which have similarly reported low readability scores for AI-generated content, suggesting that readability challenges are a common limitation across various medical specialties and not specific to lung cancer [23-26]. Furthermore, lung cancer education inherently involves complex terminology, multidisciplinary treatment approaches, and a broad spectrum of disease presentations, all of which may contribute to lower readability scores compared to simpler medical topics. These findings align with studies indicating that cancer-related information on the internet is generally not well-tailored to patients' needs [27]. Despite this, the patient evaluation showed that ChatGPT's responses were perceived as easy to understand (mean score 4.4, SD 0.61), possibly because the survey was conducted post-therapy when patients were already familiar with relevant topics and terminology. One possible strategy to improve readability in patient education materials is the fine-tuning of LLMs with curated, patient-friendly datasets or the integration of real-time readability adjustments that simplify sentence structure while maintaining medical accuracy. In addition, a hybrid approach involving AI-generated content reviewed by clinicians may enhance accessibility without compromising correctness.

The clinician evaluation of ChatGPT highlighted its strengths in relevance and correctness but noted limitations in completeness. Response 8, for example, performed best across all dimensions (relevance: 4.3, SD 0.75; correctness: 4.3, SD 0.75; and completeness: 4.2, SD 0.69), while Response 7 demonstrated inconsistencies, scoring the lowest for correctness (3.5, SD 0.50). These findings align with other studies assessing ChatGPT's accuracy in answering questions about lung cancer [28,29] and other queries in radiotherapy [30,31]. Interestingly, another study found that ChatGPT achieved high qualitative ratings for factual accuracy, conciseness, and completeness, closely mirroring expert responses [32]. The lower completeness scores suggest that ChatGPT responses, while relevant and mostly accurate, may omit critical clinical details. This limitation could be mitigated by refining prompting strategies to ensure more detailed outputs or integrating clinician oversight in AI-assisted patient education.

Patients rated ChatGPT highly for clarity and relevance, but usability and trust received comparatively lower scores. Statements like "I would also use ChatGPT for future medical questions" (3.9, SD 0.94) and "I have confidence in the information I received from ChatGPT" (4.0, SD 0.84) highlight areas where trust and reliability could be improved. Lower trustworthiness and usability scores suggest that while patients find ChatGPT-generated responses clear and relevant, concerns remain regarding the credibility of AI-generated medical information. Future implementations could improve trust through clinician oversight, AI transparency measures, and integration with evidence-based sources.

Considerations for Clinical Integration

LLMs like ChatGPT are often approached cautiously in health care due to concerns about trust, security, privacy, and ethics [33,34]. While ChatGPT is sometimes criticized for lacking a human touch and empathy [35], studies have found its responses to be more empathetic than those of clinicians in specific scenarios [36], especially for sensitive health topics where patients may feel uncomfortable consulting clinicians, nonsentient chatbot tools may offer valuable support [32].

Despite ongoing concerns about "hallucinations," where LLMs generate plausible but incorrect answers [10,11], no potential harm was identified in ChatGPT's responses in this study. OpenAI, the developer of ChatGPT, acknowledges the possibility of inaccurate outputs, likely contributing to health care providers' reluctance to adopt LLM chatbots for patient communication and education. However, other studies have shown that ChatGPT can provide highly accurate and complete responses comparable to virtual patient-clinician communication in radiation oncology [32]. To minimize the risk of misinformation, future AI-driven patient education tools should incorporate source attribution, real-time fact-checking, and clinician oversight. In addition, models specifically trained on verified medical datasets may help reduce the occurrence of incorrect or misleading information.

Strengths and Limitations

First, a key strength of this study is its comprehensive evaluation approach, combining readability metrics with both clinician and patient assessments.

This study has several limitations. First, the questions were formulated by the study team based on input from clinicians experienced in lung cancer treatment, rather than being directly collected from patients. While this approach ensured clinical relevance and reflected frequently encountered consultation topics, it may have limited the diversity of clinical scenarios and the representativeness of the findings from a broader patient perspective. Second, the study was conducted in German, which could affect the generalizability of results, as ChatGPT's performance may vary across languages [37,38]. Third, this study used GPT-4, released by OpenAI in May 2024, a paid subscription model with superior accuracy and coherence compared to the free GPT-3.5 version, which may limit accessibility by the general population. Fourth, another key limitation of this study is the lack of standardized criteria for assessing AI-generated medical responses. Future research should focus on developing structured evaluation frameworks, integrating expert consensus and establishing domain-specific benchmarks to ensure consistent assessment of AI-generated content.

Fifth and finally, while our study focused on ChatGPT, the most popular and earliest publicly released conversational LLM [22], other models, such as Bard (Google), LLAMA (Meta), and Claude (Anthropic), show promise in addressing oncology queries. However, no comparative analysis of these alternative models was conducted in this study, as the primary objective was to assess the feasibility and quality of ChatGPT's responses as a widely used reference model in patient education. ChatGPT was selected due to its widespread adoption and superior response quality demonstrated in previous studies compared to other LLMs [24,39,40]. Previous research has highlighted differences among LLMs in terms of response accuracy, completeness, and readability in health care applications,

XSL•FO
RenderX

including radiotherapy [39-44]. Future studies should explore how various LLMs perform specifically in the context of patient education in lung cancer, to identify the most suitable tools for clinical integration.

Conclusion and Future Directions

In conclusion, ChatGPT demonstrates significant potential as a supplementary tool for patient education in radiation oncology, particularly for patients undergoing radiotherapy for lung cancer. Its ability to provide clear and relevant information highlights its value in enhancing patient understanding and engagement in their treatment journey. However, limitations in completeness, accuracy, and trust underscore the importance of careful review and supplementation by health care professionals.

Further development of AI tools should focus on improving readability through fine-tuning on patient-friendly datasets or integrating real-time readability adaptation, while maintaining medical accuracy. Incorporating clinician oversight into AI-generated content could enhance both reliability and trust. In addition, the development of standardized evaluation frameworks for AI-generated health information will be essential to ensure consistent quality assessment. With continued research and refinement, ChatGPT and similar technologies have the potential to revolutionize patient education and support health care providers in delivering accurate, accessible, and personalized care.

Acknowledgments

Generative AI (ChatGPT-4o) was used to generate the 8 answers evaluated in this study, as described in the Methods section.

Abstract

Background: National guidelines recommend germline genetic testing (GT) for all patients with early-onset colorectal cancer. With recent advances in targeted therapies and GT, these guidelines are expected to expand to include broader groups of patients with colorectal cancer. However, there is a shortage of genetic professionals to provide the necessary education and support for informed consent. As such, there is a pressing need to identify alternative approaches to facilitate and expedite access to GT.

Objective: This study describes the development of a pretest education intervention, Nest-CRC, to facilitate the uptake of germline GT among patients with early-onset colorectal cancer. Patients with early-onset colorectal cancer and health care providers reviewed Nest-CRC, and their reactions and recommendations were captured using a nested mixed methods approach.

Methods: Using the learner verification approach, we conducted 2 sequential phases of surveys and interviews with English- and Spanish-speaking patients with early-onset colorectal cancer and health care providers. The surveys assessed participants' experiences with genetic services and provided immediate feedback on the Nest-CRC genetic education modules. Semistructured interviews evaluated participants' perceptions of self-efficacy, attraction, comprehension, cultural acceptability, and usability of Nest-CRC. Survey data were analyzed using descriptive statistics (mean, median, and proportions), while interview data were analyzed through line-by-line coding of the transcribed interviews. After each phase, Nest-CRC was refined based on participants' recommendations.

Results: A total of 52 participants, including 39 patients with early-onset colorectal cancer and 13 providers, participated in the study. Of these, 19 patients and 6 providers participated in phase 1 (N=25), and 20 patients and 7 providers participated in phase 2 (N=27). Most participants (phase 1: 23/25, 92%, to 25/25, 100%; phase 2: 24/27, 89%, to 27/27, 100%) agreed that each of the 5 education modules was easy to understand and helpful; 13 patients reported no history of GT, with 11 (85%) expressing interest in GT and 2 (15%) remaining unsure after completing Nest-CRC. Participants reported that Nest-CRC provided sufficient information to help them decide about GT. The tool was deemed acceptable by individuals from diverse backgrounds, and participants found it visually attractive, easy to comprehend, and user-friendly.

XSL•FO
RenderX

Conclusions: The findings revealed that Nest-CRC is a promising strategy for facilitating pretest education and promoting GT. Nest-CRC has been refined based on participant recommendations and will be re-evaluated.

KEYWORDS

genetic education; genetic testing; genetic counseling; digital health; early-onset colorectal cancer

Introduction

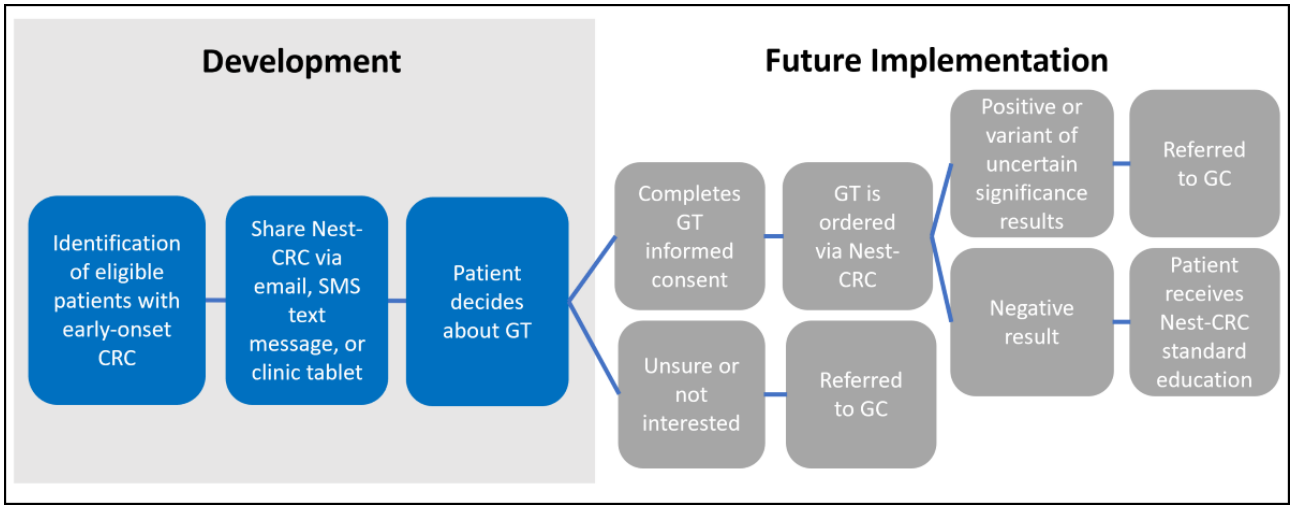
Colorectal cancer (CRC) is the third most common cause of cancer incidence and mortality among men and women in the United States [1]. By 2030, it is projected to become the leading cause of death among patients diagnosed with early-onset cancer (under the age of 50 years) [2]. Approximately 14%-25% of early-onset CRCs are linked to hereditary factors, irrespective of family history [3,4]. Identifying germline variants in patients with CRC can help reduce morbidity and mortality by enabling guided treatment decisions, risk management to prevent and detect new primary cancers early, and cascade testing for at-risk relatives [5-9]. The National Comprehensive Cancer Network (NCCN) Guidelines recommend multigene panel testing (MGPT) for *all* individuals diagnosed with CRC before the age of 50 years and consider its use for all individuals diagnosed with CRC [10]. MGPT is recommended because it can simultaneously identify gene variants associated with various cancers and simplifies referrals for genetic testing (GT), as neither family history nor patient tumor characteristics are required.

Genetic services heavily depend on clinicians to identify and refer high-risk patients for genetic counseling (GC) and GT. However, approximately 40% of patients with early-onset CRC are not referred for GC [11,12]. Additionally, racial and ethnic disparities exist in germline studies and access to genetic services [11,13]. A study conducted between 2009 and 2017, involving patients with early-onset CRC treated at a tertiary-care referral center and a safety-net health system, found that Black patients were less likely to attend GC compared with Hispanic and non–Hispanic White patients [11]. Another retrospective study, using data from 2012 to 2016 across 4 academic medical centers, found that Black and Hispanic patients with CRC were referred to genetic specialists less often than non–Hispanic White patients [13]. However, among those referred, no racial or ethnic differences were observed in GC attendance [13], highlighting a missed opportunity for guideline-concordant genetic care. Therefore, systematic strategies are necessary to ensure GT services are offered to all patients with early-onset CRC.

With the expanding indications for genetic services, there is a shortage of genetic counselors and qualified genetic professionals [14,15], which can result in delays in GT. Although oncologists and other health care providers can order GT for at-risk patients, most lack the expertise or time to provide adequate genetic education [16,17]. Consequently, the American Society of Clinical Oncology (ASCO) acknowledges GC as the standard of care but also advocates for alternative approaches to delivering genetic services [18]. Studies examining the uptake of genetic services among patients with early-onset CRC have identified cost, limited availability of services, and racial and ethnic referral disparities as key barriers [11,19]. To address these known barriers to GT, the National Institute of Health Clinical Genome Resource's Consent and Disclosure Recommendations Working Group suggested reserving traditional, provider-delivered pre- and posttest GC for patients with greater clinical and genetic complexity, such as those with conditions lacking well-established testing and risk management criteria [20]. Alternative approaches to genetic education are needed to facilitate, expedite, and expand access to GT for patients at risk of cancer without overburdening GC resources [21]. To address this, we developed a digital health tool designed for patients with early-onset CRC from diverse racial and ethnic backgrounds. This tool systematically delivers pretest education and triages patients to GC and GT.

Previous studies involving patients with cancer suggest that digital genetic education is well-accepted and effective in improving knowledge, decisional satisfaction, and reducing decisional conflict [22-24]. However, most educational interventions addressing germline testing have focused on patients with breast cancer [25-27]. To our knowledge, only 2 studies have evaluated alternative strategies for genetic education in patients with CRC. These studies were not specific to patients with early-onset CRC, and their educational content focused on tumor testing [28] or GC [29]. Therefore, in this study, we propose a digital health tool designed for patients with early-onset CRC to promote autonomy by allowing them to access relevant germline information at their convenience, make informed decisions about GT, and opt-in to pretest GC if desired. This study outlines patient and provider feedback on the digital pretest genetic education tool and provides recommendations for its implementation, using a mixed methods approach.

Methods



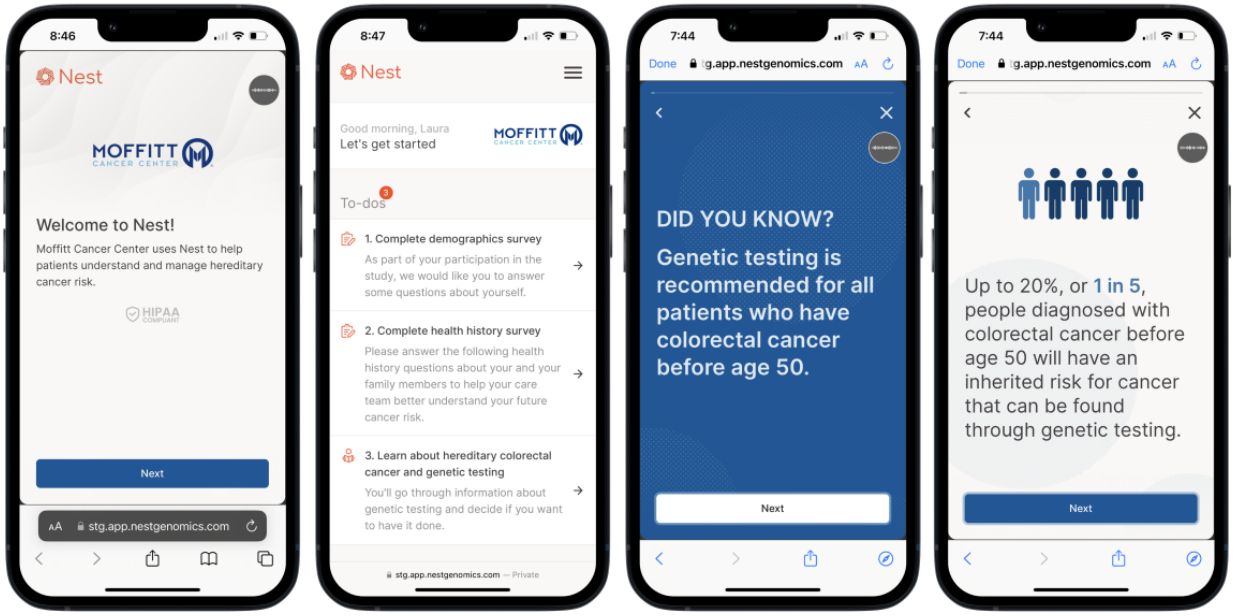
Intervention

Nest Genomics is a software company specializing in developing tools that help patients and providers scale the delivery and long-term implementation of genomic information. The Nest platform is a comprehensive, Health Insurance Portability and Accountability Act (HIPAA)–compliant solution designed to launch, implement, and scale longitudinal genomic programs, supporting both patients and clinicians throughout the care continuum—from patient identification and education to test ordering, result integration, and long-term management. Within Nest, our research team developed the Nest-CRC, a digital health tool designed to provide pretest genetic education for patients with early-onset CRC from diverse racial and ethnic groups (Figure 1). Nest-CRC is not publicly available at this time. The tool is divided into 5 brief modules. The modules

XSL•FO
RenderX

included in the first version of Nest-CRC are (1) hereditary CRC, (2) GT, (3) benefits and risks, (4) care recommendations, and (5) implications for family members. Nest-CRC takes approximately 10 minutes to complete. The information covered in Nest-CRC is supported by ASCO content recommendations for pretest genetic education [18], standard informed consent for GT, and feedback from genetic counselors and experts on the study team. Nest-CRC delivers education through text and images and is accessible on any personal device with internet access [30]. It includes images that are representative of different ages and races, with written content at a 5th-grade reading level in both English and Spanish.

Figure 1. Development and future implementation of the Nest-CRC tool. CRC: colorectal cancer; GC: genetic counseling; GT: genetic testing.



Procedure

We conducted a nested mixed methods study to develop and refine Nest-CRC for patients with early-onset CRC. Following the learner verification approach [31], we carried out 2 sequential phases of patient and provider surveys and interviews about Nest-CRC. Learner verification, which is useful for formative research, uses semistructured individual interviews to assess the appropriateness of materials for a target population. The quantitative data collected in each phase were used to describe the demographic characteristics of our sample population, their experiences with genetic services, and to obtain immediate feedback on their experience navigating each of the genetic education modules.

During phase 1, participants were emailed a link to a brief survey covering demographics, clinical characteristics, and experiences with genetic services, as well as the Nest-CRC educational modules, which included integrated questions about each module. Participants completed a semistructured interview after finishing the survey and Nest-CRC education. Patients could complete the survey and Nest-CRC on their personal device or a clinic tablet. After phase 1, we refined Nest-CRC based on participant recommendations (Figure 2). The revised version of Nest-CRC was then re-evaluated in phase 2 using the same procedure as in phase 1. However, in phase 2, participants also had the option to receive the link via SMS text message. Each version of Nest-CRC was reviewed by the entire study team for final edits.

Ethical Considerations

This study was reviewed and approved by the Moffitt Cancer Center's Scientific Research Committee and Institutional Review Board (approval number 22176) on November 15, 2022. Before enrollment, all participants were provided with a copy of the informed consent form. All patients gave verbal informed consent in person or over the phone, and all providers consented to participate via email. Participants who agreed to take part in the study received a link to the survey and Nest-CRC education. The interviewer reviewed the informed consent form again with each participant before beginning the interview. All data collected for this study were deidentified using a unique ID number. Participants received US $25 upon completion of the interview.

Recruitment

From February to August 2023, English- and Spanish-speaking adult patients with early-onset CRC with upcoming medical appointments at the Moffitt Cancer Center Gastroenterology clinic were contacted in the clinic or by phone and invited to participate in the study. Recruitment flyers in both English and Spanish were posted in various waiting areas at Moffitt Cancer Center and distributed to community partners for sharing on their social media platforms (eg, Facebook). Interested potential participants responded to flyers and internet advertisements by calling or emailing the study team. The study team then contacted these individuals to screen them, obtain informed consent, and schedule their interview.

We purposely recruited at least 20% (n=4) Spanish-speaking and 20% (n=4) Black patients for each phase. These groups were specifically targeted because a lower proportion of Spanish-speaking and Black patients seen at the oncology clinic were eligible for the study. Gastroenterologists, oncologists, nurse practitioners, and genetic counselors with at least 2 years of experience working with patients with CRC were recruited from Moffitt Cancer Center (phases 1 and 2), MedStar Health (phase 2 only), and through referrals (phases 1 and 2). Different individuals participated in each phase.

Survey Measures

Before reviewing Nest-CRC, participants were asked to complete a brief survey capturing relevant sociodemographic, clinical, and epidemiologic characteristics adapted from the Health Information National Trends Survey (HINTS) 5 [32]. Patients were asked about their age, gender, race, ethnicity, country of birth, marital status, education level, employment status, household income, and insurance, while providers were asked about their age, gender, marital status, race, ethnicity, and professional degree. Additional information collected from patients included self-reported technology literacy (using the 3-item Digital Health Care Literacy Scale [33]), health literacy (using the 3-item Short Literacy Survey [34]), clinical details about their cancer diagnosis (including the type of CRC, cancer stage, age of diagnosis, and treatment history), family history of early-onset CRC, Ashkenazi Jewish ancestry (due to the known genetic risk for CRC and other cancers in this population), awareness of genetic services (ie, GC, GT, hereditary cancers, and Lynch syndrome), and history of genetic services (ie, referrals to genetic services, GC, and GT). We also evaluated patients' perceived importance of GT for cancer prevention and early detection (adapted from HINTS 5) [32]. Providers' self-reported practice characteristics included the frequency of communication with patients about genetic risk, referrals to GT, working with patients with early-onset CRC, and working with ethnic/racial minority patients. At the end of each module (n=5), participants were asked 2 questions: whether the information was easy to understand and whether it was helpful, using a 5-point Likert scale ranging from 1=strongly disagree to 5=strongly agree. Responses of strongly agree and agree were recoded as agreed, while neither agree nor disagree, disagree, and strongly disagree were recoded as did not agree.

XSL•FO
RenderX

Upon completing Nest-CRC, participants were asked if they were interested in GT, with response options of yes, no, or unsure.

Interview Process

Interview guides were based on key elements of learner verification. Patients and providers gave feedback on the Nest-CRC tool's attractiveness, comprehension, self-efficacy, cultural acceptability, and usability (Table 1). The development of these questions was informed by prior studies using the learner verification approach [31,35,36] and refined by the study team. All interviews were recorded, and audio files were transcribed verbatim. Interviews conducted in Spanish were translated into English [37]. JRR conducted all English and Spanish interviews via Zoom (Zoom Communications/Qumu Corporation; phase 1: mean 26.96 minutes, range 17.26-37.36 minutes; phase 2: mean 26.04 minutes, range 15.07-36.02 minutes).

Table 1. Sample questions included in the interviews.

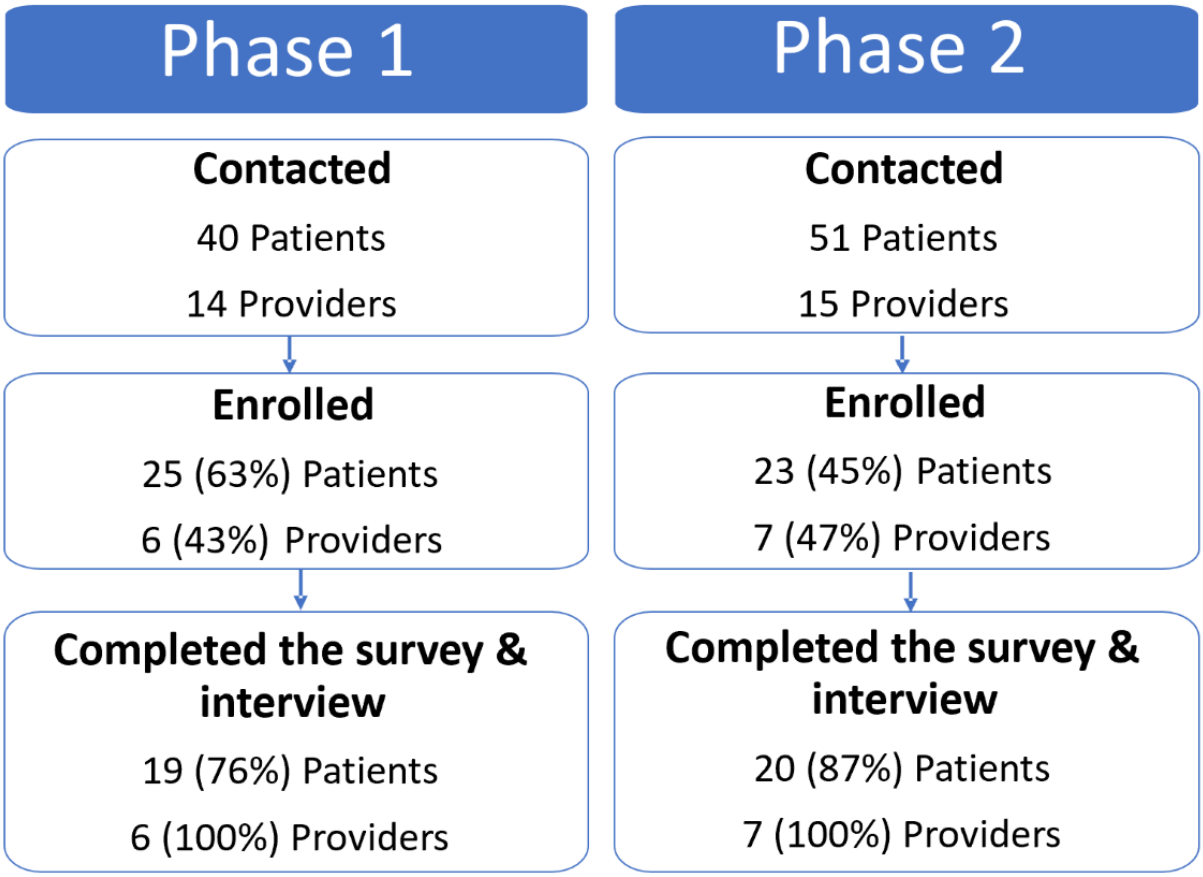
Key elements	Example of questions
Attractiveness	• What was the first thing that came to your mind when using the Nest-CRC tool? • How do you feel after going through this tool? • What attracted you or did not attract you about Nest-CRC?
Comprehension	• Overall, did you find the tool easy to understand?/Overall, did you find the tool easy to understand for patients that you typically see in the clinic?[a] • While completing Nest-CRC, can you describe any words, phrases, or sections that were difficult to understand? • What information do you think might be missing from the genetic education?
Self-efficacy	• Do you think this tool provides enough information to make an informed decision about getting or not genetic testing? • After completing the Nest-CRC tool, can you give me some examples of what happens after genetic testing?/After completing the Nest-CRC tool, would the patients have enough information for getting genetic testing?[a]
Cultural acceptability	• What are your thoughts about Nest-CRC being appealing to people from different backgrounds? • Were there any sections of the genetic education that made you feel uncomfortable?/Were there any sections of the genetic education that made you feel uncomfortable, or do you think patients might feel uncomfortable?[a]
Usability	• Overall, did you have any challenges using the tool? • Would you recommend this tool to other patients with colorectal cancer?/Would you recommend this tool to patients with early-onset colorectal cancer?[a] • If your health care provider had referred you to this tool, would you have completed it?/Would you think your patients will complete this tool?[a] • What do you think is the best way to share this tool with other patients with colorectal cancer diagnosed before the age of 50 years? • How should this tool be used in the clinic?[a]

[a]Provider-specific questions.

Data Analysis

Descriptive statistics (mean, median, and proportions) were calculated using IBM SPSS software (version 28). All qualitative data were transcribed into English and reviewed by team members. The research team met to develop the initial codebook, using deductive codes derived from the key elements of the interview guides. The themes and codebook, along with operational definitions for each code, were subsequently refined during the intercoder reliability process. Three research team members (CG, MLM, and HF) coded the transcripts using a direct content analysis approach. Intercoder reliability was assessed until Cohen κ reached 0.80, indicating substantial agreement [38]. Qualitative analysts performed line-by-line coding of all interview data using NVivo 12 software (Lumivero).

Results



Demographics and Clinical Characteristics

Phase 1

We contacted a total of 40 patients with early-onset CRC and 14 providers, of whom 19 patients and 6 providers completed the survey and interview (Figure 3). The most common reasons patients did not participate were a lack of interest or unsuitable timing due to their recent diagnosis and treatment. Providers generally declined participation passively.

XSL•FO
RenderX

Figure 3. Recruitment study flow for phases 1 and 2.

The median age of patients was 43 (range 27-51) years (Tables 2 and 3), with 10 out of 19 (53%) being female, 2 (11%) identifying as Black, 6 (32%) of Hispanic ethnicity, and 4 (21%) preferring Spanish (Table 1). About half (n=10) had at least some college education, and most were employed (n=11). One-third of the patients had stage 4 cancer (n=7), and half were undergoing active treatment (n=9). Most patients reported adequate health literacy (median 4, range 1-4) and technology literacy (median 4, range 1.6-4). Before completing Nest-CRC, 18 of the 19 (95%) patients indicated that GT was very important for cancer prevention and early detection, though only 10 (53%) and 15 (79%) reported awareness of GC and GT, respectively.

The median age of providers was 39 (range 31-46) years (Table 4). Half of the providers were female, all identified as White, and 1 was Hispanic and preferred Spanish. Two-thirds were medical or surgical oncologists, and 2 were genetic counselors. All providers had at least 2 years of experience with patients with CRC (median 11 years, range 2-13) and discussed genetic risk with patients at least 50% of the time.

Phase 2

We contacted a total of 51 patients with early-onset CRC and 15 providers, of whom 20 patients and 7 providers completed the survey and interview (Figure 3). The most common reasons for nonparticipation were the same as in phase 1. The median age of phase 2 patients was 47 (range 36-59) years, with about half being female, 4 out of 20 (20%) identifying as Black, 7 (35%) as Hispanic, and 4 (20%) as Spanish-preferring (Tables 2 and 3). Most patients had at least some college education (n=18), were employed (n=13), and had health insurance (n=18). Patients also reported adequate health literacy (median 3.7, range 1-4) and technology literacy (median 3.7, range 2-4). Similar to phase 1, before completing Nest-CRC, 15 (75%) and 18 (90%) patients indicated that GT was very important for cancer prevention and early detection, respectively. However, only 9 (45%) and 17 (85%) reported awareness of GC and GT, respectively.

Nest-CRC Findings and Recommendations

Nest-CRC Quantitative Data

In phase 1, 9 patients reported no history of GT, and after completing the education, 7 (78%) were interested in GT, while 2 (22%) were unsure; none of the participants reported having no interest in GT. In phase 2, 4 patients reported no history of GT, and all of them indicated interest in GT after completing Nest-CRC. Across both phases, most participants reported that each of the Nest-CRC modules was useful and easy to use (phase 1: 23/25, 92%, to 25/25, 100%; phase 2: 24/27, 89%, to 27/27, 100%; Table 5). The average completion time for patients in phase 2 was 11 (range 5-26) minutes.

Table 5. Comprehension and usefulness of each Nest-CRC module.

Modules	Phase 1, n (%)		Phase 2, n (%)	
	Patients (n=19)	Providers (n=6)	Patients (n=20)	Providers (n=7)
Hereditary colorectal cancer, n (%)				
Easy to understand	19 (100)	5 (83)	18 (90)	7 (100)

Family members implications, n (%)				
Easy to understand	19 (100)	6 (100)	19 (95)	7 (100)
Helpful	19 (100)	6 (100)	19 (95)	7 (100)

Qualitative Interviews

Attraction/Visual Appeal

Participants in both phases reported finding Nest-CRC visually appealing and well-suited to its goals. The layout was described by phase 1 participants as “straightforward,” “concise,” and “clean” (Table 6). Phase 1 participants appreciated how each slide presented information in “bite-sized” amounts, making it “easy to digest and read” and helping to prevent feelings of being overwhelmed, which echoed the quantitative findings. Recommendations for improvement included enhancing the “dark mode” to increase readability and incorporating more visual elements (eg, photos, animations, and diagrams) to maintain attention and simplify complex concepts.

XSL•FO
RenderX

Table 6. Interview excerpts by study phase.

Theme	Phase 1	Changes implemented for phase 2	Phase 2
Attraction/Visual Appeal	• "I really think it's concise. I think you'll lose people if you make them read through too much information even when it's important, so I thought it was – it was a good capture of the important information." [Participant #1219, patient] • "Maybe having something graphic might make it a little bit better. Because it's a lot of text. So, I don't know if maybe having either, like, a little video or animation, at least just for the introduction, that explains what genes are – and mutations or variants – are. That might be helpful." [Participant #1301, provider]	• Included more images and graphics • Simplified complex concepts • Used colors and font size to highlight important information • Improved readability for dark mode	• "Yes, I had an 8-year-old child at the time I was making that decision and wanted to know what would impact him the most [...] I thought it was pretty comprehensive [...] I found that very useful, especially having a child that I feel like, anything I needed – I wanted to know everything I could know." [Participant #2206, patient] • "I thought the technology was good, simple, you click, next, go to the next one, and when you finish number 1 it takes you to number 2. My question is, is that going to be the format you are going to use? Is it going to be that shape and color? It's a little bit boring." [Participant #2304, Spanish-speaking patient]
Comprehension	• "Yes, because I guess it said that you could be discriminated against. Obviously, that's a huge red flag in my opinion. So, that would be the only thing. It didn't really say much about it. So, that would be the only thing to deter me from getting it because, obviously, I'd have cancer. So, it's hard to get insurance period. So, if that makes it even harder to get insurance or my children hard to get insurance, then I wouldn't wanna get it. Or I would need it explained to me a little bit more so that I would know it's not really that big of a deal or it is a big deal." [Participant #1202, patient]	• Included introduction with summary information about the importance and benefits of GT[a], what to expect from the education, and the next steps for GT • Added more information about sporadic, familial, and hereditary cancer, GT versus somatic/tumor testing, incidental findings from GT, and insurance discrimination • Simplified information and provided examples about GT, patients who are at greater risk/in need of testing, and treatment recommendations based on results • Included additional optional information about genes, most common types of hereditary colorectal cancer syndromes, GC[b], and insurance discrimination • Added word definitions • Explained that cancer-causing gene variants are also known as gene mutations and referred to them as mutations throughout. • Added at the end a summary of the information covered	• "I thought that the explanations were really easy to understand for people like myself not in the medical field [...] So, it was really easy to understand. And I think kinda gave us a lot of information but not make it overwhelming." [Participant #2203, patient] • "I wanna suggest if there's any data about how minorities are hit pretty hard with colon cancer. If you could possibly put something like that in there because I know sometimes myself – I'm an African American – sometimes minorities feel a little bit afraid about doing the GT [...]" [Participant #2215, patient]
Cultural Acceptability	• "We know that this population [cancer patients under 50], they have different needs about treatment and other things and this is something that would be very helpful for this population." [Participant #1106, provider] • "I think the text was short enough that it was easy to read through, but I guess maybe having audio in case people, I don't know, can't read well." [Participant #1102, provider]	• Added voice-over feature	• "I think the language is quite basic, and concise, but very appropriate. I don't think some words are difficult to understand for a person from Peru or Venezuelan or Argentinean. The vocabulary is easy to understand. I didn't see any questionable vocabulary." [Participant #2304, Spanish-Speaking patient] • "[A language option] would be easier for [my mother and grandmother]. [...] Maybe having that little option might be better for them and more comfortable for them to participate." [Participant #2218, patient]

XSL•FO
RenderX

Theme	Phase 1	Changes implemented for phase 2	Phase 2
Self-Efficacy	• "It is easy to use, easy to navigate, bite-sized bits of information, which is completely different from all the other information you're getting in this process, quick, structured well, and it does take you towards the information you need to make a decision." [Participant #1213, patient] • "I think another reason I have felt more comfortable about it is because my provider had mentioned it to me and kinda talked about it, so I kind of understood it. So, it was just basically like an extra confirmation." [Participant #1215, patient] • "Well, I guess that's one comment then. That wasn't clear to me. [...] I don't remember seeing like if you don't have questions and want to proceed with testing, we can do it today versus seeing a counselor. And like, and then you see a counselor if you have any positives, or you could just see a counselor before testing because that wasn't clear to me. [...]" [Participant #1102, provider]	• Added information about GT cost, data security, GT/GC process and wait time, and behavioral and environmental cancer risk factors • Added and simplified information about genetic test results and care implications • Reordered the content so personal and family benefits will be presented before the risks • Insurance discrimination information was simplified	• "I mean, honestly overall it's a thing of – it's a positive thing overall. It's just – it's simple to be done and there's not – there won't be repercussions for finding out information [...] 'Cause that's what something that people worry about is – so, if I find out this is a hereditary thing are my kids gonna be denied whatever, insurance or whatever down the road because I did this now [...] So, you know – I think between that and how simple the test – knowing that there won't be those repercussions and knowing how simple the testing is I think that was a good message for me." [Participant #2208, patient] • "And that's the tricky part. If somebody gets diagnosed with colon cancer, the first they are thinking is am I going to live? Am I going to not live? And what's the treatment? They're not truly thinking about genetics. So, maybe once they met with the surgeon and oncologist and have had a treatment plan. At that time maybe a good way to bring in that. We have universal protocol anyways for colon cancer. Every colon cancer should be tested. So, it has to be brought up at some point. [...]" [Participant #2101, provider]
Usability/Utility	• "I think the app is pretty simple to navigate... I think overall, this does a pretty good job of making sure that somebody at 50 that doesn't have a whole lot of experience with technology and somebody at 20 who basically that's all he does is technology are able to use it. Again, I think it's pretty good across the board, but you're still gonna have some outliers." [Participant #1210, patient] • "Yes, because it was difficult for me because I needed my daughter's help and when my daughter wasn't there, I couldn't enter because I would copy the information and I would go to a link, and it wouldn't let me enter. Yes, it was difficult to me... Oh, that [being sent a text with a direct link] would be easier for those of us who don't know that much about technology. It would be easier where there is just a link, and you click on it and it takes you to the information." [Participant #1306, Spanish-speaking patient]	• The education was sent via SMS text message, and a direct link was provided via email or SMS text message • An audio option was implemented • Added an option to obtain additional information	• "I did like that it allows for audio and visual learning. That was kinda one of my favorite parts because a lot of times, essentially, some patients can hear what you have to say, but the ability to be able to kinda pause and listen or go back and listen again, I think that was a very smart use of the learning modality. I thought that the information was very clear and concise, and it wasn't very cumbersome. It wasn't just a lot of information on each slide." [Participant #2105, provider] • "A circle that came out there? I could see it moving but I didn't know what it was to read it for me. I thought they were listening to me. I kept reading and doing the up and down but I didn't use it to listen." [Participant #2301, Spanish-speaking patient] • "But I guess maybe what might be helpful is – I don't know how to say this. Sorta like an outline or something. You know what I mean? So that you can skip forward or skip back [...]." [Participant #2203, patient]

[a]GT: genetic testing.

[b]GC: genetic counseling.

XSL•FO
RenderX

The main factors most patients and providers emphasized in phase 2 were a desire to protect family members and trust in science and medical providers. Patients stated that a recommendation from a provider to review the education would influence their interest in it. The information provided in the education, along with its ease of use, was highlighted in phase 2 as the primary factor that attracted participants.

For the most part, participants did not have strong opinions about the visuals of the tool. Most described it as "clean" and "easy to navigate" and reported that the text was clear and easy to read. One participant found the aesthetic dull and "boring" and felt it needed more color. Another participant mentioned that the lack of personal interaction decreased their interest, preferring to speak with a person instead.

Comprehension

Participants in both phases found the information easy to comprehend and described the intervention as "straightforward," "simple," "succinct," "understandable for a layperson," and "super easy to understand."

Nearly all phase 1 patients stated that they understood GT could be used to determine genetic predisposition for their CRC and that learning whether they carry a particular gene could be helpful for family members. The most commonly cited point of confusion in phase 1 was the possibility of discrimination based on their GT results. This was surprising to many participants, with some requesting links or resources for further information. Other recommendations from phase 1 participants included adding information on the most common types of hereditary CRC syndromes (eg, Lynch syndrome, familial adenomatous polyposis), clarifying which patients are most at risk or in need of testing, distinguishing between GT and somatic/tumor testing, addressing incidental findings from GT (eg, beyond CRC, such as BRCA1), defining specific gene associations, discussing treatment options based on variants, reducing redundancies in "informed consent," and communicating clearly to lay audiences (eg, clarifying language and providing examples). When suggested by the interviewer, patients agreed that a dictionary tool to define unfamiliar terms would be useful.

Phase 2 participants felt the intervention provided just the right amount of information: educational, yet not overwhelming for a new patient. Most phase 2 providers found the intervention easy to understand, free of jargon, and containing an appropriate level of detail.

Although participants were overall very satisfied, they suggested some additional educational topics. One of the most commonly requested topics by both patients and providers was information on what other cancer and health condition risks can be detected via GT. The general consensus was that most patients would want GT to detect different cancers if it were covered by insurance or affordable. Some participants raised privacy concerns regarding who can access their results and what can be done with their DNA and results in the future. Many providers suggested that it could be beneficial to outline privacy policies within the intervention. Participants were also interested in the impact and next steps for family members based on their GT results. One participant requested more data on cancer prevalence by race/ethnicity.

Some participants wanted more information (eg, the likelihood of having Lynch syndrome, more details about specific genes, and variants of uncertain significance), while others felt the level of information provided was sufficient and that additional details should be discussed with a genetic counselor. In both phases 1 and 2, there was disagreement regarding the preferred term "variant" versus "mutation" and when to use each.

Cultural Acceptability

All participants in phase 1 and phase 2 indicated that they felt the information was acceptable to a wide audience of varied backgrounds. None reported concerns that the content of Nest-CRC was offensive or inappropriate for any groups. Instead, participants described the material as "neutral," "broad," and believed "it can help anyone."

Most of the concerns regarding the acceptability of Nest-CRC in phase 1 were related to accessibility. English-preferring participants inquired whether the education was available in Spanish and emphasized the need for patient-friendly language. Participants found the online delivery to be appropriate, given that the target audience is under 50 years of age, but recommended reevaluation if Nest-CRC is expanded to older patients. Participants also suggested adding an audio voice-over option or videos within Nest-CRC to improve accessibility for blind people/those with visual impairment, those not fully literate in English, or those who prefer listening over reading.

One phase 2 participant appreciated that the materials were inclusive of adopted patients who may be unaware of their family history. Phase 2 participants were also appreciative of the audio voice-over option.

Self-Efficacy

Both phase 1 and phase 2 participants described Nest-CRC as "very informative" and "comprehensive," and most felt that the intervention provided enough information to help them decide if they wanted GT without being overwhelming. Most patients had already undergone GT or were interested in it, evaluating Nest-CRC as a helpful way to be "proactive," with some wishing it had been available when they were first diagnosed.

Trust in their care team's recommendations was a major facilitator for using Nest-CRC. Participants responded positively when asked if they would complete the intervention if their provider recommended it, including patients who were undecided about GT. A few participants did not fully understand the benefits of GT (eg, therapeutic decision-making, risk management recommendations, and cascade testing), given that they already had cancer, with one commenting that it would be "pointless" now. Other potential barriers to GT included cost, information sharing/data security, and fear and anxiety around test results. Some participants also described fear of insurance discrimination as a potential barrier and felt this risk should be better clarified.

Self-efficacy for phase 2 participants was bolstered by their greater satisfaction with the information provided about insurance, costs, and the risks of discrimination, as well as the

XSL•FO
RenderX

available legal protections. Participants identified information on screenings and sample collection modalities (saliva vs blood) as important topics to support GT decision-making. Many providers and patients noted an assumption that GT was more invasive or complicated than it is and felt that providing information about the minimally invasive process could increase interest. The option for saliva testing was highlighted as important to make GT more appealing to patients afraid of blood and needles and more manageable for those undergoing multiple treatments or procedures for cancer care.

For phase 2, the remaining barriers to GT decision-making included unresolved concerns about discrimination and the ability to afford GT. Despite being informed that most insurance plans cover GT, participants remained concerned that their results could be positive and that cascade testing could be recommended for uninsured family members. One patient, who had previously experienced mishandling and misuse of medical results, expressed distrust in the efficacy of policies and institutions despite education about protections. Some newly diagnosed younger patients stated that being diagnosed with cancer was overwhelming and found it difficult to process information and make decisions, even with the necessary resources. With this in mind, some participants recommended that providers bring up or offer Nest-CRC again during the second or third visit to allow patients time to check insurance coverage for GC and GT.

Usability/Utility

Participants in both phase 1 and phase 2 described using the Nest-CRC tool as “user-friendly,” “very easy to use,” and “seamless.” They found the tool logically structured and easy to navigate, and appreciated that it is accessible on both desktop and mobile devices.

Phase 1 participants encountered minor technical issues, such as difficulty getting the link to work and not being able to return to where they left off. Participants felt usability could be improved by providing a direct link (rather than requiring copying and pasting into a browser), adding an audio option, allowing easier navigation of content out of sequence, and offering access to Nest-CRC via tablet in the clinic waiting room.

Phase 2 participants who noticed the audio option rated it positively, even if they preferred to read. However, this feature was not apparent to all users. For users with their phone set to “silent,” the audio option was also silenced, even if the phone volume was turned up. This led to confusion among many participants who were unable to hear the audio. One patient even thought the tool was recording audio because they could not hear it and noticed the sound wave animation within the audio button.

Summary and Next Steps

Most participants found each of the modules easy to understand and helpful. In general, patients described the content as straightforward, easy to comprehend, beneficial to anyone, informative, and useful for making decisions about GT. Following phase 1, usability was improved by providing participants with a direct link to Nest-CRC, sending links via SMS text message, and adding an audio option. The educational modules were also reordered to highlight the benefits first and end with the risks. Several additions were made to the educational content, including optional pathways and links for more detail on specific topics (eg, Lynch syndrome), definitions of key terms (eg, genes), graphs, images, and clarifying information about GT cost, insurance discrimination, and the GT process.

For the next phase, the audio voice-over will be improved, and additional optional pathways (eg, genes commonly tested in MGPT) will be incorporated. The revision will include more information about variants of uncertain significance, as well as content explaining the difference between GT and somatic testing, and addressing GT privacy concerns. Patients will also have the option to select their preferred language. Navigation within Nest-CRC will be simplified to allow easier return to core educational content from optional paths and modules.

Discussion

Principal Findings

Nest-CRC was developed as a user-friendly, scalable digital health tool designed to improve access to GT by facilitating pretest education at a lower cost. Findings indicated strong attraction, comprehension, cultural acceptability, self-efficacy, and usability of Nest-CRC in both phases. Endorsement of Nest-CRC was high, with participants recommending it be offered routinely and repeatedly to patients at different stages of the cancer journey, as some patients may prioritize GT immediately, while others may postpone it until survivorship care. Nest-CRC was also described as an acceptable alternative for empowering patients with information about GT and supporting their decision-making. Therefore, it was identified as a viable strategy for streamlining patients with early-onset CRC toward GT.

Comparison With Prior Work

NCCN guidelines recommend MGPT for all patients with early-onset CRC [10], but referrals to genetic services for these patients are inconsistent [11,12]. A prior study from 2 Texas health systems, evaluating data from 2009 to 2017, revealed that 58% of patients with early-onset CRC were referred for GC, and only 37% completed GT [11]. A more recent study, examining retrospective data from 2010 to 2019 at Cleveland Clinic, found that 62% of patients with early-onset CRC were referred to GC, 49% completed GC, and 48% completed GT [12]. In our study, less than half of the patients reported a history of GC, while two-thirds reported a history of GT. The proportion of patients reporting GT in our study was higher than previously reported rates for patients with early-onset CRC. However, interviews revealed that some patients were confusing their experiences with somatic testing and germline testing, which may have contributed to the elevated reporting of GT. Among those patients with early-onset CRC who denied GT at baseline, most expressed interest in GT after completing Nest-CRC. Additionally, the few patients who were unsure about GT showed interest in GC. This suggests that Nest-CRC can be used to streamline the triage of patients with early-onset CRC

XSL•FO
RenderX

for GT, while complex patients needing more support can be prioritized to maximize the efficiency of limited GC resources.

Prior studies examining barriers to genetic services among patients with early-onset CRC have identified cost, a shortage of qualified genetic professionals, and racial/ethnic referral disparities [11,19]. In our study, patients expressed concerns about the cost of GT, insurance coverage and discrimination, and the potential misuse of their DNA. While the cost of GT remains a concern, it has decreased substantially, making it more affordable for many individuals without health insurance. In the United States, patients who meet insurance criteria for GT typically pay between US $0 and US $100 out of pocket, while those without insurance may pay around US $300. Additionally, some laboratories offer financial assistance. Furthermore, the United States has federal and state laws that protect patients from insurance discrimination. For example, the Genetic Information Nondiscrimination Act (GINA) prevents nonmilitary employers and health insurance companies from using GT results against patients [39]. However, GINA does not apply to life, disability, or long-term insurance companies. Some states, like Florida, have enacted laws that protect patients from life, disability, or long-term insurance companies using GT results against individuals residing in the state [40,41]. Therefore, patients' commonly reported concerns about GT could be alleviated through education about existing resources and federal and state protections.

To address barriers to accessing GT information and services, the Clinical Genome Resource's Consent and Disclosure Recommendations working group recommended a brief pretest genetic education approach for more straightforward cases, reserving traditional GC for patients with greater clinical and genetic complexities or those without well-established testing recommendations [20]. Automated educational tools, such as videos and written materials, have proven effective in delivering genetic education, particularly for patients with high-risk cancer [21,22,25,42]. For example, a study involving patients with pancreatic cancer found that when oncology providers used an educational video to obtain GT informed consent, the rate of GT increased 6.5 times compared with previous years, when traditional GC referrals were used [21]. However, these advances still rely on clinic staff and providers to obtain informed consent and order GT.

Nest-CRC provides an alternative for GT education that can further alleviate the burden on patients, clinic staff, and institutions. Like other patient-driven digital tools [42,43], Nest-CRC can be completed conveniently from home, enhancing accessibility without incurring out-of-pocket costs for the patient. For institutions, the annual cost of using Nest-CRC can be tailored to the specific functionalities required, averaging a few thousand dollars per month—less than the cost of an entry-level GC assistant. Unlike a single assistant, Nest-CRC can scale the volume and capabilities of genetic services without being impacted by patient load, staff turnover, or the need for ongoing training. By automating workflows for education, consent, test ordering, and results return, tools such as Nest-CRC can significantly enhance clinic efficiency. While this study focuses on the perceived benefits of pretest genetic education, implementing a platform such as Nest has the potential to generate substantial cost savings and operational efficiencies across other routine tasks, such as family history collection, patient tracking, risk model calculations, and care plan management. As the demand for genetic services continues to grow, digital health tools such as Nest-CRC could be leveraged to identify high-risk patients and promote GT across various health care settings, such as primary care, oncology clinics, and even the general public. In this way, Nest-CRC offers an acceptable alternative strategy to expand equitable access to GT among high-risk patients.

Strengths and Limitations

The primary goal of this study was to evaluate the reactions and recommendations of English- and Spanish-speaking patients and providers to Nest-CRC, with preliminary data on patients' interest in GT as a secondary aim. This study is innovative in providing valuable insights from a diverse group of patients and providers, highlighting key considerations for developing pretest genetic education for patients with early-onset CRC. However, due to the small sample size, quantitative data were limited to descriptive purposes and were used primarily to describe the study sample and support the qualitative findings by incorporating patients' immediate feedback on the educational content. While we intentionally recruited Black and Spanish-speaking patients to ensure diverse representation, the findings should not be generalized to all patients with early-onset CRC. It is also important to note that during interviews, some participants expressed uncertainty about their GT history; therefore, the self-reported GT data should be interpreted with caution. This uncertainty underscores the potential benefit of a comprehensive digital health platform where GT history and related lifelong care recommendations can be easily accessed and shared with patients' clinicians and family members as needed.

Conclusions and Future Directions

Adults with early-onset CRC are at higher risk for having a hereditary cancer syndrome. GT to identify the causative variant can facilitate screening and risk reduction measures for both patients and their relatives. Despite GT being recommended for all patients with early-onset CRC, racial disparities persist in referrals for GT, access to GC, and uptake of both GC and GT. These issues are further compounded by a shortage of qualified genetic professionals and patients' concerns about the cost of genetic services. Our findings suggest that Nest-CRC is a promising strategy to scale genetic services by augmenting pretest genetic education and promoting GT uptake among patients with early-onset CRC from diverse racial and ethnic backgrounds. Future studies should implement digital GT platforms in clinical settings to evaluate their feasibility and acceptability among high-risk patients and their relatives from diverse racial and ethnic backgrounds, as well as assess their impact on lifelong care recommendations and survival outcomes.

Acknowledgments

This project was funded by the Society of Behavioral Medicine Bridging the Gap Research Award and the National Cancer Institute (grant T32 CA090314; principal investigators: Thomas Brandon and SV). We also want to acknowledge the support of Stefania Alastre Arcusa, MSPH, LCGC, for reviewing and providing feedback on the Nest-CRC education in Spanish for phases 1 and 2.

Data Availability

Deidentified data generated and analyzed during this study will be made available (as allowable according to institutional review board standards) by emailing the corresponding author.

Authors' Contributions

JRR wrote the first draft of the manuscript. JRR and M Sholeh were involved in data collection, data curation, and quantitative data analysis. MLM, CG, and HF conducted qualitative data analysis and wrote the first draft of the qualitative results. JRR and SV conceptualized the study and were responsible for funding acquisition, project administration, and supervision of the study team. M Snir, ES, and TS implemented Nest-CRC. JRR, M Snir, ES, TS, M Sholeh, LB, BDG, JP, and SV contributed to the development and revisions of Nest-CRC. All authors reviewed and edited the manuscript.

Conflicts of Interest

M Snir is the CEO of Nest Genomics, and ES and TS are employees of Nest Genomics. The remaining authors declare no potential conflicts of interest.

Abstract

Background: Human papillomavirus (HPV) is the primary cause of cervical cancer, a largely preventable disease. Although extensive information about HPV is available and could help women prevent infection, a widespread lack of knowledge transmission hinders many women in Saudi Arabia from taking necessary preventive steps. Previous studies have reported low levels of HPV awareness among women in Saudi Arabia, highlighting the importance of understanding the barriers to effective information dissemination. Identifying the factors that influence the transmission of HPV-related knowledge is essential for designing targeted and impactful public health interventions.

Objective: This study aimed to explore the factors that either block or facilitate the transmission of HPV-related facts among women in Saudi Arabia, using the HPV facts transmission model as a theoretical framework.

Methods: A qualitative case study design was used, involving semistructured interviews with 20 women in Saudi Arabia aged 23 to 42 years. Participants were recruited using convenience and snowball sampling. The data were analyzed using pattern matching to assess how participant responses aligned with 11 predefined propositions from the HPV facts transmission model, which integrates individual and social influences on health information–seeking behavior.

Results: Of the 11 propositions, 8 (73%) were supported by the data. Five were individual-level factors (personal need to learn, stigma, language barriers, technology use, and individual qualities), while 3 were social-level factors (social promotion, social support, and cultural norms). These factors were classified as barriers, resources, or both, depending on their influence on women's intention to seek HPV-related knowledge. For instance, personal motivation, curiosity, and digital access facilitated knowledge acquisition, while stigma, limited Arabic-language resources, and conservative social norms served as major deterrents. Three propositions (social structure, suppression structure, and interaction or collaboration) did not align with participant experiences and were excluded from the final model.

Conclusions: Understanding these barriers and resources is essential for developing targeted interventions to improve HPV knowledge dissemination. Strategies should include culturally appropriate awareness campaigns, accessible Arabic-language educational materials, and the integration of digital tools to encourage confidential learning. Addressing stigma through community engagement and structured education programs can further enhance HPV fact transmission, ultimately supporting informed decision-making and preventive health behaviors among women in Saudi Arabia.

Introduction

Cervical cancer is the fourth most common cancer among women worldwide [1] and the eighth most common among women Saudi in Arabia aged 14 to 44 years [2]. In Saudi Arabia, the age-standardized rate of cervical cancer is relatively low at 2.2 per 100,000, yet the disease carries a 35% fatality rate [2]. Notably, >99% of cervical cancer cases are attributed to human papillomavirus (HPV) infections [3], making HPV knowledge a critical component of prevention. Despite the availability of information about HPV, such as that provided by authoritative sources such as the Centers for Disease Control and Prevention website [4], many women remain unaware of the health consequences of HPV [5]. For instance, a study among female university students in Saudi Arabia revealed that 95% demonstrated poor knowledge of cervical cancer and its link to HPV [6], while another study in Jazan City reported a mean knowledge score of only 1.99 out of 10 [7].

This persistent knowledge gap is not due to an absence of information but rather reflects barriers to effective information seeking and transmission. Factors such as social stigma surrounding sexually transmitted diseases (STDs), including HPV, constrain women's willingness and ability to search for and internalize sexual health knowledge [8]. Poor awareness has been associated with delayed health care–seeking behaviors for STDs [9], further compounding public health challenges. For instance, one national survey of 755 women in Saudi Arabia found that only about 21% of them showed adequate knowledge about cervical cancer and HPV [10].

To address this gap, we previously developed the HPV facts transmission model (Figure 1 [5]), a conceptual framework grounded in the health action process approach [11], which categorizes the barriers and resources influencing women's access to, understanding of, and engagement with HPV-related information. The model emphasizes individual and social factors across preintentional (motivation), intentional (planning), and action phases. It proposes that motivation to seek knowledge is shaped by perceived risk, outcome expectancy, and self-efficacy. Once motivated, women enter an action planning phase, determining how and when to acquire information. This process culminates in the actual seeking and internalizing of HPV facts—what the model refers to as action and action control [5].

Figure 1. HPV Facts Transmission Model, including barriers and resources propositions. HPV: human papillomavirus.

In this study, we build upon our previous work by empirically testing the motivation phase of the model through a qualitative investigation. Specifically, we explore how the model's barrier and resource propositions influence women's intentions to seek and acquire HPV-related knowledge. By doing so, we aim to validate the relevance of the HPV facts transmission model in real-world settings and to inform culturally sensitive strategies to enhance HPV awareness and education.

Methods

Overview

In our previous work, we developed and proposed the HPV facts transmission model [5] to explore the mechanisms influencing the dissemination of HPV-related information. This study builds upon that foundation by qualitatively examining

XSL•FO
RenderX

the factors identified in the model, with a specific focus on the intention to seek and acquire knowledge about HPV. The HPV facts transmission model suggests that various factors can either facilitate or hinder the transmission of HPV-related information in Saudi Arabia, as outlined earlier in this paper. To investigate these factors, we use a qualitative case study design [12], which includes the following elements: questions and propositions, units of analysis, logic to link data to propositions, and interpretation of findings. This paper adheres to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist, ensuring comprehensive and transparent reporting of qualitative methodologies (Multimedia Appendix 1 [13]). The researchers, all female, have extensive expertise in qualitative studies, which informed the design, execution, and analysis of this research.

Ethical Considerations

This study was reviewed and approved by the institutional review board (IRB) of Claremont Graduate University (3101). Ethics approval was obtained to ensure compliance with human participant research guidelines and to protect their rights and well-being throughout the research process. Before participation, all participants provided written informed consent after being informed about the study's objectives, procedures, and their rights, including the right to withdraw at any time without consequences. Given the sensitivity of the topic, verbal consent was also reaffirmed before each interview. To protect participant confidentiality, no personally identifiable information was collected. Participants were assigned unique codes (eg, P1 and P2) to anonymize their responses, and all data were securely stored and accessible only to the research team. In addition, interviews were not audio-recorded to allow participants to speak freely, with detailed notes taken instead. Participants were not financially compensated for their involvement to minimize potential coercion and ensure unbiased participation.

Question and Propositions

This study aimed to answer the following question: What factors influence the intention to transmit HPV-related facts? As part of our previously developed HPV facts transmission model (illustrated in Figure 1), we identified 11 propositions related to factors that may either block or promote the transmission of HPV facts to women in Saudi Arabia. These propositions were originally conceptualized in our prior work based on theoretical frameworks and background literature. In this qualitative study, we empirically examined these propositions to determine their relevance and assess their role in influencing HPV knowledge–seeking behaviors.

The propositions for the *individual level* are as follows:

- *Individual qualities* affect the intention to transmit HPV facts.
- *Personal need to learn* affects the intention to transmit HPV facts.
- *Language barriers* affect the intention to transmit HPV facts.
- *Technology use* affects the intention to transmit HPV facts.
- *Stigma* affects the intention to transmit HPV facts.

The propositions for the *social level* are as follows:

- *Social structure* affects the intention to transmit HPV facts.
- *Suppression structure* affects the intention to transmit HPV facts.
- *Culture and tradition* affect the intention to transmit HPV facts.
- *Social promotion* affects the intention to transmit HPV facts.
- *Social support* affects the intention to transmit HPV facts.
- *Interaction and collaboration* affect the intention to transmit HPV facts.

Data Collection

Semistructured interviews were used as a primary data collection technique. Interviews were conducted between April and June 2017. Questions about the 11 propositions were developed (Figure 1). When possible, questions were based on existing instruments. When not possible, background literature was searched to create questions. For example, the proposition *personal need to learn*—defined as the willingness to accept new knowledge [14]—was connected to the research objective, and the following interview question was generated: "If you know the health risks for any STDs such as HPV, are you intending to search for and learn about HPV? Why?" This example illustrates how each proposition informed the specific research questions used during data collection (Multimedia Appendix 2). Table 1 summarizes the methods used in developing the interview questions.

Interactions and collaboration	Existing validated instrument: the Interactions and Collaboration section from the Online Student Connectedness Survey	[29]

All interviews were conducted in Arabic by the corresponding author, who was a doctoral student at the time of the study. At the time of the study, no prior relationship had been established between the researcher and the participants to minimize bias and ensure objectivity. Participants were informed about the general purpose of the study but were not given detailed insights into the researcher's personal goals or assumptions to prevent response bias. To further minimize bias, the interviewer remained aware of potential assumptions throughout the research process, particularly regarding knowledge transmission and health information–seeking behaviors. The researcher team's interest in the topic stemmed from prior work on HPV information dissemination and a commitment to understanding the barriers and facilitators influencing women's access to HPV-related knowledge.

All interviews were conducted via phone calls, each lasting between 20 and 60 minutes. Interviews were not audio-recorded due to the sensitivity of the topic, allowing participants to speak freely. Instead, detailed field notes were taken during and immediately after each interview, capturing participant responses, key themes, and nonverbal cues. To ensure linguistic and cultural accuracy, the interview questions were developed as follows: (1) the first author wrote the questions in English and then translated them into Arabic; (2) an independent Arabic expert checked them for grammar and clarity; (3) a third bilingual person reviewed the questions in both languages; and (4) finally, the first author reviewed all questions once more.

Sample

All participants were women in Saudi Arabia aged ≥20 years, recruited from the community. The age criterion was selected based on prior research indicating that HPV infrequently affects women aged <20 years [30]. Participants were recruited using convenience and snowball sampling, a widely used approach for sensitive research topics [31], after obtaining IRB approval. Initial participants were approached through personal and professional networks via WhatsApp, and they subsequently referred other eligible participants. Study invitations containing a brief description of the research purpose, eligibility criteria, and contact information were circulated through existing WhatsApp groups and direct messages within educational, health, and professional circles. Interested women were asked to privately respond directly via WhatsApp or email to express their interest in participating. Those who responded were subsequently provided with detailed study information and an explanation of the informed consent process. Recruitment continued until data saturation was reached, ensuring diverse perspectives from women.

Before data collection, the first author pilot-tested the interview questions with 3 women in Saudi Arabia (aged 30-40 years) recruited via snowball sampling. Each participant was interviewed separately, and following each interview, questions were modified and calibrated to improve clarity. No interviews were repeated.

Data Analysis: Pattern Matching

This study used pattern matching as its primary analytic technique. According to Bitektine [32], this method requires "a theoretical pattern of expected outcomes," as well as "an observed pattern of effects," and then making "an attempt to match the two." The researchers used pattern matching to make sense of the participants' perceptions and opinions regarding the lack of HPV information transmission [16].

The researchers examined the data to determine whether the propositions block or promote the transfer of HPV facts, focusing only on the intention mechanism. During the analysis, the definitions and explanations of each proposition were used to assess how well they matched participant responses. For

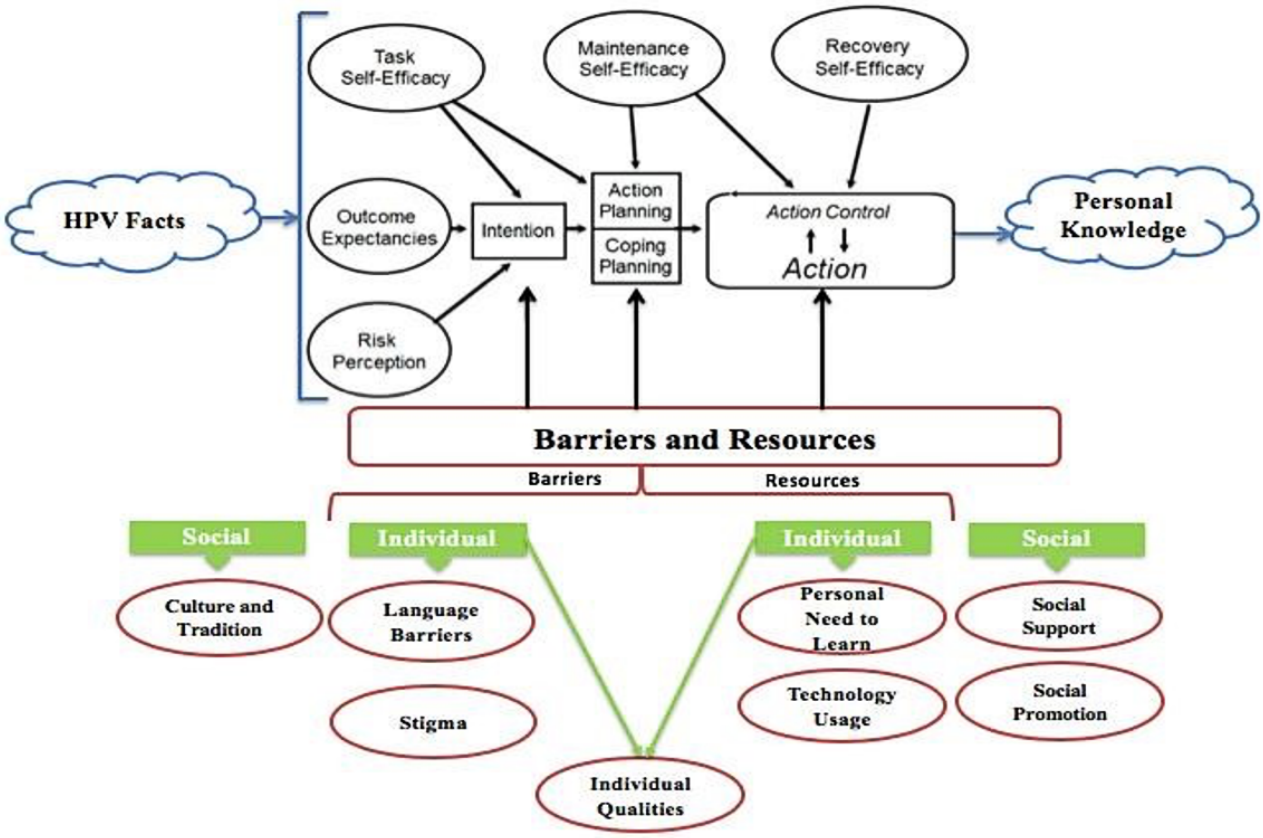
XSL•FO
RenderX

example, the proposition concerning culture and tradition suggests that single (unmarried) women in Saudi Arabia are often more hesitant to discuss sexual health topics compared to married women. This aligns with findings by Al-Saggaf [33], who reported that searching for and discussing sexual health topics is culturally sensitive for unmarried women in Saudi Arabia. Throughout the analysis, we used this framework to determine whether the suggested proposition matched the participants' responses. Analysis was conducted manually by the authors.

Positionality of the Research Team

The research team consisted of female researchers with expertise in qualitative research and public health, providing a culturally informed perspective on HPV knowledge–seeking behaviors. The corresponding author, who conducted the interviews, had no prior relationship with the participants, ensuring minimal bias in data collection. To further enhance trustworthiness, reflexivity was maintained by critically examining how the researchers' perspectives, cultural backgrounds, and assumptions might shape data interpretation. This helped ensure that the findings were grounded in participant experiences rather than researcher bias.

Results



HPV Facts Transmission Model Examination

A total of 20 women aged between 23 and 42 years were interviewed; of these, 13 (65%) were married and 7 (35%) were single women. The women were from different regions of Saudi Arabia: 15% (3/20) each from the East, South, Center, and North, and 40% (8/20) from the West. The interviews each lasted between 20 and 60 minutes.

Of the 11 propositions, 8 (73%) were found to match the data well, while 3 (27%) did not. The *individual-level factors* include the *personal stigma*, *the need to learn*, *language barriers*, *technology use*, and *individual qualities*. The *social-level factors* include *social promotion, culture and tradition, and social support*. These 2 levels of factors can be arranged, as illustrated in Figure 2, into *barriers* and *resources*. Factors can be classified as either *barriers* or *resources*, based on how they impact women's intention to search for and learn about HPV.

The subsequent subsections provide a detailed elaboration of the analysis for the matched and mismatched propositions.

Figure 2. HPV Facts Transmission Model, including barriers and resources after analysis. HPV: human papillomavirus.

Matched Propositions: Each Factor's Effects on Intention

The analyses show that, with respect to the effects of women's searching and learning behaviors on their *personal knowledge*, 4 factors act as *barriers*, 5 factors act as *resources*, and 1 factor acts as both.

Culture and Tradition

Some participants asserted that *culture and tradition* can block the transfer of the facts about HPV. When the researchers asked the participants about their ability to talk about and discuss STDs such as HPV with others, a single woman answered as follows:

> *This topic is not easy to talk and discuss.* [P6]

XSL•FO
RenderX

In contrast, a married woman responded as follows:

> *I can talk, discuss with anyone, I do not care, but for single and divorced women, it is not appropriate.* [P8]

According to single women, talking about and discussing STDs such as HPV is not easy, as illustrated by P6, who claimed "I am shy." All the married women interviewed for this study claimed not to care about what others may say about them. This reflects the findings by Al-Saggaf [33] regarding *culture and tradition* in Saudi Arabia. The predicted pattern matches the empirical pattern as follows:

- Empirical pattern—*culture and tradition* can deter the intention to transfer HPV facts.
- Predicted pattern—"*culture and tradition* affects the intention to transfer HPV facts."

Language Barriers

Language barriers are a factor that can block the transfer of facts about HPV. As all the participants speak Arabic as their first—and in some cases only—language, they search for and learn about health information in Arabic. One example of this was a quote from a participant who stated the following:

> *I search and learn using the Arabic Language even though there are not a lot of materials in Arabic.* [P10]

The lack of educational materials about HPV available in Arabic can serve to block information seeking.

Some participants reported that if there were no Arabic materials available, they would stop their attempts to search for and learn about this type of information. A participant stated the following:

> *The only obstacle that I may face is the language barriers.* [P4]

Therefore, language is a *barrier* that can affect women's acquisition of knowledge when searching for and learning about HPV. The predicted pattern matches the empirical pattern as follows:

- Empirical pattern—*language barriers* can deter the intention to transfer HPV facts.
- Predicted pattern—"*language barriers* affects the intention to transfer HPV facts."

Stigma

Stigma results in bad feelings that affect personal and social relationships [25], which also can affect searching and learning behaviors regarding HPV. Most participants interviewed in this study search and learn secretly without telling anyone. A participant said the following:

> *If I could not get the information that I need regarding HPV, I may...ask someone whom I trust, but not a close one, such as my auntie because I am shy.* [P6]

Another participant responded the following:

> *...everything in my phone is hidden, where nobody can find it, not even my husband...In my society, if the husband knows that his wife is searching and learning about any sexual topics, he may divorce her.* [P5]

Stigma leads some women in Saudi Arabia to avoid talking about HPV with their close family members. Participants' responses touched on their tendency to stop searching for and learning about HPV as well as avoid seeking answers from close family members due to fear of being marked with the stigma of HPV.

- Empirical pattern—stigma can deter the intention to transfer HPV facts.
- Predicted pattern—"stigma affects the intention to transfer HPV facts."

Personal Need to Learn

> *Personal need to learn is a factor that can promote the transfer of HPV facts. Gaining the knowledge that a link exists between HPV and cervical cancer seems to lead women to ask questions about HPV infection. A participant stated the following:*
>
> *Knowing the health risk of HPV really increased my intent to search and learn more about it; the nearer the distance between an individual and the risk, the more cautious an individual will be.* [P4]

A family history of cancer appears to intensify the influence of personal need on women's health information–seeking and learning behaviors. A participant stated the following:

> *Since HPV causes cervical cancer, I may search and learn about this infection more because I have a family history of cancer.* [P1]

According to Duggan and Banwell [14], *personal need to learn* affects information dissemination or transmission. When women understand the serious health risks they face, they are more likely to seek out new knowledge to reduce those risks.

Therefore, *personal need to learn* also matches the predicted pattern:

- Empirical pattern—*personal need to learn* can promote and facilitate the intention to transfer HPV facts.
- Predicted pattern—"*personal need to learn* affects the intention to transfer HPV facts."

Technology Use

The participants use technology in their daily lives, particularly smartphones. They use their smart devices to contact others, play games, search for information, and learn. One interviewee responded as follows:

> *Using technology is the easiest way to get information faster.* [P3]

Another interviewee said the following:

> *Technology is usually available to use anytime and anywhere.* [P20]

This factor is another resource at the individual level that participants use to obtain knowledge regarding any topics, including HPV. The women who were interviewed enjoy using technology because they can access information easily, quickly,

XSL•FO
RenderX

anytime, anywhere, and anonymously. The empirical pattern matches the predicted pattern:

- Empirical pattern—*technology use* can promote and facilitate the intention to transfer HPV facts.
- Predicted pattern—"*technology use* affects the intention to transfer HPV facts."

Social Support

Social support is defined as acquiring support (eg, help, information, or encouragement) from family, friends, and other sources [34]. Participants stated that if they were unable to obtain the information they needed through technology, they would seek it from trusted sources such as sisters, friends, or physicians. Thus, women in Saudi Arabia generally receive support from society.

This factor of social support was reflected in the participants' responses. A participant reported the following:

> *I do not think that somebody will support me, but I do not care. I usually search secretly; nobody knows since I am using my laptop.* [P6]

Another participant stated the following:

> *No one will support me to search and learn about HPV, but I can ask my sisters, friends, and physicians if I need more information.* [P1]

These quotes suggest that, in the absence of support, the interviewed women may use technology to search for and learn about STDs. However, if they need additional information, they may seek assistance from others by asking specific questions.

The analysis results indicate that the *social support* factor promotes the intention to transfer HPV facts to women in Saudi Arabia who may benefit from such information, which thus matches the predicted pattern:

- Empirical pattern—*social support* can promote and facilitate the intention to transfer HPV facts.
- Predicted pattern—"*social support* affects the intention to transfer HPV facts."

Social Promotion

All participants agreed that education programs may assist in increasing women's *personal knowledge* of HPV infection. When the researchers asked about the effectiveness of education programs, a participant replied as follows:

> *Yes, I think having some education programs will help increase women's awareness about STDs such as HPV and will educate them about it...this is considered as an easy way to get information.* [P1]

Another participant said the following:

> *Yes, this is a very good way to increase women's sexual knowledge, but in an appropriate environment.* [P20]

These quotes suggest that education programs can provide women with easy access to accurate information, which is a supportive way to educate them on HPV.

As a result, *social promotion* through, for example, education programs can be considered a resource that promotes the transfer of HPV facts. This matched the predicted pattern:

- Empirical pattern—*social promotion* can promote and facilitate the intention to transfer HPV facts.
- Predicted pattern—"*social promotion* affects the intention to transfer HPV facts."

Individual Qualities

Individualqualities can either facilitate or hinder the transfer of information about HPV, affecting women's *personal knowledge*. *Individual qualities* consist of several characteristics, including curiosity, creativity, and willingness to change [4]. Moreover, the researchers observed that curiosity was the most influential factor affecting women's knowledge. The more curious women are, the more willing they are to search for and learn about STDs. For example, when the researchers asked a participant about when she could search for and learn about STDs, she responded as follows:

> *I search and learn about some of the STDs such as HIV, but only if I am curious about it, and I will not search and learn about any topic that I am not interested in.* [P9]

Most participants agreed that if women are neither curious nor interested in HPV, they will neither search for nor learn about it. A participant said the following:

> *I do like to find new information and increase my knowledge if I think the topic is interesting.* [P11]

These 2 variables—women's curiosity and their interest in the topic—are important elements that differ among women. These elements affect the searching and learning behaviors regarding STDs that enhance *personal knowledge*, which matches the predicted pattern:

- Empirical pattern—*individual qualities* can promote and facilitate the intention to transfer HPV facts.
- Predicted pattern—"*individual qualities* affects the intention to transfer HPV facts."

Mismatched Propositions

After analyzing the interview transcripts, the researchers removed 3 mismatched propositions, as described in the subsequent sections.

Social Structure

Social structure is defined as the social rules people follow in a society [26]. Participants agreed that searching for, learning about, talking about, and discussing HPV to increase women's *personal knowledge* do not disobey society's rules. A participant reported the following:

> *I do not think that searching and learning about STDs such as HPV is against the society's rule...because knowing this information is similar to any other information that I may know, and it is not against the Islamic rules.* [P1]

Another participant reported the following:

XSL•FO
RenderX

> *I do not think that searching and learning about STDs such as HPV is against society's rules; people now change. They want to educate themselves, especially if it is a disease.* [P7]

Saudi society seems to be changing, and the societal rules women in Saudi Arabia follow do not seem to have a strong effect on the transmission of HPV facts. The proposition concerning *social structure* does not manifest in promoting or blocking women in Saudi Arabia from searching for and learning about HPV. *Social structure* does not appear to be a factor in the HPV facts transmission model, as the interviewed Saudi women seem to engage in searching and learning activities with little concern for societal rules.

Suppression Structure

Suppression structure refers to how powerful individuals or groups may stop other individuals or groups from continuing their actions or activities [28]. The analysis result indicates that this proposition neither promotes nor blocks the transfer of the facts about HPV to women in Saudi Arabia who wish to enhance their knowledge.

When the researchers asked participants how they would react if someone in a position of power, such as a father or husband, forced them to stop their searching for and learning about HPV, a responded as follows:

> *No one can stop me because this is my personal choice...and this is my life, and I can do what I want.* [P2]

However, a single woman reported the following:

> *My mom may stop me, but not because searching and learning about HPV is against the society's rules or anything else. She will stop me because I have an obsessive-compulsive disorder (OCD) and she is worried about me.* [P6]

These quotes suggest that *suppression structure* is likely not a factor that might affect the HPV facts transmission model.

Interactions and Collaboration

According to Barab et al [31], the proposition *interactions and collaboration* opens the opportunity to share experience and leverage a web-based interactive education program. Nonetheless, all participants classified HPV as a stigmatized disease, citing this stigma as the reason they prefer to search for and learn about this infection privately.

When the researchers asked them about their preference to search and learn about STDs, such as HPV, 1 participant stated the following:

> *I prefer to search and learn about HPV alone by myself because the way people think is different (not as me), and it is comfier to me (to search and learn by myself).* [P1]

This quote suggests that the interviewed women prefer to search for information about STDs, such as HPV, alone, as they feel more comfortable doing so.

Consequently, *interactions and collaboration* is likely not a factor that affects the HPV facts transmission model. This proposition will not create an opportunity to share experiences or facilitate online interactive discussions because HPV is a stigmatized disease.

Discussion

Principal Findings

This study examined the factors influencing HPV fact transmission among women in Saudi Arabia, using the HPV facts transmission model as a guiding framework. The initial model proposed 11 factors, but the qualitative analysis identified only 8 that shaped participants' intention to seek and acquire HPV-related knowledge. These included 5 individual-level factors (personal need to learn, language barriers, stigma, technology use, and individual qualities) and 3 social-level factors (social promotion, social support, and cultural norms).

The findings reveal that personal need to learn and technology use were the strongest facilitators, enabling women to seek HPV-related information actively. In contrast, language barriers, stigma, and cultural norms emerged as key barriers, limiting knowledge transmission. Interestingly, social support played a dual role, acting as both a facilitator and a barrier, depending on the nature and source of support. These findings contribute to understanding the complex interplay between individual motivations, cultural norms, and technological influences in shaping women's HPV knowledge–seeking behaviors.

Comparison to Prior Work

The personal need to learn was identified as a key motivating factor, consistent with prior research on health information–seeking behaviors. Our findings align with those of Barbour et al [12], who argued that individuals actively seek health information when they recognize potential risks to their well-being. Similarly, the gratification theory by Wilson [35] states that "people are active seekers of information to gratify their needs."

Technology use emerged as another important facilitator of HPV fact transmission. Participants emphasized the potential of digital platforms for overcoming barriers to information seeking, particularly through anonymized access to educational resources. This finding aligns with research by Hansen and Johnson [20], who introduced the concept of "veiled viral marketing"—a strategy that enables the dissemination of health information while preserving user anonymity [20]. Similarly, recent studies have highlighted the effectiveness of gamified mobile apps in enhancing users' engagement with health information and empowering them to make informed health decisions [36,37].

Barriers to HPV knowledge transmission in this study also align with global research on stigma and language limitations. Participants reported a lack of Arabic-language educational materials, which restricted their ability to access reliable HPV-related information. Similar findings have been reported in Latinx communities in the United States, where language barriers negatively impact health care access and patient outcomes [38]. Our study suggests that localized, culturally

XSL•FO
RenderX

relevant digital health interventions, such as Arabic-language eHealth platforms, could help mitigate these barriers and expand HPV awareness among women in Saudi Arabia.

Stigma was another major barrier, preventing women from openly discussing HPV or actively seeking information. This aligns with prior studies on STD-related stigma, which demonstrate that fear of judgment and cultural taboos affect women's health care–seeking and decision-making behavior [39]. Similarly, our study found that women in Saudi Arabia tend to search for HPV information privately, avoiding discussions with family members or peers. Efforts to reduce health-related stigma in Saudi Arabia have been successful in other domains. For instance, the National Mental Health Program has effectively used community education campaigns to improve mental health literacy and normalize discussions about psychological well-being [40,41]. Similar awareness strategies could be applied to HPV education, focusing on reducing stigma, increasing public awareness, and normalizing sexual health discussions. However, as with mental health advocacy, HPV-related interventions will need to navigate cultural sensitivities carefully and ensure that educational campaigns respect social norms while promoting open dialogue.

Individual qualities are the final factor at the individual level that may promote or block women's searching and learning behaviors to enhance their personal health knowledge. Among the various characteristic of this factor, curiosity emerged as particularly substantial. Participants expressed a greater inclination to search for and learn about HPV when they found the topic personally relevant or intriguing. This aligns with the Gratification Theory by Wilson [35], which suggests that individuals actively seek information to fulfill their personal knowledge needs. Wilson [35] further describes the concept of selective exposure, where individuals tend to seek out information that matches their interests and preexisting beliefs. This was evident in this study, where women who perceived HPV as a serious health risk were more likely to seek information, whereas those with less personal curiosity demonstrated lower engagement in knowledge acquisition.

At the social level, 3 factors—social promotion, social support, and cultural traditions—emerged as key influencers in HPV fact transmission. Social promotion, particularly in the form of educational programs, was identified as an effective method for enhancing HPV awareness among participants. Kirby et al [26] demonstrated that STD education programs positively influenced participants' sexual health knowledge and behaviors, reinforcing the importance of structured, targeted awareness campaigns. However, some participants in this study emphasized that the effectiveness of social promotion depends on access to appropriate educational environments, indicating the need for well-designed interventions that are both culturally appropriate and widely accessible.

Social support was also found to be a major factor influencing HPV fact transmission, with trusted family members and friends playing a major role in facilitating or hindering knowledge sharing. The importance of social support in health education has been well documented. For example, Pratt's study on hygiene education in 1905 found that socially supported individuals exhibited better health outcomes compared to those without support [42]. This aligns with the findings of this study that women who had access to supportive social networks were more likely to engage in HPV-related discussions and seek further knowledge. Conversely, participants who lacked support or feared judgment were less likely to openly discuss HPV or seek information.

In contrast, cultural traditions were identified as a barrier to HPV knowledge transmission, particularly for single women. Participants reported that searching for, discussing, talking about, and becoming educated on sexual topics are generally perceived as challenging tasks for single women, while these tasks typically do not bother married women. This finding aligns with the research conducted by Fageeh [43], which identified a lack of sexual health awareness as a primary factor contributing to STD transmission between couples in Saudi Arabia. The cultural discouragement of discussions surrounding sexual health continues to hinder information dissemination, suggesting the need for culturally sensitive awareness initiatives that respect social norms while promoting accurate health education.

In addition, 3 social-level propositions—social structure, suppression structure, and interactions or collaboration—were not supported by participant responses and were therefore eliminated from the final model. Participants largely agreed that learning about HPV does not violate societal norms, indicating that women in Saudi Arabia are increasingly educated and empowered to seek health information. For example, the campaign by Fageeh [43] on STD awareness was successfully launched in Saudi Arabia, suggesting that societal changes are making health education more accessible. If *social structure* affected the ability to disseminate HPV facts, then launching a campaign would have been impossible.

Finally, the proposition interactions and collaboration was eliminated due to mismatching. Although interactive health education programs have been effective in other contexts [44], participants in this study preferred private, self-directed learning rather than collaborative discussions about HPV. This highlights the importance of confidential educational approaches, such as digital health tools, to accommodate women's preferences for privacy while seeking health information.

Theoretical and Practical Contributions

This study makes significant contributions to both theory and practice by deepening our understanding of HPV knowledge transmission and offering insights for health interventions. Theoretically, this study provides an exemplar for the theory of the problem by Markus [41], which states that a research article should explain how and why a problem occurs, supported by qualitative data or other empirical evidence. By identifying the barriers and facilitators influencing HPV fact transmission, this study establishes a theory of the problem, offering a structured explanation of why HPV knowledge remains inadequately disseminated among women in Saudi Arabia. The refined HPV facts transmission model meets the standards for problem-driven theoretical contributions by Markus [41], as it is concrete, contextually specific, and focused on a real-world phenomenon. From a practical perspective, this research

XSL•FO
RenderX

provides actionable insights for public health practitioners, educators, and policy makers. The study identifies 8 key factors that act as barriers, resources, or both in HPV fact transmission. These findings can inform the design of targeted interventions aimed at enhancing HPV awareness and education in Saudi Arabia.

Specifically, this study highlights the importance of the following:

- Leveraging digital health solutions such as mobile apps, social media campaigns, and online educational platforms to address language barriers and stigma while ensuring confidential access to HPV-related information
- Enhancing social support networks and encouraging trusted sources of information, such as health care providers, community leaders, and family networks, to facilitate accurate HPV knowledge sharing
- Implementing culturally sensitive educational programs and ensuring that awareness campaigns respect social norms while promoting factual, accessible health information

By validating and refining the HPV facts transmission model, this study provides a conceptual framework that can be used to inform public health initiatives, guide future research, and enhance HPV-related interventions. These findings emphasize the need for culturally appropriate, evidence-based strategies to improve HPV knowledge transmission, ultimately supporting cervical cancer prevention efforts in Saudi Arabia and similar contexts.

Limitations and Future Directions

The study has some limitations that should be considered when interpreting the findings. First, it is important to note that the data were collected 8 years ago. Since then, the modes and speed of health information transmission, particularly digital platforms and social media, have evolved substantially. While the insights remain valuable for understanding cultural and structural influences on HPV-related information seeking, the findings should be interpreted within the temporal context of the study. Future research should examine how technological advances and shifts in public health communication strategies have reshaped information access and behaviors in more recent years. Second, participant personal experiences with HPV, such as having tested positive for the virus or having received the HPV vaccine, were not collected. These factors could have influenced participants' decision to take part in the study as well as their motivation to seek information about HPV, potentially shaping the perspectives they shared during the interviews. Third, participants were not given the opportunity to review their interview transcripts or the results of the thematic analysis. Although reflexive and iterative coding processes were used to enhance analytical rigor, member checking might have strengthened the credibility and accuracy of the findings by allowing participants to clarify or expand on their perspectives. Fourth, as in all qualitative research, the potential for researcher bias exists and may influence the data collection, analysis, and interpretation. Although we used strategies such as peer debriefing and maintained detailed reflexive notes to enhance trustworthiness, complete objectivity in qualitative interpretation cannot be assumed. Fifth, the use of snowball and convenience sampling means that our findings are specific to the study participants and may not be transferable to the broader population. However, the aim was not to draw wider inferences but rather to gain a profound understanding of the factors influencing HPV facts transmission within the specific sample, and efforts were made to include women from various regions to capture diverse perspectives. Sixth, the voluntary nature of participation may have introduced selection bias. While we cannot eliminate selection bias entirely, we minimized its potential impact by inviting all interested women, regardless of their knowledge or opinions, to participate. Seventh, the focus was primarily on women's marital status in relation to cultural influences, without fully exploring other potential cultural variations. Regional differences could significantly impact individuals' experiences and behaviors related to sexual health education. To mitigate this, we made an effort to include women from different regions of Saudi Arabia in our sample. However, we acknowledge that a more in-depth exploration of other cultural factors, including regional nuances, would be necessary in future research to provide a more comprehensive understanding of how cultural context shapes HPV-related knowledge-seeking behavior across different parts of the country.

Despite these limitations, this study provides a valuable foundation for future research. Future studies could explore the development and testing of digital interventions, such as IT- or information system–based tools, to improve the accessibility and effectiveness of HPV information dissemination. In addition, incorporating other qualitative data-gathering techniques, such as focus groups, could provide richer insights into participants' experiences and further inform intervention strategies. Future research could also explore the role of organizational social support in facilitating knowledge sharing about stigmatized health conditions, such as HPV. Assessing how organizations can provide support for individuals in seeking information and reducing stigma could offer valuable insights into the development of effective interventions. By understanding the factors that promote or block the transmission of HPV-related information among women in Saudi Arabia, strategies can be devised to enhance knowledge dissemination and support informed health-related decisions, ultimately contributing to improved women's health.

Conclusions

HPV is the primary cause of cervical cancer worldwide; however, despite the availability of factual information, many women remain uninformed or misinformed, limiting their ability to take preventative measures against infection. This study examined the factors that facilitate or hinder the transmission of HPV-related knowledge among women in Saudi Arabia, offering insights into the barriers and enablers that shape health information–seeking behaviors. The findings identified 8 key factors that impact HPV fact transmission, categorized into individual-level and social-level influences. The study's findings underscore the importance of addressing these barriers through culturally appropriate interventions. Public health strategies should focus on leveraging digital health resources, fostering supportive social networks, and implementing targeted educational programs to improve HPV awareness. By addressing

XSL•FO
RenderX

sociocultural constraints and structural limitations, these interventions can help enhance knowledge dissemination and promote informed decision-making among women in Saudi Arabia.

Abstract

Background: Online communities, platforms that facilitate social connections, have gained attention in the medical field, particularly for their potential to support patients. However, there is currently no online community specifically designed for patients with cancer receiving outpatient care. This study introduces a customized online community aimed at providing companionship and sharing to enhance the quality of life (QOL) among these patients.

Objective: The purpose of this study was to assess the feasibility and initial effectiveness of a newly developed online community app in improving the QOL of patients with cancer receiving outpatient care.

Methods: This pilot intervention-only study involved patients with cancer participating in a 4-week online community intervention through a mobile app. Eligible patients were aged 18 years or older, diagnosed with cancer, with an Eastern Cooperative Oncology Group Performance Status score of ≤2. The feasibility of the intervention was evaluated by community task participation rate, community task completion rate, and community daily login rate. Patients completed a QOL questionnaire (European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30, QLQ-C30) at baseline (T0), week 2 (T1), and week 4 (T2). After the intervention, participants were free to answer 3 questions about their user experience.

Results: Baseline assessments were conducted on 30 patients, with 25 patients assessed at T1 (83.3%) and 22 at T2 (73.3%). The 4-week average community daily login rate was 60.37% (18.11/30 on average), with community task participation and community task completion rates reaching 42.25% (12.68/30 on average) and 22.38% (6.7/30 on average), respectively. Notably, after the study ended, participants continued logging into the app and completing tasks. Patients who actively engaged in community activities demonstrated significant improvements in global health status (mean 11.04, SD 10.3 vs mean –6.56, SD 11.58; *P*=.004), emotional function (mean 17.7, SD 22.93 vs mean –2.89, SD 13.9; *P*=.04), and constipation (mean 11, SD 16.5 vs mean 14.67, SD 17.39; *P*=.005) at T2, compared to those less active. The intervention enhanced emotional functioning and overall health and alleviated insomnia symptoms among active participants.

Conclusions: The online community intervention, emphasizing companionship and sharing, was well accepted by patients with cancer and demonstrated initial effectiveness in enhancing the QOL. The study findings suggest that such interventions can provide a supportive environment for patients to cope with psychological, social, and physical challenges. Future validation of its effectiveness will require well-designed randomized controlled trials, and continued optimization tailored to specific user groups will be crucial to meet the evolving needs of the community. The core value of the online community lies in companionship and sharing, which can serve as a foundation for future research and development in this area.

Introduction

Cancer and its treatments cause not only physical pain but also psychological, social, and spiritual suffering to patients. However, the lack of accessible psychosocial support resources, compounded by their uneven distribution, results in many patients with cancer being unable to receive the necessary rehabilitation guidance and psychological care [1,2]. Furthermore, disparities in cancer incidence and outcomes, influenced by socioeconomic status, race, and geographic location, exacerbate these challenges [3]. These inequalities underscore the urgent need to address gaps in health care and psychosocial support to improve patient outcomes.

The socioecological model [4,5] emphasizes the interaction between individual, interpersonal, community, and societal factors, with each level influencing causal relationships and preventive strategies. Despite this, existing interventions often focus predominantly on individual or interpersonal levels, with insufficient attention to community or societal dimensions. Social connections are considered a biological necessity directly linked to survival [4,5]. Patients with cancer often experience a lack of such connections, leading to social isolation and loneliness [6,7]. Recent studies have demonstrated that loneliness among cancer survivors is correlated with an increased risk of mortality [8]. Survivors who report feelings of loneliness face a significantly higher risk of death compared to those reporting low or no loneliness, with a clear dose–response relationship [8,9].

In this context, isolation refers to the sense of being disconnected from others and lacking companionship in real-world communities [10,11]. Community-level care can mitigate these effects by offering a platform for individuals to connect, build relationships, and share experiences and feelings [12]. It is important to note, however, that some individuals may still experience loneliness even within social circles [13]. The role of the community is thus to provide a safe environment where individuals can express inner worries and emotions [14].

As a result, extending psycho-oncology services to the community has become an essential component of care of patients with cancer. A recent intervention study led by community workers demonstrated that programs targeting low-income and minority patients with cancer significantly improved their quality of life (QOL) [15]. Nonetheless, several studies have identified barriers to the effective implementation of community care [16]. Unmet needs such as psychological adjustment, nutritional support, exercise management, and interpersonal communication are increasing among patients with cancer. These needs are frequently unmet at the community level, contributing to psychological distress and a diminished QOL for many patients.

Shifting from traditional real-world communities to online communities may offer an effective solution to overcoming these barriers [17-20]. Research indicates that one of the most promising aspects of eHealth is the growth of electronic communities, which create or enhance online communities based on shared interests to facilitate experience sharing and emotional support [17]. Online communities, facilitated through electronic media, have emerged as a viable intervention for mental health and social support [21]. For example, “PatientsLikeMe” is an online community that offers communication and support for individuals with various diseases [22]. On this platform, patients can connect with others who share similar experiences, fostering mutual understanding and emotional support [23]. These findings suggest that online care and community functions can substantially improve the QOL for patients with cancer.

In line with the socioecological model, our team has developed an online community for patients with cancer outside of the hospital setting. This community aims to provide a range of programs focused on companionship and mutual sharing, fostering social connections among patients and ultimately enhancing their QOL. The objective of this study is to assess the feasibility of implementing this intervention and to conduct an initial evaluation of its effectiveness in improving the QOL for patients with cancer.

Methods

Participants and Procedure

This pilot study adhered to the standards outlined in the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) guidelines [24]. Eligibility criteria were as follows: (1) age 18 years or older, (2) a confirmed cancer diagnosis via pathology, (3) an Eastern Cooperative Oncology Group Performance Status score of ≤2, and (4) fluency in Chinese with the ability to understand instructions provided during the online community process. Exclusion criteria were (1) inability to use a smartphone to participate in the online community, (2) a history of severe mental disorders, and (3) poor physical condition.

Procedure and Data Collection

The study was conducted at Peking University Cancer Hospital & Institute, targeting patients with cancer receiving outpatient care. Recruitment occurred through direct outreach in outpatient clinics, referrals from collaborating oncologists, and online advertising via social media and cancer-related forums to identify potential participants. Upon obtaining informed consent, eligible patients had their characteristics and baseline assessment data collected. Participants then downloaded and engaged with an online community app under the guidance of the research team. Follow-up assessments were scheduled according to the study protocol.

The online community app automatically administered questionnaires at designated evaluation points, with assessments occurring at week 2 (T1) and week 4 (T2). After the 4-week intervention, the app remained accessible, allowing participants to continue using it voluntarily at their own discretion.

Intervention

We developed a customized online community app named “Qianliu Health” (meaning “overcoming diseases together with thousands of companions, actively recovering” in Chinese) (Figures 1 and 2). This app facilitated social connections for patients with cancer receiving outpatient care through features

XSL•FO
RenderX

promoting companionship and sharing. Community activities included daily check-ins and patient-selected activities. Daily check-ins involved fixed-time notifications sent to participants, reminding them to engage in community activities, with recognition provided for completion. Patient-selected activities enabled participants to autonomously choose from a variety of community activities that matched their interests.

Figure 1. The specific intervention measures of the online community.

XSL•FO
RenderX

Figure 2. Screenshots of the app.

Sharing refers to the process through which participants exchange information and experiences, express emotions, and share important moments from their daily lives [25]. Specific tasks within the sharing component included: (1) users sharing daily meals for peer feedback and nutrition plan discussions (check-in task with daily platform reminders); (2) daily exercise check-ins, including step tracking and ranking within the community walking challenge (patient self-report and check-in task with daily platform reminders); (3) sharing personal achievements or daily highlights (non–check-in task and patient's autonomous choice); and (4) interactive sharing within the community on topics such as disease, treatment, nutrition, stress, and symptom management (non–check-in task and patient's autonomous choice).

Companionship refers to the provision of emotional support, social interaction, and a sense of belonging through the online community [26]. This component fosters a supportive environment where patients can connect with others facing similar challenges, share experiences, and offer mutual support. Specific tasks within the companionship component included (1) daily mindfulness meditation exercises, featuring 50 audio and video materials developed specifically for patients with cancer, allowing them to select preferred content for their practice, with regular supervision and support from professional therapists (check-in task with daily platform reminders); (2) setting up core buddies for direct one-on-one private chats, offering support and comfort, fostering companionship, and providing psychological support (noncheck-in task, patient's autonomous choice); and (3) seeking assistance from other patients in chat rooms on topics such as disease, treatment, exercise, nutrition, stress, and symptom management (non–check-in task and patient's autonomous choice).

To enhance participant engagement in community activities, the following strategies were implemented: (1) customized push notifications were sent 3 times daily (morning, noon, and evening) to encourage participation in designated community activities; (2) participants were awarded honors and personal growth points upon completion of each designated activity; (3) an automatic assistant was used to initiate discussions and promote active participation in chat rooms; (4) biweekly online community classrooms were hosted, where health care professionals conducted sharing sessions, fostering patient interaction within chat rooms; and (5) a team of 3 psycho-oncology-trained nurses contacted inactive participants by phone to encourage continued app usage.

Measurement

Feasibility

Feasibility in this study was evaluated through several metrics. First, user engagement was assessed using the following metrics:

Community Task Participation Rate

This metric measures the proportion of participants who engage in at least one community activity (check-in task) per day.

Participants receive daily prompts to complete specific tasks, such as sharing meals or exercise check-ins. Engagement is recorded if participants complete at least one of these tasks on a given day. The participation rate is then calculated by dividing the number of days with at least one completed task by the total number of follow-up days.

Community Task Completion Rate

This metric evaluates the proportion of participants who complete all scheduled tasks (check-in tasks) per day.

Participants are prompted daily to complete multiple tasks, such as meal sharing, exercise check-ins, and meditation. Engagement is recorded if participants complete all scheduled tasks on a given day. The completion rate is then calculated by dividing the number of days with all tasks completed by the total number of follow-up days.

Community Daily Login Rate

This metric measures the proportion of days participants log into the app compared to the total number of follow-up days.

XSL•FO
RenderX

Operationalization: The login rate is calculated by dividing the number of days participants log into the app by the total number of follow-up days. This metric serves as a general indicator of engagement with the online community.

Initial Effectiveness

Given the correlation between participation rate and the effectiveness of the online community intervention, participants were categorized based on their level of engagement into 2 groups: the active participants (4-wk daily login rate ≥70%) and inactive participants (4-wk daily login rate <70%). The initial effectiveness of the online community intervention was the change in the score on the QOL from baseline to 4 weeks between active or inactive participants, as measured by the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (QLQ-C30), with a particular focus on the global health status and EF dimensions. The Chinese version of QLqQ-C30 consists of 30 items, with items 29 and 30 scored on a 7-point scale, while the remaining items are scored on a 4-point scale [27,28]. The instrument includes 15 domains: 5 functional domains (physical, role, cognitive, emotional, and social functioning), 3 symptom domains (fatigue, pain, and nausea or vomiting), 1 global health status domain, and 6 single items, each treated as a domain. These scores were measured and analyzed using standard scoring procedures in this study.

General Demographic and Disease Data Questionnaire

Demographic data collected included age, gender, education, and marital status. Disease-related information encompassed cancer diagnosis, disease stage, current cancer treatment status, current symptom treatment, and comorbidities.

User Survey

Following the intervention, participants were invited to respond to 3 open-ended questions regarding their user experience: (1) How was your experience in the online community? (2) Did you find the online community useful for you? Would you recommend it to others? (3) What do you think is the greatest value of the online community? These questions were delivered via in-app push notifications, and participants completed their responses directly within the app. No character limits were imposed on responses. All responses were collected and exported via the backend system. As this was not a formal qualitative study, no coding analysis was performed, and participant feedback was summarized inductively.

Statistical Analysis

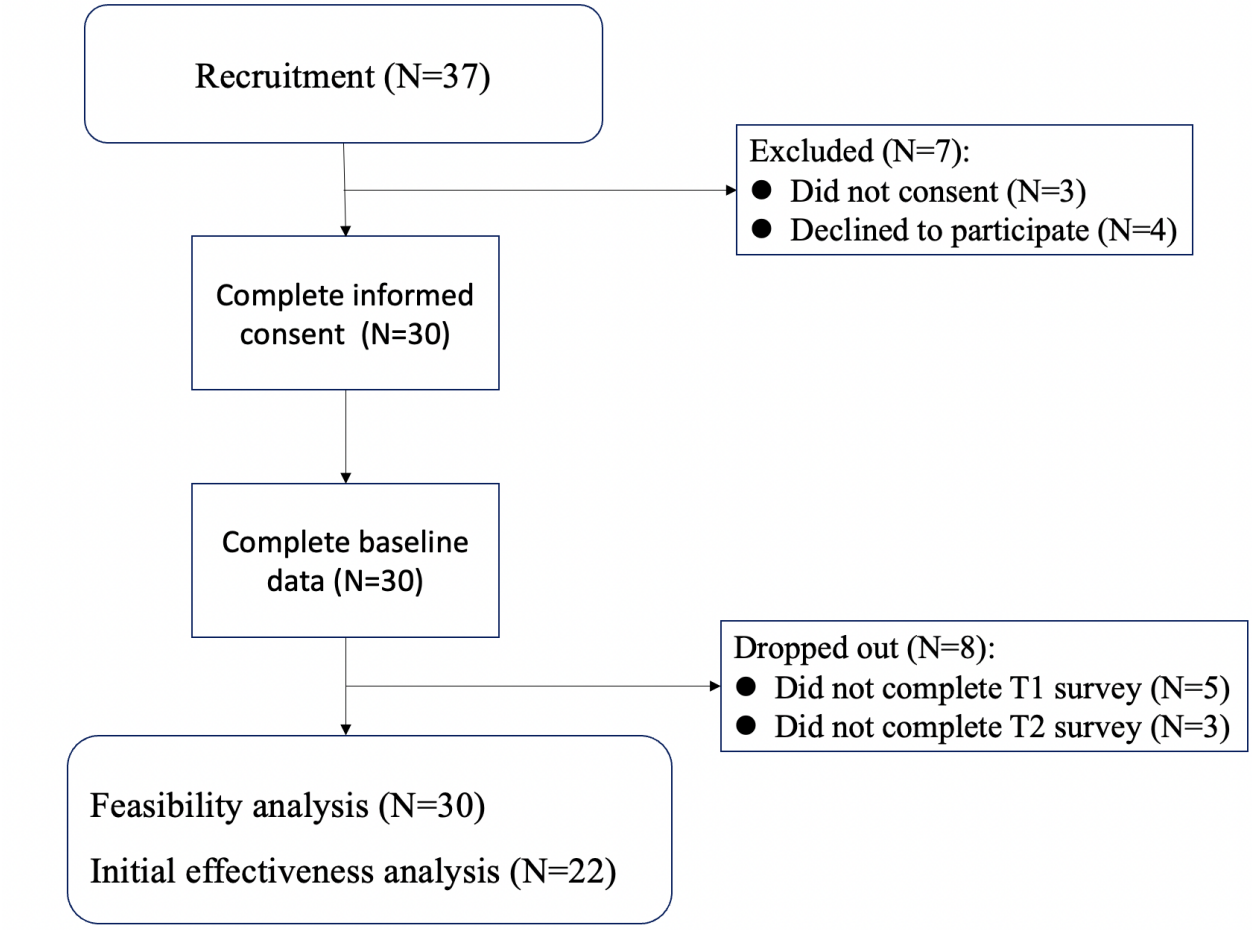
Based on previous similar studies [17,29-31], a convenience sample of 30 patients was selected to evaluate the feasibility and initial effectiveness of this study.

Baseline characteristics were summarized using mean and SD for continuous variables or number and percentage for categorical variables. Feasibility was assessed through the completion rate of community tasks. Differences between active and inactive participants in baseline characteristics and outcomes were assessed with the use of 2-sided Fisher exact tests and chi-square tests for categorical variables and independent-samples Student *t* tests for continuous variables. Assessments for QOL characteristics were conducted for active participants, and a paired *t* test was used to determine whether there was a statistically significant change between the baseline and week 4 scores.

SPSS software (version 17.0; IBM Corp) was used for data analysis. All *P* values were 2-sided, and $P<.05$ was considered statistically significant.

Ethical Considerations

The study was reviewed and approved by the Institutional Review Board and Ethics Committee of Peking University Cancer Hospital (approval number 2022YJZ94) and was conducted between September 2022 and January 2023. All participants provided written informed consent prior to enrollment, ensuring they understood the study's purpose, potential risks and benefits, and their rights as participants. To protect privacy and confidentiality, all data collected were anonymized or deidentified, with personal information securely stored and accessible only to authorized personnel. While no direct financial compensation was provided, participants received recognition and encouragement through community activities and personalized feedback, which were considered forms of nonmonetary compensation.



Results

Patient Characteristics

A total of 37 patients expressed interest in participating in the study, of which 30 patients were ultimately enrolled, yielding an overall participation rate of 81%. At the T1 assessment, 5 of 30 subjects (17%) were lost to follow-up, and at T2, 8 of 30 subjects (27%) were lost to follow-up, primarily due to worsening conditions and the need for hospitalization. Ultimately, 22 subjects were included in the analysis (Figure 3). Table 1 provides a summary of the baseline demographic and clinical characteristics of all 30 enrolled patients, while Table 2 presents the characteristics of the 22 participants included in the final analysis, categorized by their level of engagement (active or inactive).

Feasibility

The feasibility of the online community intervention was evaluated through several key metrics. The average daily login rate was 60.37% (18.11/30 on average) over the 4-week intervention period, with a range of 57.6% to 62.9%. The community task participation rate was 42.25% (12.68/30 on average), varying between 39.0% and 47.6%. The community task completion rate averaged 22.38% (6.7/30 on average), with a range of 19.6% to 25.3%. Poststudy engagement was also assessed, revealing that participants continued to interact with the app even after the intervention ended. A 15-week follow-up showed a daily login rate of 32.9% (an average of 4.28/13 participants), a task participation rate of 19.0% (an average of 2.47/13 participants), and a task completion rate of 6.6% (an average of 0.86/13 participants) (Table 3).

Table . The online community's daily login rate, task participation rate, and task completion rate.

Stage	Week	Daily login rate (%)	Task participation rate (%)	Task completion rate (%)
Intervention	W1	62.9	42.9	25.3
Intervention	W2	57.6	39	20.1

Participation in the Online Community on Working Days Versus Nonworking Days

The average daily login rate on nonworking days (Saturday, Sunday, and holidays) was 55.6%, with 37.4% of members engaging in tasks (Multimedia Appendix 1). In contrast, on working days (Monday to Friday), the average daily login rate was 60.4%, with 44.7% of members participating in tasks. Regarding the number of rehabilitation actions (including daily meal logging or choosing different types of meditation) performed by participants, the average number of actions per

XSL•FO
RenderX

individual on nonworking days was 8.8 (SD 2.9), compared to 7 (SD 3) on working days.

The Initial Effectiveness of Online Community

Compared to inactive participants, active participants in the online community showed significantly greater improvements in the following QLQ-C30 dimensions: EF (mean 17.7, SD 22.93 vs mean −2.89, SD 13.9; *P*=.04), constipation (mean 11, SD 16.50 vs mean 14.67, SD 17.39; *P*=.005), and QL (mean 11.04, SD 10.3 vs mean −6.56, SD 11.58; *P*=.004) (Table 4).

Table . Mean (SD) change in QLQ-C30[a] scores from baseline to 4 weeks between the active or inactive participant groups.

QLQ-C30 dimensions	Active participants (n=12), mean (SD)	Inactive participants (n=10), mean (SD)	*t* test (*df*)	*P* value[b]
Physical functioning	2.33 (11.16)	2.22 (18.41)	0.635 (20)	.54
Social functioning	9.30 (14.77)	1.89 (24.27)	1.181 (20)	.26
Emotional functioning	17.70 (22.93)	−2.89 (13.90)	2.304 (20)	.045
Cognitive functioning	1.89 (13.29)	0.11 (16.75)	0.249 (20)	.82
Role functioning	−3.78 (7.5)	18.44 (31.61)	1.354 (20)	.19
Dyspnea	11.00 (16.5)	7.33 (14.55)	0.500 (20)	.62
Appetite loss	11.07 (28.74)	3.67 (30.62)	–1.053 (20)	.31
Insomnia	25.85 (36.41)	−7.44 (27.77)	1.206 (20)	.26
Nausea and vomiting	5.59 (14.56)	5.33 (22.01)	−1.242 (20)	.23
Pain	1.89 (24.27)	1.78 (19.52)	−.011 (20)	.99
Fatigue	8.59 (17.26)	3.67 (14.55)	−1.629 (20)	.12
Constipation	11 (16.5)	14.67 (17.39)	3.212 (20)	.005
Diarrhea	−0.04 (16.58)	11 (16.50)	−1.415 (20)	.19
Financial difficulties	0.00 (16.5)	3.67 (11)	−0.555 (20)	.60
Global health	11.04 (10.3)	−6.56 (11.58)	3.406 (20)	.004

[a]QLQ-C30: Quality of Life Questionnaire Core 30.

[b]The *P* value was calculated with the use of 2-sided Student *t* tests for independent samples. *P*<.05 was considered statistically significant.

Intervention can enhance EF and overall health and improve insomnia symptoms among active patients. The EF (mean 63.54, SD 23.58 vs mean 87.63, SD 13.96; *P*=.03) and QL (mean 56.25, SD 13.33 vs mean 73.96, SD 11.23; *P*=.01) after intervention were significantly higher than before intervention for active participants. Insomnia (mean 49.96, SD 30.99 vs mean 20.67, SD 17.11; *P*=.04) after intervention was significantly lower than before intervention (Table 5).

[a]The *P* value was calculated with the use of a paired *t* test. $P<.05$ was considered statistically significant.

User Survey

A total of 22 participants provided responses to the participation experience questions, among whom 14 explicitly stated that the online community was effective and that they would recommend it to others. Below, we present the experiences of 2 representative participants.

Case 1

A 67-year-old male patient with lung cancer, with a history of depression, initially expressed reluctance to participate, as he did not wish to focus on his illness. However, despite his verbal refusal, his daily login rate averaged 51%, and he completed 7 meditation tasks. Although he refrained from direct interaction and preferred to remain anonymous, his continued active participation in the community was a notable observation.

Case 2

A 54-year-old patient with breast cancer, currently undergoing hormonal therapy for 45 days, demonstrated a daily login rate of 100%. She consistently completed walking check-ins, dietary, and meditation tasks. While not highly proactive in initiating communication with others, she expressed a desire for feedback and engaged in private conversations with community members. Despite experiencing some anxiety, she reported that the community provided her with a stable and supportive environment for recovery.

Discussion

Principal Findings

This study evaluated the feasibility and initial effectiveness of an online community intervention designed to enhance QOL in patients with cancer receiving outpatient care. The findings suggest that such an intervention is feasible and may offer preliminary benefits. Specifically, participants with higher levels of engagement demonstrated greater improvements in selected QOL domains, including QL, EF, and CO, over a 4-week period compared to those with lower engagement.

Comparison to Prior Work

Feasibility of the online community intervention was supported by acceptable task completion rates and consistent engagement patterns, comparable to those reported in similar eHealth and peer-support studies. Attrition, a well-documented challenge in digital health research, particularly in self-guided internet-based interventions, was relatively moderate in our study. Scholars have referred to this phenomenon as the “science of attrition” [32], and when compared to prior studies [33], our participation rate was relatively satisfactory. These findings suggest that the online community may have good clinical applicability.

As a pilot study, recruitment was intentionally broad rather than targeting a specific subgroup of patients. Interestingly, we observed that participants who engaged with the community on weekends and holidays demonstrated higher levels of activity and completed more community tasks. Moreover, a small subset of participants continued to engage with the platform beyond the study period, a behavior pattern previously described as “super user” dynamics [33]. These observations suggest that digital communities may particularly appeal to individuals who seek connection and shared experiences. However, future studies with larger samples are needed to better characterize these subgroups.

The user survey revealed diverse engagement patterns among patients. Some participants expressed initial reluctance but gradually found the community to be a safe and comfortable space for interaction. This aligns with previous research

XSL•FO
RenderX

indicating that online cancer communities often facilitate information exchange, peer response, and resource sharing [34,35]. Passive engagement, such as reading rather than posting, was also observed, a pattern consistent with prior work identifying the role of observational participation in minimizing emotional risk [35]. Variability in engagement by disease stage has also been noted in studies of breast cancer communities, with more advanced-stage patients often engaging more deeply on an emotional level [36]. These findings highlight the importance of recognizing different participation styles and tailoring community features to accommodate diverse user needs.

In addition to feasibility, this study explored the initial effectiveness of the intervention. Notably, patients who were more active in the community experienced greater improvements in QOL scores from baseline to week 4, particularly in emotional functioning, global health status, and constipation symptoms. These exploratory findings align with previous research suggesting that social support and community engagement can alleviate emotional distress and enhance overall well-being among individuals with cancer [25,37]. Similar associations have been reported in studies of peer-support groups and online health communities [29,38].

The observed improvement in CO, while modest, may reflect the interaction between psychological and physical well-being, as has been suggested in prior research [39]. However, given the small sample size and nonrandomized design, these subgroup findings should be considered exploratory.

The finding that greater engagement may be associated with more favorable outcomes is consistent with research from larger digital platforms. For example, data from PatientsLikeMe indicate that active users report greater perceived benefits compared to less active users [22]. Encouraging meaningful engagement may therefore be an important consideration in the design and implementation of future community-based digital interventions.

Limitations

This study has several limitations that must be considered when interpreting the findings. The small sample size, short intervention duration, and exploratory nature of subgroup analyses limit generalizability. The absence of randomization or stratified analysis increases the risk of bias and confounding. While the results are promising, they should not be interpreted as evidence of effectiveness. Rather, they underscore the potential value of further investigation.

Conclusions

This pilot study demonstrated that an online community intervention for patients with cancer receiving outpatient care is feasible and well received. Exploratory findings suggest potential improvements in QOL among participants who actively engaged with the platform. Future research with larger samples and more rigorous designs is needed to evaluate effectiveness and inform implementation.

Abstract

Background: A growing number of people are living with comorbid dementia and cancer (CDC), and they are particularly likely to require support from family caregivers. Carers of people with CDC play a vital supportive role but have reported unmet support needs, including a lack of CDC-specific information resources and peer support. A targeted online peer support forum may provide an accessible way to help address unmet needs of carers of people with CDC.

Objective: This study aimed to explore the types and frequency of social support provided on an online peer support forum for caregivers of people with CDC, hosted by a dementia charity in the United Kingdom.

Methods: We conducted a mixed methods study using descriptive statistics and qualitative content analysis. All posts (N=893) on the forum since its launch in November 2018 to April 2024 were exported into Microsoft Excel for analysis. Descriptive statistics were used to examine forum use and user characteristics. Deductive content analysis was conducted to explore the types and frequency of social support provided on the forum. Posts were analyzed according to an adapted version of Cutrona and Suhr's Social Support Behavior Code, consisting of 5 main categories of support: informational, emotional, esteem, network, and tangible. Coding was completed independently by 2 coders, and any coding disagreements were resolved by reaching a consensus through discussion.

Results: A total of 258 usernames posted on the forum since its inception. There were 893 posts; 583 (65.3%) were coded as providing social support. All 5 Social Support Behavior Code categories were present in the forum posts. Informational support was the most common type of social support provided on the forum, which mostly involved providing suggestions for caregiving and coping strategies and sharing personal experiences that provide CDC-specific knowledge or insight. This was followed by emotional support, which consisted mostly of expressing shared understanding and empathy for caregivers in their unique situation of CDC and providing expressions of care for the recipient's well-being. Esteem, network, and tangible support were less common, though they included providing validation and relief of blame to other caregivers, typically in decision-making regarding cancer treatment; reminding caregivers that others were available on the forum for support; and expressing willingness to answer questions about their CDC caregiving experience.

Conclusions: This study demonstrates the use and value of a CDC-specific online forum as a source of social support for carers of people with CDC, facilitating users' access to CDC-specific information and peer support. The relatively new forum shows promise as a free and accessible resource that can contribute to addressing carers' informational and peer support needs.

Introduction

Background

Prevalence of both cancer and dementia increases with age [1,2], and owing to the aging population and rise in multimorbidity, a growing number of people are now living with comorbid dementia and cancer (CDC) [3-5]. A recent analysis of UK primary care data found that 1 in 13 people aged ≥75 years with cancer also have dementia [3], though this is likely to be an underestimation due to dementia underdiagnosis [6]. In recent years, there has been a surge in research examining cancer care and outcomes for people with CDC [7], and this work has consistently highlighted the crucial role of family carers for this group [8-11]. Dementia is characterized by progressive cognitive, functional, and behavioral impacts, such as impairments in memory, comprehension, language, and judgment [12]. Therefore, people with CDC may have difficulty with recognizing and communicating cancer-related symptoms, making treatment decisions, navigating cancer care and treatment, and self-managing symptoms and side effects [8,10,13-15]. Thus, people with CDC are especially likely to require support from family caregivers, who are integral in enabling people with dementia to access and undergo cancer treatment and care [8,10].

The adverse impact of caregiver burden on physical health outcomes and psychological well-being is well-documented [16-18], and providing care for people with *multiple* chronic conditions, especially when dementia is present, is particularly burdensome [19,20]. Recent qualitative work has documented the complex challenges faced by carers of people with CDC. For instance, the combination of extensive care responsibilities required for cancer management and the negative impact of dementia on care recipients' ability to understand and self-manage such care results in heightened responsibility for carers, who report intense feelings of pressure to act as their care recipient's advocate [21]. Carers play a crucial role in the recognition and management of cancer symptoms and side effects, helping care recipients to cooperate with cancer investigations and treatment and assisting with difficult cancer-related medical and nursing care (eg, ostomy or wound care), all of which can be further complicated by behavioral and psychological symptoms of dementia [10,21,22]. Dementia also produces greater complexities in cancer treatment decision-making, and where care recipients lack capacity, family carers report ethical dilemmas in deciding whether to pursue anticancer treatment or a palliative care pathway and associated feelings of guilt and perceived stigma around their decision-making [13,21-23]. Carers of people with CDC report feelings of uncertainty, anxiety, stress, and guilt [10,21], and where care recipients have a reduced insight into their cancer diagnosis and prognosis, carers report feeling as though they are carrying the emotional burden alone, contributing to feelings of loneliness and isolation [21,22].

Carer supportive interventions and services are imperative to reduce the negative impact of caregiving on carers' own health and well-being, and several studies have highlighted the need for support services and resources for caregivers of people with CDC [9,10,23]. Our team's previous in-depth qualitative study was the first to examine the psychosocial support needs and preferences of caregivers of people with CDC [21]. The participants voiced that the practical and emotional burden of their caregiving role was exacerbated by a lack of CDC-specific information and resources to help them navigate their dementia caregiving role in the context of comorbid cancer, which left them fraught with uncertainty. Carers of people with CDC voiced a desire for peer support opportunities, in particular for CDC-specific information and emotional support from others who understand the unique challenges of navigating cancer-related decision-making, treatment, and care for people who are also living with dementia. Despite expressing a need for support from caregiving peers, none of the interviewed participants had met other carers of people with CDC, and owing to their intense care regimes, they highlighted the difficulty of attending face-to-face support groups due to lack of time and difficulty leaving their care recipient. In response to these findings, which underscored the need for tailored CDC-specific peer support and information for this group, our team established a new online peer support forum to help connect carers of people with CDC and address these unmet support and information needs. Subsequent qualitative studies involving carers of people with CDC, by our team and others [7], have also corroboratively highlighted a need and desire for CDC-tailored information and support among this group.

According to the stress process model of caregiving, access to social support, such as that from peers, has the potential to improve an individual's appraisal of a stressor and buffer the impact of caregiving stress on carers' well-being [24,25]. Social support is a broad concept and can be categorized into different types of supportive behaviors. Several classifications have been proposed; these most commonly include informational support (eg, provides knowledge, advice, or factual input), emotional support (eg, provides empathy, encouragement, or expressions of care), and instrumental support (eg, offers to provide physical services, goods, or aid) [26,27]. Peers facing similar stressors are thought to be in a unique position of understanding to offer specific social support that cannot be provided by those in an individual's existing networks [28]. Peer support has been associated with positive outcomes in caregiver samples, including greater perceived social support, confidence, and coping, and lower levels of depression and anxiety [29-31]. Moreover, as peer support groups are based on fostering mutual aid [32], participants often also report deriving benefit from providing support to others, such as an increased sense of confidence, self-efficacy, and achievement [32-35]. Indeed, carers of people with CDC, particularly those no longer in their caring role, reflect on having acquired specialized knowledge and expertise over their caregiving trajectory and having a desire

XSL•FO
RenderX

to help others in the same position as a way of finding positive meaning from their experience [21].

While peer support group interventions have traditionally been delivered face-to-face, the now ubiquitous use of computers, mobile devices and social media has provided an accessible alternative means of support provision. Increasing numbers of people now use online support groups to seek and provide information, advice, and support [36], and greater caregiving demands and perceived burden have been found to predict greater likelihood of visiting online support groups [37]. Content analyses of online peer support groups for other communities show that, similar to face-to-face support groups, they can provide an important source of social support, most commonly informational and emotional support [38-47]. Correlational studies have found positive associations between support received from online groups and users' psychological well-being, including lower levels of depression and loneliness and increased quality of life, optimism, and empowerment [48-52], and use of online support forums has been found to buffer the effect of caregiver strain on mental and physical well-being [53].

Online peer support communities have several unique features that may make such support particularly suitable for carers of people with CDC. First, they can typically be accessed 24/7, from home, and do not require the simultaneous presence of group members, therefore overcoming key barriers to attending face-to-face support groups reported by carers of people with CDC [21,54]. The asynchronous nature of online support forums removes the perceived obligation to respond, and users can be more selective in the information and support they obtain [55,56], which further allows carers of people with CDC to access such support around their busy caregiving regimes. Second, the ability to be anonymous and the absence of social cues in text-based communication helps create a nonthreatening environment in which carers may feel more able to discuss sensitive or stigmatized topics without fear of judgment [55,57]. Given the ethical dilemmas and sense of guilt and perceived stigma that carers of people with CDC can experience when supporting cancer treatment decision-making [21-23], an online support community could provide a "safe space" for carers to express such feelings with understanding others. Finally, online support groups remove geographic barriers and can thus bring together more widely dispersed and diverse groups of people, increasing possibilities for connectivity with peers and access to specialized information beyond that available in offline support networks [55,58-61]. Owing to the single-disease framework that still dominates health care (ie, care systems focused on treating single diseases while not appreciating multimorbidity), finding information and support relating to a specific combination of chronic conditions is difficult. An online peer support community could facilitate bringing carers of people with CDC together, providing a sense of community with similar others that they do not otherwise have. Furthermore, the collective experiences and knowledge shared in such a community could provide a valuable and specialized information resource specific to the combination of dementia and cancer, helping to address support and information needs unmet in their offline support networks [60].

Objectives

An online peer support community may thus provide an accessible way to help address the support needs of carers of people with CDC. In partnership with UK dementia charity Alzheimer's Society, in 2018 we established an online support forum specifically for carers of people with CDC, which, to our knowledge, is the first of its kind specifically for this group [62]. In this paper we examine, for the first time, the types and frequency of social support provided on this CDC peer support forum since its inception.

Methods

Launching the Online Forum for Carers of People With CDC

Our team applied for and secured a research partnership with the Alzheimer's Society, proposing a new designated peer support forum specifically for caregivers of people with CDC to be created by the charity and housed within their existing online community: Dementia Support Forum (DSF). DSF is a free online community for people with dementia and their carers and supporters. It houses a number of different forums for subcommunities of people affected by dementia (eg, "I have dementia" and "I care for a person with dementia"). Within each of the forums, users can create or respond to discussion threads to both seek and provide information and support, such as asking and responding to questions, sharing experiences and advice, expressing concerns, and connecting with other users. DSF forums and discussion threads can be viewed publicly by anyone who visits the website. However, to post within forums or to privately message users, individuals must register as a member, which is cost-free. Although the forum is public, the online community guidance pages advise users on how to protect their privacy online, such as discouraging the use of identifiable information in their usernames or posts. In addition, the exchange of personal contact information is not permitted on the online community. The community is managed and moderated by a small team of trained staff and volunteers, who monitor user posts daily. In the context of health-related online communities, such moderation is important to reduce the risk of misinformation and to safeguard users' well-being, maintaining a safe and supportive environment [63].

The new forum was titled "Caring for a person with dementia and cancer" and launched at the end of November 2018. It aimed to provide users with targeted CDC-specific information and peer support from others who understand the unique challenges of caring for a person with CDC. While the forum is hosted by the Alzheimer's Society, we have worked in partnership with the charity to contribute to the content and activities on the forum. For instance, to promote and facilitate initial discussion and use of the new forum, we implemented several launch activities. These included (1) advertising the launch via the Alzheimer's Society's monthly newsletter, social media channels, and within the DSF online community; (2) populating the forum with some existing discussion threads concerning caring for a person with CDC that had previously been posted in other areas of DSF; (3) creating some initial discussion threads based around specific topics relevant to CDC; and (4)

XSL•FO
RenderX

hosting 2 expert question and answer (Q&A) threads on the forum with a Macmillan dementia nurse (a nurse specializing in providing care and support to individuals affected by both dementia and cancer, funded by UK charity Macmillan Cancer Support). Such activities are common when launching new online support forums [45,64].

Data Collection

All user posts on the forum since its launch in November 2018 were extracted into Microsoft Excel for content analysis on April 14, 2024, with the exception of the expert Q&A threads (as these were regarded as specialist rather than peer support). To protect user anonymity, potentially identifiable information (eg, names of people and places) was removed. "Posts" is used to describe both threads and replies. Descriptive data were also extracted into a data-charting form in Excel, including number of thread views and replies, number of individual posters, and, where provided on their public user profile, sociodemographic characteristics of posters (ie, gender, age, and caring status).

Data Analysis

Descriptive statistics examined the frequency of forum use and characteristics of forum users. Qualitative content analysis was used to examine the types and frequency of social support exchanged on the forum. Deductive content analysis, situated within a postpositivist research paradigm, involves coding data according to preexisting coding categories that are imposed by previous theory or research findings; this is the process of "deduction" [65,66]. The aim of the content analysis in this study was to examine the provision of different types of social support on the online forum. A deductive approach was thus taken to categorize the data according to an existing theoretical framework of social support: the Social Support Behavior Code (SSBC) [27]. The SSBC is a coding framework originally designed to categorize social support communication behaviors during stressful life events and comprises 23 behaviors within five main categories of social support: (1) informational, (2) emotional, (3) esteem, (4) network, and (5) tangible assistance. Since its development, the SSBC has been adapted for suitability to an online context and used widely to explore the social support behaviors exchanged in online peer support forums and groups for a wide range of samples experiencing different health conditions, or families and carers affected by these. These include, for example, people with depression [39], HIV or AIDS [45], Huntington disease [42], irritable bowel syndrome [41], patients who underwent bariatric surgery [38], people affected by methamphetamine [44], parents of people with autism spectrum disorder [47], families affected by childhood cancer [43], and carers of people with dementia [67].

The SSBC used in this study was adapted in line with other studies using the SSBC to analyze data from online support groups [38,40,42-45,47], preserving the core categories of social support but modifying specific subcategories for online relevance. For instance, some subcategories were removed due to lack of relevance to the remote or public nature of the community (ie, "listening," "loan," and "confidentiality") [38,42,47]. Other subcategories and their definitions were modified for the online context (eg, "physical affection" was modified to "virtual affection") [38,42,45,47], and lastly, new subcategories were added to reflect other types of social support common in online forums, such as "personal experience," "community companionship," and "expressions of care" [45,47]. The final coding taxonomy comprised 20 subcategories; refer to Table 1 for all the categories and their definitions.

Consistent with other studies using the SSBC [38,42-45,47], the framework was used to code for the provision of social support in individual forum posts (as opposed to analyzing dialogue between users, which was beyond the scope of this study). Posts could be coded as more than one type of support. All posts were coded independently by 2 postdoctoral researchers: MLP, who has experience in conducting qualitative research with carers of people with CDC, and DH, who has experience in psychosocial dementia-related research, including the provision of web-based support. Both authors coded a sample (134/893, 15%) and met to discuss and clarify understandings of the categories before going on to code all posts. On completion of coding, agreement between coders, calculated on a post-basis, was 82.0% (732/893) of posts. The 18.0% (161/893) of posts for which there was initial disagreement were discussed between the coders to reach a consensus on coding; a third opinion was not required.

XSL•FO
RenderX

Table 1. Definitions of the social support behavior codes and their frequency on the online forum for carers of people with CDCa.

Support type	Purpose of communication	Instances, n (%)
Informational support (n=615)		
Suggestion and advice	Provides ideas or suggestions for action and coping	227 (36.9)
Referral	Refers the recipient to a specific source, community resource, or website	136 (22.1)
Situational appraisal	Helps reassess or redefine the situation being faced by the recipient, often in a way that makes it more positive or shows new information that could be helpful	37 (6)
Teaching	Provides detailed information, facts, or news about the situation or about skills needed to deal with the situation	58 (9.4)
Personal experience	Shares information about their own experience, often in a way that demonstrates specific knowledge	157 (25.5)
Emotional support (n=503)		
Virtual affection	Physical affection expressed (but virtually), such as “hugs and kisses”	59 (11.8)
Sympathy	Expresses sorrow or regret for the recipient’s situation or distress	110 (21.9)
Understanding and empathy	Expressions of understanding of the situation or disclosing a personal experience in a way that conveys understanding	174 (34.6)
Encouragement	Provides the recipient with hope, optimism, or confidence	43 (8.5)
Expressions of care	Conveys supporter’s engagement of recipient’s well-being	115 (22.9)
Prayer	Offers prayer or blessings for the recipient, reminders of faith	2 (0.4)
Esteem support (n=99)		
Compliments	Says positive things about the recipient or emphasizes the recipient’s abilities	21 (21.2)
Validation	Expresses agreement with the recipient’s perspective on the situation, emphasizes similar views	46 (46.5)
Relief of blame	Tries to alleviate any feelings of guilt the recipient has about the situation	32 (32.3)
Network support (n=207)		
Access	Messages that appeared to broaden the recipient’s social network by establishing access to a new member: “welcome” messages	112 (54.1)
Presence	Offers to be here, reminders that others are available to offer support	41 (19.8)
Community companionship	Indicates the community’s unique position to share experiences, the importance of community closeness, and gratitude for community support	54 (26.1)
Tangible assistance (n=7)		
Performs a task	Performs an action on behalf of the recipient or the group	5 (71.4)
Active participation	Offers to join the recipient in an activity; includes concrete plans or planning to do something together	0 (0)
Express willingness	Offers or expressions of willingness to help	2 (28.6)

[a]CDC: comorbid dementia and cancer.

Ethical Considerations

This study received ethics approval from the Psychology Local Research Ethics Committee at Leeds Beckett University (0223/MPMW). The DSF online community does not require account registration to view forum posts, and the guidance pages remind users that the community is publicly visible to anyone on the internet. It therefore meets the criteria for being perceived as public by its users and consent was not required for this analysis [68,69]. Such distinctions are typically used in other internet-mediated research studies to determine whether consent is required [41,44,70]. Nevertheless, permission was obtained from the DSF online community manager and all posts were anonymized during data extraction.

Results

Forum Use and Characteristics of Users

Since its launch in November 2018 (up until April 2024), 258 unique usernames posted on the CDC forum, with the number of posts by each user ranging from 1 to 58 (mean 3.50; SD = 6.30, median 2 (IQR 1-4)). Of the 258 users that posted on the forum, 63 (24.4%) provided their gender on their profile. Of these 63 posters, 49 (78%) were female and 14 (22%) were male. Most (242/258, 93.8%) identified themselves as current or former carers. Though it was not always clear if their care recipient had CDC or dementia only, 28.5% (69/242) specifically identified themselves as existing (or previous) carers

XSL•FO
RenderX

of a person living with CDC; a further 4.1% (10/242) expressed that they were caring for someone with suspected CDC (eg, some posters were caring for a relative with dementia and were debating pursuing investigations and treatment for suspected cancer), and 1 user was a person living with CDC.

Since its launch, 893 posts have been made by forum users, including 110 discussion threads and 783 replies, with threads receiving an average of 7.13 replies (median 5 (IQR 3-10), range 0-34). Examination of viewing figures suggests a much larger number of people are using the forum simply to view the discussion between other users, and the 2 expert Q&A threads, rather than to post contributions themselves. As the website's view counter rounds to the nearest thousand, we were unable to calculate precise viewing metrics, but views of the threads ranged from 388 to >15,000, with most threads having >2000 views (69/112, 61.6%). The 3 most highly viewed threads received over 10,000, 12,000, and 15,000 views, respectively.

Provision of Social Support on the Forum

Overview

Of the 893 posts made by forum users, 583 (65.3%) were coded as containing aspects of social support. All categories of the SSBC were present in the forum posts, and out of the 20 SSBC subcategories, 19 (95%) were present. Some posts contained multiple subcategories of one type of support (eg, a post may contain both the "referral" and "situational appraisal" subcategories of informational support). Thus, the frequency of individual instances of the 5 main types of social support is different from the number of posts that contained each type of social support; both are reported throughout the findings. Table 1 presents the frequencies of all the SSBC categories exchanged on the forum.

Informational Support

Informational support was the most common type of support shared by forum users (n=615), and 393 (67.4%) of the total support posts from users contained at least one subcategory of informational support. "Suggestion and advice" was the most common type of informational support shared on the forum (n=227), followed by "personal experience" (n=157), "referral" (n=136), "teaching" (n=58), and "situational appraisal" (n=37).

"Suggestion and advice" included posts that suggested ideas or techniques to help others with coping or with their caregiving role. Such suggestions included appropriate support that could be accessed, questions to ask the physician, and techniques that may help improve difficult situations for carers of people with CDC (eg, not repeatedly reminding care recipients of their cancer diagnosis to reduce associated distress). For instance, one user shared their concerns about an upcoming visit from a Macmillan nurse potentially causing confusion for their mother with dementia and secondary liver cancer, and the difficulty of then having to reinform their mother of her cancer diagnosis. Another user replied to suggest asking the Macmillan nurse to not mention the cancer diagnosis in their visit:

> *I wonder if it would be possible for the Macmillan nurse to be vague with your mum as to why she is visiting. Perhaps she could say it's just a check-up as she's feeling so unwell and not mention the cancer. I imagine these nurses must have dealt with people with dementia before and I don't see the point of upsetting your mum when she'll forget what she's upset about and I can't see it making any difference to her treatment.*

Some users provided suggestions and advice to others to help support cancer diagnosis and treatment decisions for a person living with dementia. For instance, one user posted that their mother had advanced dementia and was recently diagnosed with breast cancer; they expressed uncertainty over the decision for their mother to have a mastectomy and shared that they felt overwhelmed about making the "right decision." Others replied offering advice to help with the decision-making process:

> *I think if I could, I would ask for the least intrusive treatment to be provided to ensure my mother could be kept as comfortable and pain free as possible.*
>
> *I think that I would be asking what other treatment will be necessary along with the mastectomy e.g. chemotherapy, radiotherapy and considering whether your mother could cope with both the treatment and the side effects.*

"Personal experience" included posts where users shared their own experiences of CDC or caregiving which provided knowledge and insight for others. For example, some users shared their experiences of making cancer care and treatment decisions, to help those currently struggling to make such decisions:

> *Dads oncologist said that she thought dad would not cope well with chemo and because of his dementia and frailty the gastro doctor would not consider the operation. We took their advice. Dad had palliative care only with just a stent to enable him to eat. Good decision as he is still here 10 months later having had a good quality of life.*
>
> *When we had a decision to make about treatment, we opted for palliative care—but I have to say, I was very disappointed with what that consisted of and Mum's last year with us was pretty appalling. Had I had all the facts at that time, I think I would have risked an operation—it couldn't have made things worse for her—but refused chemo, which could have made her very sick on top of everything else!*

Another user posted that they were concerned about their mother's lack of communication and expressed that they did not know if it was due to her dementia progression or her lung cancer causing pain. One user shared their own experience of their mother who had dementia only:

> *Just to say, though, re not knowing you, with my mother (who had no other illnesses) this happened quite suddenly. One week her eyes would light up when she saw me coming—the next, they were just blank. After that I was just a 'nice lady' who made her cups of tea and brought her chocolate. So it could well be a 'normal for dementia' thing.*

XSL•FO
RenderX

"Referral" posts on the forum included signposting to information or support on websites, in books, and via other sources. Signposting included weblinks to factsheets and information to help with getting care needs assessments, finding local support, the later stages of dementia, power of attorney, and how to communicate compassionately with people living with dementia:

> *You might find this link helpful in knowing how to respond to your mum...*

Other referrals recommended approaching more specific support sources to help with a concern or situation, which included referrals to social services, the general practitioner, Local Authority Adult Services, support lines, speech and language therapy teams, and NHS 111 (a free, 24-7 nonemergency medical helpline in England). For example, one poster expressed that they were struggling to cope with the cancer caregiving responsibilities of a complicated medication routine and daily trips to the hospital coupled with their husband's dementia and no longer wanted to be responsible for him. Several users responded directing the poster to call NHS 111 for urgent support:

> *I would phone 111 today. He needs an urgent assessment by social services. They have to take care of him by Duty of Care.*
>
> *Ring 111 now before you crack. You must do this for your own sake.*

Instances of "teaching" support included sharing information about the symptoms and diagnoses of dementia, progression and stages of dementia, capacity to make decisions regarding cancer treatment, the impact that operations and cancer treatments can have on dementia symptomatology, delirium following hospital visits and treatments, and teaching about available support and how it can be accessed. Examples of such support are as follows:

> *I'd like to explain that Alzheimer's is in fact a form of dementia—there are others, like vascular dementia, Lewy Bodies and Picks, but they are all types of dementia, so if your mum has been diagnosed with Alzheimer's then this means she has dementia.*
>
> *Unfortunately, operations and treatments, as well as being gruelling, can accelerate the decline of a person with dementia.*

Posts containing "situational appraisal" support encourage reassessing a situation to view and feel about it more positively by providing new information and insight; such situations included, for example, the threat of potential cancer investigations and diagnoses, and feeling dissatisfied with planned cancer treatment or care. For instance, one user posted that their mother's physician had suggested a computed tomography scan to confirm whether her breast cancer had spread to her brain, or whether her symptoms were due to her dementia. They expressed doubt about whether the possible benefits of this would outweigh the stress of attending the appointment. Others responded helping to redefine the situation more positively, highlighting that receiving a specific cancer diagnosis can provide access to more systems of support:

> *I agree with many others. Diagnosis of cancer will get you into a system of support, even if the decision is made not to treat. Diagnosis of dementia will get you nothing. It may also give you a time frame.*

Another user posted that her mother had been diagnosed with breast cancer and expressed her frustrations that the consultant had suggested that due to her mother's dementia, a treatment plan of hormone tablets would be more appropriate than surgery. One user responded highlighting the negative impact some treatments and operations can have on dementia, suggesting the treatment plan may have been made with her mother's best interests in mind:

> *You're right—it is both shocking and depressing, but the consultant may have good reasons for giving this treatment. Obviously I don't know your mum or what stage she's at but most people find that surgery/a hospital stay often makes dementia worse. Could your mum cope?*

Emotional Support

Emotional support was the second most frequent type of support provided on the forum (n=503), with at least one type of emotional support coded in 337 (57.8%) of the total support posts. "Understanding and empathy" was the most frequent type of emotional support shared on the forum (n=174), followed by "expressions of care" (n=115), "sympathy" (n=110), "virtual affection" (n=59), and "encouragement" (n=43). Just 2 instances of "prayer" support were coded in forum user posts.

"Understanding and empathy" includes posts that expressed understanding of the recipient's situation. Users often responded to posts by sharing their own similar experiences and challenges in a way that conveyed shared understanding, showing the recipient that they are not alone:

> *I have the same dilemmas as you, is dad not finishing his breakfast because his tumour has grown or is he just not hungry? Does he sleep all day because of the cancer or is it the dementia?*
>
> *Sounds familiar! My mum had oesophageal cancer and vascular dementia. She did know she was ill, and with the first diagnosis of cancer told the doctors that she didn't want anybody—not even her—to know what stage she was at, nor did she want any treatment. Then things went downhill with both the dementia and cancer. What a nightmare for all concerned!*

Other times users empathized with the recipient's emotions:

> *Two things in your post really stood out for me. The word "frazzled" is such an apt description, and how I feel much of the time, despite my mother being in residential care.... I find your comment about cancer interesting too, and one that I can so relate to.*
>
> *I can fully relate to all your feelings.*

"Expressions of care" describes posts that demonstrate care for the recipient's well-being. Often, such posts were simply wishes of care and support to those who were particularly struggling:

XSL•FO
RenderX

I really hope you can find some help soon, you need to look after yourself in this situation.

Take care of yourself Xx

Other times "expressions of care" were provided after users had shared more positive news, such as medical results or the receipt of support. For instance, one user, whose husband had Alzheimer and vascular dementia and was in hospital with suspected kidney cancer, followed up with the news that the scans had shown no signs of cancer and that he had been discharged from hospital. Other users expressed care to the poster by sharing that they were pleased to hear this update:

that is such good news and now he and you can relax. glad he's now settled

That's good to hear @username and I'm glad that your husband is now out of hospital and back in his care home. It must be a huge relief for you.

Another user posted to share that their husband who had mixed dementia had now been diagnosed with liver cancer, and that although he had deteriorated rapidly, they were grateful for the medical support available. Others shared that they were pleased the poster was getting the support they needed:

Having the proper support certainly makes a massive difference and I'm glad that you are getting it. Take care

I'm sorry to hear of your husband's diagnosis, but am so glad you are getting good support from the general practitioner and other services.

"Sympathy" was often expressed in response to individuals who described difficulty coping with their caregiving role or uncertainty surrounding dementia and cancer symptoms and prognoses:

What a worry for you, I'm so sorry...

I truly feel for you in your position.

Some posts expressed physical affection virtually; this "virtual affection" was often shared in response to users who had expressed difficulty coping with their current situation:

I tearfully and gratefully accept your hugs and return the same.

Sending love and hugs your way. I know it's not easy I really do x

"Encouragement" described posts that aimed to bolster recipients' confidence and optimism, with such posts tending to encourage the recipient to "keep going":

We are all with you and all desperately looking for an end and closure. Keep plodding with the rest of us.

You're right, it will be hard, but you will get through it. When I moved my mother it was three months of hell (for me, not her—she knew nothing about it!) Stay strong

Esteem Support

There were 99 instances of esteem support in the posts analyzed on the forum. Of the total number of posts containing social support (n=583), 76 (13%) contained one or more instances of esteem support. "Validation" was the most common type of esteem support shared on the forum (n=46), followed by "relief of blame" (n=32) and "compliments" (n=21).

"Validation" described posts that expressed agreement with the recipient's perspective or shared similar views. Many validation posts expressed agreement with forum users' care or treatment decisions or decisions not to tell the care recipient about their cancer diagnosis:

I think you are right we have to filter out any information that is going to cause our loved ones any distress.... I think it's the right thing to do, go with your instincts x

Others validated the recipient's emotional response to a situation. For example, one user expressed that they had felt a sense of relief after their father's cancer diagnosis. Another user replied to express their agreement:

Although it was a shock finding out mum has terminal lung cancer as well as Alzheimer's, I agree it will at least bring it all to a end and we may be spared how our dad died of Vascular Dementia.

Another user shared her frustration that her friends did not understand the impact caregiving was having on her life and had told her that she should feel lucky she still has her mum. A user replied agreeing with her frustration and perspective on the situation:

What a load of rubbish telling you you're lucky to have your mum, if she's anything like my mum it's not your mum! I think I'd have snapped

"Relief of blame" describes posts that try to alleviate any feelings of guilt or blame that are experienced by the recipient. Such posts typically attempted to alleviate feelings of guilt or shame in relation to cancer treatment decisions and associated complex emotions experienced by caregivers.

For example, one user posted about their father with Alzheimer disease being diagnosed with an aggressive form of cancer and how they were struggling with the idea of their father not having any surgery. They reported feeling "the burden of responsibility of doing the best for him." One user who had also cared for their father with CDC and opted for palliative care responded to help alleviate feelings of guilt:

I don't feel guilty and neither should you. These are difficult decisions to make and we do our best.

In another example, one user who was struggling caring for their mother with dementia and cancer expressed that they wished their mother would pass away from her lung cancer, to give them an "end to it all, a way out." Another user replied trying to ease any guilt the recipient may have in feeling this way by assuring them that it was normal:

Don't beat yourself up it's natural to want it all to be over watching a loved one in so much distress has you praying for death so they can finally rest in peace.

"Compliments" describes posts that say positive things about the recipient or emphasize their abilities. Such posts on the

XSL•FO
RenderX

forum were often in response to users who expressed doubt in themselves or their caregiving ability, such as expressing that they felt they were not doing enough or were letting their loved one down. Other users often responded to praise their caregiving efforts:

> *He was given every possible care by you both when he needed it most, you both could not have done anymore*
>
> *It sounds to me like you are trying to do the best you can for your Mum, asking for med review, testing for urinary tract infections etc, it must be especially hard from a distance. Just because you cannot give your Mum the calmness and serenity you wish for her, does not mean you are letting her down*

Network Support

There were 207 occurrences of network support shared on the forum. Of the total number of posts containing social support (n=583), 134 (23%) contained one or more instances of network support. Posts sharing network support included instances of "access" (n=112), "community companionship" (n=54), and "presence" (n=41) support.

"Access" describes posts that broaden the recipient's social network by welcoming them to the community or helping to establish access to other members. Posts coded as "access" support on the forum mostly consisted of welcome posts: "Hello @username, a warm welcome from me." Though some posts helped users to access other online community members caring for people with dementia and cancer, instructing them of how they could be notified when there are new posts in the CDC-specific forum:

> *It may be helpful to click on this link >watch forum< then you will be notified when there are any new posts and discussions in the dementia and cancer sub-forum that you may be interested in reading :)*

"Community companionship" describes posts that emphasize the online community's unique position to share experiences, the importance of community closeness or gratitude for community support. Community companionship on the forum mostly consisted of posts emphasizing the knowledge and support available on the forum and encouraging the recipient to keep posting:

> *Now that you have found us I hope you will keep posting as the membership has vast collective knowledge and experience.*
>
> *I hope you find the forum to be a friendly and supportive place. Unfortunately what you describe is very common but you have come to the right place for understanding and support.*

"Presence" describes posts that remind the recipient that there are others in the online community that are there for them, and are available to offer support:

> *Sorry I am not a lot of support but you are not on your own*
>
> *We are all with you*

Tangible Assistance

Of the total number of posts containing social support (n=583), 7 (1%) contained instances of tangible assistance support. Posts sharing tangible assistance included instances of "performs a task" (n=5) and "express willingness" (n=2). There were no instances of "active participation." Tasks performed included looking up specific information for the recipient, such as the opening hours for an Admiral Nurse Helpline (a UK-based helpline offering specialist dementia support from dementia nurses), or venues in the recipient's local area that cater for people with dementia:

> *I just had a look at their opening hours, they are open tomorrow—*
>
> *Monday to Friday 9am-9pm*
>
> *Saturday and Sunday 9am-5pm*
>
> *Open bank holidays (9am-5pm), except 25th December*
>
> *I hope you find them helpful.*

Both instances of "express willingness" were posts offering to answer questions about their experience of caring for someone with CDC:

> *if you want to ask me anything else please do ask, you can message me if you want to and I will be happy answer.*

Discussion

This study (1) described the launch of a new online peer support forum specifically for carers of people with CDC, the first support of its kind for this caregiver group; and (2) provided the first examination of the types and frequency of social support provided by carers of people with CDC on an online forum.

The Forum Provides a Source of Social Support for Carers of People With CDC

The findings demonstrate that the forum provides a source of various different types of social support for carers of people with CDC and was modestly used by its users. Deductive content analysis demonstrated the types of supportive communication that were exhibited on the forum using a theoretical framework of social support (SSBC) [27]. All 5 types of social support on the framework were exhibited on the forum; the most common support provided was informational and emotional support, and the least common was tangible assistance. This is in line with analyses of other online peer support forums [38,39,41,43-45,47].

In terms of informational support, users most commonly shared their own personal experiences which provided knowledge and insight for others, including for example, sharing their decision-making and cancer treatment experiences to help those currently struggling with such decisions, which is a particular challenge for carers of people with CDC [21-23]. Sharing suggestions or advice for coping and referrals to specific sources of support were also common forms of informational support. Regarding emotional support, users most commonly shared understanding and empathy of others' experiences, which is a

XSL•FO
RenderX

key mechanism of peer support groups [28]. Given that carers of people with CDC report that individuals in their existing social networks do not always understand their unique challenges, and that dementia-only support groups are often insufficient due to the lack of specificity to CDC [21], provision of understanding and empathy from other carers in the same situation on the forum is likely to be particularly beneficial.

The forum therefore provides a source of various different types of social support for users and thus has the potential to address some of the unmet informational and emotional needs expressed by carers of people with CDC [21]. From a transactional stress and stress-buffering perspective, use of the forum may have the potential to increase carers' perception of social support availability, improving their appraisals of their ability to cope with their caregiving role and in turn, have positive effects on their well-being [25,71,72]. However, future work is needed to evaluate the perceived benefits of the forum by obtaining user feedback.

Online forums are low cost to implement and can overcome barriers to attending face-to-face support groups, such as those reported by carers of people with CDC [21,54]; and can help to connect carers who may otherwise lack access to CDC-specific information and peer support in their offline networks [21,55,58-61]. However, as with any online community, there are some limitations to consider regarding accessibility and use. For instance, the forum will not be accessible for all carers of people with CDC, such as those without internet access or those with limited digital literacy. Furthermore, the potential for misinformation to be shared is a particular challenge in the context of health-related online communities [63]. Nevertheless, expert Q&As have been hosted on the forum to provide specialist CDC support, and the forum is moderated daily by trained staff and volunteers, helping to mitigate this risk. Finally, while the asynchronous nature of the online forum may be beneficial for carers of people with CDC, who report particularly intensive caring regimes [21,55,56], it may be less suitable for those seeking immediate responses or support.

Potential to Facilitate Positive Meaning-Making

Interestingly, instances of situational appraisal were also observed on the forum, whereby users helped others to reassess their situation in a more positive light. The situational appraisal subcategory of the SSBC is akin to the concept of positive reappraisal, a meaning-focused coping strategy whereby an individual attempts to control the meaning of a stressor by searching for positive aspects of the experience [73]. Positive reappraisal has been highlighted as an important factor in coping for carers of people with CDC [21], likely owing to the chronic and progressive nature of cancer and dementia not amenable to direct coping efforts [73-75]. This is important because according to the stress process model of caregiving, caregiver outcomes are not the direct effect of objective aspects of caregiving burden but are mediated by caregivers' appraisals of stress. Thus, the ability to reappraise their situation in a more positive light has the potential to reduce the impact of caregiving on health and well-being outcomes [24,76-83]. Indeed, many interventions aim to facilitate positive reappraisal coping strategies [84-87], including on an online peer support platform [88]. In a randomized controlled trial of a web-based peer support platform that provides support with cognitive reappraisal techniques for people with depression [88], those that had greater depressive symptoms and low use of reappraisal techniques at baseline benefited significantly more from the intervention than from an expressive writing condition. Moreover, the intervention had significant indirect effects on depression and on perseverative thinking, which were mediated by improvement in reappraisal. Peer interactions on online platforms may thus provide a mechanism through which positive reappraisal can be facilitated. While this study demonstrated instances of peers facilitating positive reappraisals occurring naturally on the forum, it may be beneficial to promote this in a more structured way in the future (eg, by creating structured discussion threads that include quotes of positive experiences and reappraisals shared by carers of people with CDC and that invite shared discussion from users).

Furthermore, the various types of supportive communication exhibited on the forum also demonstrates that forum users utilized the forum to provide support to others as well as receive support themselves. Carers of people with CDC, particularly those who are now bereaved, have reported a desire to find positive meaning from their experience by helping others, sharing the specialized knowledge they have acquired over the caregiving trajectory [21]. Research has found that providing support to others on a peer support platform is associated with better psychological outcomes, including decreased depressive symptoms and health concerns, and increased subjective happiness, psychological quality of life, personal satisfaction, and use of positive reappraisal [89-92]. The ability to provide help to similar others on the forum may thus also have the potential to facilitate positive meaning-making for carers of people with CDC.

Strengths, Limitations, and Future Directions

Strengths of this study include the use of 2 independent coders and high intercoder agreement, as well as the inclusion of all posts on the forum as opposed to a subset. Another strength of the study is the use of a validated theoretical framework of social support, which has been consistently used in other similar analyses of online communities for other populations [27,38,40,42-45,47]. However, as the analysis was conducted according to preexisting social support categories, future studies may wish to take an inductive approach to analyzing the content of posts on the forum, which could provide insights that are missed in deductive analyses.

While the findings demonstrate the availability of many types of CDC-specific social support on the forum, and thus the *potential* for the forum to meet unmet informational and emotional needs expressed by carers of people with CDC [21], future work is needed to obtain feedback from forum users to evaluate the perceived value and usefulness of the forum and the ways in which it could be improved. Furthermore, owing to the anonymous nature of online forums, many posters did not provide demographic information on their public profiles; therefore we know little about the users of the forum. Any future work gaining feedback from forum users could thus obtain more

XSL•FO
RenderX

sociodemographic data, which could give valuable insights into who the forum may be most useful for.

After a trial period of 12 months, the Alzheimer's Society decided to continue hosting the new forum as a permanent feature of their online community, and it is now being signposted in the Macmillan Cancer Support booklet for carers of people with dementia and cancer [93]. While the number of posts and individual posters on the forum has been moderate, viewing figures suggest a much larger number of people are using the forum. This is common in online communities; the "90-9-1 rule" describes a pattern of participation in online social networking whereby approximately 1% of the users are daily or heavy users, 9% are infrequent users, and 90% do not interact with others, but participate only to observe others interacting, often referred to as "lurkers" [94,95]. "Lurkers" still report benefits from using online support groups, and evidence suggests that "lurkers" and "posters" do not differ significantly in many health-related psychosocial outcomes [96-100]. This suggests that the forum could be useful to a much larger audience than those who are actively posting. Indeed, discussion threads between other users and the expert Q&As held with experts in CDC can act as a lasting resource of information for users who view the forum, regardless of whether they post to seek out support directly. Given that 1 in 13 people aged >75 years with cancer also have a diagnosis of dementia [3], and this group have more comorbidity and are especially likely to rely on support from caregivers [8,10], the information and support on the forum is likely to be beneficial to a significant number of people.

Conclusions

This study demonstrates the value of a new CDC-specific online forum as a source of social support for carers of people with CDC. The forum shows promise in facilitating users' access to CDC-specific information and peer support, which they typically do not have access to offline. It also has the potential to facilitate positive meaning-making through peer-to-peer interactions and through using the forum to help other carers of people with CDC. It offers a practically feasible and low cost method of addressing both informational and peer support needs expressed by carers of people with CDC and removes their reported barriers to accessing traditional peer support. In the current economic climate, e-resources like online forums are becoming more important sources of support than ever before and given that they are accessible and generally low cost to implement, the new forum provides a worthwhile contribution of support for this caregiver group.

Acknowledgments

This work was supported by a doctoral scholarship awarded to MLP from the School of Humanities and Social Sciences, Leeds Beckett University.

Data Availability

The dataset analyzed during this study may be available from the corresponding author on reasonable request.

Authors' Contributions

MLP, LA, CS, and BG all contributed to the study conceptualization and methodology. MLP curated the dataset of forum posts, and MLP and DH both analyzed all data. MLP wrote the original draft of the manuscript, and all authors reviewed and edited the manuscript.

Abstract

Background: Breast cancer survivors have increased cardiovascular risk compared to those without cancer history. Cardiovascular disease is the most common cause of death in breast cancer survivors. Cardiovascular risk in breast cancer survivors is impacted by both cancer treatment–associated effects and in risk factors for breast cancer and cardiovascular disease overlap. Strategies to improve screening for and management of cardiovascular disease in breast cancer survivors are needed to improve the delivery of survivorship care.

Objective: This study aims to assess current cardiovascular risk counseling practices and perceived cardiovascular risk in breast cancer survivors.

Methods: Semistructured interviews were conducted from May to December 2021 with breast cancer survivors identified as having a primary care clinician within an academic family medicine center in Charleston, South Carolina. The interview guide and content were developed using the Health Belief Model with a focus on cardiovascular risk behaviors, risk perception, and barriers to risk reduction. Analysis of categorical data was conducted by frequency and quantitative variables by mean and SD. Template analysis was performed for qualitative analysis. Outcome measures included self-reported history of cardiovascular disease, risk perception, and risk behaviors.

Results: The average age of participants (n=19) was 54 (SD 7) years; 68% (13/19) were White and 32% (6/19) were Black or African American. Of the interviewed women, 90% (17/19) reported a personal history and 90% (17/19) reported a family history of cardiovascular disease. Only 53% (10/19) had previously reported receipt of cardiovascular counseling. Primary care most commonly provided counseling, followed by oncology. Among breast cancer survivors, 32% (6/19) reported being at increased cardiovascular risk, and 47% (9/19) were unsure of their relative cardiovascular risk. Factors affecting perceived cardiovascular risk included family history, cancer treatments, cardiovascular diagnoses, and lifestyle factors. Video (15/19, 79%) and SMS text messaging (13/19, 68%) were the most highly reported mechanisms through which breast cancer survivors requested to receive additional information and counseling on cardiovascular risk and risk reduction. Commonly reported barriers to risk reduction such as physical activity included time for meal planning and exercise, resources to support dietary and exercise changes, physical limitations, and competing responsibilities. Barriers specific to survivorship status included concerns for immune status during the COVID-19 pandemic, physical limitations associated with cancer treatment, and psychosocial aspects of cancer survivorship.

Conclusions: Breast cancer survivors identified that factors associated with their cancer diagnosis and treatment both impacted their cardiovascular risk and introduced additional barriers to risk reduction. Potential strategies to improve counseling and awareness around cardiovascular risk include video and messaging platforms. Further risk reduction strategies should consider the unique challenges of cancer survivorship in delivery and implementation.

KEYWORDS

cardiovascular health; cancer survivorship; lifestyle counseling; breast cancer; cancer survivors

Introduction

Breast cancer survivors are at increased risk of cardiovascular disease in part due to pre-existing comorbidities and cardiotoxicity associated with treatment [1]. Breast cancer survivorship has increased significantly, with over 3 million current breast cancer survivors. Breast cancer survivors are at increased risk of cardiovascular disease including heart failure, myocardial infarction, coronary artery disease, and vascular disease compared to those without a history of malignancy [2]. The etiology of the increased risk includes common risk factors, pre-existing comorbidities, and cardiotoxicity associated with breast cancer treatment. The likelihood of morbidity and mortality from cardiovascular disease exceeds that of breast cancer for many older women and those who have a personal history of cardiovascular disease [3-5]. In breast cancer survivors

XSL•FO
RenderX

older than 50 years of age, 35% of nonbreast cancer–associated mortality was attributed to cardiovascular disease [6]. In one cross-sectional study, over 60% of breast cancer survivors were diagnosed with hypertension, over 50% with hyperlipidemia, and 5% - 6% had a reported history of heart failure or stroke [7]. Cardiovascular comorbidity is common in breast cancer with significant implications for morbidity and mortality requiring screening, counseling, and management with a multidisciplinary health care team including primary care.

Comorbid risk factors for breast cancer include increasing age, alcohol consumption, dietary patterns, family history of cardiovascular disease, elevated BMI, and physical inactivity [2]. Breast cancer treatments can increase the risk of cardiovascular disease, including chemotherapy, endocrine therapy, and radiation therapy, although the specific cardiovascular risk profiles vary based on treatment history [2,8]. Management of comorbid medical conditions has also been shown to be suboptimal during active cancer treatment. Cancer disease processes themselves may cause subclinical myocardial damage [9]. Current strategies for risk factor reduction in breast cancer survivors include aggressive management of comorbid conditions, including hypertension, diabetes, and hyperlipidemia, and promotion of lifestyle factors such as smoking cessation, maintaining an appropriate body weight, and increased physical activity [1,10-12]. Survivorship guidelines for breast cancer recommend screening and management of cardiovascular risk among patients with breast cancer; however, current screening practices and management are inadequate [3,13]. Lifestyle interventions including nutrition, physical activity, and weight management are essential components to integrate into survivorship care to reduce cardiovascular risk [14].

When considering cardiovascular disease and breast cancer risk, it is advised to weigh factors both of breast cancer reoccurrence and cardiovascular disease risk [15]. However, previous studies have identified that women at increased risk of cardiovascular disease also have an increased risk of cancer reoccurrence [16]. Interventions targeting cardiovascular risk reduction also have the potential to impact breast cancer outcomes. Despite this, limited qualitative and interventional studies have evaluated strategies and interventions for cardiovascular risk reduction in breast cancer survivors. Observational studies have demonstrated that increasing physical activity and dietary changes improve all-cause survival and improve cardiovascular risk in breast cancer survivors [17,18]. Pilot studies using exercise-based interventions have been demonstrated to improve cardiovascular fitness in breast cancer survivors. A randomized trial by Lee et al [19] demonstrated an improved cardiovascular risk profile following participation in a 16-week exercise program [20]. Cardiovascular risk reduction consistent with guidelines and evidence-based interventions focuses on smoking cessation, increased physical activity, and dietary changes, although the specific dietary recommendations vary based on guidelines and interventions studied [21]. The purpose of this project is to identify multilevel barriers and facilitators to cardiovascular risk reduction among breast cancer survivors to best advise breast cancer survivors and to support the development of interventions focused on the unique demands of breast cancer survivors following treatment.

Methods

Qualitative analysis using semistructured interviews informed by the Health Belief Model was conducted to evaluate cardiovascular counseling and perceived risk in breast cancer survivors.

Inclusion Criteria

Inclusion criteria included female breast cancer survivors aged 40 - 65 years without metastatic disease seen by primary care at the Medical University of South Carolina in Charleston. The clinic population at the time of study initiation was predominately White and approximately 30% Black or African American. A majority of clinic patients were insured with either public or commercial insurance. For the purposes of this study, survivorship was defined as women who had completed their primary treatment for breast cancer. However, ongoing maintenance therapy, including endocrine therapy, was not considered an exclusion criterion.

Interviews

Participants were contacted using MyChart messaging within the electronic health record. Potentially eligible participants were identified through an electronic health record data inquiry based on the history of breast cancer and primary care appointments at the academic medical center within the last 3 years. Only individuals who had opted into a system-wide query about research contact were included in outreach. Of the individuals contacted, 11% (19/170) participated in the study. Outreach was stratified by age (<50 years old and >50 years old) and race (White, Black, or African American) with outreach equally to these groups to promote representation consistent with clinic demographics. A total of 19 semistructured interviews were conducted on Teams (Microsoft Corp) using audio recording only by a trained female, master-level study coordinator. The interview duration ranged from 11 to 17 minutes. Interviews were conducted until saturation of depth and diversity of themes occurred. Neither the interviewer nor the study team had previous interactions with the participants. Study objectives were provided to interview participants prior to informed consent. Interviews were transcribed and reviewed for accuracy. Participants were not contacted following the initial interview. Participants were provided with contact information for the study team with an opportunity to reach out about any additional questions or study results. Our research team is composed of primary care clinicians and public health researchers involved in primary care research, including researchers with expertise in onco-primary care. Our team values patient self-efficacy and the importance of interdisciplinary coordination of care guided by a patient-centered approach to care. To reduce potential bias, the study team member completing the interviews was not involved in data coding. Coding was completed independently and reviewed by consensus.

XSL•FO
RenderX

Conceptual Framework

The study was grounded in the Health Belief Model as a conceptual framework [22]. The Health Belief Model was selected based on its capacity to understand how individuals respond to communication of health-related information and their subsequent engagement in health-related behaviors. The Health Belief Model has been extensively used to assess cardiovascular risk perception, barriers to behavior change, and the development of interventions to address these [23-27]. More specifically, in this study, the focus on communication of information about cardiovascular risk in breast cancer survivors was predicted to inform and desire to and engagement in health behaviors to reduce cardiovascular risk. The interview guide was developed by the primary author after a review of previous literature, with revision following feedback from the research study team. Training was provided in the interview guide. Key constructs evaluated included perceived susceptibility to cardiovascular disease, perceived severity, self-efficacy, perceived barriers, and cues to action for engaging in cardiovascular risk reduction behaviors. Perceived susceptibility provides essential information on the participant's assessment of the probability of cardiovascular disease. Perceived severity focused on the understanding of the potential severity of health impacts of cardiovascular disease and its relation to breast cancer survivorship status. Participants identified their perceived barriers to engaging in health behaviors to promote improved cardiovascular health. Self-efficacy was assessed based on the patient's reported belief in their capacity to engage in health behaviors to reduce cardiovascular risk. Cues to action included experiences or actions within the participant's environment that prompted the decision to engage in cardiovascular risk reduction behaviors. Interview questions also included questions about adherence to cancer survivorship guidelines.

Template Analysis

Template analysis was conducted using an interview guide and codebook developed using the Health Belief Model [22,28-31]. Template analysis uses a structured template while still permitting a flexible coding process for the analysis of qualitative data. Since the interview guides in this study were based on the Health Belief Model framework, template analysis allowed researchers to use an initial template developed based on the constructs of the Health Belief Model framework, while also allowing codes to be updated in the coding process [30]. Coding was conducted by 3 independent coders with previous experience with qualitative analysis who each independently coded all transcripts. Following initial limited interview coding, further coding continued by consensus of themes which remained consistent across all coders. Nvivo (Lumivero) was used to assist in coding. Saturation of themes was reached after 19 interviews.

Ethical Considerations

The study was deemed by the Medical University of South Carolina institutional review board as exempt (Pro00073820) with a waiver for written informed consent. All participants provided verbal consent for participation. Participants self-reported current exercise participation, consumption of fruits and vegetables, and current cardiovascular health conditions. Interview transcripts were deidentified prior to coding and analysis. Interview participants received a US $35 gift card as compensation for their time for participation.

Statistical Analysis

Descriptive statistics including mean and SD were calculated for continuous variables and frequency data for qualitative variables.

Results

Participants

A total of 19 participants were enrolled in and completed interviews. The average participant age was 54 (SD 7; range 43 - 66) years. Participants averaged 3 primary care and 3 oncology visits annually. Over half (10/19, 52%) of participants reported receiving counseling on cardiovascular risk. Counseling was provided by primary care (8/10, 80%) and oncology (3/10, 30%). Demographic information is provided in Table 1. Themes and illustrative quotes identified are displayed in Table 2. Themes were consistent across participants based on age and race.

Table . Health Belief Model themes.

	Quotation example	Theme
Perceived barriers	• "I'm almost 100 percent sure [my exercise limitations are] due to breast cancer treatment because I have some lung involvement. And so, you know, I've had issues with having a pleural effusion where it builds up the liquid in your lung." [INT7]	• General barriers identified included fatigue, limited time, and medications • Treatment-associated barriers included physical limitations and associated anxiety and stress
Overcoming barriers	• "But when I'm on the road, it's hard to find foods that fall in those categories ... When I know ahead of time that I'm going to have a pick up at a certain time. I'll make sure I either eat before I leave or I pack a lunch. But lots of times ... I only got like a 30 minute window to get them to pick it up." [INT17] • "So I think making the time about prioritizing ... prioritizing the time to exercise, and to shop appropriately, to eat healthy, so making the right decisions." [INT2] • "I think the main thing affecting me was I was kind of feeling because of what I went through, I was suffering a lot with PTSD and anxiety and all that. And I think because of that, I wasn't focusing too much on my health. I was stress eating and gained 20 pounds because I was like so stressed out from what happened and being on the hormonal meds and shot every month, it just really messed with my I guess, my whole, like, energy level and motivation." [INT4]	• Discussions with clinicians identified as factors promoting change • Scheduling considerations impact exercise and nutrition and mechanisms to prioritize change • Individual motivation important determinant for cardiovascular risk reduction
Perceived susceptibility	• "Genetics. On my father's side, everyone has died of heart disease, and I apparently got his genes." [INT3] • "I would say it's pretty high and I say that basically because when I had my radiation, they told me my tumor happened to be on my left side, so my radiation happened to be my heart. And so they told me that I was a high risk for congestive heart failure in the future." [INT12] • "I've never correlated the breast cancer to heart disease. I'm gonna need to think a little bit more about that. But I've never done that. So I would say no, because I just never thought about it in that way." [INT2]	• Individual factors impacting perceived risk include current personal cardiovascular disease, family history of cardiovascular disease, and lifestyle factors • Cancer and treatment-associated factors impact perceived risk of breast cancer in some individuals although there was uncertainty in others
Communication regarding cardiovascular risk and cancer	• "Possibly in the beginning ... My oncologist may have [discussed cardiovascular risk], but at that point, I think I was so overwhelmed with everything else that I probably didn't listen that well." [INT6] • "So, like, if I am at risk as being a breast cancer patient for heart issues, then that's something that I would want to stay on top of and have more information and have my primary care doctor or my oncologist talk to me about in ways that I could get on top of that before anything crazy happens." [INT7]	• Timing important factor in communication between health care team and patients about cardiovascular risk • Communication limited about cardiovascular risk and breast cancer.

XSL•FO
RenderX

	Quotation example	Theme
Self-efficacy	• "I stopped smoking was one [way I took control of my health]. Because the reality of possibly having cancer in another location or not healing from the procedure. I never realized that they actually kept you from healing. And diet improved. Everything had to improve." [INT5] • "I'm a survivor, thank God. And I think it has a lot to do with my healthy choices. But if you don't, if you're not educated on that stuff, most people don't know, you know. So it's important to talk to professionals and see what's the best thing for you to do." [INT8]	• Motivation to change and resources to support effective behavior change both reported as necessary by participants
Cues to action	• "You know, there's a publication that the [health system] puts out. I want to say four times a year ... There's a lot of just good little health tips, reminders that just kind of keep things at the forefront when you're starting to get busy." [INT1]	• Weight change and perception of body image motivation for lifestyle change • New diagnoses of cardiovascular disease in an individual or relative impacted motivation to seek care • Health promotion materials influence motivation for cardiovascular risk reduction

Perceived Barriers

Perceived barriers included both factors unrelated to cancer, as well as those associated with the late and long-term effects of breast cancer and treatment. Commonly reported barriers included fatigue, time limitations to participation in exercise or meal planning, motivation to change, and available resources to support behavioral changes to support cardiovascular risk reduction. Cancer-specific barriers included physical limitations, including those from previous cancer treatments that impacted the capacity for exercise. Anxiety and stress, especially associated with changes in health status associated secondary to cancer and cancer treatment, were reported and identified as a barrier to behavior changes in exercise and nutrition. Medication side effects following treatment were cited by one participant as a limitation to participation in exercise.

Overcoming Barriers

Engagement of the health care team and individual motivation for change were identified as factors promoting cardiovascular risk reduction behaviors. Participants reported that treatment of mental health conditions improved their capacity for behavior change. Participants highlighted the need for time management for meal preparation and exercise. The availability of group classes and discussions with clinicians in the health care team increased motivation for behavioral change.

Perceived Susceptibility

Participants identified breast cancer treatment–associated factors including radiation and chemotherapy as contributing to cardiovascular risk. Others expressed uncertainty about the potential impact of cancer treatment on their cardiovascular risk but desired more information on this from their health care team. Individual factors associated with risk perception included current diagnosis of cardiovascular disease or history of a cardiovascular event. A family history of cardiovascular disease was reported as increasing an individual's perceived personal risk of cardiovascular disease. Perceived protective factors included participant engagement in diet modification, regular exercise, and medication management of cardiovascular conditions.

Communication Regarding Cardiovascular Risk and Cancer

Participants reported limited communication regarding cardiovascular risk specifically related to their cancer history. However, they desired to receive information on cardiovascular risk. Timing of communication about cardiovascular risk further removed from the time of initial diagnosis and treatment was preferred.

Self-Efficacy

Participants identified self-efficacy as important in facilitating care and risk reduction. The ability to cook and resources for healthy food were identified as factors to support cardiovascular health. Motivation for change was identified as a necessary prerequisite for change.

Cues to Action

Participants reported inciting stimuli to engage in risk reduction behaviors as a new diagnosis of cardiovascular health conditions either in themselves or in family members or friends. Individuals who were experiencing symptoms reported a stronger motivation to seek medical care and engage in risk-reduction behaviors. Participants valued outreach from trusted organizations, including health care organizations, about behaviors to improve health and reduce cardiovascular risk as important in keeping their desire for change at the forefront of their priorities.

Sources of Information

The majority of individuals valued information from their health care team or other medical resources designed for patients. Specific sources of information on cardiovascular risk included clinicians, medical publications, and both medical and

XSL•FO
RenderX

nonmedical internet sites. The timing of communication impacted the reception of the discussion regarding risk. Some participants reported the initial stages of treatment as overwhelming in the amount of information delivered and reported being more treatment-focused at that time. Participants did desire to receive information about their cardiovascular risk both from their oncologists, as well as their primary care clinician. Desired mechanisms of delivery of information on cardiovascular risk in survivors of breast cancer included video (n=15, 79%), SMS text messaging (n=13, 68%), telephone (n=11, 58%), and mobile apps (n=10, 53%).

Summary

Based on the use of the Health Behavior Model, themes that promoted engagement in cardiovascular risk reduction were identified in each of the constructs assessed. Perceived barriers included both traditional barriers to cardiovascular risk reduction, as well as treatment-associated barriers derived from both mental and physical health. Factors promoting overcoming these barriers included clinician engagement with patients about cardiovascular risk reduction and the need for individual motivation for change to accomplish this. Although clinician communication was essential in promoting change, the timing of communication was identified as important. Immediately after diagnosis, breast cancer survivors preferred to focus discussion on treatment options. The availability of both financial resources and accessible resources supported the self-efficacy of participants with video and SMS text messaging as the preferred mediums for health information. Cues to action included changes in family and individual health. These interviews and themes have the capacity to inform further counseling and the development of interventions to support cardiovascular risk reduction both in breast cancer survivors and other cancer survivor populations.

Discussion

Principal Findings

Breast cancer survivors face additional cardiovascular risk following treatment, which impacts both overall and breast cancer–specific survival. Survivorship guidelines recommend screening and management strategies to reduce cardiovascular risk. Limited information is available on the barriers and facilitators of engaging breast cancer survivors in cardiovascular risk reduction behaviors. This qualitative study using semistructured interviews sought to evaluate facilitators and barriers to cardiovascular risk reduction in breast cancer survivors. Consistent with previous literature, uptake of survivorship guidelines including participating in physical activity and regular consumption of fruits and vegetables was limited [4]. The participants in the study overall received multiple treatment modalities that had the potential to increase individual cardiovascular risk.

The primary findings of the study included that there were opportunities to improve communication about cardiovascular risk in breast cancer survivors both within primary care and oncology. Breast cancer survivors valued communication about cardiovascular risk reduction, while also identifying the timing of delivering this information as important in engagement with subsequent risk reduction behaviors. Specifically, participants noted the importance of cardiovascular risk counseling as they progressed through treatment and into survivorship, rather than just at diagnosis. Many participants reported that they did not receive information on cardiovascular risk and were interested in learning more about their individual risks and the impact of their treatment on cardiovascular risk. These findings are in alignment with previous studies on both cancer survivors and health care professionals who identified that there was a knowledge gap among breast cancer survivors about cardiovascular risk. Cancer survivors consistently identified interest in discussions about heart disease and risk factors [32-34]. Although health care providers are generally aware of the increased cardiovascular risk in cancer survivors, system-based barriers include a lack of training, competing demands, and time limitations that limit the capacity for counseling and screening [34]. Furthermore, patient-level factors including socioeconomic factors and having a fatalistic outlook have been reported by health care clinicians as barriers to adopting risk reduction strategies [32,33]. In this study, the need for resources to promote self-efficacy was similarly identified by multiple participants even in a population with access to primary care [35].

Participants identified previously known barriers and facilitators to cardiovascular risk reduction, including motivation, time limitations, and resources to support efforts for change. Participants simultaneously identified breast cancer–specific factors as both significant components of their risk perception and as limitations to participation in risk-reducing behaviors. These same barriers were identified in previous formative research for intervention development, with the identification of cancer and other health conditions limiting the ability to increase physical activity. These studies simultaneously identified the need for individual motivation to facilitate change [34]. Participants in this study identified the need for multimodal changes, which aligns with previous literature supporting the greater efficacy of interventions that address factors beyond physical activity alone [30,31,34].

Breast cancer survivors desired additional communication about cancer-specific cardiovascular risk factors, preferably delivered after initial diagnosis and treatment have been established. Cardiovascular risk reduction strategies, including physical activity, have been demonstrated to reduce cardiovascular risk and improve quality of life, and therefore increased attention to cardiovascular risk reduction is essential to promoting improved survivorship care of breast cancer survivors [36,37]. Therefore, additional interventions that promote cardiovascular risk reduction and consider the elevated risks and unique barriers faced by breast cancer survivors are essential.

This study supports and aligns with existing literature regarding the need to support self-efficacy and consider the physical limitations of breast cancer survivors following treatment. Previous research identifies the critical role of clinicians in identifying and communicating the cumulative role of risk factors in cancer survivorship on cardiovascular risk and the importance of patient-clinician communication [38]. Engagement in communication about cardiovascular risk is limited and especially important in cancer survivors at increased

XSL•FO
RenderX

risk, including those with existing cardiovascular disease and obesity. Primary care clinicians can serve an important role in screening for cardiovascular risk, promoting risk reduction, and pharmacologic management when indicated [39]. Based on this study, primary care clinicians often initiate this discussion and have an opportunity to improve communication about risk and promotion of health behaviors. When primary care clinicians were surveyed about barriers and enablers of care, system-level barriers including lack of time and training were critical to address to promote improved cardiovascular survivorship care [32]. Clinical risk assessment and management tools have been identified as strategies to improve the delivery of cardiovascular disease care to reduce morbidity and mortality. This study identifies the need to consider mental health support and treatment in facilitating cardiovascular risk reduction. In addition, it identifies the importance of timing in the delivery of cardiovascular risk-reducing education during the breast cancer treatment-survivorship continuum in order to optimize the uptake of risk-reducing measures.

Strengths and Limitations

The proposed study is novel in its evaluation of breast cancer survivors–specific perceived risks and susceptibility to breast cancer, as well as potential survivorship-associated barriers to engagement in risk reduction. However, the study has a number of limitations. First, the study focuses on participants from a single academic medical center, which may limit its transferability. Further studies should include participants from a diversity of geographical locations and practice settings. A stratified recruitment approach was used to broaden the perspectives obtained as part of the interview process. Second, participants were selected based on having an existing primary care clinician, as the study included the role of primary care clinicians in survivorship. Future work would benefit from the inclusion of individuals with reduced access to care. Third, study findings may have been impacted by participation bias, where either the desire to engage in cardiovascular risk reduction behaviors or existing cardiovascular disease may have impacted the decision to participate. There are elevated rates of cardiovascular disease in breast cancer survivors, and this perspective is proportionally represented in this study. Another limitation is that the interview guide was not pretested before implementation. The interview guide was based strongly on the constructs of the Health Belief Model, which have been extensively studied. Future investigations could ensure the validity of the interview guide as related to capturing Health Belief Model constructs as related to cardiovascular risk in breast cancer survivors. Finally, the study is limited by the small sample size. This study focused on a limited number of individuals in order to obtain more breadth of information. While the achievement of theme saturation strengthens the study findings, future quantitative studies are needed to further evaluate the identified themes using a larger sample size to promote the development of interventions that improve communication between health care team members and breast cancer survivors about cardiovascular risk and engagement with risk reduction behaviors.

Conclusions

Breast cancer survivors face unique cardiovascular risks influenced by their diagnosis and treatment, which introduce barriers to effective risk reduction. Participants in this study expressed a desire for enhanced counseling on cardiovascular health, highlighting a significant knowledge gap regarding their risks and the impact of cancer treatments. Many reported insufficient communication from health care providers about cardiovascular risks, particularly after the initial treatment phases. To address these issues, health care systems should leverage electronic communication methods, such as video and SMS text messaging, to deliver tailored cardiovascular risk information. Interventions must consider the specific challenges of survivorship, including physical limitations and mental health concerns, to effectively engage survivors in risk-reducing behaviors. This study highlights the importance of improving adherence to guideline-based care for breast cancer survivors and emphasizes the need for further research to develop comprehensive strategies that facilitate cardiovascular health in this population. By prioritizing timely and accessible information, we can enhance self-efficacy and support better health outcomes for breast cancer survivors.

Acknowledgments

The authors would like to acknowledge Suzanne Perkins for her contributions to recruitment, data collection, and interviews. The authors would additionally like to thank Dr Emily Ramsayer for her contributions to data analysis and Nekia Robinson for her role in manuscript revision. This study was funded by pilot funding through the Cancer Control Group at Hollings Cancer Center at the Medical University of South Carolina. Generative artificial intelligence was not used in manuscript writing.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

STM contributed to conceptualization, formal analysis, funding acquisition, methodology, and writing including the original draft and review and editing. VD contributed to conceptualization, methodology, supervision, and writing including the original draft and review and editing. NS contributed to formal analysis, methodology, and writing in all stages of development.

Abstract

Background: Adolescent and young adult survivors of cancer (aged 15 - 39 years) frequently engage in hazardous alcohol use, which can have multiple mental and physical health effects.

Objective: The aim of this study was 2-fold, to identify the necessary adaptations to an existing motivational interviewing-based mHealth (mobile health) alcohol reduction intervention, called Tracking and Reducing Alcohol Consumption (TRAC), for posttreatment adolescents and young adults, and to develop a tailored intervention for this vulnerable and underserved population.

Methods: This was a qualitative study consisting of key informant interviews with posttreatment adolescents and young adults aged 18 - 39 years, oncology and psych-oncology providers, and community advocates (n=15) to inform the adaptation of TRAC. Thematic qualitative analysis of interview findings was conducted to determine necessary changes to the intervention protocol and content, which would ultimately lead to the development of the new TRAC adolescent and young adult intervention.

Results: Key informant interviews revealed a need for the intervention to address cancer-specific alcohol use triggers such as scan-related anxiety, financial toxicity, and reproductive health concerns. They also indicated the need to provide education on the link between alcohol and cancer and to reduce the time burden of the intervention, given the many competing life demands of adolescents and young adults. Significant changes were made to the TRAC intervention to create the TRAC adolescent and young adult. We reduced the number of required sessions from 8 to 4, introduced a session devoted to managing cancer-specific triggers, and provided survivors with more information about alcohol and its relationship to cancer.

Conclusions: There is potential to increase alcohol intervention relevance and fit for adolescents and young adults by including tailored content relevant to their life experiences while also maintaining core components of such interventions, such as self-monitoring and goal-setting. Remote, brief interventions are important for ensuring acceptability. The new TRAC adolescent and young adult intervention represents a potentially valuable tool in addressing high rates of hazardous alcohol use among this population and warrants further evaluation in randomized trials.

Introduction

Background

Each year in the United States, nearly 90,000 people aged 15 - 39 years (adolescents and young adults) are diagnosed with cancer [1]. A total of 5-year survival for adolescents and young adults is over 80%; most will live an additional 36 - 59 years after diagnosis [1], highlighting the critical importance of maximizing their physical and mental health to support quality of life and avoid premature mortality. Unfortunately, adolescent and young adult cancer survivors report poorer physical and mental health compared with their unaffected peers and have a greater than 2-fold risk of dying from noncancer-related causes, such as cardiovascular disease [2-5].

Hazardous alcohol use (ie, heavy or binge drinking) is one modifiable factor that may contribute to adolescent and young adult cancer survivors' physical and mental health. Over 50% of adolescent and young adult cancer survivors exceed moderate drinking recommendations [6], and 36% - 45% of survivors report engaging in binge drinking, defined as consuming 5 or more drinks (for males) or 4 or more drinks (for females) in a 2-hour period [6,7]. Given known health risks of hazardous alcohol use in the general population (eg, increased risk of heart and liver disease, stroke, depression and anxiety, and reduced fertility), as well as in cancer survivors specifically (eg, increased risk of certain cancer incidence, recurrence, and even premature mortality) [2-5], helping adolescent and young adult cancer survivors reduce hazardous drinking should be a key component of survivorship care.

Unfortunately, few interventions have been developed and tested to address risky alcohol use among cancer survivors, let alone among adolescent and young adult cancer survivors. Evidence of the effectiveness of such interventions is limited, with many studies focusing on general behavioral health interventions rather than alcohol use specifically [8]. Few have leveraged mHealth (mobile health) or similar technology-based interventions that may significantly increase reach not only among adolescent and young adult cancer survivors who show near ubiquitous use of smartphones [9], but also among those living in rural and underserved areas who have limited access to mental health providers [10] and may experience stigma when seeking help [11,12]. Finally, no interventions have been developed to address the potentially distinct needs of adolescent and young adult cancer survivors who, by virtue of their developmental and life stage, may face additional social pressure to drink and may experience unique stressors that may trigger drinking, such as mental health concerns stemming from their cancer experience [13].

Objectives

The purpose of this study was to identify modifications needed for a previously developed mHealth intervention, originally designed to reduce alcohol use among people living with HIV ("TRAC") and shown to have high acceptability, feasibility, and significant pre-post effects on alcohol use in a pilot trial [14]. We also sought to develop a new, tailored intervention for posttreatment adolescent and young adult cancer survivors. We focused on the posttreatment period to ensure survivors had experienced sufficient time to establish more routine drinking patterns, as well as to avoid the likelihood that active cancer treatment side effects may impact drinking levels [15,16]. In addition, we specifically examined rural adolescent and young adult cancer survivor experiences and needs to ensure the resulting intervention would reach this underserved, vulnerable population.

Methods

Framework and Study Design

This study was part of a larger project aimed at developing an mHealth intervention to reduce hazardous alcohol use among posttreatment adolescents and young adults that was approved by the University of Kentucky Institutional Review Board (67410). We used Escoffery et al's [17] synthesis of the common steps outlined across adaptation frameworks to guide overall study design. The formative qualitative research described in this paper was guided by the following adaptation steps: understand the needs of the new target population (posttreatment adolescents and young adults) with respect to alcohol interventions, determine how core components of the original intervention aligned with the new population context, consult with subject experts and stakeholders, and determine potential changes in the original intervention's structure, content, and delivery methods to ensure alignment between the intervention and needs of adolescents and young adults. Steps of pretesting and pilot testing the adapted intervention were achieved through an open pilot and pilot randomized controlled trial, which will be described in a future paper. The COREQ (Consolidated criteria for Reporting Qualitative research) checklist [18] was used to guide reporting throughout this manuscript and is included as Checklist 1.

Description of Existing Intervention (Tracking and Reducing Alcohol Consumption)

The original Tracking and Reducing Alcohol Consumption (TRAC) intervention was designed as an alcohol reduction intervention for individuals living with HIV. It focused on increasing motivation to reduce hazardous drinking and awareness of drinking behaviors, building skills to reduce alcohol use, and identifying general triggers for drinking. In this original intervention, there was minimal discussion surrounding potential HIV-specific triggers for drinking [14]. Over an 8-week period, 8, 30-minute sessions were conducted remotely via video chat or telephone call with a trained interventionist (Can be found in Table 1 for session content of the original TRAC intervention). Throughout the intervention period, participants completed twice-daily self-monitoring of alcohol use via mobile surveys and a BACtrack Mobile Breathalyzer, which uses law enforcement-grade sensors to determine breath alcohol concentration (BrAC). The study interventionist discussed the previous weeks' alcohol use as reported via these self-monitoring tasks during weekly intervention sessions.

Table . Original Tracking and Reducing Alcohol Consumption intervention (preinterviews).

Session number	Session emphasis	Session content
Session 1	Developing a change plan	1. Review current drinking behaviors, when or why they drink 2. Identify reasons for changing drinking behaviors (change plan) 3. Self-monitoring and phone training
Session 2	Triggers for drinking alcohol	1. Urges and cravings 2. Emotional triggers 3. Situational and environmental triggers 4. Social triggers
Session 3	Skill building: distraction	1. Breathing awareness 2. Personal distraction techniques
Session 4	Skill building: managing urges and cravings	1. Delay before acting 2. Negative consequences of drinking 3. Positive consequences of not drinking
Session 5	Skill building: managing emotional triggers	1. Improve the moment 2. Do something relaxing
Session 6	Skill building: managing social triggers	1. Drink refusal 2. Seek social support 3. Seek spiritual support
Session 7	Skill building: managing situation and environmental triggers	1. Consuming alternate food or drink 2. Engaging in alternate behavior 3. Avoiding the situation or environment
Session 8	Looking ahead	1. Summative self-assessment 2. Planning for the future

Participants

Key informant interview participants (n=15) included adolescent and young adult cancer survivors, providers, and community advocates to represent the perspectives of key stakeholders and subject experts. These partners were chosen because they were expected to offer important perspectives on the unique psychosocial needs adolescents and young adults might face that could influence drinking, the health care needs pertaining to psychosocial interventions to address alcohol use among adolescents and young adults, and the specific challenges adolescents and young adults from rural and underserved areas might experience that could influence intervention acceptability and feasibility. Oncology and psycho-oncology providers were selected to determine what clinical resources for discussing alcohol use are used with their patients, if any, and to hear provider perspectives on potential intervention content. Community advocates and survivors were selected based on their work with or experience as adolescent and young adult survivors of cancer and their insight regarding unmet needs of this population.

Recruitment was accomplished via convenience sampling. We used the University of Kentucky Markey Cancer Center Community Impact Office to identify community advocates, professional networks to identify oncology and psycho-oncology providers, and reviewed clinic schedules at the University of Kentucky Markey Cancer Center to identify potentially eligible survivors. We also contacted survivors who recently completed a related survey and had indicated interest in participating in follow-up research. Survivors were eligible if they were between the ages of 18 and 39 years, had been diagnosed with cancer between the ages of 15 and 39 years and identified as a survivor of cancer (ie, had completed cancer treatment), and were residents of a rural area (determined by the zip code of their primary residence). Oncology providers included physicians, nurses, nurse practitioners, or physician assistants who had been in practice for at least 6 months and saw at least 25% adolescent and young adult cancer patients in their practice. Psycho-oncology providers included social workers, psychologists, or other mental health providers who treated adolescent and young adult cancer patients and had been in practice for at least 6 months. Community advocates included partners from the Kentucky Cancer Consortium and the Kentucky American Cancer Society who had previous experience with adolescent and young adult populations and the specific challenges that come with living in rural Kentucky. Individuals who were unable to speak English were excluded from the key informant interviews. Participants were approached either in person or remotely through email or phone calls and completed a brief screening survey to determine eligibility. All participants provided documentation of informed consent via REDCap (Research Electronic Data Capture) [19,20] before beginning the interview. Key informants received US$40 as compensation for their participation.

RenderX

Sample Size Considerations

Sample size is often driven by factors beyond saturation [17], and in this case, the sample size was driven by the goal of the interviews, which was to include different partner perspectives on the development of a new, tailored intervention. Other considerations for sample size for the interviews included pragmatic concerns related to time and resource constraints in the context of the larger 2-year project, as these interviews were but the first phase in a series of studies designed to develop and pilot this new intervention. After completion of the interviews, we conducted a small open pilot to refine protocols (n=4), followed by a randomized pilot trial (N=40) that sought to evaluate feasibility and acceptability of intervention content; analysis of the full results of these remaining phases is ongoing. Thus, the short timeline, limited resources, and the goals of the research (ie, to hear different perspectives on the new intervention) guided decisions regarding overall sample size and recruitment efforts for the interviews. The implications of this approach are discussed in more detail in the Limitations section.

Interview Protocol

Key informant interviews lasted between 45 and 60 minutes and were conducted through videoconferencing, by phone, or in-person at a clinic using a semistructured interview guide developed by the principal investigators. In-person interviews were completed in a private room with only the interviewer and participant present. Participants who completed the interview remotely (either via phone call or videoconference) were instructed to find a private location for the interview. All interviews were audio-recorded and transcribed verbatim, supplemented by field notes made by the interviewer during the interview. Participants did not receive copies of these transcripts or audio files. There were no follow-up interviews or surveys. The semistructured interview guides, which contained over 20 questions with follow-up probes, elicited feedback on the relevance, appropriateness, acceptability, and feasibility of TRAC content and delivery. Refer to Table 2 for highlighted interview questions that yielded some of the more informative responses. The interviewer was a male research staff member trained on the interview protocol by the principal investigators, who had a Master's degree in Social Work and experience working in substance use treatment settings. He provided reference materials to the participants before the interview, including a diagram of the study steps and components and excerpts from the participant manual. Individuals from all 3 participant groups were generally asked the same questions, though there were some differences. Oncology and psycho-oncology providers were asked questions about their approaches to assessing and counseling on alcohol use in their practice. Survivors were asked whether they had received any information or recommendations from their providers about maintaining a healthy lifestyle posttreatment, what those recommendations were, and if they had been told about alcohol's relationship to cancer recurrence or development of other cancers. In addition to the interview, key informants also completed a brief demographic questionnaire that collected information on gender, race and ethnicity, and education and income level.

[a]Adaptation Steps: (a) Understand needs of posttreatment adolescents and young adults with respect to alcohol interventions; (b) determine core component alignment; (c) determine potential changes in structure, content, and delivery methods

Analysis

Interview transcripts were analyzed using a thematic approach put forth by Braun and Clarke [21]. Analysis steps involved: (1) reading and discussing two randomly selected interviews, (2) identifying key concepts as preliminary codes, (3) creating a draft codebook with operational definitions for each code, (4) double-coding the initial two randomly selected interviews by line-by-line coding (ie, independent coding by TB and KH, with discrepancies rectified to achieve a final set of agreed-upon codes for each interview), (5) finalizing the codebook, (6) revising the initial two previously coded interviews to reflect the final codebook, (7) double-coding all remaining interviews until we reached ≥80% agreement (4/7 survivor interviews and 5/8 provider and advocate interviews were double coded), and (8) analyzing all coded interviews in NVivo (Lumivero) [22]. In total, 2 separate codebooks were created (survivor or provider and advocate). Participants were not contacted to provide feedback on the codebooks or findings.

Ethical Considerations

All procedures were approved by the University of Kentucky Institutional Review Board (67410). All participant data were held in confidence and kept secure, and only the approved study staff involved with the research and those responsible for overseeing the research had access to information that may identify the participants. All participants completed informed consent before beginning any research activities. Consenting was completed electronically using the REDCap eConsent framework. Participants were first given basic information about the study, and if they expressed interest, they were given the opportunity to complete a brief screening survey to determine eligibility. If participants met eligibility criteria, a member of the study team obtained their informed consent. Participants were told that they may stop their participation in the study at any time, without consequence. The research team also provided contact information for the principal investigators and the University of Kentucky's Office of Research Integrity. Participants were encouraged to contact these individuals if they had questions or concerns regarding this research or questions about their rights as research participants.

To protect confidentiality, participants were assigned a unique study ID number. Any identifying information was not stored alongside their survey or interview responses. Electronic data were stored within REDCap. Audio files and transcripts of the interviews were stored in a password-protected HIPAA (Health Insurance Portability and Accountability Act)-compliant Microsoft OneDrive folder housed at the University of Kentucky. Only approved study staff had access to the study data. As part of this study, participants could earn up to US$40. Upon completion of the interview, participants were paid using gift cards.

Results

Participants

Participants included 7 adolescent and young adult cancer survivors (mean age 24 [4.8] yrs; range=19 - 38; 71% female; 100% white), 3 oncologists (Mean years in practice 16 [3.5] yrs; 67% female; 67% white), 3 psycho-oncology providers, all of whom were licensed mental health practitioners (Mean y in practice 17 [3.5] yrs; 100% female, 100% white), and 2 community advocates (Mean age 45 [12.7] yrs; 50% female; 50% white; Table 3).

While data on alcohol use from one survivor participant was missing, among the remaining 6 participants, 83% were current drinkers, and 67% reported past month hazardous drinking (ie, reported getting "drunk or intoxicated" at least once). Responses were similar across groups, with no major differences in perspectives between survivors, clinicians, and community advocates. The following sections describe key themes obtained from their responses.

Theme 1: Lack of Provider Discussions About Alcohol and Need for Intervention

Survivors, oncology providers, and psycho-oncology providers all spoke about the lack of discussion about alcohol use during posttreatment and long-term follow-up care. Most oncology and psycho-oncology providers interviewed said they rarely discussed alcohol use with patients, if at all. One clinician remarked, "That's usually something I don't bring up," [Oncologist, ID 14] while another said alcohol use is discussed only if it is "clinically relevant" [Psycho-Oncologist, ID 3]. Of the 6 oncology and psycho-oncology providers interviewed, only one reported discussing alcohol use with their patients, and only then to "try to educate people about the recommended dose" [Psycho-Oncologist, ID 10].

Survivors who were interviewed likewise reported that they received little to no information about alcohol use once they completed cancer treatment. "They didn't really give me any restrictions," said one survivor [ID 4], while another said "I have received no information about alcohol and cancer" [ID 9]. Others recalled that providers advised them to "maintain a

XSL•FO
RenderX

healthy diet and exercise," [ID 26] or "wear sunscreen," [ID 9] for example, but did not explicitly mention alcohol.

Theme 2: Time Commitment and Requirements of Intervention

The time commitment required of participants in the intervention was a concern for key informants, with one survivor describing the original 8-week TRAC program as "a lot for a working person" and "kind of overwhelming" [ID 68]. Other survivors expressed concerns that the time commitment may be a barrier to participation, saying "some people might think 'I don't want to do this for 8 weeks'" [ID 26] and "I think you're running into people not finishing, or just not wanting to do it, because it is too time consuming" [ID 68]. Likewise, providers and community advocates also expressed concerns about the required time commitment of the intervention. "I think 8 sessions will be tough to get," remarked one advocate [ID 18], and "doing something for an hour, you're going to lose their interest" [Oncologist, ID 15]. Participants from all 4 groups recommended flexible approaches to the intervention to help reduce the time burden. These approaches included changing the delivery format based on personal preference, that is, allowing participants to choose 8, 30-minute sessions or 6, 40-minute sessions based on what fit best in their schedules.

Participants also expressed concern about adherence to twice-daily surveys for the full 8-week period, with one participant stating they "wonder about compliance with daily surveys, that would be one thing that might be hard for people for 8 weeks" [Psycho-Oncologist, ID 11]. Participants offered ideas to better encourage completion of these daily monitoring tasks, including monetary compensation, prize drawings, and the ability to track other health behaviors relevant to survivors.

Theme 3: Information on Cancer Survivorship, Cancer Recurrence, and Alcohol Use

Both the oncology and psycho-oncology provider groups had strong recommendations surrounding the intervention content, specifically content about survivorship and recurrence in the context of survivors' alcohol use. Participants from these groups suggested providing "more context about the relationship between alcohol and the cancers listed in the intervention manual" [Oncologist, ID 14]. One psycho-oncology provider suggested adding information about "specific health issues related to cancer, and how alcohol might impact those issues as well," (eg, worsened mental health as a result of cancer diagnosis and treatment, conditions caused by drug side effects) [ID 11]. However, participants noted the need to be mindful of the wording used when discussing alcohol use and cancer to avoid triggering feelings of guilt or shame, saying "you need to make it non-judgmental right from the get go," [Oncologist, ID 14] and "I think helping them understand how drinking can be problematic without making them feel guilty or stigmatized" [Psycho-Oncologist, ID 3].

Theme 4: Inclusion of Cancer-Specific Triggers

All 4 groups remarked on the need to expand on the types of alcohol use triggers discussed in TRAC as there are unique circumstances and stressors which impact the lives of cancer survivors. One survivor participant stated, "There's a potential for medical triggers—like having to go back to the doctor" [ID 4]. Another participant echoed this sentiment, saying,

> *There would be a benefit of including some potential triggers related to their cancer survivorship status, like, drinking to manage anxiety about follow up scans* [Psycho-Oncologist, ID 10.]

Other suggestions included discussing the financial burden that many survivors face due to cancer treatment and including information relating to reproductive health concerns or fertility, with participants from multiple groups stating that these could be triggers for adolescents and young adults.

Theme 5: Hesitation Toward Mobile Breathalyzers

The use of breathalyzers was an area of concern for interviewees, with many suggesting that intervention participants may find them off-putting. One survivor remarked, "It's almost downgrading [sic]…they might feel bad about themselves when they do it" [ID 68], with another survivor suggesting that they would not complete a breathalyzer reading if they have been drinking because they would not want to see that recorded—"I wouldn't be against it, but I wouldn't actually use it. I've had too much to drink…do I really want that being recorded?" [ID 20]. Others expressed concerns about the data obtained from breathalyzers—whether participants would complete the readings if they had been drinking, or if participants would fabricate data to avoid feelings of judgment. One provider participant stated that "[relying] on them to be able to give you that data when they're impaired is probably wishful thinking" [Oncologist, ID 14]. Informants recommended using neutral, nonstigmatizing language when discussing the monitoring procedures with participants. A participant from the community advocate group emphasized this, saying, "It will be important that they feel respected, valued, and safe to be willing to be that vulnerable" [ID 16].

Adaptations Following the Key Informant Interviews

Significant changes were made to TRAC based on feedback from the key informant interviews, resulting in the new TRAC adolescent and young adult intervention. The most notable changes involved (1) reducing the length and time commitment of the intervention to accommodate the busy schedules of adolescents and young adults and (2) adding new content to address the link between alcohol and cancer and cancer-specific triggers among adolescent and young adult cancer survivors. Core components (eg, identifying and managing triggers) were maintained. Refer to Table 4 for a summary of the new intervention content and key intervention changes, discussed in more detail below.

XSL•FO
RenderX

Table . New tracking and reducing alcohol consumption in adolescents and young adults intervention.

Session number	Session emphasis	Session content	Summary of changes from TRAC[a]
Session 1	Understanding your drinking and reasons for change	1. Education on alcohol and cancer survivorship 2. Review current drinking behaviors, when and why they drink 3. Identify reasons for changing drinking behaviors (change plan) 4. Skill: Breathing awareness, deep breathing	1. Removed self-monitoring and phone training (moved to orientation) 2. Added education on alcohol and cancer survivorship 3. Added breathing awareness and deep breathing skill training (TRAC Session 3)
Session 2	Managing your biggest trigger for drinking	1. Introducing concept of triggers and different types 2. Managing emotional OR situational or social triggers 1. Building skills and brainstorming strategies for addressing relevant triggers 3. Skill: Riding the wave for urges and cravings 4. Suggested activities to do instead of drinking	1. Combined TRAC sessions 2 and 5 - 7 on emotional, situational, and social triggers into one session (participants choose which is most relevant) 2. Added urge surfing skill building to replace TRAC Session 4 (Managing Urges & Cravings) 3. Added list of suggested activities to do instead of drinking (TRAC Session 3)
Session 3	Understanding and managing cancer-specific triggers	1. Fear of recurrence and surveillance 2. Managing financial concerns OR Reproductive health worries 3. Building skills and brainstorming strategies for coping with relevant triggers (eg, creating a survivorship care plan, seeking support from others)	All new content developed for TRAC-adolescent and young adult
Session 4	Looking ahead	1. Summative self-assessment 2. Planning for the future 3. Finding resources in your community	Added additional resources for ongoing support

[a]TRAC: tracking and reducing alcohol consumption.

Adaptations to Reduce Overall Time Commitment

TRAC (8 sessions) became TRAC adolescent and young adult (4 sessions)—collapsing the 3 sessions devoted to the types of potential triggers into one, and adding a separate session focusing solely on triggers specific to cancer survivorship. A key part of reducing the number of intervention sessions involves allowing survivors to choose which topics are most relevant to them for discussion, which also allows the intervention to feel more tailored to their needs and experiences. In the new TRAC-adolescent and young adult intervention, participants are asked to describe the context of their typical drinking experiences, and the counselor works with them to determine if they are most often drinking due to social, situational, or emotional triggers. They then focus specifically on those kinds of triggers during the intervention (versus covering all types of triggers, as done in the original TRAC intervention). These sessions are intended to last 30 - 45 minutes.

A brief orientation session with the study coordinator was also added to enrollment procedures so that the interventionist did not need to spend time discussing the self-monitoring tasks or overall study procedures. This orientation session lasts between 15 and 20 minutes and includes a review of study protocols, training on the mobile breathalyzers and self-monitoring procedures, and scheduling future study tasks. Importantly, in response to concerns raised during the interviews, the study coordinator emphasizes the confidentiality of breathalyzer results and addresses any participant concerns about the breathalyzer during this session.

As an added measure to reduce study burden for this population, we reduced the number of required self-monitoring tasks; in the original TRAC intervention, participants completed both a breathalyzer reading and mobile survey twice each day (4 tasks total). Though completion rates for these were relatively high in the original intervention (median of 85% of mobile surveys and 78% of breathalyzers) [14], it was tested in an older adult population with fewer competing life demands than adolescents and young adults. In recognition of these and the concerns raised

XSL•FO
RenderX

by participants, it was determined that for TRAC-adolescent and young adult, we would ask participants to complete one morning survey and one evening breathalyzer reading (2 tasks total), completed at the time of their choosing.

Tailoring Intervention Content for Adolescent and Young Adult Survivors

For Session One, we developed a fact sheet that described the link between alcohol use and cancer, given that the topic is not often discussed in survivorship settings. This fact sheet (Can be found in Figure 1 for example) describes suggested drinking limits, the link between certain types of cancer and alcohol use, information about alcohol use and cancer recurrence and development of second primaries, how tobacco use and alcohol intersect to increase cancer risks, and other health effects of alcohol use. All participants receive this fact sheet in their participant manual, and the interventionist discusses it with them at the beginning of the intervention.

As mentioned, we also added a new session focused specifically on cancer-related triggers for alcohol use as reported through the key informant interviews (Session 3). We included content on fear of recurrence and surveillance, which addresses "scanxiety" and provides strategies for addressing cancer-related worry. These strategies include tips on how to find trustworthy information online, making a survivorship care plan, and suggestions for challenging negative thoughts, among others. Participants could choose between discussing financial toxicity or fertility concerns. For each topic, participants were encouraged to set actionable goals for addressing these concerns through seeking support or additional information, and they also received a resource guide to help them achieve those goals.

In addition, based on suggestions received from key informants to bolster adolescent and young adult engagement over the full study period, we added the option to track more health behaviors and outcomes through daily surveys (eg, mood, sleep quality, and physical activity). It was determined that participants would be allowed to track up to 3 of these additional health metrics and would receive a weekly report of their responses.

XSL•FO
RenderX

Figure 1. Excerpt from alcohol and cancer fact sheet.

Discussion

Principal Findings

Both survivors and providers suggested that alcohol use is not routinely discussed in cancer care. This has been reported in previous research [23], though the literature in this area is scarce; in a large representative sample of US survivors, approximately 40% reported not discussing alcohol use with their clinician. Another study [24] of head and neck cancer survivors found that while only approximately 40% of survivors who drank recalled receiving advice from their oncology clinician regarding their alcohol use, those who received such advice were significantly more likely to reduce their alcohol use. These studies not only point to the need for developing approaches to address alcohol use in the context of cancer care, but also to the potential value of such approaches in reducing alcohol use among survivors.

XSL•FO
RenderX

Participants in the key informant interviews provided many suggestions for adapting TRAC content to better suit the adolescent and young adult survivor population. Several of these changes concerned reducing the time commitment of the intervention, including reducing the number of sessions from 8 to 4 and decreasing the number of required daily assessments. These changes were made to better accommodate the life circumstances of adolescents and young adults, many of whom are already struggling to cope with challenges relating to their education, career and employment, and intimate or familial relationships [25,26].

We also added cancer-specific triggers for alcohol use to the intervention to better tailor the content for adolescent and young adult survivors. Our goal in discussing cancer-specific triggers was to provide survivors with the necessary resources to manage the stress associated with these triggers and to increase coping self-efficacy, which in turn may help to reduce alcohol use as a coping mechanism [27,28]. Information relating to the financial concerns of survivors was added to the intervention. Financial toxicity, which can be described as the issues that arise in patients' physical and mental health due to the costs of medical care, can have a significant impact on the lives of adolescent and young adult survivors—data show that adolescents and young adults see higher medical costs than their unaffected peers [29], and, depending on the type of cancer and treatments received, survivors may face challenges in entering or returning to work [30]. Previous research suggests that financial concerns and survivors' mental health are closely related [31]. We also added content related to fertility and reproductive health concerns, which was discussed as a potential trigger by key informants and has been shown to be a common stressor for adolescent and young adult survivors. A qualitative study showed that survivors felt as though fertility was an afterthought in their cancer care and wanted more information about reproductive health [32]. Another study demonstrated the gaps in survivors' knowledge about their own fertility and reproductive health [33], which, when left unaddressed, can be distressing for survivors. Finally, we also added content on cancer-related worry and fear of recurrence. These sources of stress have been found to have a negative impact on survivors' overall quality of life [34], and survivors who report having a fear of recurrence or worry surrounding medical appointments or scans—"scanxiety"—report increased psychological distress [8,35]. Given the impact of these topics on adolescents' and young adults' mental health, it is not surprising that key informants suggested that they may also impact drinking.

In making the aforementioned changes to the intervention, the necessity of considering adolescents' and young adults' unique triggers for alcohol use and their life circumstances when developing interventions became clear, especially in light of the significant stressor of a cancer diagnosis, its treatment, and its physical and psychosocial sequelae. Obtaining feedback from members of this group and key stakeholders in their care was invaluable, and the willingness to participate and bolster care for this understudied group was a strong facilitator for this type of formative work. A barrier to adapting this intervention for adolescents and young adults was the diversity of members of the adolescent and young adult population, which spans all genders, includes people ranging from age 15 to 39 years who represent very different life stages, and includes people who were diagnosed as both adolescents and young adults. Thus, the population of adolescents and young adults is relatively heterogeneous, making it difficult to identify triggers that are relevant for the whole population. For that reason, we maintained core alcohol triggers (emotional, situational, and social) and added what are likely the most common cancer-specific triggers adolescents and young adults may experience (fear of recurrence, financial worry, and worry about fertility). To personalize the intervention and meet the need of maintaining brevity, adolescents and young adults are guided to choose their most salient core trigger and work through the content for fear of recurrence as a trigger, with the option of also completing financial worry or worry about fertility, depending on relevance to them. Future researchers aiming to adapt interventions for the adolescent and young adult population should take care to consider the heterogeneity of this group, obtain feedback from individuals representing various subgroups of this population, and consider offering opportunities for participants to tailor interventions to better suit their interests and circumstances.

Limitations

This study is limited by its lack of racial or ethnic diversity among participants and its small sample size, though a large sample was not the purpose of this current study. Of the 15 key informants who participated in interviews, the majority were white, non-Hispanic. Though consistent with our cancer center's catchment area, we acknowledge that this sample may not represent those of different racial or ethnic backgrounds. Our focus in this study was specifically on survivors who live in rural areas and may not represent survivors who live in urban or suburban areas. Further tailoring to the TRAC-adolescent and young adult intervention may be needed to adapt to the specific needs of populations not represented in the key informant interviews. In addition, current hazardous alcohol use was not a criterion for eligibility for survivors to participate; however, most did meet criteria for hazardous use.

Conclusions

There is potential to increase alcohol intervention relevance and fit for adolescents and young adults by including tailored content relevant to their life experiences while also maintaining core components of such interventions, such as self-monitoring and goal-setting. Remote, brief interventions are important for ensuring acceptability. The new TRAC-adolescent and young adult intervention represents a potentially valuable tool in addressing high rates of hazardous alcohol use among this population and warrants further evaluation in randomized trials. As mentioned, this study was part of a larger project to develop and pilot a tailored alcohol reduction intervention for adolescent and young adult survivors of cancer. An open pilot trial and pilot randomized controlled trial (ClinicalTrials.gov NCT05087875) were completed to determine the feasibility and acceptability of this new intervention. Results of the RCT are forthcoming. If efficacious, TRAC-adolescent and young adult has the potential to provide an accessible, scalable

XSL•FO
RenderX

intervention approach for addressing alcohol use among posttreatment adolescents and young adults.

Abstract

Background: Survivors of metastatic lung cancer (MLC) face a heightened risk of developing second primary cancers (SPCs), which significantly impact long-term outcomes. Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, but their potential role in reducing SPC risk remains underexplored. This study investigates the association between ICI treatment and the incidence of SPCs in a large, real-world cohort of patients with MLC.

Objective: This study aims to evaluate whether treatment with ICIs is associated with a reduced risk of developing SPCs in patients with metastatic or locally advanced lung cancer, using real-world data from the TriNetX global health research network.

Methods: We conducted a retrospective cohort study using the TriNetX Global Collaborative Network, which aggregates deidentified electronic health records from more than 135 million patients. Adults diagnosed with MLC between February 2004 and February 2024 were included. Patients were divided into 2 cohorts based on ICI exposure. Propensity score matching was applied to balance baseline characteristics. Kaplan-Meier survival analysis and Cox proportional hazards models were used to assess the incidence of SPCs and the composite outcome of SPC or death.

Results: Among 2844 eligible patients, 685 received ICIs and 2157 did not. After propensity score matching, both cohorts included 685 patients. The 5-year incidence of SPCs was lower in the ICI group (1.5%) compared to the non-ICI group (4.2%), with a hazard ratio of 0.49 (95% CI 0.24 - 1.01), suggesting a potential protective effect. Furthermore, ICI treatment was significantly associated with a reduced risk of the composite outcome of SPC or death (hazard ratio 0.74, 95% CI 0.62 - 0.89). Median follow-up was 20.2 (IQR 60-not reached) months for the ICI group and 68.4 (IQR 36-not reached) months for the non-ICI group.

Conclusions: In this large real-world cohort, ICI treatment was associated with a lower risk of developing SPCs and improved overall outcomes in patients with MLC. These findings support the hypothesis that ICIs may offer a preventive benefit beyond their primary oncologic indications. While the retrospective nature and data limitations warrant cautious interpretation, this study underscores the value of real-world evidence in identifying novel therapeutic benefits and guiding future prospective research.

Introduction

The trajectory of cancer treatment has undergone a transformative evolution, heralding the integration of immune checkpoint inhibitors (ICIs) as a seminal component in the therapeutic armamentarium [1].

This shift has been characterized by innovative strategies encompassing neoadjuvant, adjuvant, and, more recently, perioperative applications of ICIs, changing treatment paradigms and integrating immunotherapies to improve therapeutic outcomes and patient survival [2]. These strategies aspire to enhance the efficacy of primary tumor management, reducing disease relapse, enabling less invasive surgical interventions,

XSL•FO
RenderX

and targeting minimal residual diseases in a spectrum of cancer types.

A recently identified positive facet of significant interest is the potential role of ICIs in mitigating the risks associated with the occurrence of second primary cancers (SPCs)—observed in over 7% of cancer survivors [3]. Amidst a confluence of risk factors such as genetics, environmental exposures, and therapeutic side effects, SPCs emerge as a significant risk impacting long-term survival of cured patients, warranting innovative preventive strategies. A retrospection into clinical data suggests a spectrum of impacts associated with ICIs usage, ranging from associations with reduced SPC occurrences [4-7] to a lack of conclusively protective effects [8,9]. This nuanced clinical tableau underscores the inherent complexities and variables, including histologic considerations and therapeutic contexts, that influence the potential effectiveness of ICIs as a preventive arsenal against SPCs. Although a phase II randomized trial is currently enrolling to answer this important question (NCT05855811) [10], it seems fundamental to continue evaluating the potential impact of ICIs on the risk of SPC, using new extensive retrospective cohorts of patients with cancer. That is why, therefore, we analyzed data from the TriNetX global health research platform that includes data on 30 million patients from Europe to the United States to contribute to improving scientific knowledge [11,12].

The primary objective of this study is to use real-world data from the TriNetX federated data network to investigate the impact of ICIs on the risk of SPC in patients treated for metastatic or locally advanced lung cancer. This exploration aims to provide insights into the potential of ICIs to serve as a preventive strategy against SPCs, thereby informing clinical practice and guiding future research in this critical area.

Methods

Data Source and Patient Selection

This noninterventional, retrospective cohort study used data from the international TriNetX Global Collaborative research data network. The primary goal of this research is to evaluate the effect of ICIs treatment for metastatic lung cancer (MLC) on the likelihood of developing a SPC outside the lungs in a real-world scenario. We studied patients from TriNetX with MLC aged 18 years or older. TriNetX is a global collaborative research network that provides real-time access to electronic medical records (diagnoses, procedures, medications, laboratory values, and genomic information) from more than 135 million patients from 114 health care organizations (HCOs), primarily from North America and Western Europe [12]. All data collection, processing, and transmission is done in compliance with all Data Protection laws applicable to the contributing HCOs, including the EU Data Protection Law Regulation 2016/679, the General Data Protection Regulation (GDPR) on the protection of natural persons with regard to the processing of personal data, and the Health Insurance Portability and Accountability Act (HIPAA), the US federal law that protects the privacy and security of health care data. The Global Collaborative Network is a distributed network, and analytics are performed at the HCO, with only aggregate results being returned to the platform. Individual personal data does not leave the HCO. TriNetX is ISO 27001:2013 certified and maintains a robust IT security program that protects both personal data and health care data. Data collection and quality control methods have been described [11]. As a federated network, research studies using TriNetX are compliant with requests from ethics committees of all contributing countries [13]. To comply with legal frameworks and ethical guidelines guarding against data reidentification, the identity of participating HCOs and their individual contribution to each dataset are not disclosed.

Selected patients were men or women, aged 18 or older, with a diagnosis of MLC between February 1, 2004, and February 1, 2024, to capture the full evolution of ICI use in clinical practice. This extended timeframe allows for robust comparisons across different treatment eras and reflects real-world changes in therapeutic strategies over time. SPCs were identified using *International Classification of Diseases* codes for new primary malignancies at anatomical sites other than the lung, with a minimum latency of 6 months after the initial lung cancer diagnosis, to distinguish them from recurrences or metastases [14]. Due to data limitations, most SPCs identified were metachronous, and synchronous cases could not be reliably assessed. Patients were excluded when (1) a patient died or had a non–lung cancer diagnosis within the first 6 months after the metastasis diagnosis, (2) patients never had a visit to the HCO before the metastasis diagnosis, (3) patients never had a follow-up visit after 6 months of the metastasis diagnosis, (4) patients had lung cancer as the SPC given the difficulty in clinical practice in differentiating a second primary lung cancer from a new metastatic localization of the treated lung cancer, and (5) patients did not have any data of treatment after the metastasis. The initial group of participants was then divided into 2 cohorts. The “ICI” group included patients treated with ICI after the metastasis diagnosis and the “non-ICI” group included patients never treated with ICI. For this study, data were collected until February 25, 2024 (ie, database extraction date). The details on the codes and criteria used to define the cohorts can be found in the Multimedia Appendices 1 and 2.

Statistical Analysis

All the statistical analysis was done using the TriNetX platform’s built-in analysis features. ICI and non-ICI cohorts were propensity score matched (PSM) before the comparison on age at the moment of the metastasis diagnosis, gender, race (when available), de novo MLC, smoking, and patient dependency status [15,16]. The index event of both cohorts was the metastasis diagnosis, and the follow-up time window was 10 years.

Baseline characteristics before and after PSM are presented with the number and percentage for categorical variables and mean and SD when variables are numeric. Categorical variables are compared between cohorts with the Fisher exact test *P* value and the standardized mean differences. Numeric variables are compared with the *t* test *P* value and standard difference.

Kaplan-Meier analysis was performed on the matched cohorts to calculate the time between the MLC diagnosis and the SPC. Cox proportional hazard ratios (HRs) and 95% CIs are presented.

Ethical Considerations

This study was conducted using data from the TriNetX Global Collaborative Network, which provides access to aggregated and deidentified electronic health records. As such, it was exempt from institutional ethics review [17]. All data handling complied with relevant data protection regulations, including the GDPR in the European Union and the HIPAA in the United States. Data collection and quality control methods have been described [11], and research studies using the TriNetX federated network are compliant with ethics committee requirements of all contributing countries [13]. To safeguard participant privacy, only aggregated counts and deidentified information are used, and no protected health information or personal data is made available to platform users. The process of deidentification has been formally attested by a qualified expert in accordance with Section §164.514(b)(1) of the HIPAA Privacy Rule (last updated in December 2020). As such, additional institutional review board approval or informed consent is not required for studies performed within TriNetX. This formal determination by a qualified expert, refreshed in December 2020, supersedes the need for TriNetX's previous waiver from the Western Institutional Review Board.

Results

The current analysis considered the 2844 patients with metastatic primary lung cancer selected in the TriNetX network. The study population included 685 patients in the ICI group and 2,157 in the non-ICI group. Patient characteristics are summarized in Table 1. After PSM, both cohorts included 685 patients. A total of 251 (36.6 %) in ICI and 252 (36.8%) non-ICI patients were women, with a mean age of 66.8 (SD 9.7) years and 67 (SD 10) years, respectively. Among them, 216 (31.5%) patients had de novo metastatic disease and 171 (25%) were smokers or former smokers in the ICI cohort. In addition to ICI, 684 of 685 (99.9%) patients in the exposure cohort received at least 1 chemotherapy regimen, and 75 of 685 (10.9%) patients received at least 1 more targeted treatment. Concerning locoregional treatment, 231 of 685 (33.7%) patients were treated by radiotherapy and 41 of 685 (6%) patients had surgery in a metastatic setting. The median follow-up was 20.2 (IQR 60-not reached) months for ICI and 68.4 (IQR 36-not reached) months for non-ICI.

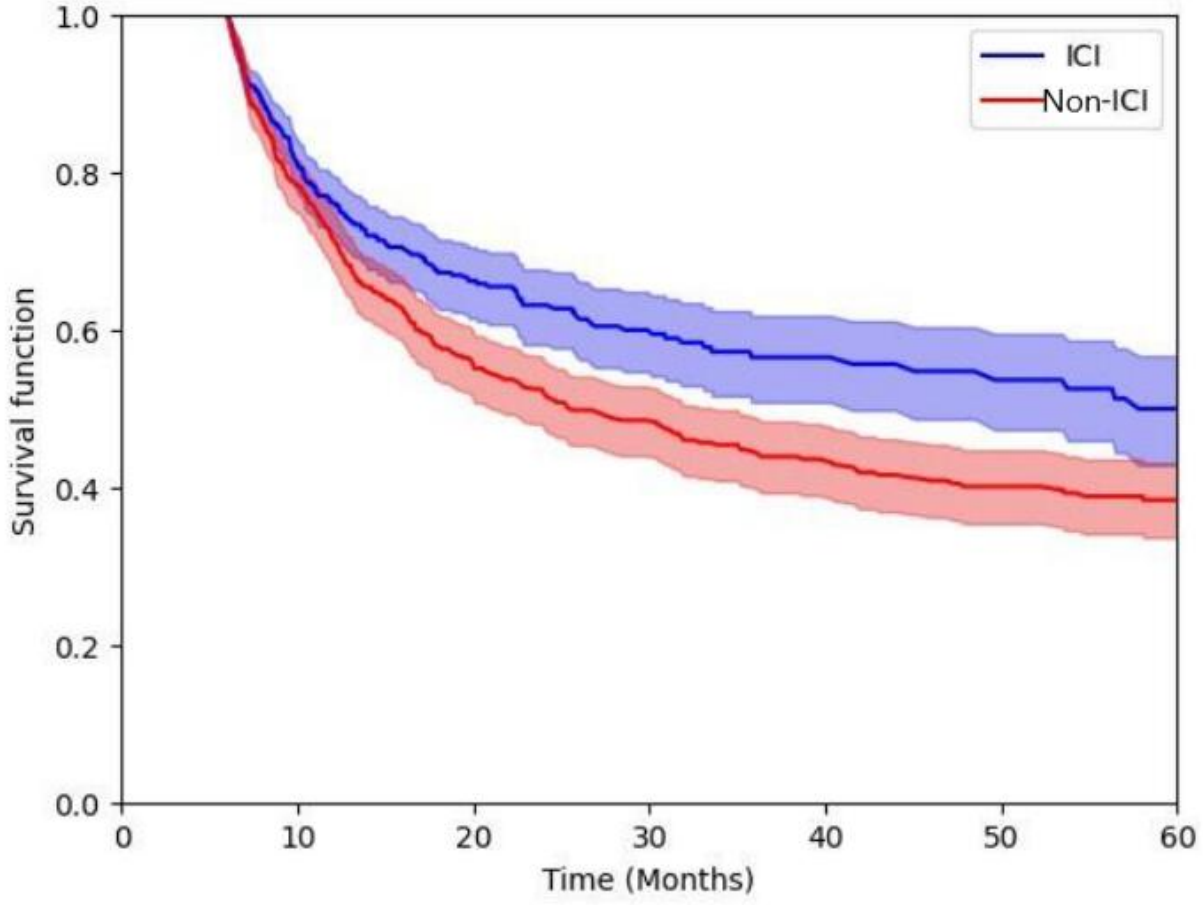
[a]ICI: immune checkpoint inhibitor.

Overall, 39 of 685 (2.8%) patients had a diagnosis of SPC, out of which, 10/685 (1.5%) patients with SPC were reported in the cohort of receiving ICI for their lung cancer in a median interval of 13.9 months (IQR 7-22) versus 23 (3.6%) in a median interval of 17.8 (IQR 9-28) months in patients who did not receive ICI (HR 0.49, 95% CI 0.24 - 1.01; *P*=.05) (Figure 1). Among the patients who received ICI, the median time between the diagnosis of advanced or metastatic LC and ICI was 34 days (IQR 21-68 days). The median time between ICI initiation and the diagnosis of SPC was 9 (IQR 1.4 - 15.1) months.

XSL•FO
RenderX

Figure 1. Kaplan-Meier curve for second primary cancer. ICI: immune checkpoint inhibitor; SPC: second primary cancer.



Months	0	10	20	30	40	50	60
ICI	685	388	211	146	146	146	146
Non-ICI	685	476	284	240	172	133	107

Age, gender, race, de novo MLC, smoking, and patient dependency status were identified as potential confounding variables and were included in the propensity score analyses. Standardized mean differences after weighing were within ±0.1 for all observed confounding variables (Multimedia Appendix 1).

Figure 2 presents the time from the diagnosis of MLC to the date of SPC diagnosis or the date of death in patients having received ICI or not for lung cancer. Treatment with ICI for lung cancer was associated with a significant risk reduction of SPC or death (HR 0.74, 95% CI 0.62 - 0.89; *P*<.01). The median months to MLC or death were 9.6 (IQR 4-20)and 11.2 (IQR 5-25) for patients treated with ICI and not treated with ICI, respectively.

Discussion

Principal Findings

Our study, encompassing 2844 patients with metastatic primary lung cancer from the TriNetX network, indicates a significant impact of ICIs on the incidence of secondary primary cancers and overall survival, showcasing the power of large-scale data in generating valuable insights. This study highlights the critical role of big data and digital health in advancing cancer treatment and research. The TriNetX network, encompassing numerous international centers, exemplifies how big data can be leveraged to conduct extensive and robust studies. The analysis, balanced post-PSM with 685 patients in each cohort, revealed that ICI treatment was associated with a reduced risk of developing SPCs. Specifically, the incidence of SPCs excluding lung cancer was 1.5% in the ICI group compared to 3.6% in the non-ICI group, translating into a risk difference of −0.028 and a favorable HR of 0.49. In addition, our findings demonstrated a reduction in the risk of SPC or death in patients treated with ICIs, with a significant HR of 0.78. This suggests not only the efficacy of ICIs in treating primary tumors but also their potential role in preventing secondary malignancies. The median time to MLC or death was notably higher in the ICI-treated group, further emphasizing the survival benefits of ICIs. The interpretation of the composite endpoint “SPC or death” is limited by the potential confounding effect of overall survival, as death may censor the observation of SPCs. Moreover, patients treated with ICIs may live longer, thereby increasing their window of risk for developing SPCs, which could paradoxically elevate SPC incidence in this group despite a protective effect of immunotherapy.

Comparison With Prior Work

Our findings align with prior studies suggesting a decreased incidence of patients with SPCs treated with ICIs, such as those by Heudel et al [4-7]. However, our work extends these observations by analyzing a larger, more recent, and real-world cohort of patients with MLC (N=2844) with PSM and an updated follow-up through 2024. Unlike previous studies that included various primary tumor types, we focused specifically on metastatic or locally advanced lung cancer, enhancing the

XSL•FO
RenderX

interpretability within a defined clinical context. Moreover, our study leverages the robust infrastructure of the TriNetX platform [18], enabling federated access to real-world data across multiple international HCOs and offering methodological transparency and reproducibility. Recent immunogenetic research supports a biological rationale for ICI-mediated protection: a large UK Biobank study identified specific HLA alleles associated with either increased or decreased SPC risk, suggesting that the adaptive immune system, and thus immune modulation via ICIs, may play a key role in SPC prevention [18]. In addition, population-level evidence from Sweden highlighted strong bi-directional associations between myeloid malignancies and various SPCs, likely involving immune dysfunction or treatment-induced changes [19]. Taken together, these studies reinforce the hypothesis that immune surveillance mechanisms are central to SPC susceptibility. Our results, combined with this growing body of evidence, support the concept that ICIs may offer not only survival benefits but also a protective effect against SPCs, especially in patients with immune-related predispositions.

Strengths and Limitations

Of course, our study of many limitations began with its retrospective nature. Even if the TriNetX network is extremely important, with numerous international centers, it clearly appears that the scope of the available data remains limited since we do not have, for example, the histological subtypes, or the smoking status, and even less the molecular characteristics of cancers. These missing data constitute a major limitation to the conclusions of our study and to the question of the accessibility and the sharing of these data, which are necessarily present in the electronic medical records [20]. Learned societies have recently established recommendations on real-world data studies, the quality of the conclusions of which is directly linked to the quality of the data obtained [21].

However, the effectiveness of big data and digital health hinges on the quality and comprehensiveness of the data. We must not forget the importance of real-world data that are complementary to clinical trials [22], particularly on subjects such as the appearance of a SPC for which these patients are often excluded from traditional clinical research studies. It therefore appears fundamental to continue collaboration within, for example, the TriNetX network because the greater the volume and completeness of the data, the greater the confidence in the conclusions of these retrospective studies [12]. For this, it seems necessary for each hospital to define its digital data strategy, which must include a data collection strategy (by aligning them from the start with international benchmarks), for the qualification of this data, for their analysis with quality control, and a sharing strategy [23]. This entire strategy must, of course, respect the regulations in force and integrate a priori the question of interoperability to facilitate data sharing and enhance research outcomes [24,25].

Future Directions

To maximize the potential of big data and digital health, continued collaboration within networks such as TriNetX is essential. The greater the volume and completeness of the data, the higher the confidence in the study conclusions. Recommendations from learned societies on real-world data studies emphasize the importance of data quality, suggesting that the robustness of study conclusions is directly linked to the quality of the data obtained.

Conclusions

In conclusion, our study showed that patients treated with ICIs for a first lung cancer had a reduced risk of an SPC and underscores the significant benefits of using big data and digital health in cancer research. The ability to conduct real-life studies on an international network such as TriNetX allows for the inclusion of diverse patient populations and the generation of real-world evidence that complements clinical trials. Despite current data limitations, continued network collaborations and strategic data management can enhance the relevance and impact of real-world data studies, ultimately improving patient outcomes and advancing medical knowledge.

Abstract

Background: Cancer survivorship is a complicated, chronic, and long-lasting experience, causing uncertainty and a wide range of physical and emotional health concerns. Due to the complexity of cancer, patients often seek out multiple sources of health information to better understand the aspects of their cancer diagnosis. The high variability among patients with cancer presents significant challenges in treatment, prognosis, and overall disease management. Artificial intelligence (AI) chatbots can further personalize cancer care delivery. However, there is a knowledge gap regarding cancer survivors' perceived facilitators and barriers to adopting and using AI chatbots.

Objective: In this study, we examined cancer survivors' experiences of using existing AI chatbots and identified their facilitators and barriers to the adoption of AI chatbots.

Methods: We conducted a qualitative study to investigate the perceptions of cancer survivors, conducting semistructured interviews to understand their prior use of existing AI chatbots in general. We asked the participants about their perceptions regarding AI chatbot acceptability and comfort level; trust and adherence; and concerns, barriers, and suggestions. We used the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist for this qualitative report.

Results: Of 21 participants, 17 (81%) were female patients with breast cancer, 15 (71%) were aged 50 to 64 years, 19 (90%) were White, and 9 (43%) had a graduate degree. Participants' responses were grouped into three overarching themes: (1) patients' perceptions of interacting with chatbots compared to health care professionals, (2) patient-chatbot interaction, and (3) chatbot information processing. All participants who were interviewed reported that they would prefer interacting with health care professionals over a chatbot. The lack of empathy shown by chatbots was a major concern among cancer survivors. Many patients criticized chatbots for tending to provide a general overarching response to their questions rather than being specific to their cancer diagnosis. The main concerns of cancer survivors with using chatbots were the overabundance of general information that was often not relevant to their diagnosis and privacy of patient information.

Conclusions: The findings of this study underscore the critical importance of empathetic responses during AI chatbot interactions for cancer survivors, as the lack of personalized and emotional responses can lead to distrust and frustration. Clinically, these tools should be integrated as supplementary resources to enhance patient engagement while preserving essential human support. Policymakers need to develop guidelines that promote responsible use of AI in cancer care, prioritizing patient confidentiality and trustworthiness. AI chatbots have the potential to significantly improve the support provided to cancer survivors, but it is crucial to address the identified barriers and enhance user acceptance.

Introduction

Cancer is a complex and highly individualized disease [1]. Cancer survivorship, which extends from the time of diagnosis through the balance of life, is a complicated, chronic, and long-term experience that can cause uncertainty and a wide range of physical and emotional health concerns [2]. Due to the complexity of cancer, patients often seek out multiple sources of health information to better understand the aspects of their cancer diagnosis. Patients with cancer show extreme variability in disease progression, treatment response, and side effects, at least partly due to genetic differences, tumor heterogeneity, and immune system variations [3,4]. This variability makes treatment standardization and outcome prediction difficult, necessitating personalized treatment strategies that general medical guidelines may struggle to accommodate accurately [5-7]. Patients with cancer also require continuous monitoring and tailored supportive care to address complicated prognoses, as patients with similar diagnoses may experience vastly different disease trajectories and treatment-related side effects [8]. These complexities underscore the need for the provision of personalized, evidence-based oncological information tailored to unique cancer cases to optimize treatment efficacy and improve patient outcomes [9].

Artificial intelligence (AI) chatbots have revolutionized health information seeking [10]. These large language model (LLM)–based conversational agents enhance health care by improving access to medical information, supporting clinical decision-making, and automating administrative tasks, reducing the burden on health care professionals (HCPs) [11,12]. They also improve patient engagement through symptom tracking, medication reminders, and mental health support while aiding medical education with up-to-date resources [13]. Additionally, LLMs contribute to early disease detection by analyzing patient data trends, ultimately improving diagnosis and treatment outcomes.

Previous research evaluating chatbots predominantly focuses on accuracy and does not sufficiently examine user acceptance [10,14]. One study reported that chatbots may aid in drafting responses to patient questions, although there were concerns about the level of empathy provided compared to humans [15,16]. Chatbots may be able to provide personalized responses—as a supplement to medical care—about treatment side effects, pain management options, receiving follow-up care, and navigating complex health information. Current research evaluating responses to cancer-related prompts using generative pretrained transformer (GPT)–based chatbots indicates that there is a need for further development and optimization for health care implementation [11-15]. Recent developments in cancer-focused chatbots such as OncoGPT (OncoAI Labs), Prostate Cancer Info (Prostatica Digital Health), IBM watsonx Assistant, and other AI-guided bots underscore the growing interest and potential for chatbots in oncology [16-19]. However, there is a knowledge gap regarding the barriers and facilitators that influence the adoption and use of AI chatbots among cancer survivors [20].

Examining the user acceptance of chatbots in cancer care is essential for determining how patients, caregivers, and HCPs incorporate these tools into their decision-making and support systems [21]. Patients with cancer require highly personalized and trustworthy information. If they do not trust chatbots or find chatbots useful, these tools may fail to provide meaningful support. Additionally, understanding user acceptance helps to identify barriers, such as privacy concerns, lack of emotional support, and data risks, which can inform the design of more patient-centered and clinically reliable chatbot interventions. High user acceptance can enhance patient education, symptom management, and emotional well-being, ultimately improving health outcomes [22]. Without proper acceptance, even the most advanced chatbot technology may remain underused, limiting its potential impact in oncology care. This study aimed to understand the user experience of cancer survivors using AI chatbots and characterize the facilitators and barriers to the adoption of AI chatbots.

Methods

Study Design

This qualitative study used a descriptive phenomenological design to explore cancer survivors' experiences with AI chatbots. Phenomenology was chosen to capture the participants' lived experiences and perceptions [23]. Our research team used the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist (Checklist 1) for the topics that were applicable to this qualitative report [24].

Participants

Our study included adults older than 18 years who met the definition of breast and prostate cancer survivors and who received cancer care in the United States. We chose to focus on breast and prostate cancer, as these are the most common cancer types in the United States and have the highest survival rates [25]. Experience of using a chatbot was not required. To determine the eligibility of cancer survivors for our study, we used the definition provided by the National Cancer Institute [26]: "An individual is considered a cancer survivor from the time of diagnosis through the balance of life." Treatment status was not considered an inclusion or exclusion criterion. By scanning a QR code in the study flyer, interested individuals were able to access a Qualtrics screening survey, which was used to determine the eligibility of cancer survivors (Multimedia Appendix 1). The email addresses of interested individuals were collected through the Qualtrics survey, and eligible cancer survivors were invited by email to participate in our study. No eligible participants refused participation or dropped out.

Ethical Considerations

The study was determined to be exempt from review by the University of North Carolina Institutional Review Board (approval number 23 - 1451). We recruited participants by sharing an electronic study flyer with local and national cancer survivor organizations. Recruitment was conducted between September 2023 and December 2024. All participants completed a screening survey to determine study eligibility. The screening survey data were anonymized but not deidentified. Informed

XSL•FO
RenderX

consent was obtained from all participants. The participants were informed about the ability to opt out of the study at any time. All participants received a US $25 gift card as compensation.

Recruitment Procedure

Only 4 prostate cancer survivors were recruited. However, this study did not aim to examine the differences in experiences between breast and prostate cancer survivors. Instead, it aimed to include diverse perspectives. We determined that there were similarities in the responses to interview questions between prostate and breast cancer survivors; therefore, we believe that saturation was adequately achieved for both groups.

Data Collection

The participants were asked to participate in a semistructured interview to share their experiences and perceptions regarding AI chatbots in health care. The interview guide contained an introduction, instructions, and 8 questions separated by section (Multimedia Appendix 1). In total, 4 questions were related to acceptability and comfort level; 2 questions were related to trust and adherence; and 2 questions were related to concerns, barriers, and suggestions. The participants were asked about their experiences with the use of or perceptions about any chatbots, rather than one specific chatbot, to expand the scope of responses. This study was qualitative in nature; therefore, we did not develop a hypothesis for our interview questions.

We used one-time, one-on-one Zoom interview sessions (version 6.5.12; Zoom Communications Inc) as our setting for data collection, with only the participant and researchers present. One of 3 research assistants conducted the interviews in this study (HM, SM, and MC). Two research assistants (HM and SM) were trained by a third research assistant (MC) while they shadowed her during the initial interviews, to ensure consistency in interview technique. The interviews were 20 to 30 minutes long and were conducted between September 10, 2024, and December 23, 2024. No repeat interviews were conducted. Field notes were collected during each interview. Participants were recruited until thematic saturation was reached for both cancer groups combined. We defined thematic saturation as the point at which no new codes or themes emerged, as described by Guest et al [27]. We determined that saturation had been achieved once responses to interview questions became repetitive across prostate and breast cancer survivor participants, and no substantial differences in themes were observed. All interviews were audio recorded on a secure, password-protected recording device. Audio recordings were uploaded to a secure, password-protected, Health Insurance Portability and Accountability Act–compliant server, along with audio file transcripts and field notes taken during interviews to capture key points. Before the interview, the participants were assigned a number to eliminate the possibility of identifying them from their responses. Audio recordings were separated by participant number, and no transcripts were returned to the participants after the interviews were concluded.

Data Analysis

An inductive thematic analysis was used to identify themes and patterns directly from the data collected in the interviews [23]. This method helped us to gain a nuanced understanding of the data while allowing for the emergence of unexpected themes and patterns common across participant responses. A codebook was developed to facilitate the analysis of patient transcripts via a priori coding based on the interview guide and emergent coding during the interview process. One researcher (MC) initially developed a draft of the codebook, and it was then refined by 4 researchers (HM, CR-B, AH, and SM). The overarching codes covered interactions with AI, perceptions of AI, perceptions of HCP communication, and cancer-specific patient experiences. Subcodes were then created within these parent codes to include specific patient concerns. Each interview was independently coded, by random assignment, by 2 of 5 authors (HM, CR-B, AH, SM, and MC). Interview transcripts were coded in Dedoose (version 9.2.22; SocioCultural Research Consultants, LLC). Coding discrepancies were discussed and resolved through consensus between 5 authors (HM, CR-B, AH, SM, MC, and SK). Data analysis was conducted after the conclusion of participant recruitment and the interview process. Stakeholders and participants were not involved in the development of codes or interpretation of findings.

Overarching Themes

After analyzing the coded transcripts in Dedoose, we identified various patterns that intersected across participant interviews. Three overarching themes emerged from the patterns identified. After coming to an agreement on each theme, 3 authors (HM, AH, and CR-B) retrieved all text with codes related to the respective themes. For each theme, relevant participant quotations were pooled into one table. Minor themes, or subthemes, corresponding to each theme were identified. Subthemes represented experiences or perceptions shared by multiple participants and contributed to a broader theme. Afterward, we independently ranked the relevance of each excerpt based on how adequately it illustrated each respective theme. We selected 2 excerpts for each subtheme. Each quotation was identified by participant number. Findings from these excerpts were then identified as either a facilitator or a barrier to the use of chatbots for the relevant themes.

Results

Principal Findings

Of 21 participants, 17 (81%) were female patients with breast cancer, 15 (71%) were aged 50 to 64 years, 19 (90%) were White, and 9 (43%) had a graduate degree (Table 1).

The experiences of patients with cancer interacting with a chatbot while receiving cancer care centered mainly around three themes: (1) patients' perceptions of interacting with chatbots compared to HCPs, (2) patient-chatbot interaction, and (3) chatbot information processing. Theme 1 describes the factors influencing patients' perceptions and experiences of interacting with and using chatbots versus interacting with HCPs. Theme 2 describes how patients can use chatbots, how chatbots present information, and how patients interpret chatbot responses. Theme 3 describes patient perceptions regarding how chatbots process information to create responses. Under each theme, we identified 3 to 4 subthemes. Barriers and facilitators were identified for themes 2 and 3. Barriers and facilitators were

XSL•FO
RenderX

not applicable to theme 1, as the findings focused on patients' general perceptions of chatbots relative to HCPs rather than on specific interactions with a chatbot where barriers or facilitators would emerge. Furthermore, because all participants indicated that they would prefer to seek medical advice about their cancer from an HCP rather than a chatbot, no barriers or facilitators were identified for theme 1, as these were merely factors that influenced patient preference for HCPs. Figure 1 summarizes all findings.

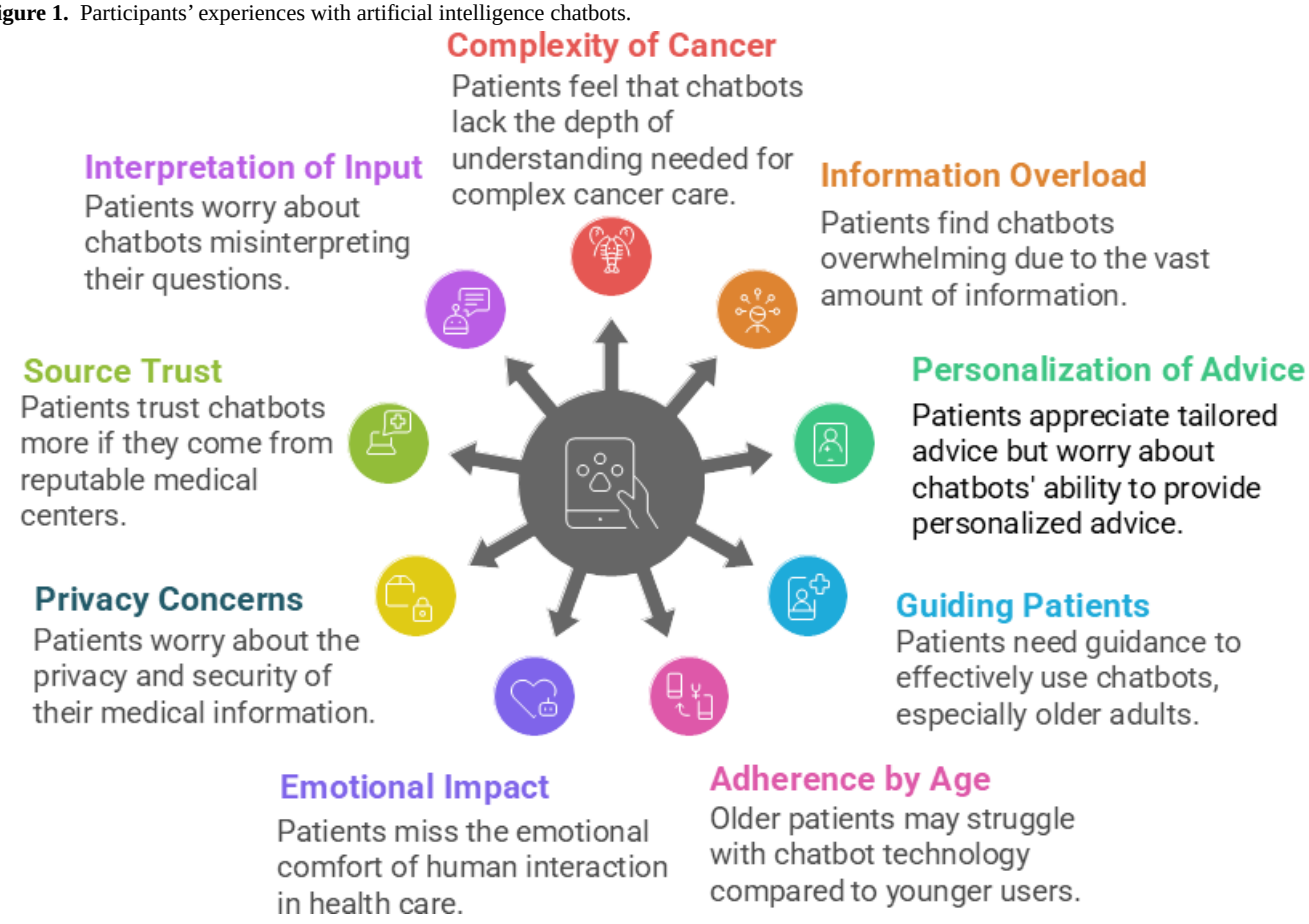

Table . Demographics of participants.

Characteristic	Prostate cancer survivors (n=4), n (%)	Breast cancer survivors (n=17), n (%)	Total participants (N=21), n (%)

Figure 1. Participants' experiences with artificial intelligence chatbots.

Theme 1: Patient Perceptions of Chatbots Compared to HCPs

There were ultimately two factors that influenced patients' preference for an HCP over a chatbot: (1) complexity of cancer and (2) information overload (Table 2). All participants indicated that they would prefer to seek medical advice for their cancer from an HCP rather than a chatbot.

While all participants indicated that they would prefer HCP input, some participants shared instances or characteristics of chatbots that would increase their likelihood of using a chatbot before seeking information from an HCP. One participant stated that the risk that is posed to their health and cancer outcomes affects whether or not they trust a chatbot's response. The participants generally reflected that they do not feel the need to consult with an HCP if their question is about a minor issue, such as a minor side effect of a procedure. Furthermore, the participants shared that if the chatbot provided evidence-based sources to consult along with its response, they would be less likely to follow up with their HCPs.

XSL•FO
RenderX

Table . Perceptions of patients with cancer regarding interactions with chatbots, categorized by subtheme.

Subtheme	Illustrative quote	Patient characteristics			
		Cancer type	Age group (years)	Race/ ethnicity	Education
Complexity of cancer	"I think it's because I feel that [HCPs] know more specifically of what's going on with me personally and they're able to see the big picture where I'm just not sure I can go in there and give the chatbot more details, but I still don't know if they don't know my full medical history and record. It's always good to just double-check and verify with my physician or oncologist just to make sure."	Breast cancer	35 - 49	White	Graduate degree
Complexity of cancer	"If it was something more specific like eat more ginger, I don't know, just as an example that maybe I need to check with my doctor to confirm that that's not going to interact with any of my medications that I'm already on or something like that because the chatbot is not going to know all of my medical history, all of my medications, that sort of thing. If it's more of a general question then I might not check with my doctor."	Breast cancer	35 - 49	White	Bachelor's degree

XSL•FO
RenderX

Subtheme	Illustrative quote	Patient characteristics			
		Cancer type	Age group (years)	Race/ ethnicity	Education
Information overload	"[AI] takes the personal care, the customer care, customer service out of medicine, if you will. That's how we were brought up, you consult with a physician, they're supposed to know your entire history. [Physicians] are supposed to be able to pull from parts A, B, and C into your situation and know that this could happen to you or this has happened to you as opposed to an AI is just going to answer one direct thing. And I don't know how far it would go down a rabbit hole, and I don't know if they're designed to go down rabbit holes, but physicians are, and they know when to stop and when not to stop."	Breast cancer	50 - 64	White	Bachelor's degree
Information overload	"There are so many different options available that I found...which led me to spending an inordinate amount of money and time looking into certain things. When I had the wonderful opportunity to talk to one of our professors at UNC surgeon, it was probably one of the shortest conversations I ever had because...I said, I have these questions, and she just plain told me, here's the way to go, and I felt comfortable with that."	Prostate cancer	50 - 64	White	Graduate degree

Complexity of Cancer

The complexity of individual cancer cases was a major reason that patients preferred to seek advice from an HCP. Participants shared that empathy from HCPs is crucial for patients during their cancer journey, especially if they are dealing with a complex and difficult diagnosis. One participant reflected on how they dealt with more emotional and physical issues during their second diagnosis, causing them to consult with physicians on whether their experience was normal. Their physicians were able to empathize with their fear and encourage them that their treatment path was appropriate for their diagnosis. The participants shared that they felt that the chatbot lacked the level of empathy they would have experienced while speaking to a human.

Given the potential impact of lifestyle on cancer outcomes, patients preferred communication about changing behaviors to address emerging health issues and concerns with HCPs. Participants reflected that they felt the need to seek additional answers for cancer more than they would for other health issues. Because the grade or stage of cancer can quickly change, receiving advice from HCPs for steps to manage cancer and associated symptoms is more critical. Additionally, the participants voiced that HCPs know the more specific big picture

XSL•FO
RenderX

details about individual cases than a chatbot would. They expressed that, because chatbots do not have access to a patient's full medical history, they would feel more confident in following a chatbot's advice after they verify the information with their physicians or oncologists.

Several participants described instances where they would consult with an HCP for more input if they had a condition or were making a lifestyle change, especially if it could affect their cancer management and outcomes. The participants shared that if the chatbot recommended that a patient make a lifestyle change, they would feel the need to consult with their physician to confirm that it would not interact with their current treatment plan. Seeking HCP input on recommendations from a chatbot was especially important to the participants because chatbots do not know a patient's medical history.

Information Overload

Participants reported that chatbots tend to provide too much information in response to questions, causing uncertainty about which recommendations to follow. One participant shared that the chatbot provided them with an overwhelming amount of information, causing them to spend a large amount of time and money trying to navigate which advice to follow. However, once they sought advice from an HCP, the HCP immediately gave them directions on what to do next, which the participant trusted.

Furthermore, HCPs have knowledge about the nuances of cancer cases and can analyze information that could affect well-being on a certain treatment plan, including individual medical history, medications, and lifestyle behaviors. Additionally, they know the appropriate amount and type of information to be provided to patients to ensure that they understand their case and the proper treatment plan correctly. The participants reflected that chatbots do not have the capacity to do this because they do not tend to take patient-centered approaches when disseminating information.

Theme 2: Patient-Chatbot Interaction

Theme 2 included four subthemes: (1) personalization of advice, (2) emotional impact of AI chatbot interactions, (3) guidance for patients regarding the effective use of AI chatbots, and (4) adherence to AI chatbot advice by age group (Table 3). Of the top 8 quotes identified under this theme, 4 represented facilitators, and 4 represented barriers.

XSL•FO
RenderX

Table . Perceived barriers and facilitators of patient-chatbot interaction among patients with cancer, categorized by subtheme.

Subtheme	Illustrative quote	Patient characteristics				Barrier or facilitator
		Cancer type	Age group (years)	Race/ ethnicity	Education	
Personalization of advice	"If [chatbots] could understand the treatment plans, the pathways, and future follow-up care...because it's different for every type of breast cancer...if they could better understand what the particular person's diagnosis is, then that would help them give a better, more focused, targeted answer."	Breast cancer	35 - 49	White	Graduate degree	Facilitator
Personalization of advice	"You maybe don't have to re-ask questions, don't have to revisit topics. For example, I was having trouble with urinary incontinence. The chatbot would already have our previous conversations and then could go deeper into the subject or skip some of the early information gathering."	Prostate cancer	50 - 64	White	Bachelor's degree	Facilitator
Guidance for patients regarding the effective use of AI[a] chatbots	"If there were vetted sources, in particular AI engines that had been investigated by your doctor's office and there was a brochure...particularly for older people...that could kind of show you how to use [chatbots] in a safe way and get the right of information, I think that that might work."	Breast cancer	35 - 49	White	Bachelor's degree	Facilitator

XSL•FO

Subtheme	Illustrative quote	Patient characteristics				Barrier or facilitator
		Cancer type	Age group (years)	Race/ ethnicity	Education	
Guidance for patients regarding the effective use of AI chatbots	"...keeping the responses succinct, short so that they were easy for people to understand.... I work in training, and we usually say to write to a sixth-grade level...it would be nice to have [responses] as simple as possible."	Breast cancer	50 - 64	White	Graduate degree	Facilitator
Adherence to AI chatbot advice by age group	"The older population...will have more issues because it wasn't around back in the day. I came from the generation of a rotary phone dial connected to a cord connected to the wall. There were no cell phones, so I don't have it. I'm in that kind of middle generation, but I bet you if you talk to older people, they will maybe not understand bots more than me."	Breast cancer	50 - 64	White	Bachelor's degree	Barrier
Adherence to AI chatbot advice by age group	"The younger generation are going to know [how to use chatbots], but us older people, if you've been out of the workforce for a few years and you're not up to the new electronic things, it's going to leave some of us behind."	Breast cancer	50 - 64	White	Associate degree	Barrier

XSL•FO
RenderX

Subtheme	Illustrative quote	Patient characteristics				Barrier or facilitator
		Cancer type	Age group (years)	Race/ethnicity	Education	
Emotional impact of AI chatbot interactions	"[AI] would be a cold option compared with talking to a real person...if you've ever experienced anxiety or depression when you're going through cancer...then you realize that getting answers off the web...is not very comforting. If someone can look you in the eye or you hear their voice on the phone...it's more comforting."	Breast cancer	50 - 64	White	Graduate degree	Barrier
Emotional impact of AI chatbot interactions	"But a lot of issues that we deal with are anxiety, depression, suicidal tendencies and concern about reaching out for healthcare based on past experiences.... There's a whole 'nother realm that AI doesn't give you...and it's not as personal. I would choose personal every single time."	Breast cancer	50 - 64	White	Bachelor's degree	Barrier

[a]AI: artificial intelligence.

Facilitators of Patient-Chatbot Interaction

Participants voiced that a key facilitator was AI chatbots providing personalized responses based on a patient's specific needs. They shared that they would want chatbots to understand their situation and provide a more tailored response to their diagnosis as well as give a focused, targeted answer. For example, the participants said that the benefit of AI chatbots saving previous conversations would be that the participants would not have to repeat questions. Instead, the chatbot could skip the phase of gathering information that was already discussed and instead go deeper into the subject to facilitate personalization of advice. Additionally, the participants said it would be helpful if chatbot responses were short and easy to understand so that the information would not be overwhelming. Ultimately, understanding cancer is complex, and it would be better if chatbots kept the answers as simple as possible. One participant voiced that, because AI is going to be the future, it would be helpful if there were AI tools already reviewed and approved by their HCP and if educational resources were provided at clinics, such as a brochure to guide patients on how to effectively use AI chatbots. They emphasized that this is especially important for increasing trust among older generations.

Barriers to Patient-Chatbot Interaction

Adherence to AI chatbot advice varied by age group. The older the participants, the less likely they were to follow chatbot advice. The novelty of chatbots was emphasized to be an influential factor impacting mistrust in chatbot responses among older populations in particular. Participants reflected that the inability of AI chatbots to collect individualized information from patients contributed to the lack of personalized responses. They indicated that they had greater trust in chatbot responses to general questions. However, the participants indicated that they need more detailed responses at times and that chatbots often do not have all the information to give an adequate response because the specific details pertaining to a diagnosis are different for every cancer survivor.

Regarding the emotional impact of AI chatbot interactions, another concern of participants was the lack of empathy in chatbot responses. The participants expressed that cancer is an

XSL•FO
RenderX

emotional experience, and many people going through treatment also face mental health challenges such as anxiety, depression, and suicidal thoughts. They described that getting answers from the internet was a colder option compared to speaking with an HCP. It was implied that chatbots only focus on the physical symptoms and there are personal factors that AI chatbots do not address.

Theme 3: Chatbot Information Processing

Our team identified theme 3 as chatbot information processing. The participants reflected on three subthemes: (1) privacy of information, (2) sources of information, and (3) the chatbot's interpretation of inputted information. Facilitators and barriers were identified for all subthemes (Table 4).

XSL•FO
RenderX

Table . Perceived barriers and facilitators of chatbot information processing among patients with cancer, categorized by subtheme.

Subtheme	Illustrative quote	Patient Characteristics				Barrier or facilitator
		Cancer type	Age group (years)	Race/ethnicity	Education	
Privacy of information	"I guess [my top concern] would be the privacy part. Just making sure that whatever is shared through that tool is kept private and not too many hands or [*sic*] dipping in and information get [*sic*] exposed or taken away. But [privacy] would be my top concern."	Breast cancer	50 - 64	African American/Black	Associate degree	Facilitator
Privacy of information	"Is there a chance it's using my information or my questions and feeding that information to insurance companies or things like that?"	Prostate cancer	50 - 64	White	Graduate degree	Barrier
Sources used by the chatbot	"I think [using AI chatbots] would depend on the source of the chatbot. I would be more likely to trust one that came from a medical center."	Breast cancer	50 - 64	White	Graduate degree	Facilitator
Sources used by the chatbot	"[The chatbot] may give wrong information. So that's certainly possible. I wouldn't trust my life with it for sure."	Prostate cancer	50 - 64	White	Graduate degree	Barrier
Chatbot's interpretation of input information	"It could be missing context because a bot is going to go based on a knowledge base of information, understanding the question that I'm asking and the most appropriate answer based on [my] questions, but I may not know the right question..."	Breast cancer	50 - 64	White	Bachelor's degree	Barrier

		Cancer type	Age group (years)	Race/ethnicity	Education	
Chatbot's interpretation of input information	"I think it depends on the language that the person enters into the chatbot.... [The patient] could receive information that could influence their healthcare decisions, that could give them poor outcomes."	Breast cancer	35-49	White	Bachelor's degree	Barrier

Facilitators of Chatbot Information Processing

Regarding privacy, a participant shared that they would be more comfortable if an explicit button was provided within the interface to ensure that any information provided by the patient to the chatbot would not be collected. In terms of facilitators of trust in the information provided by chatbots, the participants mentioned that information obtained from reliable sources would be more accurate than the information available on the internet. Participants expressed greater trust in sources that were directly linked to medical centers and research. Additionally, the participants shared that if the chatbots provided links to their sources of information, it would allow them to dig deeper and feel more confident about chatbot responses. Additionally, a participant suggested that it would be helpful if chatbots could incorporate and interact with the resources provided to the patient by their HCP.

Barriers to Chatbot Information Processing

Privacy was cited as a barrier to engaging with chatbots for health-related questions. Some patients stated that they had not asked cancer- or health-related questions to chatbots because they did not have expectations of privacy. Others were concerned that whatever they shared could be exposed. For example, one participant expressed concerns about chatbots providing their information to insurance companies, which could potentially affect their care. This common concern that patient information would be collected by the chatbots and potentially distributed or accessed by other entities appeared to be a limiting factor for chatbot engagement.

The potential impact on patient decisions and downstream health outcomes was cited as a consideration for trusting chatbot responses. Many participants emphasized the importance of accurate information in their health decisions. The information shared with patients, especially for issues related to cancer, could be a matter of life and death. Participants shared that a chatbot's responses could impact whether a person seeks care immediately. The influence of chatbot responses in health care decisions and potential poor outcomes was also a shared concern among participants.

Many barriers to trusting chatbot responses were related to where chatbots source their information. Some participants were concerned that chatbots would not be able to distinguish misinformation from information as the source. One participant also felt that, in addition to dispensing potential misinformation, chatbots give out too much information without any filter. A few participants expressed their wariness from experiences of receiving misinformation from AI in general. One participant shared that in their experience, AI provides answers that appear to be real but then provides fabricated author and journal names. Some participants acknowledged that even if chatbots provide sources, users may have differences in their ability to evaluate the quality of the sources. Another participant mentioned that if they had not personally provided the source that they wanted summarized, they would not trust a chatbot's ability to choose the best sources of information. Together, the potential for chatbots to provide misinformation and subsequently influence health outcomes was a common barrier identified by the participants.

Another barrier identified by the participants was that chatbots may interpret patient questions incorrectly on the basis of the wording used, affecting the way the chatbots source the information. One patient pointed out that they might not know how to word their question to a chatbot to express their concerns and that the chatbot could be missing the context needed to understand their question correctly. Similarly, another patient expressed that the responses and information received from a chatbot are dependent on the language that the person enters into the chatbot. Thus, it appears that some limitations also stem from the limitations of the information and prompts provided by patients.

Discussion

Principal Findings

This qualitative study aimed to investigate the user experience of cancer survivors using AI chatbots to seek health information. The participants, who were breast and prostate cancer survivors, evaluated the quality and accuracy of health care advice provided by AI chatbots for breast and prostate cancer. Our findings show that the user experience of cancer survivors centered around their preferences between chatbots and HCPs, perceptions around patient-chatbot interaction, and the information processing ability of chatbots.

XSL•FO
RenderX

We found that the lack of empathy shown by chatbots was a major concern among cancer survivors. Some participants expressed concerns with the lack of empathy in chatbot responses, which explains why they preferred to seek health care advice from HCPs instead of chatbots. HCPs can recognize and respond to patients' emotional needs. In contrast, a chatbot was seen as more of a cold option, especially for patients who dealt with mental health challenges during their cancer journey. However, this preference also depended on whether a patient expected empathy when seeking health care advice, as multiple participants expressed not wanting empathetic responses from a chatbot. Previous research on patients with cancer suggests a positive association between physician empathy and patient outcomes such as higher satisfaction, decreased emotional distress, and decreased anxiety [28-31]. This emphasis on clinician empathy suggests that the expectation and perception of empathy is a current gap in the adoption of AI chatbots.

The topic of personalization overlapped across all 3 themes. The level of personalization often impacted patient satisfaction with chatbots in response to inquiries. Many patients criticized the general responses provided by chatbots to their questions and would have preferred responses specific to their cancer diagnosis. Participants voiced their preference for chatbots to better understand their specific health condition and to provide a more tailored response. HCPs can provide more tailored responses because of their access to patients' electronic health records (EHRs), their relationship and communication with their patients, and their knowledge of their patients' health needs and preferences [32,33]. Chatbots should have access to patients' EHRs to provide a personalized experience that meets the expectations of cancer survivors.

We found that a primary concern of cancer survivors regarding chatbot use was the overabundance of general information that is often not relevant to their diagnosis. Previous studies report that adults feel overwhelmed by the amount of information on cancer, a phenomenon referred to as cancer information overload [34]. Recent research on the use of AI in urological cancer shows that applying machine learning algorithms is promising for overcoming this information overload, as they enable a more focused and efficient search [35]. Our findings confirm that survivors prefer chatbots that provide tailored information relevant to their health condition without extraneous and irrelevant information.

Privacy and trust were major roadblocks to the adoption of chatbots. Many participants shared their concerns about providing personal information to chatbots because of privacy concerns. "AI explainability" is a term that indicates transparency around the design of chatbots, data storage, security, and the information sources used [36]. The participants voiced concerns around not understanding what happens to information that is inputted into chatbots. Generational differences related to digital literacy may further impact trust and knowledge about how to best use chatbots. Nevertheless, having a chatbot that better details its methods to protect medical data will be important to enhance trust among older groups. The existing literature shows that digital health technologies have the potential to reduce cancer care health disparities and that limited digital health literacy is a barrier to digital technology engagement [36]. Therefore, implementing explainable AI chatbots in the context of cancer care is important to address this variability in digital literacy.

The participants saw merit in chatbots being introduced and recommended by HCPs, as this may enhance trust and self-efficacy. The participants' feedback suggests that chatbots should not replace their HCPs. Instead, they should be used to supplement HCP interactions. Integrating HCP-endorsed chatbots into care pathways may strengthen patients' trust and willingness to engage with AI tools. If HCPs can guide patients regarding the safe use of chatbots, patients will feel more confident to use chatbots, especially older individuals who have less trust. Patients may be more willing to trust chatbots if HCPs recommend their use. Including recommended links to vetted medical sources within responses may also reduce the sense of being overwhelmed that patients feel with the overload of information provided by chatbots. It would also direct patients to chatbots that provide informed responses. An HCP-endorsed chatbot, where HCPs seek answers from a chatbot and validate the information before sending it to patients, could enhance trust and improve the provision of tailored responses to patient concerns. However, this could also potentially increase HCP burden and patient wait times for responses. Enhancing the quality of chatbots for use among cancer survivors could directly benefit HCPs and patients by reducing HCP burden and improving the speed at which patient concerns are addressed. Chatbots could provide 24-7 access to information for patients who seek answers to their questions, thereby reducing the volume of patient inquiries that HCPs need to respond to. Additionally, chatbots could deliver immediate responses to patients at any time, reducing wait times and therefore enhancing patient satisfaction and quality of care.

Our findings align with recent systematic reviews of patient perspectives regarding AI in oncology care. For example, recent studies reported that patients prioritize empathy and personalization, consistent with our themes [37,38]. Similarly, another study highlighted that trust and transparency are key determinants of chatbot adoption [39].

Limitations

There are several limitations to this study. Most participants included in the study identified as White, limiting the generalizability of our findings to other racial and ethnic groups. The study included 4 prostate cancer survivors, not to compare them with breast cancer survivors but to gather diverse perspectives. Similarities in responses indicated that saturation was sufficiently met for both groups. Experiences of different minoritized patient populations may provide insight into their interactions with chatbots in their cancer care journey. Furthermore, all participants had received some type of college education, which may limit the generalizability of these findings to individuals with different educational backgrounds. Education could potentially influence the perspectives around the adoption and use of AI chatbots. Additionally, most patients interviewed in this study were female breast cancer survivors. Perspectives from patients with different cancer diagnoses may provide broader insights into chatbot use in cancer care. Additionally, despite 4 prostate cancer survivors participating in this study,

XSL•FO
RenderX

our findings may not be generalizable to all prostate cancer survivors. While the specific findings of this study may not be generalizable to patient populations beyond breast and prostate cancer survivors, they provide valuable insights into patient perceptions of AI chatbots. In addition, the findings are based on participants' perceptions of self-reported encounters and hypothetical scenarios rather than recorded chatbot use data, which poses some limitations on the ecological validity. Future studies could investigate real-time chatbot interactions to better capture the impact on engagement. Furthermore, while the participants exhibited a range of familiarity with and experience of chatbots, the participants' digital literacy was not formally assessed. This poses some limitations to the representativeness and generalizability of our study.

Conclusion

In this study, cancer survivors generally had a positive outlook on the implementation of chatbots in cancer care. Participants' perceptions of chatbots compared to HCPs suggest that chatbots are more suitable as a supplemental resource than a complete replacement for HCP interactions. The barriers identified by patients provide valuable insight into how chatbots can be improved and tailored to meet the needs of patients with cancer. Transparency in data privacy, reducing information overload, and providing links to trusted sources were commonly shared as potential recommendations to improve chatbots for use in cancer care. Moreover, patient education in the clinical setting on how to use these tailored chatbots and ask the right questions can improve the user experience and patients' trust in chatbots. The study participants' perceptions of virtual care and AI chatbots suggest that, while there are perceived benefits of virtual chatbot-based health care, certain aspects of the interface and interaction could potentially be improved to better suit patient needs. Future research could build on the findings of this study by evaluating these identified factors through observations of real-time chatbot interactions, reviews of use patterns, and questionnaires on patients' perceptions. Integrating a more formal evaluation of digital literacy could also provide greater insight into how chatbots can better suit the needs of patients with a range of technological experience. Future research could also investigate the impacts of different levels of integration of chatbots in medical care. AI chatbots can potentially improve the delivery of valuable health care information for patients with cancer; however, additional work is needed to tailor these chatbots to the expectations and needs of patients.

Abstract

Background: Colon cancer is a leading cause of cancer-related deaths worldwide, with survival influenced by risk factors, treatment type, and patient characteristics. Traditional statistical models, such as Kaplan-Meier curves, have been widely used to estimate survival probabilities. However, these models often have difficulty handling complex interactions, covariates, and nonlinear relationships between risk factors. Recently, machine learning (ML) techniques have emerged as promising tools for improving survival prediction by handling large covariates and capturing complex patterns.

Objective: This study compares several ML models to accurately estimate colon cancer survival by leveraging data from the Kentucky Cancer Registry. By identifying key risk factors, these analyses aim to improve risk stratification, treatment planning, and prognosis for overall colon cancer survival within subgroups.

Methods: We conducted a retrospective analysis of colon cancer cases diagnosed between 2010 and 2022 (n=33,825), using Kentucky Cancer Registry data linked to mortality records, with approval from the University of Kentucky Institutional Review Board (#63067). We compared multiple predictive modeling techniques, including Cox proportional hazards, accelerated failure time models, Extreme Gradient Boosting, random survival forests, least absolute shrinkage and selection operator (LASSO), and elastic net regression, to estimate survival probabilities. The Kaplan-Meier method provided baseline survival estimates, and multivariate models, including ML approaches, evaluated contributions of key risk factors. Model performance was compared across evaluation metrics such as the Brier score, concordance index, out-of-bag error, and Continuous Ranked Probability Score. Missing data were handled via multiple imputation, and leave-one-out cross-validation was applied to reduce overfitting.

Results: The ML models identified key covariates influencing survival outcomes, such as age, treatment type, positive nodes, tumor stage, smoking, and comorbidities. In the overall model, patients who refused or received no treatment had a 3.24-fold higher risk of mortality compared to those who underwent surgery at primary and regional sites. Elevated mortality risk was also observed among smokers (24% higher than non-smokers) and Appalachian residents (7% higher than non-Appalachian residents). Our overall model achieved a concordance index of 0.8146, with strong discriminatory performance across subgroups, including early-age diagnosis (0.8175), late-age diagnosis (0.7841), Appalachia (0.8135), non-Appalachia (0.8126), White patients (0.8164), and Black patients (0.7881). The results highlight the strengths and limitations of each ML approach, with the random survival forest and LASSO models outperforming traditional methods such as the Cox model in prediction accuracy and model discrimination.

Conclusions: Our study demonstrated the utility of ML in identifying risk factors associated with colon cancer survival, with positive lymph nodes, age at diagnosis, treatment received, clinical tumor size, tumor grade, smoking status, geographic region, and marital status emerging as dominant predictors across all statistical models. This comparative analysis offers valuable insights for clinical decision-making and prognosis, highlighting the potential of ML to identify risk factors specific to different subgroups, ultimately advancing personalized care for patients with colon cancer.

Introduction

Colon cancer, also known as colorectal cancer (CRC), is a leading cause of cancer-related deaths globally [1,2], typically developing from adenomatous polyps in the colon or rectum. While advancements in screening, early detection, and treatment have improved survival rates from about 50% in the 1970s to approximately 64% today [3], CRC remains a significant public health concern because there are still many deaths and because of survival disparities influenced by stage at diagnosis, the presence of metastasis, and various individual and biological risk factors [1]. Early-stage detection offers better survival outcomes (5 y survival rate of ~90% for localized cases vs ~14% for late-stage diagnoses) [4], yet disparities persist across subgroups, particularly among non-Hispanic Black patients, driven by factors such as socioeconomic status and health care access [3]. Understanding risk factors, both generally and specific to demographic and regional subgroups, is relevant to informing interventions, both broad-based and targeted, for better survival outcomes. Specifically, between 2016 and 2020, Kentucky's CRC mortality rate was 16.2 per 100,000, compared to the national rate of 13.1 [5]. Thus, in Kentucky, survival rates are notably lower than the national average. The state's overall 5-year survival rate for colon cancer is approximately 61% [3]. Indeed, Kentucky has one of the highest CRC mortality rates in the United States, which is partially due to high rates of smoking, obesity, and physical inactivity, all of which are modifiable risk factors [4]. Limited access to health care and early screening programs, particularly in rural or Appalachian regions, contributes to delayed diagnoses and poorer survival outcomes [4,6]. Although Kentucky has implemented various cancer control initiatives, such as increasing access to screenings, these efforts have been less effective in rural areas, where health care resources remain scarce [7,8]. As a result, more patients in Kentucky are diagnosed at later stages compared to those in other states, which significantly impacts their chances of survival [9,10].

Colon cancer is influenced by both nonmodifiable and modifiable risk factors. Age is one of the most significant nonmodifiable risk factors, with most cases diagnosed in individuals aged 60 years and above due to accumulated genetic mutations and cellular damage over time [11,12]. A family history of CRC, particularly in first-degree relatives (parents, siblings, or children), implies a higher risk [13], as do inherited genetic syndromes, such as familial adenomatous polyposis and Lynch syndrome, which involve mutations in mismatch repair genes [14]. Among modifiable risk factors, smoking and alcohol use elevate CRC risk through DNA damage and carcinogenic metabolites like acetaldehyde [15,16], with combined use posing an even greater threat [17,18]. Physical inactivity, obesity, and chronic inflammatory conditions like Crohn disease and ulcerative colitis also heighten risk [19]. Regular exercise is associated with reduced CRC risk, by enhancing gastrointestinal motility, reducing systemic inflammation, and supporting a healthy body weight [19,20]. Abdominal obesity increases CRC risk [21] via visceral fat, which triggers chronic inflammation and hormone dysregulation (involving, eg, insulin and leptin) [21,22], particularly for proximal colon cancers [23]. Dietary habits, hormonal factors (especially in women), and screening practices also impact CRC risk, with early detection through colonoscopy, sigmoidoscopy, or fecal occult blood tests significantly improving survival rates [24,25].

The prognosis for patients with colon cancer largely depends on the cancer's stage at diagnosis, as defined by the TNM staging system [26], which classifies cancer based on tumor size (T), lymph node involvement (N), and the presence of metastasis (M). Patients with stages I and II typically have localized disease, with no lymph node involvement and high survival rates (90% - 95%) when treated early [27]. In stage III, cancer has spread to nearby lymph nodes (but not to distant organs), leading to moderate survival rates (40% - 70%), depending on treatment effectiveness [27]. Stage IV involves distant metastasis, commonly to liver or lungs, resulting in significantly lower survival rates (10% - 15%) [28]. Nonetheless, newer treatment approaches such as targeted therapies, immunotherapies, and palliative care have improved survival and quality of life for patients with metastatic disease [29-31]. Colon cancer continues to be a major global health challenge, underscoring the importance of accurate survival estimation to guide clinical treatment decision-making and public health strategies [32]. Survival outcomes are influenced by early detection, timely intervention, and modifiable lifestyle factors such as diet, exercise, and smoking cessation, although genetic predispositions and medical conditions like inflammatory bowel disease further complicate individual risk profiles. Early screening continues to be the most effective strategy for improving colon cancer survival outcomes.

In recent years, numerous studies [33,34] have applied ML techniques to predict outcomes in colon cancer, demonstrating promising performance in risk stratification and prognosis. However, many of these studies focus on a single model or dataset, limiting generalizability and offering limited comparison across model types using standardized metrics [35]. Additionally, interpretability and the role of geographically linked social determinants, such as residence in medically underserved regions like Appalachia, are often underexplored [10]. This study addresses these gaps by systematically comparing traditional and modern ML approaches including Cox proportional hazards, accelerated failure time (AFT) models, Extreme Gradient Boosting (XGBoost), random survival forests (RSFs), least absolute shrinkage and selection operator (LASSO), and elastic net regression using a large, population-based dataset. By incorporating region-specific variables and evaluating models with consistent performance criteria, this study offers novel insights into both predictive accuracy and the complex risk factors influencing colon cancer survival.

XSL•FO
RenderX

Accurately predicting survival outcomes based on individual risk factors remains a major challenge [36-38], despite significant progress in cancer surveillance and treatment. Understanding how these risk factors influence colon cancer survival is critical for enhancing the effectiveness of surveillance efforts and guiding targeted public health interventions. However, cancer survival surveillance using registry data is often complicated by incomplete or unreliable cause-of-death information, which can undermine the precision of public health interventions and cancer control strategies [39-41]. In this study, we explore the influence of risk factors on prognostic outcomes in colon cancer survival using ML models. Specifically, we seek to answer 2 key questions: (1) how do different risk factors impact cancer survival across various population subgroups? (2) which risk factors emerge as the strongest predictors of survival outcomes within these subgroups?

Methods

Data Source and Cohort Selection

The Kentucky Cancer Registry (KCR), a part of the Surveillance, Epidemiology, and End Results (SEER) Program and the National Program of Cancer Registries, provides comprehensive, population-based data on cancer incidence, survival, treatment, and patient demographic factors in Kentucky. KCR routinely links cancer incidence data to Kentucky state mortality data and National Death Index data to ensure updated mortality information. This study included all 33,825 noninstitutionalized adult patients (aged ≥18 y) diagnosed with colon cancer during the study period. Patients with missing diagnosis, treatment, or staging data were excluded, ensuring data integrity.

Ethical Considerations

This retrospective study utilized deidentified case-level colon cancer data from the KCR for the period January 1, 2010, to December 31, 2022. The study was approved by the University of Kentucky Institutional Review Board (#63067) following the completion of the data use agreement. Because the data were fully anonymized prior to analysis, informed consent was waived. Participant privacy and confidentiality were ensured through strict deidentification procedures, in compliance with institutional policies and federal regulations governing human participant research.

Patient, Disease, and Treatment Factors

Potential risk factors were selected based on a review of existing literature on colon cancer survival and input from oncology and epidemiology experts on our research team. Clinically relevant variables extracted from the KCR included patient demographic and risk factors such as age at diagnosis, sex, race, ethnicity, marital status, smoking status, cigarette pack years, and geographical residence (Appalachian or non-Appalachian regions of Kentucky). Age at diagnosis was categorized into 2 groups: early onset (18 - 60 y) and late onset (over 60 y). Due to the low representation of certain groups, patients who were neither White nor Black were categorized as "Other." Likewise, ethnicity was classified into "Not of Spanish or Latino origin" and "Other." Marital status was grouped into broader categories, with divorced and separated individuals combined into a single "Divorced or Separated" category, and those living with a partner or having unknown marital status grouped under "Unknown."

Histological types [25] not matching "8140" (Adenocarcinoma NOS), "8210" (Papillary Adenocarcinoma, Papillary subtype), "8240" (Tubulovillous Adenocarcinoma), and "8480" (Mucinous Adenocarcinoma) were categorized as "Other/Unspecified." Treatment records were similarly streamlined based on the first course of treatment: patients reporting no treatment, unknown treatment, or refusal were grouped under "No/Unknown or Refused Treatment." Those undergoing surgery for primary or regional sites were listed as "Surgery (Primary and Regional)," while individuals receiving multimodal treatment with surgery, chemotherapy, or radiation belonged to "Surgery+(Chemotherapy and/or Radiation)." Therapies not included in the categories described above were classified as "Other."

Colon cancer staging is often performed using either the American Joint Committee on Cancer (AJCC) TNM system or the SEER Summary Stage system. The AJCC TNM staging is detailed, providing specific breakdowns of the tumor's size, regional lymph node involvement, and presence of distant metastasis [42]. However, we chose to rely on the SEER 2018 Summary Stage, a simplified system that categorizes cancer's spread into broader groups: in situ (confined to the origin site), localized (confined to the organ of origin without spread), regional (spread to nearby tissues or lymph nodes), distant (spread to distant organs), and unknown (extent of spread cannot be determined). While the AJCC system offers a more granular, detailed assessment of cancer progression, the SEER Summary Stage aggregates these details into more general categories and is more consistent across years, making it useful for large-scale epidemiological studies and population-based cancer survival tracking [43].

Insurance coverage was reclassified into 4 primary categories to streamline analysis. Patients with private or employer-based insurance were grouped under "Private Insurance." Those covered by government-funded programs, including Medicare, Medicaid, TRICARE (Military), Workers' Compensation, Veterans Affairs, and the Indian Health Service, were classified as "Government-Related Programs." Patients who were uninsured or self-paid were categorized as "Uninsured or Self-Pay," while individuals with nonspecific, unknown, or unreported insurance status were assigned to the "Other/Unknown Payers" group.

Statistical Analysis

Descriptive analyses were conducted to summarize patient and clinical characteristics of the colon cancer cohort. Continuous variables, such as age, were reported as means, medians, standard deviations, minimum, and maximum values. Categorical variables, including sex, tumor stage, treatment status, and comorbidity indicators, were summarized using frequency counts and percentages. The descriptive analysis provided an overview of the colon cancer study population cohort and served as the foundation for subsequent survival modeling. They also facilitated the identification of demographic

XSL•FO
RenderX

and clinical patterns and covariate distributions relevant to prognosis and interpretation of survival differences across patient subgroups. The results are presented in Table 1.

Table . Distribution of colon cancer characteristics (continuous variables)[a].

Risk factors	Frequency, n	Mean (SD)	Median (IQR)	Minimum	Maximum
Age (y)	33,825	65.95 (13.74)	67.00	18.00	103.00
Cigarette pack years	18,602	16.76 (27.29)	0.00	0.00	300.00
Tumor size clinical (mm)	7094	49.04 (36.74)	46.00	0.00	989.00
CS[b] lymph nodes	19,932	72.72 (125.04)	0.00	0.00	800.00

[a]Analyses are based on a retrospective cohort study of patients with colon cancer using data from the Kentucky Cancer Registry collected between January 1, 2010, and December 31, 2022.

[b]CS: clinical stage.

Classical survival analysis methods, such as the Kaplan-Meier estimator [44] and the Cox proportional hazards model [45], have long been the standard approach for analyzing time-to-event data due to their interpretability, capacity for coping with right censoring, and well-established statistical foundations. Yet, they may not be well suited to high-dimensional data. The Kaplan-Meier estimator relies on stratification. If only a few strata are specified, then the results may be subject to confounding or may obscure interactions. If many strata are specified, then the results may be limited by small stratum sizes or may be subject to concerns about multiple comparisons. In contrast, ML methods like XGBoost, RSFs, LASSO, and elastic net Cox regression [1] models offer greater flexibility. RSFs can capture interactions and nonlinear relationships without assuming proportional hazards, while elastic net provides variable selection and regularization in high-dimensional settings. AFT models, though parametric, can serve as a bridge between classical and ML approaches by directly modeling survival time.

We now outline our key statistical approaches for identifying risk factors associated with colon cancer survival (from time of diagnosis until death or right censoring) in Kentucky adults. We begin by summarizing the colon cancer data from the KCR. We constructed nonparametric Kaplan-Meier curves [44] to evaluate differences in survival distributions across subgroups and to explore associations between individual risk factors and survival. To assess the joint impact of risk factors, we used multivariable models, employing both classical and ML approaches. Classical methods included the Cox proportional hazards model [45] and the AFT model [46], which rely on specific assumptions such as proportional hazards (for Cox) or predefined survival time (for AFT) distributions. We also used the ML methods of XGBoost [47], RSF [48], LASSO regression [49], and elastic net [50], which offer greater flexibility.

Subgroup analyses were also conducted to identify influential predictors of survival outcomes within strata based on race (White, Black, and other patient subgroups), time of diagnosis (early onset: 18 - 60 y vs late onset: over 60 y), and geographic region (Appalachian vs non-Appalachian Kentucky). These stratified analyses allowed us to assess whether the impacts of key risk factors differed across demographic and regional subgroups so that subgroup-specific predictors of colon cancer survival might be identified.

The multivariate Cox proportional hazards model is a semiparametric statistical method used in cancer survival studies and allows for the simultaneous analysis of multiple risk factors, estimating the hazard of death while controlling for confounders. This approach is beneficial in identifying independent risk factors impacting survival, while adjusting for the effects of other covariates. Additionally, the model enables the investigation of differences between subgroups, providing a more comprehensive understanding of the factors affecting survival outcomes.

The AFT model is an alternative to the Cox proportional hazards model that is useful when the proportional hazards assumption is not met or when focusing on modeling time to an event rather than hazards. The AFT model assumes that covariates accelerate or decelerate survival time, which is useful in assessing how risk factors can shorten or extend a patient's survival time. Unlike the Cox model's focus on hazard ratios, the AFT model directly interprets time, offering clearer insights into absolute survival durations, an essential factor in understanding patient prognoses.

XGBoost is a powerful and scalable ML algorithm widely used for structured data. Built on the framework of gradient-boosted decision trees, it is highly effective in tasks such as classification, regression, and survival analysis. Its popularity stems from its ability to handle large datasets efficiently and reduce overfitting through regularization methods. Additionally, XGBoost supports parallel and distributed computing, which speeds up model training and accommodates missing data.

The RSF is a nonparametric ML technique that extends the traditional random forest algorithm to survival data. In our study, the RSF model was utilized to predict patient outcomes based on extensive risk factors. Its major advantage lies in its ability to capture interactions and nonlinear relationships between risk factors, dynamics that traditional models like Cox or AFT might miss. Moreover, RSF's capacity to handle censored data and missing values makes it robust for real-world clinical datasets. The model also aids in feature selection by identifying the strongest predictor variables, helping clinicians focus on key risk factors that drive survival outcomes.

XSL•FO
RenderX

The LASSO and the elastic net regularization techniques were utilized for the colon cancer survival data because the number of risk factors was relatively large. Regularization is a method of constraining or penalizing model parameters to prevent overfitting, leading to better model fit and generalization.

LASSO Regression

LASSO is a regularized version of linear regression, where the model is penalized using the L1norm (sum of the absolute values of the coefficients). The goal of using LASSO is to improve the prediction accuracy and interpretability of the model by forcing some of the coefficients that do not contribute to predicting survival to exactly 0. This essentially is equivalent to performing feature selection. The mathematical formulation of the LASSO is as follows:

$$\beta lasso\hat{} = \operatorname{argmin}\beta \left(\sum i=1n(yi - XiT\beta)2+\lambda\sum j=1p|\beta j| \right)$$

Here, yi is the observed target or censored time for colon cancer death in an ith individual, Xi is the vector of risk factors, βj is the coefficient of the jth predictor or risk factor, λ is the regularization parameter that controls the strength of penalty, and *p* is the number of parameters.

Elastic Net

Elastic net is a regularization technique that combines both L1 regularization (LASSO) and L2 regularization (Ridge). It was introduced to overcome some of the limitations of LASSO, particularly when dealing with highly correlated risk factors. Elastic net performs better in situations where there are many predictors, some of which may be correlated. The mathematical formulation of elastic net is as follows:

$$\beta elastic\ net\hat{} = \operatorname{argmin}\beta (\sum i=1n(yi - XiT\beta)2+\lambda 1\sum j=1p|\beta j|+\lambda 2\sum j=1p\beta j2)$$

Here, λ1 and λ2 are the regularization hyperparameters corresponding to L1 and L2 penalties, respectively.

The LASSO procedure was chosen because we believe that only a subset of the predictors is most relevant for colon cancer survival prognosis. LASSO is particularly effective for sparse data, where many features are present, but only a few are significant, and its automatic feature selection enhances model interpretability. Elastic net was selected because the risk factors may be correlated with each other, and elastic net is better suited for handling multicollinearity.

Model Performance

Model performance was evaluated using the Brier score (Figures 1 and 2), standardized out-of-bag (OOB) Continuous Ranked Probability Score (CRPS), and concordance index (C-index; see the *Result* section) to assess both calibration and discrimination across the overall cohort and predefined subgroups. The Brier score evaluates the accuracy of predicted probabilities by measuring the mean squared error between predictions and outcomes, with strengths in calibration and sharpness. The CRPS extends the Brier score to continuous outcomes and, when standardized and computed using OOB samples, offers an unbiased performance estimate that helps guard against overfitting. The C-index measures a model's ability to correctly rank outcomes, making it useful for survival or ranking tasks. Multiple imputation was used to address missing data, and leave-one-out cross-validation was employed to reduce overfitting and ensure robust performance estimates. All hypothesis tests were performed at the 5% significance level. All statistical analyses were conducted using R statistical software [51] or Python [52]. The reporting of this study conforms to STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) and TRIPOD+AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis Using Artificial Intelligence) guidelines [53-55].

Results

Overview

The results from a total sample of 33,825 including 15,838 patients who were alive and censored as of December 31, 2022, are shown below. The following risk factors for colon cancer survival were investigated: age at diagnosis, treatment, sex, race, ethnicity, marital status, smoking status, cigarette pack years, tumor grade, positive lymph nodes, clinical tumor size, geographic region (Appalachian status), histology classification or type, clinical stage (CS) lymph nodes, insurance, and SEER 2018 summary classification of the tumor. Tables 1 and 2 show the distribution of the risk factors, while Tables 3 and 4 (Tables S1 and S2 in Multimedia Appendix 1) display or compare findings from the various methods.

Table . Comparison of concordance index (C-index) for population subgroups for the fitted models[a].

Subgroups	C-index for population subgroups models					
	Cox	AFT[b]	XGBoost[c]	LASSO[d]	Elastic net	RSF[e]
Overall	0.7605	0.7606	0.7007	0.7544	0.7569	0.8141
Appalachia	0.7624	0.7626	0.6971	0.7607	0.7614	0.8131
Non-Appalachia	0.7827	0.7819	0.7103	0.7581	0.7564	0.8101
Early diagnosis	0.7754	0.7755	0.7210	0.6852	0.7310	0.8158
Late diagnosis	0.7417	0.7420	0.7030	0.7369	0.7409	0.7832
White patients	0.7634	0.7633	0.7419	0.7598	0.7595	0.8161
Black patients	0.8037	0.8041	0.6889	0.7449	0.7469	0.7849

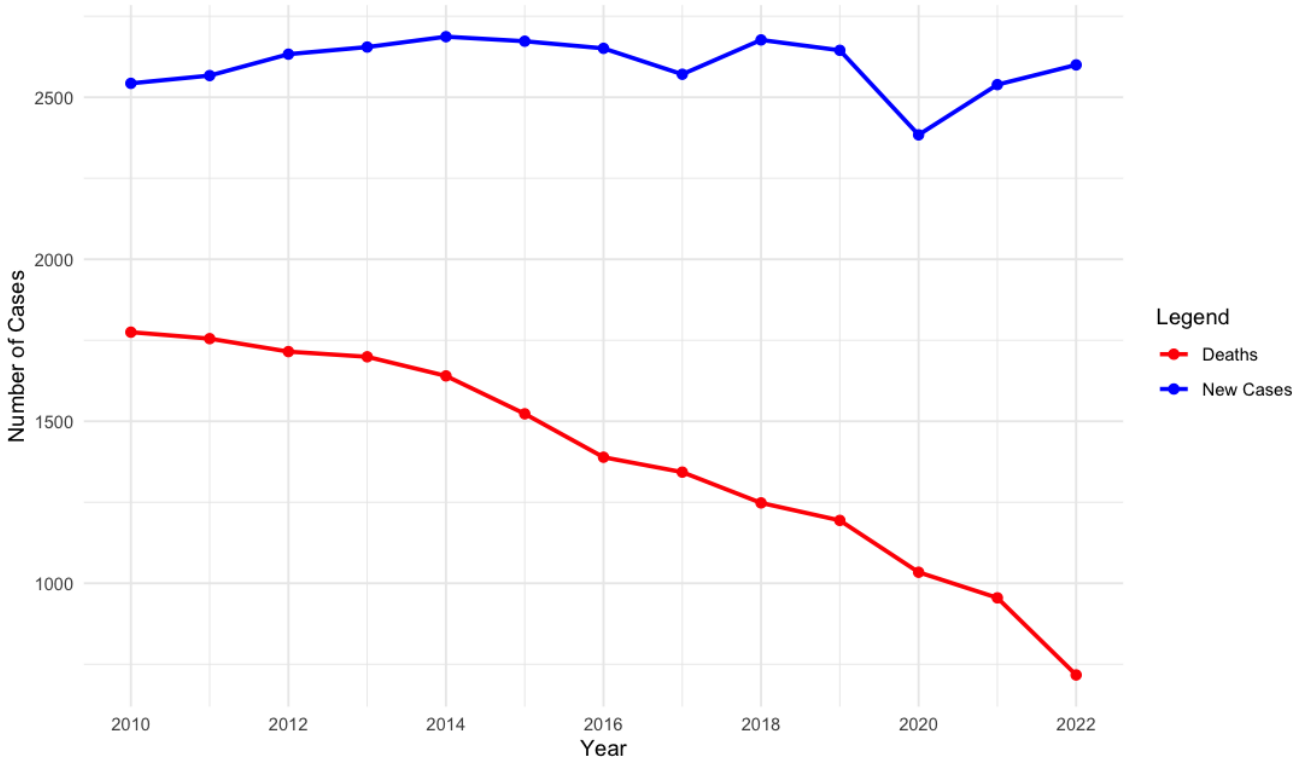
[a]Analyses are based on a retrospective cohort study of patients with colon cancer using data from the Kentucky Cancer Registry collected between January 1, 2010, and December 31, 2022.

[b]AFT: accelerated failure time.

[c]XGBoost: Extreme Gradient Boosting.

[d]LASSO: least absolute shrinkage and selection operator.

[e]RSF: random survival forest.



The RSF model demonstrated strong overall discriminatory performance, achieving a C-index of 0.8146, indicating a high level of agreement between predicted and observed survival outcomes. Model evaluation across key subgroups showed similar robust performance: patients diagnosed early (0.8175), patients diagnosed late (0.7841), Appalachia (0.8135), non-Appalachia (0.8126), White patients (0.8164), and Black patients (0.7881). The slightly higher C-index in the early diagnosis and White patient subgroups suggests marginally better discrimination in these populations, while the modestly lower score in the late diagnosis and Black patient subgroups still reflects acceptable performance. These results support the generalizability and reliability of the RSF model across diverse demographic and clinical strata. Overall, the model demonstrated stable predictive accuracy and effective risk stratification for colon cancer survival.

Survival and Prevalence of Colon Cancer Death

Figure 3 shows the annual incidence and mortality of colon cancer, highlighting temporal trends including a slight dip in 2020 likely due to the COVID-19 pandemic disruption in screening and diagnosis. This decline may reflect delayed detection rather than a true reduction in CRC disease burden. Figure 4 shows Kaplan-Meier curves for CRC survival stratified by each risk factor, highlighting statistically significant differences between the distributions of at least 2 subgroups for each risk factor. Model accuracy for both the LASSO (λ=0.01) and elastic net (λ_1 =0.02, λ_2 =0) procedures was evaluated using leave-one cross-validation to minimize overfitting and enhance predictive performance. Elastic net results closely mirrored those of the LASSO and are omitted for brevity. Figure 5 illustrates the variable importance for the risk factors in the model. The plot highlights the order of importance, with the “red” boxplots indicating significant predictors of survival. These predictors are ranked based on their contribution to the model’s ability to accurately assess survival outcomes.

Figure 4. Kaplan-Meier colon cancer survival curves comparison colorectal cancer (CRC) cancer survival distribution by risk factors and time since diagnosis, with vertical dashes representing 2-, 5-, 10-, and 15-year survival probabilities. Analyses are based on a retrospective cohort study of patients with colon cancer using data from the Kentucky Cancer Registry collected between January 1, 2010, and December 31, 2022.

XSL•FO
RenderX

Figure 5. The overall ranking of risk factor importance and for each subgroup, as determined by the random survival forest model. Analyses are based on a retrospective cohort study of patients with colon cancer using data from the Kentucky Cancer Registry collected between January 1, 2010, and December 31, 2022. Overall is the overall model. “Overall” displays the significant risk factors in a "red" box plot and the nonsignificant ones in a "blue" box plot. “Early1” or “Early2” represent individuals diagnosed at early or late age, respectively. “App1” and “App2” correspond to results of individuals residing in non-Appalachia and Appalachia regions, respectively. “White” and “Black” show the results stratified by White and Black patient subgroups, respectively. Red and blue colored boxplots correspond to significant and nonsignificant risk factors, respectively.

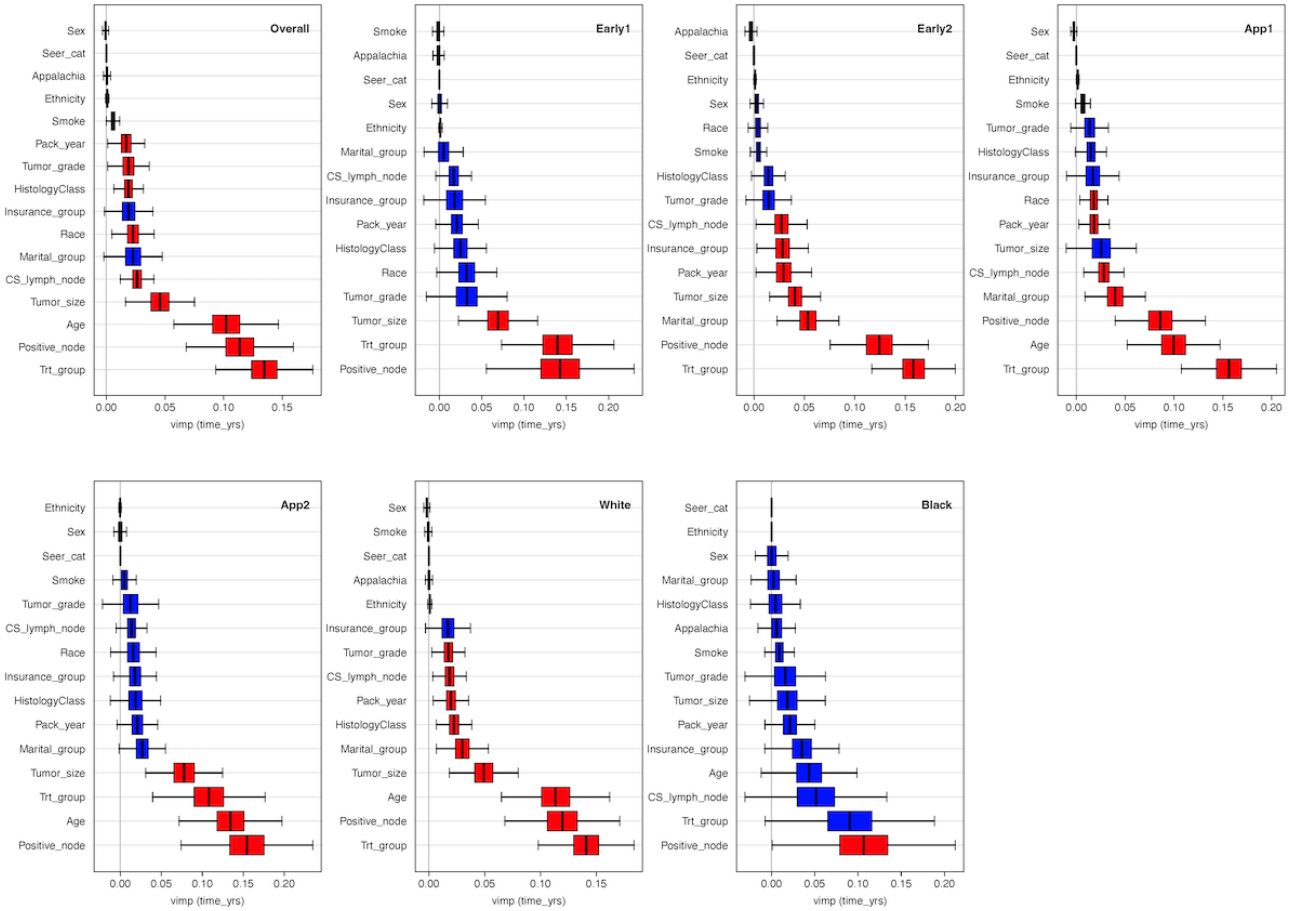

Table 4 shows the C-index values for the Cox, AFT, XGBoost, LASSO, elastic net, and RSF models across various subgroups. Among the ML models evaluated, RSF consistently achieved the highest C-index values, indicating superior discriminatory performance and a better overall fit to the survival data. This suggests that RSF is better able to capture complex, nonlinear relationships and interactions among the risk factors, which traditional models may overlook. While classical models like Cox and AFT performed reasonably well, their performance was generally outpaced by the more flexible ensemble-based RSF. These findings highlight the potential value of nonparametric ML approaches in improving predictive accuracy for survival outcomes.

Figure 1 displays the Brier scores by population subgroups for the Cox proportional hazards model. As shown, the Brier scores for the Cox model range between 0 and 0.25, indicating reasonably good predictive accuracy across the subgroups. Lower Brier scores reflect better performance in terms of both discrimination and calibration, suggesting that the Cox model fits the data relatively well. The consistency of low Brier scores across diverse subgroups further supports the model’s robustness among the classical methods. These results highlight the suitability of the Cox model for risk prediction in these population subgroups.

Figure 2 shows the evaluation of the predictive models from RSF for overall cohort and subgroups using the Brier score. The overall model showed consistent and stable performance at each point in time, while subgroup analyses indicated slightly higher Brier scores among Black patients, Appalachian residents, and those with late CRC diagnoses, suggesting modestly reduced calibration and predictive ability. However, the differences were not substantial, indicating no major bias in model performance across these groups.

Model Results: Overall

In the Cox model, the most significant predictors of colon cancer survival, listed in order of importance (determined by *P* values), were positive nodes, treatment group, age, tumor size, CS lymph nodes, and tumor grade, with the remaining factors having no significant impact on survival (Table S2 in Multimedia Appendix 1, “Overall” column). The AFT model identified the same set of key predictors as the Cox model; sex was also significant in the AFT model, but the other predictors mentioned above were ranked in the same order for the AFT model (Table S1 in Multimedia Appendix 1, “Overall” column). However, in the RSF, the importance of risk factors differed slightly, with treatment group, positive nodes, age, clinical tumor size, CS lymph nodes, marital status, race, histology, insurance, cigarette pack years, tumor grade, smoking status, ethnicity, Appalachia,

XSL•FO
RenderX

and sex following in descending order (Figure 5, overall panel). The effects of ethnicity, Appalachia, and sex were relatively small compared to those of other factors. The standardized OOB CRPS estimate was 0.155, with an OOB requested performance error of 0.254, indicating a very good fit of the model.

Table 3 presents the results for the LASSO model. For instance, the hazard ratio for overall age is 1.035, indicating that for each additional year of age, the hazard of death from colon cancer increased by 3.5%. Patients who underwent surgery (primary and regional) had a 69.1% lower risk of hazard compared to those who refused treatment or had no treatment, representing a significant reduction in risk. The most effective treatment regimen was surgery combined with either chemotherapy or radiation therapy, which showed the greatest benefit compared to all other treatment options. Female patients had a 13.5 lower hazard of colon cancer death compared to male patients (compare Figure 4 panel C). Black patients had an 8.7% higher risk of colon cancer death compared to White patients, even after adjusting for other risk factors in the model.

Racial Subgroup

The significant risk factors for predicting colon cancer survival differ across racial groups, as identified by the AFT (Table S1 in Multimedia Appendix 1) and the Cox (Table S2 in Multimedia Appendix 1) models. Among White patients, the most important predictors are treatment, positive nodes, age, tumor size, tumor grade, CS lymph nodes, sex, and histology. For Black patients, however, the key predictors shift slightly, with positive nodes, smoking status, insurance, age, histology, CS lymph nodes, and cigarette pack years emerging as the primary factors. These differences highlight the potential impact of both genetic and lifestyle factors on survival outcomes in different racial groups.

In the RSF model for the White patients, the risk factors were ranked in the following order of importance: treatment group, positive nodes, age, tumor size, marital status, histology, cigarette pack years, CS lymph nodes, and tumor grade. The standardized OOB CRPS was 0.149, with an OOB requested performance error of 0.241. The rest of the risk factors had minimal impact on survival predictions. For Black patients, the key predictors included positive nodes, treatment group, CS lymph nodes, insurance, age, cigarette pack years, tumor size, and smoking. The standardized OOB CRPS was 0.184, with an OOB requested performance error of 0.327. All other risk factors contributed minimally to influence survival outcomes (Figure 5 panels White and Black patients). The above analysis was not repeated for the “Other” racial group due to limited data.

Geographical Region

In both the AFT and Cox models, key risk factors for colon cancer survival vary between individuals living in the Appalachia region and those outside of it. For non-Appalachia residents, significant factors include treatment group, positive lymph nodes, age at diagnosis, tumor grade, marital status, and clinical tumor size (in the AFT and Cox models), with histology and CS lymph nodes also emerging as significant factors in the Cox model (Table S2 in Multimedia Appendix 1). In contrast, for Appalachia residents, survival is influenced by treatment group, age at diagnosis, positive lymph nodes, clinical tumor size, marital status, tumor grade, CS lymph node, and histology classification. The main differences between the 2 groups are the inclusion of CS lymph node and histology as significant factors for Appalachia residents, while clinical tumor size and smoking status are less relevant for non-Appalachia patients.

In the RSF model, the risk factors associated with colon cancer survival differ slightly between individuals living in Appalachia and those in non-Appalachia regions. For non-Appalachia residents (Figure 5, App1), the most influential factors, in order of importance, include treatment group, age at diagnosis, positive lymph nodes, marital status, CS lymph nodes, race, cigarette pack years, and smoking status. The impact of clinical tumor size was not quantified precisely but appeared to be high. Insurance, histology classification, and tumor grade also had high relevance for survival. The rest of the variables had a minimal impact. The standardized OOB CRPS was 0.151, and the OOB requested performance error was 0.244. In contrast, for patients in Appalachia (Figure 5, App2), the key significant risk factors were positive lymph nodes, age at diagnosis, treatment group, clinical tumor size, and smoking status. The standardized OOB CRPS was 0.191 and the OOB requested performance error of 0.353. The impact of cigarette pack years, histology, insurance, race, tumor grade, CS lymph nodes, and smoking status was not quantified precisely but appeared to be high. The primary differences lie in the order of importance, with treatment received and positive lymph nodes being important for both non-Appalachia and Appalachian residents, with factors such as marital status, insurance, and clinical tumor size being more prominent outside Appalachia.

Early- Versus Late-Age Diagnosis

In both the Cox and AFT models, the risk factors for colon cancer survival differ slightly between early and late stages. For early diagnosis, the most significant risk factors across both models include positive nodes, treatment group, tumor grade, tumor size, histology, and race. In the Cox model, clinical tumor size is also an important factor, while the AFT model does not highlight this. For late diagnosis, both models identify treatment group, positive nodes, tumor size, marital status, and CS lymph node as key predictors. The Cox model ranked CS lymph node and tumor size higher than marital status, while the AFT model emphasizes CS lymph nodes and marital status with different weights (Tables S1 and S2 in Multimedia Appendix 1).

In the RSF model, the key risk factors for patients diagnosed at early age with colon cancer include positive nodes, treatment group, and tumor size. Other high-priority factors are tumor grade, race, histology, cigarette pack years, insurance, CS lymph nodes, and marital status, while the remaining factors have a minimal impact on survival (Figure 5, panel Early1). For patients diagnosed at an older age, the key risk factors shift slightly to include treatment group, positive nodes, marital status, clinical tumor size, insurance, cigarette pack years, CS lymph nodes, and histology. Tumor grade is also a high-priority factor. Race, smoking status, sex, ethnicity, and Appalachia status contribute minimally to survival outcomes (Figure 5, panel Early2).

Discussion

Key Findings

The main findings of this study highlight that several individual and contextual risk factors significantly influence colon cancer survival. Across almost all models, positive sentinel lymph node, age at diagnosis, treatment received, clinical tumor size, tumor grade, smoking, geographic region, and marital status consistently emerged as dominant predictors. The highest risk of death (Table 3) was observed among individuals who received no treatment or refused treatment, compared to those who underwent any other form of treatment (primary and regional). Social determinants of health such as insurance (which serves as a proxy for poverty), Appalachia region, marital status, and modifiable risk factors such as smoking significantly impact survival. Not having insurance, smoking, living in the Appalachia region, and being married are associated with higher risk of dying. The comparison of classical and ML models demonstrated that ML approaches, particularly RSF and LASSO, offered improved predictive accuracy and variable importance insights compared to traditional methods. Consistent with prior studies, these results affirm that men have a higher risk of colon cancer death than women [56-58].

Overall, smokers had a higher hazard of mortality compared to non-smokers, a finding consistent with the results reported by Tsao et al [59]. Additionally, Appalachian residents had higher hazard than non-Appalachians (Table 3). In non-Appalachian residents, the hazard of death was higher for those with distant metastasis compared to those with in situ localized cancer diagnosis. In contrast, Appalachian residents had a higher hazard of death with distant metastasis, suggesting an interaction between geography and cancer spread, which may be compared with the findings of Wang et al [60].

Model Comparisons

When comparing significant risk factors across racial groups in the Cox model, it was evident that while the type of treatment received was a significant predictor of survival for the White patients, it did not appear to be a useful predictor for the Black patients (Table S2 in Multimedia Appendix 1). This disparity may highlight the possibility that Black patients often seek treatment later in the disease course, potentially reducing the effectiveness of the treatment they receive. However, modifiable risk factors such as smoking, cigarette pack years, and insurance status were found to impact survival among Black patients compared to White patients. This suggests that addressing these factors could help narrow the gap in colon cancer survival between White and Black patients.

In the RSF model, differences emerged in how treatment and socioeconomic factors (like insurance and smoking history) influence survival outcomes across racial groups. Both groups shared predictors like positive nodes, clinical tumor size, and tumor grade, but White patients' survival was more impacted by treatment received than positive node, while Black patients' survival was more impacted by positive node than treatment received. Other important risk factors affecting survival include smoking and insurance, which showed differences compared with White patients. This contrast suggests that while biological factors (such as tumor characteristics) are universally relevant, socioeconomic and access disparities exacerbate survival gaps between racial groups. Overall, positive lymph nodes, treatment, age at diagnosis, CS lymph nodes, tumor size, tumor grade, and histology were important risk factors in both Appalachian and non-Appalachian areas of Kentucky. CS lymph nodes, however, were more influential within the non-Appalachian population compared to patients in Appalachia.

For the Cox model, while positive nodes, treatment group, and histology were consistently significant for both early and late diagnosis, tumor characteristics and social risk factors like marital status varied between the 2 groups (early vs late diagnosis). These findings suggest that we need to integrate critical risk factors into individualized prognostic models.

Strengths

The key strength of this study is its comprehensive comparison of both classical and ML survival models and using large, population-based cancer registry data. By evaluating multiple modeling approaches including classical methods like Cox proportional hazards, AFT models, RSF, LASSO, and elastic net, our study offers valuable insights into the strengths and limitations of each method in predicting key risk factors associated with colon cancer survival. This side-by-side evaluation (Tables 3 and 4, Tables S1 and S2 in Multimedia Appendix 1, and Figures 1-5) enhances our understanding of how different algorithms handle clinical and demographic risk factors, ultimately contributing to more accurate and interpretable survival predictions. The inclusion of subgroup analyses further strengthens the findings by highlighting how predictive performance and risk factors vary across different population subgroups.

Limitations and Future Directions

First, a major limitation of this study is the lack of access to detailed, case-level data, which prevented us from analyzing several important modifiable risk factors such as alcohol consumption, obesity, familial associations or family history of CRC, inflammatory bowel disease, and dietary intake (including consumption of processed and red meats). These factors are well-established contributors to CRC risk and may also influence survival outcomes. The absence of these variables could lead to residual confounding and limits our ability to fully characterize the risk profile of patients. Future studies incorporating more granular lifestyle and clinical data would provide a more comprehensive understanding of survival determinants and allow for the evaluation of modifiable behavioral risk factors.

Clinical Implication

The findings from our survival analysis models (Kaplan-Meier curve, Cox, AFT, XGBoost, RSF, LASSO, and elastic net) provide several actionable insights for both clinical practice and public health. Across all models, consistent predictors such as positive lymph node involvement, tumor size, tumor grade, and age were associated with both early and late diagnoses of CRC. Clinically, this supports the development of risk-stratified care pathways, where patients presenting with these characteristics can be prioritized for more intensive surveillance and earlier

XSL•FO
RenderX

intervention. For example, individuals with larger or high-grade tumors may benefit from more frequent imaging or expedited treatment planning. Incorporating these factors into clinical decision-making tools could help optimize resource allocation and improve outcomes through early detection and treatment.

Beyond clinical implications, the models also highlight social and structural determinants of health that warrant attention. Race and insurance status, which were significant in the AFT and RSF models, suggest potential disparities in access to timely diagnosis. These findings can inform public health strategies such as targeted screening and outreach programs in underserved communities. The significance of marital status, particularly in late diagnosis, points to the role of social support in health care engagement, indicating a need to connect socially isolated individuals with navigators or support services. Additionally, the inclusion of cigarette pack-years and CS lymph node involvement as key factors further supports integrating lifestyle and clinical history into risk prediction frameworks, enhancing early identification of high-risk patients in both clinical and community settings. Together, these findings support the creation of risk-adapted screening, surveillance, and treatment pathways, as well as inform broader policy interventions aimed at improving access and reducing disparities in CRC outcomes.

Colon Cancer Survival and Prognosis

Different subgroups may have varying risk profiles influencing colon cancer survival and prognosis, highlighting the limitations of a one-size-fits-all approach. Understanding subgroup-specific risk factors enables tailored interventions, screening, and treatment strategies for diverse populations. By leveraging results from classical and ML survival models including Cox, AFT, RSF, LASSO, and elastic net methods, clinicians and researchers can identify the most relevant predictors of patients' survival outcome and develop individualized risk assessments. For example, the AFT model indicates that among early-onset patients, smokers experience death approximately 10% sooner than never-smokers, whereas in late-onset patients, this difference increases to 13%. Such insights highlight modifiable risk factors like smoking and suggest prioritization for targeted intervention in the higher-risk subgroups.

Colon cancer survival outcomes are shaped by both modifiable risk factors, such as smoking, insurance status, and geographic disparities, and non-modifiable factors, including age, genetics, and comorbidities. Early detection through screening remains the most effective strategy [61,62], as it significantly improves survival by enabling timely and effective treatment. Integrating these findings across different subgroups supports more precise, personalized treatment and preventive strategies, ultimately reducing the burden of colon cancer at both individual and population levels.

Conclusion

This study evaluated multiple survival analysis models, including the Cox proportional hazards model (Cox model), the AFT model, XGBoost, RSF, the LASSO regression, and elastic net. Each of these models has distinct strengths and assumptions, making them suitable for different aspects of our research questions. Both LASSO and elastic net are powerful regularization techniques that helped improve the model generalization, interpretability, and predictive accuracy.

Acknowledgments

The authors also thank Jaclyn McDowell, DrPH, at the Kentucky Cancer Registry for her assistance in extracting the colon cancer data and Jerod Stapleton, PhD, for reading through this manuscript.

Funding

Manuscript preparation was supported in part by the funds from the Department of Biostatistics at the University of Kentucky.

Data Availability

The dataset analyzed during this study is publicly available from the Kentucky Cancer Registry.

Authors' Contributions

RA conceptualized the study and led the study design, data collection, formal analysis, data interpretation, synthesis, and writing of the original draft and revisions. MEO assisted with drafting the introduction, contributed to interpretation of findings, and reviewed the manuscript. BH provided guidance on data extraction, analysis, interpretation, and reviewed the manuscript. RC contributed to the interpretation of results and manuscript review. OA contributed to conceptualization, provided critical feedback, ensured alignment with journal submission guidelines, and reviewed the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Parameter estimates from both the accelerated time model and Cox model, shown for the overall cohort and for each subgroup.

Abstract

Background: Despite the known benefits of physical activity, cancer survivors remain insufficiently active. Prior trials have adopted digital health methods, although several have been pedometer-based and enrolled mainly female, non-Hispanic White, and more highly educated survivors of breast cancer.

Objective: The objective of this study was to test a previously developed mobile health system consisting of a Fitbit activity tracker and the MyDataHelps smartphone app for feasibility in a diverse group of cancer survivors, with the goal of refining the program and setting the stage for a larger future trial.

Methods: Participants were identified from one academic medical center's electronic health records, referred by a clinician, or self-referred to participate in the study. Participants were screened for eligibility, enrolled, provided a Fitbit activity tracker, and instructed to download the Fitbit: Health & Wellness and MyDataHelps apps. They completed usability surveys at 1 and 3 months. Interviews were conducted at the end of the 3-month intervention with participants and cancer care clinicians to assess the acceptability of the intervention and the implementation of the intervention into clinical practice, respectively. Descriptive statistics were calculated for demographics, usability surveys, and Fitbit adherence and step counts. Rapid qualitative analysis was used to identify key findings from interview transcriptions.

Results: Of the 100 patients screened for eligibility, 31 were enrolled in the trial (mean age 64.8, SD 11.1 years; female patients=17/31, 55%; Hispanic or Latino=7/31, 23%; non-White=11/31, 35%; less than a bachelor's degree=14/31, 45%; and household income <US $75,000=11/31, 35%). The mean (SD) years since diagnosis was 7.1 (8.2), and the two most frequent cancer diagnoses were prostate (9/31, 29%) and breast (4/31, 13%) cancer. Participants provided positive feedback on the MyDataHelps app usability; the overall app quality received a mean score of 3.79 (SD 0.82) on a 5-point Likert scale (1=worst, 5=best). Interviews with 10 patients yielded four themes: (1) Fitbit and app setup was easy but the research team provided assistance, when needed, which was helpful, (2) motivational messages within the app were not memorable, (3) step counts and Fitbit notifications were motivating, and (4) medical professionals viewing their data were acceptable. Interviews with 5 cancer care clinicians yielded four themes: (1) some patients used wearables but rarely discussed data with clinicians; (2) activity trackers can be helpful to motivate patients and keep them accountable; (3) objective activity measures—similar to BMI, weight, and blood pressure— that they can track over time and refer to afterward were preferred; and (4) training and systematic processes to view these data as part of active workflow were desired.

Conclusions: Implementing a remotely delivered, light-intensity physical activity program was feasible and acceptable in a sample of diverse cancer survivors. Future studies should consider registry-based methods and work with clinicians to engage hard-to-reach survivor populations who have low physical activity levels and disproportionately high adverse health outcomes.

Introduction

The health benefits of physical activity for cancer survivors are widely known. Yet, few survivors are active during (<10%) and after cancer treatment (20% - 30%) [1,2]. Per the American Heart Association recommendation, cancer care clinicians should provide phsyical activity referrals to prevent cardiovascular disease in survivors [3]; however, clinicians do not always suggest these referrals [4]. Notably, acknowledging an individual's unique perspective and offering choices rather than referrals to one singular program have been shown to increase effectiveness [5,6].

There has been a recent increase in the number of physical activity programs that exist for survivors. Virtual group programs have appeared as an option that is preferred by some survivors, allowing them the social support they seek in a group format with the convenience of participating in a program from one's own home [7,8]. In a previous study, clinic-based referrals to group in-person and group virtual programs were acceptable to cancer survivors, but some also expressed a desire for a nongroup digital program option [8]. In cancer survivors, digital health programs can be effective in promoting physical activity and reducing participation barriers [9]. However, engaging diverse groups of survivors in digital programs continues to be a challenge [10], along with sustainably integrating digital programs into clinical survivorship care [11]. Ninety percent of US adults own a smartphone and 40% - 60% a wearable device [12,13]. As digital health programs are becoming increasingly more accessible, more strategies are needed to increase the reach of these programs, particularly as the number of cancer survivors grows annually [14].

This pilot study differs from past research in several ways. First, most prior digital health trials used pedometer-based interventions as opposed to Fitbit-based interventions [15], and many of these studies incorporated counseling and other forms of support in their interventions [15]. Additionally, the majority of trials using wearable physical activity trackers with cancer survivors have been done in homogenous populations, such as White, college-educated [10], and survivors of breast cancer [10,15]. Past evidence on the optimal frequency and timing of SMS text messages in this context is lacking and what evidence there is has been inconclusive [10]. Finally, very few studies have focused on older adults, who comprise the majority of cancer survivors in the United States [10].

Thus, the purpose of this study was to test a previously developed mobile health system in a diverse group of cancer survivors with the goal of refining the program and setting the stage for a larger future trial [16,17]. We tested the feasibility of using a wrist-based wearable activity tracker (Fitbit) and smartphone app dyad with survivors, including seeking feedback on survey data collection and message prompts within the app. We also sought feedback from our clinical partners to better understand the implementation of referrals to a digital health program and perspectives on accessing patient-generated health data from these programs.

Methods

Ethical Considerations

This study took place at the University of Massachusetts Chan Medical School with remote recruitment, allowing participants to partake in study activities outside of the institution. Procedures were approved by the University of Massachusetts Chan Medical School Institutional Review Board (#H00023545) and informed consent was obtained from each participant. All participant data were deidentified and study data were kept anonymous. Participants received US $25 compensation for participation in the pilot and US $25 for participation in a follow-up interview. The study was registered at ClinicalTrials.gov (NCT05417438).

Study Design

This study used a longitudinal, nonrandomized, multilevel mixed methods approach, involving both quantitative and qualitative data collection (explanatory sequential design) from enrolled patients and cancer care clinicians between January 2023 and July 2023. Cancer survivors were enrolled in a 3-month Fitbit or smartphone app intervention. The convenience sample size was not calculated, as this was a feasibility pilot study. Outcome data for the intervention included Fitbit adherence and step counts over 3 months, usability ratings of the MyDataHelps app at 1 month, and follow-up interviews. No data were collected regarding the usability of the Fitbit: Health & Wellness app, as the app was primarily used to continuously synchronize Fitbit data with the MyDataHelps app. Clinician semistructured interviews were conducted following the data collection period for the intervention (June-July 2023).

Recruitment

Eligibility criteria for the pilot study included having a past cancer diagnosis, owning a smartphone with internet access, and being deemed appropriate to participate by a medical professional as necessary. Recruitment was first conducted using paper flyers posted throughout clinics in the UMass Memorial Health network. The flyer provided interested participants with the study team's email address and telephone number to call and SMS text message to discuss the study further. Potential participants were additionally identified by extracting data directly from the electronic health record (EHR) data hosted in the UMass Chan Data Lake. Next, potential participants were sent a letter containing information about the study and instructions to call to opt out of further contact. Two weeks after being mailed, potential participants who did not opt out were called and asked if they were interested in joining the study. Potential participants who expressed interest were screened over the phone. Approval to participate in the study was sought from clinicians for potential participants based on responses in the Physical Activity Readiness Questionnaire (PAR-Q), a 7-step questionnaire screening for evidence of risk factors during moderate physical activity and reviewing for family history and disease severity [18]. Potential participants were then sent a secure email through REDCap containing a link directing them to an electronic consent form. After going through the electronic consent form with the study team over

XSL•FO
RenderX

the phone, eligible potential participants who were interested consented using their electronic signature.

Statistical Analysis

Healthy History, Demographics, and Physical Activity Readiness

Participants self-reported their age, sex, education level, race, ethnicity, date of last cancer diagnosis, and type of cancer via a telephone screening process with the study team. Physical activity readiness was assessed using the PAR-Q. Any "yes" response prompted approval to be sought from the participant's primary care provider or cancer care clinician. Once enrolled, patients completed additional health history baseline questionnaires through surveys delivered in the MyDataHelps app.

Fitbit Adherence and Step Count

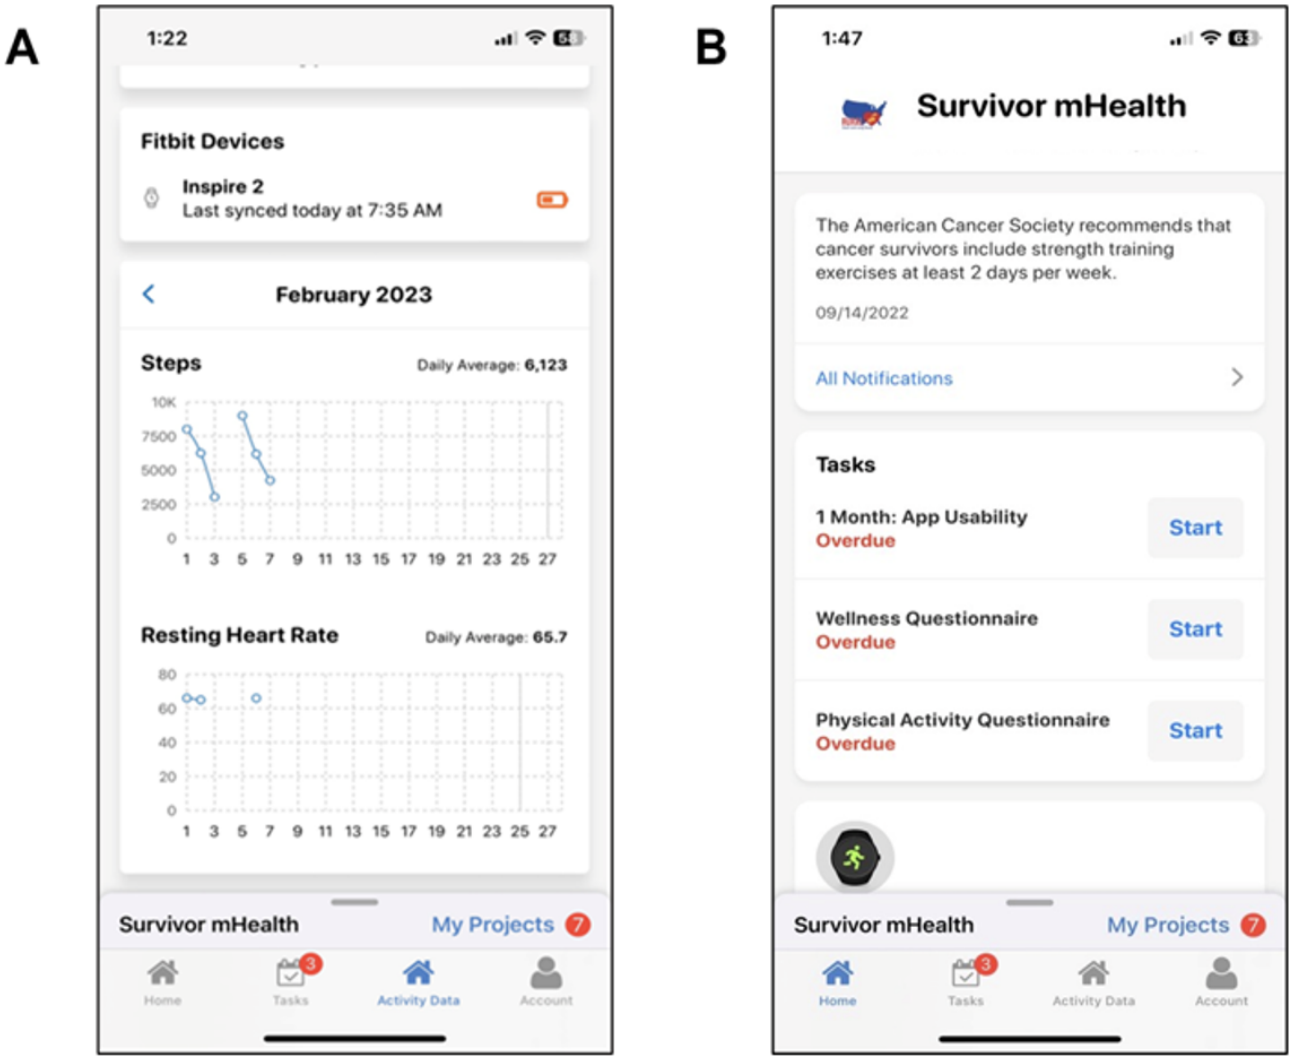
Physical activity data were adjusted for a number of valid wear days. Consistent with prior studies [19-21], valid wear days were defined as those with a daily step count of 1500 or greater as measured by the Fitbit activity tracker.

App Usability

The Mobile App Rating Scale (MARS) was used to assess the acceptability of the MyDataHelps smartphone app at 1 month through a survey delivered in the MyDataHelps app. Specific assessments of app functionality and aesthetics included ease of use, navigation, visual appeal, performance, graphics, and layout, as well as overall app quality [22]. Items were rated by participants using a 5-point Likert scale from 1=inadequate to 5=excellent. Sample questions included "how easy is it to learn how to use the app?" and "how clear are the menu labels or icons and instructions?" The MARS was scored using a mean for each category. The MARS has demonstrated internal consistency (α=.9) and interrater reliability (intraclass coefficient=0.79) [22,23].

Participant and Clinician Acceptability

Enrolled participants completed semistructured interviews (Multimedia Appendix 1) after the 12-week intervention to assess their experiences during the study, including areas of improvement. Health care clinicians' perceptions on integrating this program into clinical practice were also assessed through semistructured interviews.



Protocol for Intervention

The intervention protocol, including the MyDataHelps app, was previously user-tested in a healthy cohort [24]. All participants received a Fitbit Charge device (versions 2 and 5) to keep as part of their compensation for participating. Following consent, participants were mailed their Fitbit along with paper instructions for device and app setup (including a unique study identifier) and were provided technical support over the phone by the study team. Study participants downloaded 2 apps onto their phones: Fitbit: Health & Fitness and MyDataHelps. Upon enrollment, participants were instructed that the standard goal steps/day set by Fitbit is 10,000 steps. They were told they could modify their step-count goal based on what their current activity level was and what they felt was achievable. Participants were instructed to wear their Fitbit for a total of 3 months, during which time they received standard Fitbit: Health & Fitness push notifications to their Fitbit devices, such as alerting them of achievement of goal steps per day, time spent in active heart rate zone minutes (if participants enter a high-intensity workout zone), and movement reminders (to get up and move if inactive for a period). These messages are preset by Fitbit to be delivered to participants based on their individual data.

Participants' smartphones also received push notifications from MyDataHelps to promote adherence to the study surveys, along with weekly push notifications of motivational messages (Figure 1). These messages were templated messages to inform participants about the benefits of exercise and strategies to incorporate exercise into their day, derived from the American Cancer Society (eg, "Research has shown that exercise is not only safe and possible during cancer treatment, but it can improve how well you function physically and your quality of life" and "End your exercise session with stretching or flexibility exercises. Hold a stretch for about 15 to 30 seconds and relax. Examples of stretching are reaching overhead, deep breathing, and bending over to touch your toes so that you relax all the muscle groups") [25].

XSL•FO
RenderX

Figure 1. MyDataHelps app displaying Fitbit data (A) and message notifications and survey tasks (B).

Participants who experienced technical challenges or difficulties adhering to study protocols (eg, syncing Fitbit, completing surveys) were contacted by phone to troubleshoot issues. Through the MyDataHelps app, participants completed surveys 24 hours, 1 month, and 3 months after enrollment. Participants also received push notifications alerting them that the surveys were available within the app (Figure 1). Participants' Fitbit devices were synced to the MyDataHelps app. Once participants registered for MyDataHelps and synced their Fitbit: Health & Wellness account, data collection from the Fitbit activity tracker began. The study team viewed activity and survey completion data weekly and conducted outreach to participants with missing data. We continued to reach out to participants, including giving them an opportunity to complete their 3-month survey. Those who did not complete their 3-month survey were considered lost to follow-up. After participants completed all the tasks required for the study, they were allowed to keep their Fitbit and were provided a US $25 Amazon gift card.

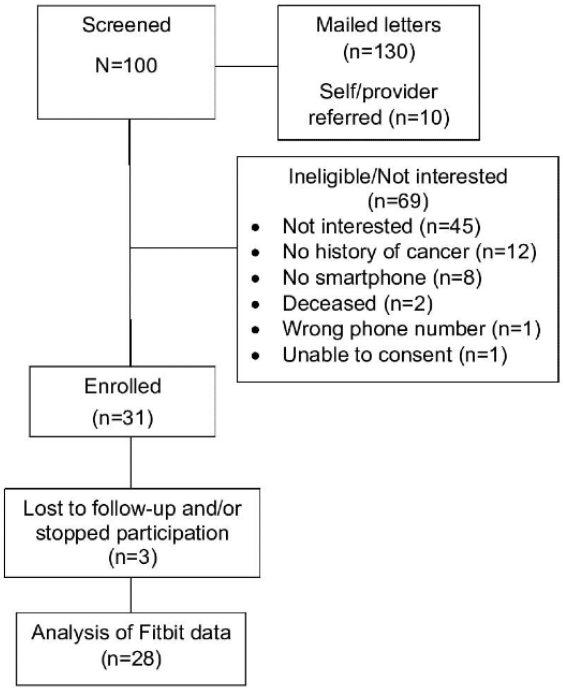
Protocol for Qualitative Feedback From Participants and Cancer Care Clinicians

Upon completion of the study tasks, participants were offered the option to take part in a 30-minute semistructured Zoom interview. Participants who took part were compensated with a US $25 Amazon gift card (in addition to the gift card provided for the completion of study tasks). Interview guides were developed by the study team using an iterative process of pretesting. The interview guide consisted of questions asking their perceptions of the program overall, as well as asking them ways to improve the current list of messages they received within the app (Multimedia Appendix 2). These guides were revisited after interviews to determine if any additional questions needed to be added, removed, or probed further. Cancer care clinicians, specifically advanced practice providers, were recruited via pre-existing relationships with the study team and through the survivorship coordinator. The survivorship coordinator emailed cancer care clinicians involved in survivorship care information about the study and about participating in interviews. Participating clinicians were asked to complete a 30-minute Zoom interview using a structured interview guide. The guide was designed to discuss implementing physical activity referrals to digital health programs into clinical workflow, along with preferences for reviewing those data. Again, the interview guide was revisited after each interview for revisions. The survivorship coordinator also provided feedback on the interview guides throughout the process. Zoom interviews were conducted by a trained member of the research team in conjunction with the study principal

XSL•FO
RenderX

investigator and recorded and transcribed electronically using an institutional review board–approved software.

Data Analysis



Quantitative analyses for demographics, usability surveys, and Fitbit data were completed using R 4.3.2 (The R Foundation) and Microsoft Excel. Analysis of Fitbit step count data (mean and SD of steps per day each week) was done on valid days, in which valid days were defined as those with a step count of 1500 or greater [20-22]. As such, the first valid day of Fitbit use was the first day the participant walked 1500 or more steps while wearing Fitbit, and data collection from Fitbit concluded 90 days following the first valid day. Any days with fewer than 1500 steps within the 90-day time frame of study participation were considered missing. Qualitative data were analyzed using rapid qualitative analysis [26]. This was done by first creating a matrix in Excel after the participants' interviews were completed. The matrix had a row for each participant and columns for each domain that corresponded with the interview guide. Domains included "experiences with patients and wearables devices," "when to integrate program into clinical practice," "preferences to clinical team viewing data," and "support needed for clinicians (eg, EHR staff) or patients." The study team (JMF, RN, AK, and ZD) then met to code the interview transcripts for 2 participants in each group, and then individually coded the remainder on their own. The study team met regularly to conduct data and coding checks and resolve any discrepancies in coding or domain assignment. The team noted the common themes between the participants' responses to each domain and identified key findings of the qualitative interviews. Each key finding discusses the main common themes within the qualitative interviews that align with the domains.

Results

Overall Results

Figure 2 presents the flow of participants from contact to the conclusion of the 12-week intervention. The study team mailed letters to 130 potential participants and had 10 potential participants either self-refer or were referred by their clinician. Of the 100 potential participants who were screened, 31 participants enrolled in the trial, achieving a response rate of 31%.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

Among the 31 participants enrolled in the intervention, the mean age was 64.8 (SD 11.1) years, 17 (55%) identified as female, 14 (45%) had less than a bachelor's degree level of education, 7 (23%) identified as Hispanic or Latino, and 11 (35%) identified as non-White (Table 1). The top two cancer diagnoses were prostate (9/31, 29%) and breast (4/31, 13%), and the mean years since diagnosis was 7.1 (SD 8.2).

Fitbit Adherence and Activity

Physical activity adherence during the 12-week intervention was assessed using Fitbit data (Table 2). Based on this measure, the mean daily step count was 7219 (SD 4418) at baseline and 6687 (SD 3183) at 12 weeks.

XSL•FO
RenderX

Table . Mean (SD) number of valid days of adherence to wearing the Fitbit activity tracker and mean (SD) steps/day during the 12-week intervention period among cancer survivors (n=28).

Intervention week	Number of valid days/week, mean (SD)	Steps/day, mean (SD)
1	1.93 (2.61)	7218.61 (4417.71)
2	4.78 (2.83)	6447.97 (3405.71)

7	5.11 (2.53)	6570.96 (3950.37)
8	5.07 (2.89)	6628.75 (3745.22)
9	4.70 (3.01)	6871.6 (4134.65)
10	4.69 (3.17)	6598.36 (3481.8)
11	4.77 (2.96)	7384.56 (4157.78)
12	4.08 (2.62)	6686.95 (3183.27)

Mobile App Rating Scale

At 1 month, 25 participants completed the MARS usability scale responding to questions about the MyDataHelps app functionality, appearance, and overall rating on a scale of 1 to 5 (1=worst and 5=best; Table 3). The highest-rated category was “performance” with a mean score of 4.36 (SD 1.02), and the lowest-rated category was “ease of use” with a mean score of 3.79 (SD 1.22). The overall app quality received a mean score of 3.79 (SD 0.82).

Table . MARS (Mobile App Rating Scale) usability scores of the MyDataHelps smartphone app; ratings range from 1=worst to 5=best.

Variable and question	Values, mean (SD)
Performance: How accurately/fast do the app features (functions) and components (buttons/menus) work?	4.36 (1.02)
Ease of use: How easy is it to learn how to use the app? How clear are the menu labels/icons and instructions?	3.79 (1.22)
Navigation: Is moving between screens logical/accurate/appropriate/uninterrupted? Are all necessary screen links present?	4.21 (1.22)
Interactions: Are interactions (taps/swipes/pinches/scrolls) consistent and intuitive across all components/screens?	4.13 (1.05)
Layout: Is the arrangement and size of buttons/icons/menus/content on the screen appropriate or zoomable if needed?	4.04 (1.02)
Graphics: How high is the quality/resolution of graphics used for buttons/icons/menus/content?	3.80 (0.85)
Visual appeal: How good does the app look?	3.84 (0.78)
Overall rating: What is your overall star rating of the app?	3.79 (0.82)

Qualitative Feedback

Ten participants completed 3-month follow-up interviews assessing their overall experiences in the program. Four themes were identified from our analyses, and illustrative quotes can be seen in Table 4. Overall, participants felt the Fitbit activity tracker and the MyDataHelps app were easy to use but also benefited from the assistance of the research team. The weekly motivational messages within MyDataHelps were not very memorable and were often confused with the daily push notifications sent directly to the Fitbit activity tracker. For example, when asked about the content of the MyDataHelps weekly messages, a participant responded, “I didn’t pay a whole lot of attention to them. I know I got ‘em maybe daily or every other day.” However, participants noted overall that the messages and notifications motivated them to be more active and accrue additional steps. Lastly, most participants were comfortable with and liked the idea of sharing their physical activity data with their clinicians.

XSL•FO
RenderX

Table . Enrolled patient feedback from qualitative interviews.

Theme	Illustrative quotes
Fitbit and app setup were easy and assistance from the research team was helpful.	• "I didn't find it [Fitbit and MyDataHelps setup and navigation] to be a problem at all once you walked me through it." "The information provided was pretty self-explanatory, even though I'm not very computer-savvy and never had a Fitbit."
Motivational messages within the app were not memorable.	• "They weren't sent often. Not, not particularly unless I set it up wrong. I think if I had gotten something on a weekly or even a daily [basis], it would motivate me." "Well, the messages, if any, were, I believe...I forget how I was able to access them...I'm trying to think of a specific message."
The step counts and Fitbit notifications to be active were motivating.	• "Tracking my steps was helpful, especially given how I've changed my lifestyle from working full-time to finally being home most of the time. And I had to make sure I put some time into taking steps or helping my health progress." • "Before, I never actually paid attention to like, 'Okay, I'm gonna do this many steps today, or I'm gonna do this.' And that was pretty cool that it gave that option to keep track of all that. And if I beat my goal from the day before, it would let me know. It would tell me, 'Congratulations!' which was kind of cool."
Patients were comfortable with and liked the idea of medical professionals seeing their data.	• "I did tell my oncologist that I was doing this study and I also spoke with my pulmonologist...And I told my primary care, and she said, "Well, that's interesting." I said, "You know the thing is, you never know what [information] is going to come along that might be helpful to you in the long run." • "I would like that because it's able to connect some of the dots, right? They're only seeing, you know, the medical side of it, but they can't see your everyday activity."

Five advanced practice providers specializing in oncology completed interviews to assess their perceptions of the digital health program and workflow integration. All 5 clinicians were female, had been practicing in their clinic for >1 year, and treated either disease-specific patients (breast, gastrointestinal, or genitourinary) or patients of all diagnoses. Clinicians were from one academic hospital (n=4) and one community hospital (n=1). Four themes were identified with illustrative quotes represented in Table 5. Clinicians noted some patients use wearables but rarely bring them up during their clinic visits. They also expressed that goal setting may be helpful for their patients and thought it may be helpful to have objective metrics of physical activity to track over time in lieu of standard weight and BMI clinical measures. Most clinicians wanted more education and training on physical activity and wearable device programs and better standard operating procedures integrated into their workflows.

Table . Clinician feedback from qualitative interviews.

Theme	Illustrative quotes
Some patients use wearables but rarely discuss data with clinicians.	"I don't know that it comes up all that often. Things have changed since Covid. I used to have tons of patients who would do this kind of thing like the Silver Sneakers-type program...Not too much beyond the generic, like, 'I shoot for X number of steps a day and I usually [get] X.'"
Activity trackers can be helpful to motivate patients and keep them accountable.	"Some people are motivated by their internal motivations. And I think Fitbit still gives you that accountability and that trackability. I've had patients that have used pedometer-esque, Fitbit-like, applications, whether it's their iPhone or something like that, and they'll say, 'Okay, I got this many steps.' And I think that it does motivate them to be more active."
Clinicians prefer objective measures similar to BMI, weight, and blood pressure that they can track over time and refer to afterward (eg, vital signs).	"Typically, what I use is their BMI...to say, 'Oh, congratulations! Your BMI last visit was this and look what it is now. I can see that you have better energy, and your wellbeing seems to be improved as well.' It could be helpful for that sort of reinforcing and motivating and monitoring portion."
Clinicians want more training and systematic processes to view these data as part of active workflow.	"With training and guidance, if that was considered part of our scope, if we felt like patients were benefiting...yeah, absolutely...if it's something that would help patients and is clinically appropriate depending on whatever training we got."

Discussion

Principal Results

Our study found that deploying a Fitbit or app dyad remotely was feasible and acceptable in this convenience sample of diverse participants with histories of several types of cancers. Participant engagement, as indicated by mean valid wear days and mean daily steps each week, was highly consistent over the course of the 12-week intervention. This finding was similar to those of past trials in cancer survivors [27-29]. The main exception to this was that on average, participants had fewer valid wear days in the first week of the intervention, which, similar to other trials, can be attributed to an initial adjustment period to wearing a Fitbit daily [30]. Though engagement was high, step counts remained relatively unchanged from baseline to 12 weeks. Lastly, several cancer care clinicians were interested in the ability to deploy such an intervention into their clinical practice for physical activity surveillance and interventions for their patients with cancer histories.

The MARS app ratings were similar to other physical activity monitoring app studies in that functionality components were rated higher than aesthetic components [24,31]. The high functionality ratings were supported in our qualitative feedback, with participants specifically noting the app being easy to use even if they themselves were not very tech-savvy. This is critical in the cancer survivor population, as 67% of US cancer survivors are over the age of 65, and this proportion is expected to grow to 74% by 2040. There are noted disparities in the use of digital health tools in advanced age [32]. However, participant qualitative feedback revealed the messages sent within the app were not very memorable. This may have been due to the message content, or possibly that they did not know where to view the messages on the MyDataHelps app dashboard. Several participants made more mention of the daily Fitbit device notifications being helpful. As motivational messaging has been shown to be effective in promoting physical activity [33,34] and was memorable to our participants on the Fitbit device, it is possible the notifications, along with vibrations, going directly to a patient's device on their wrist are more noticeable than having to open an app to see the message. Despite notifications being reported as helpful, changes in step count over time were minimal. Though consistent with prior feasibility studies in this population [27,35], it will be critical to explore the effect of intervention components on step count over time in a large randomized trial. This includes exploring the addition of social support, a feature in Fitbit, and a feasible and acceptable intervention method for cancer survivors [35].

Qualitative feedback from participants yielded several important implications of recruiting, enrolling, and retaining patients throughout the study. The first important implication was that the MyDataHelps and Fitbit: Health and Wellness apps setup was straightforward and easy to follow. Some participants noted they were not tech-savvy, but they did not find it to be an issue. Participants also appreciated the help from the study team during the initial setup and to troubleshoot any issues that arose. To provide technical support, our study team used multiple methods to meet the needs of the participants. For most, this only entailed troubleshooting issues over the phone or SMS text message. Six participants additionally required videoconferencing and screen sharing to troubleshoot technical difficulties with a visual aid. Of the 6 participants, 4 chose to come in person for the study team to troubleshoot their issues. With additional assistance by video call or in person, these participants were also able to complete the study tasks quickly. Overall, the team found that participants greatly appreciated having options to connect and talk with them. The final theme from participants indicated they were comfortable sharing data with health care clinicians. Health care professionals can be critical in helping survivors engage in physical activity. Survivors reported a lack of physical activity guidance, prescriptions, and referrals from their care team as barriers to activity [36].

Clinicians revealed that patients rarely discuss wearable devices or data with them during their clinic visits. Oncology nurses have reported that patients lack interest in discussing physical activity with them. However, clinicians liked the notion of having long-term activity monitoring as a topic to discuss with patients in lieu of discussing weight or BMI. Physical activity independent of weight loss can improve health outcomes in individuals with obesity [37], and sedentary time, which is inversely correlated with physical activity levels, is an independent risk factor of cancer incidence [38]. Using a more neutral objective measure of physical activity rather than a more sensitive metric like weight or BMI may be more acceptable to discuss with patients who have weight concerns. To do this, clinicians expressed wanting more education and training on integrating physical activity digital health tools into their workflow as options for their patients. Lack of provider knowledge has been one of the most commonly reported barriers to the provision of physical activity promotion by cancer care clinicians to survivors [39]. Additionally, integrating wearable devices and subsequent data directly into clinicians' workflow poses challenges. Prior studies have identified barriers to integrating devices into the EHR, maintaining privacy and confidentiality of patient data, lack of system interoperability and connectivity of wearable devices and health systems, and patient information or data overload [40].

Limitations

This study has limitations to note. The small sample size is a statistical limitation. Similar to most studies done in the past, this study was limited to 3 months in duration; thus, there still remains little research regarding long-term outcomes from Fitbit-based interventions, including health outcomes [11,16]. As trials longer than 6 months have noted greater dropout rates over time [16], it will be important to explore this timeframe in future trials. Another limitation regarding the study design was the lack of a control group. Although this design has been used in similar feasibility trials, the lack of a control group limits the inferences we can make pertaining to the internal validity of the intervention. Though participant step counts were fairly consistent during the trial, this consistency could be attributed to having a highly motivated sample of individuals or to the Hawthorne effect and its impact on motivation and behavior. With regard to app usability, some participants reported confusing the SMS text messages delivered by the MyDataHelps app with push notifications sent by the Fitbit: Health & Wellness

XSL•FO
RenderX

app, which may have affected their MARS usability score evaluation. Additionally, familiarity and comfort with navigating smartphone apps associated with wearable technology were not assessed. Notably, we relied on recruiting patients from an EHR patient registry list. This method may have allowed us to capture patients who would not otherwise have reached out to join the study, but also may have introduced selection bias and is less pragmatic than a program that is implemented within routine clinical workflow. While we examined step counts only, it should be noted that Fitbit tracks additional metrics of minutes and intensity of activity and time spent being sedentary that should be considered. Lastly, we ascertained that most of the clinicians wanted training, guidance, or knowledge of how to integrate these into their workflow. Given the busy workload of clinicians, it is possible that in practice they would prefer better reports and objective data to be provided, rather than actively taking part in new tasks added into their workflow. This should be examined in future trials.

Conclusions

This study showed that a remotely delivered light-intensity physical activity program was feasible and acceptable in a sample of diverse cancer survivors. Future studies should consider registry-based methods and other strategies to engage hard-to-reach cancer survivor populations who are known to experience disproportionately high adverse health outcomes and low physical activity levels. These strategies should also be directed toward making improvements to recruit and engage larger numbers of participants from diverse sociodemographic backgrounds with consideration to technology access and use. On an individual scale, since some participants may have been more intrinsically motivated than others, future trials will benefit from assessing the underpinnings of participant motivation. Lastly, future trials should place emphasis on clinic implementation, including the quality of and method of delivery for reports, given the noted importance and use of the wearable device and app integration by cancer care clinicians for their survivors to be motivated to engage in and sustain physical activity.

Acknowledgments

This work was supported by the National Cancer Institute (5P50CA244693) and the National Heart, Lung, and Blood Institute (K01HL163254). The funders did not play a role in the design of the study; the collection, analysis, and interpretation of the data; the writing of the manuscript; and the decision to submit the manuscript for publication.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Older adults (aged >65 years) are disproportionately affected by cancer at a time when Canadians are surviving cancer in an unprecedented fashion. Contrary to persistent ageist assumptions, not only do the majority of older adult cancer survivors use digital health technologies (DHTs) regularly, such technologies also serve as important sources of their health information. Although older adults' transition to cancer survivorship is connected to the availability and provision of relevant and reliable information, little evidence exists as to how they use DHTs to supplement their understanding of their unique situation to manage, and make decisions about, their ongoing cancer-related concerns.

Objective: This pilot study, which examined older adult cancer survivors' use of DHTs, was conducted to support a larger study designed to explore how digital health literacy dimensions might affect the management of cancer survivorship sequelae. Understanding DHT use is also an important consideration for digital health literacy. Thus, we sought to investigate older adult cancer survivors' perceptions of DHTs in the context of accessing information about their health, health care systems, and health care providers.

Methods: A qualitative pilot study, which involved semistructured interviews with older adult cancer survivors (N=5), was conducted to explore how participants interacted with, accessed, and searched for information, as well as how DHT use related to their cancer survivorship. Institutional ethics approval (#21 - 0421) was obtained. Interpretive description inquiry—a practice-based approach suitable for generating applied knowledge—supported exploration of the research question. Thematic analysis was used to examine the transcripts for patterns of meaning (themes).

Results: Assessing the credibility of digital information remains challenging for older adult cancer survivors. Identified benefits of DHTs included improved access to meet health information needs, older adult cancer survivors feeling empowered to make informed decisions regarding their health trajectory, and the ability to connect with interdisciplinary teams for care continuity. Additionally, participants described feeling disconnected when DHTs seemed to be used as substitutes for human interaction. The results of this pilot study were used to create 12 additional questions to supplement a digital health literacy survey, through which we will seek a more fulsome account of the relationship between digital health literacy and DHTs for older adult cancer survivors.

Conclusions: Overall, this pilot study confirmed the utility of DHTs in enhancing the connection of older adult cancer survivors to their health care needs. Importantly, this connection exists on a continuum, and providing greater access to technologies, in combination with human support, leads to feelings of empowerment. DHTs are an important aspect of contemporary health care; yet, these technologies must be seen as complementary and not as replacements for human interaction. Otherwise, we risk dehumanizing patients and disconnecting them from the care that they need and deserve.

(JMIR Cancer 2025;11:e59391) doi:10.2196/59391

KEYWORDS

older adults; cancer survivors; digital health literacy; digital health technologies; aging; qualitative; pilot study; semistructured interview

Introduction

Older adults (aged >65 years) are the fastest-growing segment of the Canadian population with unprecedented cancer survivorship [1]. Technology has become increasingly important, with older adult cancer survivors reporting that a significant proportion of their health care information is gathered from digital sources [2]. Despite such availability, finding and accessing information during transitions to survivorship are challenging [3]. Access to information plays a vital role in improving cancer survivors' health outcomes and quality of

XSL•FO
RenderX

life. Although older adult cancer survivors may have unique needs, there is little research examining the extent of digital health technology (DHT) use to support their health. DHTs "use computing platforms, connectivity, software, and sensors for health care and related uses" and include telemedicine, wearable devices, educational resources, remote patient monitoring, etc [4].

With the increasing reliance on DHTs [5], a consistent concern for older adult cancer survivors is interacting with health care systems digitally [6]. Contrary to persistent ageist assumptions, not only do 95% of this group use DHTs regularly, DHTs are substantial sources of their health information [7]. Understanding DHT use is also an important consideration for digital health literacy (DHL). DHL is the capacity "to acquire, process, communicate, and understand health information and services, make effective health decisions, and promote and improve individual and collective health in the context of the use of digital information and technologies" [7]. This pilot study, which examined older adult cancer survivors' use of DHTs, was conducted to support a larger study designed to explore how DHL dimensions might affect the management of cancer survivorship sequelae.

Methods

Ethical Considerations

The pilot study reporting was guided by the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist (Checklist 1) [8]. Institutional ethics approval (#21 - 0421) was obtained from the University of Victoria, and informed consent was secured in advance of conducting interviews. Confidentiality was maintained throughout the research process, and all transcripts were deidentified prior to analysis, with data stored in password-protected files. Participants were given a CAD $25 (US $17.53) gift card.

Recruitment

Participants were recruited through the social media platforms of local eldercare and retirement groups, and recruitment consisted of 3 recruitment posters that were posted weekly in attempts to elicit diverse responses. As only 2 participants responded to those efforts, an additional 3 participants were recruited, using the snowball method by way of the initial 2 participants' social networks. The inclusion criteria included being aged 65 years or older, speaking English, having completed cancer treatment within the past 5 years, and being a resident of British Columbia, Canada.

Data Collection

Semistructured, 90-minute, individual interviews were conducted over a secure videoconferencing platform. Interview questions investigated how participants interacted with, accessed, and searched for information, as well as DHT use related to their cancer survivorship (Textbox 1). The audio-recorded interviews were transcribed and deidentified by the research associate (CF), with two researchers (LN and HM) reviewing for accuracy, prior to analysis. Participants were offered an opportunity to review their transcript for accuracy.

Textbox 1. Interview questions. Research questions asked to the participants aimed to identify how older adults use digital health tools to interact with, access, and search for information related to their health care and cancer survivorship.

Interview questions

1. What information resource(s) did you use most often?
2. How did you manage multiple information resources?
3. How did you determine the information was credible?
4. Knowing what you know now, what information do you wish you had access to?
5. What questions did you have around your transition from treatment to survivorship?
6. What questions were the most difficult to find answers to?
7. What have you found difficult to understand about this transition?
8. What do you like/dislike about using digital health tools?
9. What makes it easy/difficult for you to use digital health tools?
10. Now that you have completed the eHealth literacy survey, and after thinking about the questions already asked, is there anything else you would like to tell us?

Reflexivity, Interpretive Description, and Thematic Analysis

All interviews were conducted by 2 PhD-prepared assistant professors (LN and HM) and an undergraduate student, who was included as a research associate (CF). The lead authors have experience with qualitative research; are from the Global North; and identify as cisgender, White, female individuals who endeavor to be reflexive on positionality and perspectives throughout the research process. Interpretive description inquiry—a practice-based approach suitable for generating applied knowledge—supported exploration of the research question [9]. Thematic analysis was used to examine the transcripts for patterns of meaning (themes) [10]. The researchers convened after independently reviewing the first transcript to ensure congruence. As the researchers became familiar with the data and generated initial codes, themes were reviewed together. Finally, the researchers agreed that the themes accurately reflected participants' responses.

XSL•FO
RenderX

Results

Participants

A total of 5 older adult cancer survivors (4 women and 1 man), with an average age of 69 (SD 2.06) years, completed interviews. All 5 had postsecondary education and stated that they accessed DHTs daily. All participants had completed cancer treatment within the past 5 years and represented different geographic areas of the province. Participants were not known to the researchers prior to the interviews; however, researcher information and an overview of the research project were included in the informed consent process. Time and an opportunity for participants to ask questions were provided prior to the interviews. Additionally, during the informed consent process, participants were assured that their data were private and were not to be shared publicly. Thus, supporting data are not available publicly.

Themes

Thematic analysis [10] highlighted the following three main themes: access, empowerment, and connection.

Access

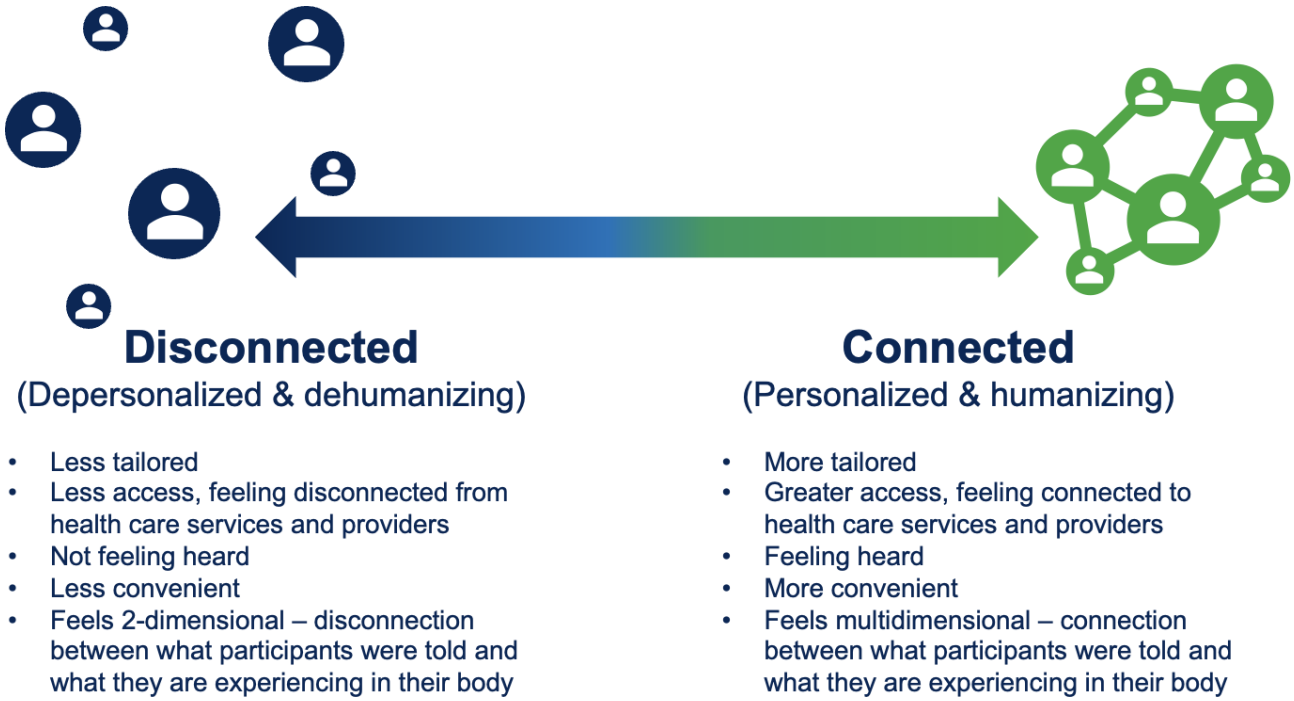
All participants agreed that access to DHTs is crucial for health care purposes and for facilitating health care needs with minimal disruption to routines. Distinguishing between access and accessibility is essential; despite owning digital devices and feeling comfortable with using them, 3 participants had no interest in or did not enjoy using digital devices for health care. However, 1 participant expressed how DHTs "were very helpful" and that they "used them for follow up with therapists and counselors." Such access allowed health care needs, such as education and remote connection to health care professionals (HCPs), to be addressed conveniently.

Empowerment

All participants associated DHT with feelings of empowerment, that is, being involved in their health decisions and being in control of their information (including access). All participants discussed the autonomy provided by DHTs. Participants explained feeling empowered by being in control, by accessing education, and by the ability to book appointment times. One participant said, "You can get all the information you need…I never cease to be amazed at what technology can do." Another participant expressed their satisfaction with DHTs, stating "I don't have to track it down; everything is just right there." As such, participants found that independently booking appointments, retrieving educational materials, and reviewing available medical records (eg, laboratory results) improved their sense of empowerment.

Connection

Participants described how DHTs enhanced connection. One participant stated that DHTs "allow for discussion that healthcare professionals wouldn't [otherwise] have time [to start]." A second participant echoed this, saying "When I was really sick, my doctor called me every day." This web-based connection was especially important in instances when participants were too ill to commute but not ill enough to be admitted to a hospital. In other cases, participants discovered community support through online groups. For example, one participant found videoconferencing with a survivorship group very helpful. Another participant stated, "I remember [medication] affected emotions; nothing could prepare you for that…My doctor and counselor didn't really talk about it...going online and finding that other people are having the same impact was very comforting." In this case, the patient found a sense of community through shared experiences on the web.



Paradoxically, participants also described experiences where human connection was absent. One participant shared an example of when an HCP noticed and addressed a physical concern as they were leaving an in-person appointment. This participant felt that this would never have been noticed in a web-based meeting. Another key observation was how intonation of voice, facial expressions, and body language of HCPs were difficult to discern and negatively impacted the participants' interpretations of interpersonal communication. One participant expressed frustration with "stereotypes placed on older people." Another stated, "People tend to treat everyone over the age of 65 like they are homogenous." Participants expressed annoyance with HCPs often overexplaining technology or assuming a lack of understanding of how to access DHTs when the participants felt that they could complete the task independently. The participants also pointed out instances in which HCPs lacked knowledge about the DHTs they expected patients to use.

Key Learnings to Inform Future Work

Participants reported that DHTs can facilitate access and empowerment. Participants' experiences also pointed to how DHTs can either foster connection or create barriers to human connection. That is, they described their feelings of connection as along a continuum from feeling disconnected from health care services to feeling connected with health care services (Figure 1). Participants outlined items that contribute to disconnection, such as the feeling of not being heard, services that are less tailored to their situation, and less accessibility. In contrast, participants further described feelings of greater connection with items such as greater access, the feeling of being heard by HCPs, and congruence between information received and what they are experiencing in their body. The results of this pilot study were used to create 12 additional questions to supplement a DHL questionnaire (Textbox 2) for the next phase of the project [11], in which we will seek a more fulsome account of the relationship between DHL and DHTs for older adult cancer survivors.

Figure 1. Connection continuum.

Textbox 2. Questions to be included in the eHealth literacy survey. After completing the interviews, the following questions, based on the insights from pilot study participants, were created to address additional areas of importance in the digital health literacy survey.

Questions to be included in the eHealth literacy survey

1. To support your survivorship, what information did you get using digital health tools?
2. Has the COVID-19 pandemic changed the way you think about digital health tools?
3. What digital health tools (apps, websites, wearables) did you use to support health and survivorship and how useful were they?
4. Did you join any support groups for people who have finished cancer treatment?
5. How often do you use digital health tools?
6. Is there anything you like about using digital health tools?
7. Is there anything you dislike about using digital health tools?
8. Is there anything you dislike about digital health tools as a part of health care?
9. If you are frustrated using digital health tools, how did you get through this frustration?
10. Where do you go if you need help with digital health tools?
11. In the past year, have you connected with a health care professional digitally?
12. What recommendations do you have about digital health tools for health professionals and organizations?

Discussion

Principal Findings

The participants in this pilot study confirmed some of the benefits of using DHTs for older adults' cancer survivorship; they can learn about their condition, connect with interdisciplinary teams for continuity of care, find connections and community support, and make educated and informed decisions regarding their health trajectory in survivorship. These findings are congruent with other studies, in which older adult cancer survivors expressed preferences for in-person visits and personalized telehealth visits [12], described how using DHTs could provide a sense of autonomy (ie, by allowing them to be actively involved with their health care) [2], and appreciated access to technology while maintaining a strong preference to be listened to with basic respect [13]. However, the propensity of health care systems to use DHTs as substitutes for human interactions to increase cost-effectiveness and efficiency can counteract those benefits. Indeed, given the existing structural ageism inherent in contemporary health care, there is a real danger of amplifying ageist processes, which can result in care that does not account for the intersection of normal aging and cancer survivorship [13]. Further, with the current lack of accounting for the burdens of navigating challenging cancer care systems, DHTs can either escalate feelings of disconnection or provide opportunities for connection and reconnection. Re-establishing the patient at the center of care and leveraging the humanity possible in DHTs are crucial; to continue to do

XSL•FO
RenderX

otherwise will ultimately lead to a sense of disengagement. DHTs are an important aspect of contemporary health care; yet, these technologies cannot replace HCP contact, or we risk dehumanizing patients and disconnecting them from the care that they need and deserve. By using DHTs compassionately and strategically for the ongoing care of older adult cancer survivors, HCPs can support this group along a continuum from feeling disconnected from health care services to feeling connected with health care services. Thus, it is imperative to determine the conditions under which DHTs complement health care and enhance rather than impair connection.

Limitations

Despite providing insights to augment the future survey, having only 5 participants inherently limits the scope and transferability of these findings. Further, although the participants represented geographic diversity, all identified as White, spoke English, and had postsecondary education; thus, this small, nonrepresentative sample may have reduced the richness of the data and the ability to achieve data saturation. Questions regarding diversity will also be added to the upcoming survey.

Conclusion

Overall, this pilot study confirmed the utility of DHTs in enhancing the connection of older adult cancer survivors to health care. Importantly, this connection exists on a continuum, and providing greater access to DHTs, in combination with human support, leads to feelings of empowerment. We are confident that applying these findings to further research will illuminate best practices for supporting older adult cancer survivors to optimize their cancer-free years.

Abstract

Background: Though telehealth has been a promising avenue for engaging cancer survivors with health care and lifestyle programming, older and rural-dwelling cancer survivors may have additional challenges in accessing digital devices and tools that have not yet been described. This study aimed to use a robust, nationally representative sample collected in 2022 to provide an updated view of digital technology use and the use of technology for health in this population.

Objective: This study aimed to examine the prevalence of digital technology use for health-related activities among older cancer survivors in both rural and urban settings. The primary outcomes of interest included (1) internet access and use for health-related activities, (2) digital device ownership and use as a tool for health behaviors, (3) use of social media for health, and (4) use of telehealth.

Methods: A cross-sectional analysis of the National Cancer Institute's Health Information National Trends Survey Cycle 6 (HINTS 6) was completed to examine the prevalence of digital technology use among older cancer survivors. For analysis, the sample was restricted to cancer survivors over the age of 60 years (n=710). Unadjusted and adjusted logistic regression models were used to test the association between rurality and digital health tool use.

Results: Overall, 17% (125/710) of the sample lived in a rural area of the United States and the mean sample age was 73 (SD 8.2) years. Older cancer survivors, regardless of rural-urban status, reported a high prevalence of internet usage (n=553, 79.9%), digital device ownership (n=676, 94.9%), and social media use (n=448, 66.6%). In unadjusted models, rural survivors were less likely than urban survivors to report that they had used a health or wellness application in the previous year (odds ratio [OR] 0.56, 95% CI 0.32-0.97; *P*=.04). In adjusted models, rural survivors were more likely to report that they had shared personal health information on social media (OR 2.64, 95% CI 1.13-6.19; *P*=.03). There were no differences in the proportion of rural and urban respondents who reported receiving health services through telehealth in the previous year.

Conclusions: Regardless of the residential status, older cancer survivors report high internet and technology use for health-related activities. These results show promise for the feasibility of using digital technologies to implement supportive care and wellness programming with older cancer survivors.

Introduction

Improvement in cancer treatments and increasing life expectancy have led to a greater proportion of older, long-term survivors of cancer. As of 2022, 67% of cancer survivors in the United States were above the age of 65 years [1]. Though there are over 12 million older cancer survivors in the United States, their perspectives regarding survivorship and long-term care needs are not well described [1-4]. There are noted cancer care disparities among rural populations where the population tends to be older and to face a higher incidence and mortality rate from cancer than younger survivors. This is likely driven by barriers to accessing state-of-the-art cancer prevention, treatment, and survivorship services that support cancer-preventive behaviors [5-9].

Telehealth and other digital health tools offer an opportunity to bridge the gaps in care between rural and urban cancer survivors. Digital tools, such as the internet, electronic wearable devices, and social media, offer ways to disseminate health promotion materials and education remotely. Given the barriers that rural residents face in accessing in-person health behavior programming and resources, remote delivery with digital health tools is one strategy for delivering this information. In fact, a systematic review of lifestyle behavior change interventions for rural cancer survivors found that programming predominately relied on delivery using a hybrid or remote format by the use of digital technology, though the evidence of effectiveness was limited [10]. Remotely delivered programming to support psychosocial well-being and lifestyle behavior change has been shown to be effective for survivorship more generally, but the evidence of acceptability and usability for survivors living in rural areas is lacking [10]. While digital literacy and access disparities have long existed between rural and urban communities, commonly known as the digital divide [11-13], the COVID-19 pandemic has provided a push to address some of these barriers and has led to greater adoption of telehealth and other digital health tools [14-16]. For example, during the pandemic, providers pushed for the use of telehealth visits to complete routine check-ups with patients, especially immunocompromised cancer patients undergoing treatment. By providing information and instructions on how to complete telehealth visits remotely, many patients became familiar with how to access digital technology. Whether additional modifications in telemedicine and digital health delivery are needed to meet the supportive care needs of older survivors is not known. To address this gap in the literature, additional work is needed to understand the access and use of digital technology in this population.

Digital health technology is a promising tool to support lifestyle behavior change programming, but the acceptability and usability of digital technology for rural cancer survivor populations, particularly older survivors, has not been fully explored. This study aimed to use a robust survey-based dataset to (1) describe the use of digital technology among cancer survivors, (2) assess the use of telehealth and other digital technology to support health, and (3) examine the association between rurality and digital health tool use and access among older (>60 y) cancer survivors who responded to this nationally representative survey in 2022.

Methods

Study Design and Population

This cross-sectional analysis was derived from the National Cancer Institute (NCI) Health Information National Trends Survey (HINTS), a nationally representative sample of the adult, noninstitutionalized population in the United States. NCI has been collecting HINTS data every few years since 2003 to evaluate trends in health information access and attitudes toward digital health technology [17,18]. Detailed information about the methodology and publicly available deidentified datasets can be found on the NCI HINTS website [19]. This analysis was deemed exempt by the University of Arizona Institutional Review Board.

This analysis uses data from HINTS 6, which was collected between March and November 2022. As this was the first full HINTS survey completed after the beginning of the COVID-19 pandemic wherein telehealth use increased appreciably [15,20], this iteration was selected to best reflect the current prevalence of digital technology use. HINTS 6 is also the first to include stratification for residential status in the sampling strategy to ensure better representation of rural participants [21]. Out of the 6252 total respondents (response rate 28.1%), those without a history of cancer (n=4982), those under the age of 60 years (n=174), or those with missing data for cancer diagnosis or age (n=119) were excluded from analyses. Cancer diagnosis was determined with a self-report question asking if the respondent had ever been diagnosed with cancer. A cutoff of 60 years of age was used to define an “older cancer survivor” to maximize the analysis sample size and realizing that cancer survivors experience accelerated aging, meaning a 60-year-old cancer survivor may be more like a 65-year-old noncancer survivor. The final analytical sample included 710 cancer survivors 60 years of age or older. Most participants completed HINTS 6 using a mailed paper copy of the survey (435/710, 61.3%) compared with a web-based version of the survey (275/710, 38.7%).

Ethical Considerations

The HINTS 6 general population survey was designated “exempt research” and approved by the Westat Institutional Review Board (IRB) (Project # 6632.03.51). HINTS 6 was designated as “Not Human Subjects Research” from the National Institutes of Health Office of IRB Operations (iRIS reference number: 562715).

Outcome Variables

The primary measures of interest pertained to (1) internet access and use for health-related activities, (2) digital device ownership and use as a tool for health behaviors, (3) use of social media for health, and (4) use of telehealth.

Internet

Internet use was assessed with the question, “Do you ever go on-line to access the internet or World Wide Web, or to send and receive email?” Respondents who indicated “yes” were

XSL•FO
RenderX

then provided a follow-up question asking how they have used the internet for health-related needs in the previous 12 months with 4 statements to consider: "Look for health or medical information," "Send a message to a health care provider or a health care provider's office," "View medical test results," and "Make an appointment with a health care provider." Respondents answered each statement with a "yes" or "no" response. Those who reported using the internet were also asked about their level of satisfaction with their home internet connection using a 5-point scale ranging from "extremely satisfied" to "not at all satisfied."

Digital Devices

Survey respondents were asked if they own any of the following digital devices: tablet computer (eg, Apple iPad, Samsung Galaxy, or Kindle Fire), a smartphone (eg, Apple iPhone, Blackberry, or Android), or a basic mobile phone. These responses were then categorized to describe participants who owned these devices, those who owned multiple devices, and those who owned no digital devices. Those who indicated they own a tablet or smart phone were asked, "In the past 12 months, have you used a health or wellness app on your tablet or smartphone?" Ownership and use of wearable devices (eg, Fitbit, Apple Watch, or Garmin Vivofit) was assessed with the question, "In the past 12 months, have you used an electronic wearable device to monitor or track your health or activity?" To assess how respondents have used digital devices to support their health, participants were asked if they had shared any health information from either their wearable device or smartphone with a health professional in the previous year.

Social Media

Social media use was assessed with the question, "In the past 12 months, how often did you do the following?" The 5 statements included: "Visited a social media site," "Shared personal health information on social media," "Shared general health information on social media," "Interacted with people who have similar health or medical issues on social media or online forums," and "Watched a health-related video on a social media site (eg, YouTube)." The response options for each included 5 categorical frequency of use options ranging from "Never" to "Almost every day." These response types were dichotomized to capture if the respondent had used social media for the purpose at all in the last 12 months or not at all.

Telehealth

Telehealth use was assessed with the question, "In the past 12 months, did you receive care from a doctor or health professional using telehealth?" Those who indicated they had not used telehealth were then asked if telehealth had been offered by their provider if they had tried to schedule medical care. Those who did choose to use telehealth in the previous year were prompted with a set of statements and asked to indicate if they agreed that the statement reflected a reason they participated in a telehealth visit.

Exposure Variables

The exposure of interest for this analysis was residential status. This variable was dichotomized into rural and urban residency using the 2013 Rural-Urban Continuum (RUC) Codes set by the US Department of Agriculture Economic Research Service [22]. This code includes 9-values and is derived along a continuum based on population size and adjacency to a metropolitan area. Based on previous analyses, urban residencies were defined as RUC codes 1 - 3, while rural residencies were defined as RUC codes of 4 - 9 [11,23,24].

Sample Characteristics

The sociodemographic characteristics included in this analysis were age, sex, race and ethnicity, occupational status, annual household income, household size, marital status, education, and census region. To ensure adequate cell sample size for analysis, the race and ethnicity variable was condensed into non-Hispanic White, non-Hispanic Black or African American, Hispanic, and non-Hispanic other. Occupational status was organized into 4 categories including employed, retired, disabled, and other (ie, unemployed, homemaker, and student). Related to cancer history, the age of diagnosis, years since diagnosis, and cancer type were included in the summary of the sample.

Statistical Analysis

This is a cross-sectional analysis of the use of digital health tools and telehealth in older cancer survivors who completed the HINTS 6 survey collected in 2022. Provided survey weights were applied using the Jackknife repeated replication method for population level estimates.

Sociodemographic characteristics, health behaviors, and cancer history were stratified by residential status (rural vs urban) and differences were assessed using Wald design-based chi-square tests of independence or *t* tests. Rurality and associations with using digital health tools and telehealth were individually assessed using both unadjusted and adjusted multiple logistic regression models. Models were adjusted for age, race and ethnicity, annual household income, and education. Sex and marital status were not found to be confounders or effect modifiers and were thus not included in the adjusted model. An α level of .05 was considered statistically significant. A post hoc sensitivity analysis was conducted excluding respondents who reported diagnosis with nonmelanoma skin cancer as this is a population of people with a cancer diagnosis that experience very different treatment and survival outcomes from the general survivor population. All analyses were completed using STATA 17 (StataCorp LLC).

Results

Demographics

Out of the 710 older cancer survivors included in this analysis, 17% (n=125) were living in rural areas (see Table 1 for detailed sample characteristics). The average age of the respondents was 73 (SD 8.2) years. While most demographic characteristics did not differ between rural and urban survivors, rural cancer survivors were more likely to identify as non-Hispanic White (93% [n=95] vs 84% [n=415]; *P*=.007) and reported a lower annual household income (*P*=.01). When considering the US census region, a greater percentage of Midwest participants were living in rural areas compared to urban areas (37.3% vs 14.4%), while a lower percentage of participants in the West

XSL•FO
RenderX

and Northeast regions were living in rural areas compared to urban areas (*P*<.001). Most respondents were retired (n=497, 71.7%) and married or living with a romantic partner (n=356, 64.7%). Though there were no differences in age at diagnosis or years since diagnosis between groups, nonmelanoma skin cancer was the most prevalent cancer type (n=149, 31.2%); rural participants reported greater prevalence of breast and gynecological cancer than urban residents (*P*=.03). There were no differences in the survey form version completed between rural and urban residents, with 59.9% (n=350) of urban respondents and 68% (n=85) of rural respondents using a paper version of the survey (*P*=.09).

There were no differences in internet use or mode of access, digital device ownership, or social media use in the previous 12 months between older rural and urban survivors (Table 2). Overall, most older survivors were using the internet (n=553, 79.9%) and predominately used a high-speed service to connect (n=486, 89.8%). Though they shared the same prevalence of internet use, rural cancer survivors were more likely to report a lack of satisfaction with their internet connection than urban survivors (8.7%, n=7, rural vs 0.4%, n=3, urban; *P*<.001). Regardless of residential status, older survivors reported high rate of smartphone ownership (n=544, 78.5%) and only 5% (n=31) reported not owning any digital devices. About half of older survivors owned more than 1 digital device (n=345, 51.7%).

Table . Weighted prevalence of internet use, digital device ownership, and social media access in the past 12 months by residential status.

	Total, %	Rural, %	Urban, %	*P* value
Used the internet at all	79.9	78.1	80.1	.67
Mode of accessing the internet [a]				
Dial-up or telephone line	1.9	2	1.9	.95
High-speed service	89.8	84.7	90.8	.29
Cellular network	69.5	74.1	68.5	.45
Internet connection satisfaction				.006
Extremely satisfied	16.4	4.6	18.8	
Very satisfied	47.4	59.2	45	
Somewhat satisfied	28.8	22.2	30.1	
Not very satisfied	5.6	5.3	5.7	
Not at all satisfied	1.8	8.7	0.4	
Digital device ownership [a]				
58.9	48.6	61.1	.12	
78.5	76.1	79	.58	
9.2	13.6	8.2	.29	
51.7	41.4	53.9	.09	
5.1	3.2	5.5	.3	
Visited a social media site	66.6	71.6	65.6	.28

[a]Categories are not mutually exclusive.

Internet

In both unadjusted and adjusted logistic regression models, the use of the internet to support health did not differ between older rural and older urban cancer survivors. Regardless of residential status, most respondents who used the internet within the past 12 months indicated that they have used the internet to look for health information (n=463, 86.5%), they have sent a message

XSL•FO
RenderX

to their health care provider (n=362, 67.5%), and they have viewed their medical test results (n=405, 78.9%; Table 3).

Table . Association of rural versus urban residence and use of digital health tools in the previous 12 months.

Digital health tools	Weighted percent, %		Unadjusted OR (95% CI)	*P* value	Adjusted OR[a] (95% CI)	*P* value
	Rural	Urban				
Internet						
Used the internet to look for health or medical information	78.7	88.1	0.50 (0.22-1.11)	.09	0.73 (0.33-1.62)	.44
Used the internet to send a message to a health care provider or health care providers office	63.6	68.4	0.81 (0.40-1.61)	.54	0.80 (0.33-1.95)	.62
Used the internet to view medical test results	69.5	80.8	0.54 (0.26-1.11)	.1	0.63 (0.28-1.44)	.27
Used the internet to make an appointment with a health care provider	42.7	58.4	0.53 (0.27-1.07)	.07	0.52 (0.22-1.21)	.13
Digital devices						
Used a health or wellness app on a tablet or smartphone	36.9	51.3	0.56 (0.32-0.97)	.04	0.85 (0.47-1.53)	.58
Used an electronic wearable device to monitor or track health or activity	19.8	28	0.64 (0.33-.21)	.17	0.81 (0.38-1.73)	.58
Shared health information from an electronic monitoring device or smartphone with a health professional	21.8	24.4	0.87 (0.46-.63)	.65	1.25 (0.56-2.78)	.58
Social media						
Shared personal health information on social media	19	10.9	1.92 (0.82-4.51)	.13	2.64 (1.13- 6.19)	.03
Shared general health-related information on social media (ie, news article)	21.9	26.3	0.79 (0.35-1.79)	.56	0.55 (0.24-1.23)	.14
Interacted with people with similar health or medical issues on social media or online forums	19.7	16.5	1.24 (0.50-3.07)	.63	1.08 (0.46-2.58)	.85
Watched a health-related video on a social media site	40.2	42.3	0.91 (0.48-1.72)	.78	0.76 (0.37-1.55)	.44

[a]Logistic regression models were adjusted for age, race and ethnicity, annual household income, and level of education.

XSL•FO
RenderX

Digital Devices

Compared with urban survivors, rural respondents who owned a smartphone or tablet were less likely to report that they had used a health or wellness application in the previous year (36.9%, n=36, rural vs 51.3%, n=234, urban; unadjusted OR 0.56, 95% CI 0.32-0.97; *P*=.04). This difference was no longer significant in adjusted logistic regression models when age, annual household income, education, and race and ethnicity were considered (adjusted OR 0.85, 95% CI 0.47-1.53; *P*=.58). There were no differences in the use of wearable devices to track activity or to share health information with a health care provider. Overall, 26.5% (n=165) of older survivors reported using a wearable device to track their health or activity. While only 23.9% (n=166) of older survivors indicated they have shared data from a smartphone or wearable device with a health professional in the previous year, 81.3% (n=135) indicated that they would be willing to do so in the future.

Social Media

Two-thirds of older adults (n=448, 66.6%) visited a social media site in the previous year. Though social media use was similar for both urban and rural survivors, older cancer survivors living in rural areas were twice as likely to report that they had shared personal health information on social media in the previous year (adjusted OR 2.64, 95% CI 1.13-6.19; *P*=.03). Less than 20% (n=115) of older cancer survivors reported having used social media or a chat forum to interact with people who have similar health issues and 25.5% (n=173) indicated that they had shared general health information on social media in the previous year.

Telehealth

There were no differences in the proportion of rural and urban respondents who indicated they had received care from their health care provider using telehealth in the previous 12 months (Table 4). Rural and urban cancer survivors were equally likely to have been offered the option to have a telehealth visit by their providers. For respondents who indicated they received care using telehealth, the primary reason for choosing to participate in a telehealth visit was provider recommendation or requirement (n=215, 81.1%). A total of 54% (n=136) of older cancer survivors indicated that they chose to participate in telehealth because it was more convenient than going to a health care office. Compared with older urban survivors, rural survivors were less likely to indicate that one of their reasons for choosing telehealth was to seek advice about whether in-person care was needed (adjusted OR 0.21, 95% CI 0.05-0.94; *P*=.04).

XSL•FO
RenderX

Table . Association of rural versus urban residence with use and reasons for use of telehealth in the previous 12 months.

Statement	Weighted percent (%)		Unadjusted OR (95% CI)	*P* value	Adjusted OR[a] (95% CI)	*P* value
	Rural	Urban				
Received care from a doctor or health professional using telehealth	33.5	42.6	0.68 (0.40-1.15)	.15	0.79 (0.41-1.54)	.49
Offered the option to have a telehealth visit for any medical care	40.6	48.2	0.74 (0.36-1.49)	.39	0.87 (0.41-1.86)	.71
Reported technical problems with the telehealth visits	37.1	26.3	1.65 (0.64-4.24)	.29	1.80 (0.52-6.23)	.35
Reasons for choosing to participate in telehealth						
Health care provider recommended or required the visit use telehealth	74.6	82.1	0.64 (0.18-2.32)	.49	0.86 (0.12-6.07)	.87
Wanted advice about whether in-person medical care was needed	10.8	26.4	0.34 (0.12-1.00)	.05	0.21 (0.05-0.94)	.04
Wanted to avoid possible infection at the doctor's office or hospital	30.4	48.9	0.46 (0.19-1.10)	.08	0.43 (0.13-1.46)	.17
More convenient than going to the doctor	59.9	53.4	1.31 (0.52-3.29)	.56	1.94 (0.63-5.94)	.24
Could include family or other caregivers in the appointment	19.1	23.2	0.78 (0.31-1.98)	.59	0.44 (0.10-1.90)	.26

[a]Logistic regression models were adjusted for age, race and ethnicity, annual household income, and level of education.

Sensitivity Analysis

Exclusion of the 149 respondents diagnosed with nonmelanoma skin cancer did not materially change the study results (see Table S1 and S2 in Multimedia Appendix 1 and Multimedia Appendix 2, respectively). In general, no associations were identified between residential status and digital tool use in this smaller sample. There were significant differences in digital device ownership, with rural survivors being less likely to own a tablet computer (37.9%, n=37 vs 56.7%, n=265; *P*=.02) and to own multiple digital devices (28.7%, n=28 vs 51.5%, n=233; *P*=.003; Table S1 in Multimedia Appendix 1).

Discussion

Principal Findings

This study is among the first to examine the use of technology among older cancer survivors with a specific focus on the use of technology that became more common overall after the start of the COVID-19 pandemic. While findings from iterations of HINTS completed before the start of the pandemic indicated that rural survivors were less likely to access the internet than urban survivors [25-27], digital health tool access and use were similar between groups in this post–COVID-19 analysis. Regardless of residential status, older survivors of cancer reported a high prevalence of internet use (n=553, 79.9%), digital device ownership (n=676, 94.9%), and social media use (n=448, 66.6%). These post–COVID-19 pandemic prevalence results are similar to those found in an analysis of older cancer survivors who responded to the National Health and Aging Trends Study. In that analysis, a rise in digital health technology use was seen after the pandemic (52% in 2021), compared with before (45% in 2019), though they did not compare rural and urban populations [28]. As this is the first analysis to compare digital technology use between rural and urban older survivors after the pandemic, our results indicate that the pandemic may have enhanced uptake of digital technology across residential areas, potentially reducing the digital divide between rural and urban survivors.

Comparison With Previous Work

One of the differences noted between groups in this sample was that rural survivors, as compared with urban survivors, were

XSL•FO
RenderX

more likely to report that they had shared personal health information on social media in the previous year. There are several hypotheses for why this difference may arise. First, rural survivors experience greater barriers to accessing in-person social support, such as travel distance and access to transportation [5,29,30], which may leave phone or computer-based support as the more feasible option. Second, rural survivors tend to experience greater symptoms of anxiety and depression and poorer health-related quality of life than urban survivors, yet have limited access to mental health professionals [5,8,31,32]. Sharing on social media may be an avenue to garner support, elicit shared experience, or share positive outcomes. There is limited information available on rural cancer survivorship and social media use. As follow-up information was not collected in the HINTS survey about what type of personal health information was shared or who it was shared with, future research should explore how rural survivors use social media and how it is used as a tool for social support or information gathering.

The access and usability results from this study show promise for remote treatment and care for older cancer survivors, particularly those living in rural areas. However, adoption of wearable devices was modest (n=165, 26.5%) and there remains a lack of evidence exploring the barriers to digital technology adoption for those who do not access these tools [33,34]. Wearable devices are one tool to promote self-monitoring of healthy lifestyle behaviors that may be especially beneficial for rural survivors who have do not have access to in-person health coaching. With only 1 in 4 older cancer survivors using a wearable device, additional work is justified to explore the acceptability of wearable devices and to classify the barriers to use. In addition, while these results show promise for increasing acceptability and usability of telemedicine for health care, there is still a question of whether remote delivery of survivorship care and lifestyle behavior change programming is acceptable, feasible, and efficacious for older, rural cancer survivors [10,35]. A recently completed pilot trial examined this question using implementation of a remotely delivered, evidence-based group exercise program for older cancer survivors living in rural areas. This trial, the tele-EnhanceFitness program, incorporated remotely monitored Zoom (Zoom Video Communications) fitness classes 3 days a week for 16 weeks and found low attrition (5%) and high class attendance rate (87%) [36]. Additional research has identified that rural survivors are interested in the incorporation of remote lifestyle programs to their care, but additional study is needed to assess the efficacy of remote programming and barriers to implementation [10,35,37,38].

Strengths and Limitations

A strength of this study is the use of the HINTS dataset. HINTS is a nationally representative survey, which includes rigorous probability sampling of the US population. The HINTS 6 sampling strategy also introduced stratification for residential status to ensure better representation of rural participants [21]. In addition, the jackknife weighting strategy used for HINTS data analysis allows for population-level comparisons and estimates. Participants used a paper copy to complete the HINTS 6 survey regardless of rural-urban status, limiting potential bias that may have arisen from digital collection of the survey. As with all cross-sectional studies, a limitation of this analysis is the inability to determine cause and effect relationship. The sample size included for analysis was small given the exclusion of any respondents without a cancer history and relied on self-report, which may be affected by recall or response bias. It also lacked diversity reflecting the larger population of cancer survivors, limiting the ability to stratify analysis by race and ethnicity. To maximize sample size and to report results for the overall survivor population, cancer survivors of nonmelanoma skin cancer were included in analysis. This may have introduced confounding by favorable diagnosis, as survivors of nonmelanoma skin cancer generally do not receive chemotherapy or radiation. Another limitation is that the questions regarding digital health technology were general with limited follow-up about satisfaction with the technology or desire for future use. Finally, all data were self-reported, although bias related to reporting of social media use has not been previously reported.

Future Directions

While digital technology use was found to be similar between older urban and rural survivors, additional research is needed to explore the barriers and facilitators to digital technology adoption for this population and the acceptability of using digital tools for remote intervention delivery. Quantitative work is warranted to examine patterns of digital technology use over time to determine any trends that have emerged since the COVID-19 pandemic. Future work should aim to expand the generalizability by recruiting a diverse sample that better reflects the overall population of cancer survivors living in rural areas.

Conclusion

These findings provide valuable insight into the acceptability and usability of digital health technology for older cancer survivors. Regardless of rural-urban status, digital health technology use was found to be high among cancer survivors. This is the first analysis of digital health technology use among rural and urban residents after the start of the pandemic, indicating the digital divide may be narrowing as use and access to technology changes over time. For cancer survivors, these results indicate digital technology is a feasible method for delivering health information. Implementation of digital technology-based survivorship and lifestyle programming shows promise as a feasible solution to overcome barriers to high-quality cancer care for older and rural-dwelling survivors, yet additional work in this area is needed.

Abstract

Background: Patients with melanoma receiving immunotherapy with immune-checkpoint inhibitors often experience immune-related adverse events, cancer-related fatigue, and emotional distress, affecting health-related quality of life (HRQoL) and clinical outcome to immunotherapy. eHealth tools can aid patients with cancer in addressing issues, such as adverse events and psychosocial well-being, from various perspectives.

Objective: This study aimed to explore the effect of the Cancer Patients Better Life Experience (CAPABLE) system, accessed through a mobile app, on HRQoL compared with a matched historical control group receiving standard care. CAPABLE is an extensively tested eHealth app, including educational material, remote symptom monitoring, and well-being interventions.

Methods: This prospective pilot study compared an exploratory cohort that received the CAPABLE smartphone app and a multisensory smartwatch for 6 months (intervention) to a 2:1 individually matched historical prospective control group. HRQoL data were measured with the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core

XSL•FO
RenderX

30 at baseline (T0), 3 months (T1), and 6 months (T2) after start of treatment. Mixed effects linear regression models were used to compare HRQoL between the 2 groups over time.

Results: From the 59 eligible patients for the CAPABLE intervention, 31 (53%) signed informed consent to participate. Baseline HRQoL was on average 10 points higher in the intervention group compared with controls, although equally matched on baseline and clinical characteristics. When correcting for sex, age, disease stage, and baseline scores, an adjusted difference in fatigue of −5.09 (95% CI −15.20 to 5.02, *P*=.32) at month 3 was found. No significant nor clinically relevant adjusted differences on other HRQoL domains over time were found. However, information satisfaction was significantly higher in the CAPABLE group (β=8.71, 95% CI 1.54 - 15.88, *P*=.02).

Conclusions: The intervention showed a limited effect on HRQoL, although there was a small improvement in fatigue at 3 months, as well as information satisfaction. When aiming at personalized patient and survivorship care, further optimization and prospective investigation of eHealth tools is warranted.

Trial Registration: ClinicalTrials NCT05827289; https://clinicaltrials.gov/study/NCT05827289

Introduction

Immunotherapy with immune-checkpoint inhibitors (ICIs) and targeted therapies with BRAF/MEK inhibitors have significantly improved clinical outcomes for patients with melanoma and have become standard treatment for patients with high-risk and advanced disease [1-6]. Nevertheless, these novel systemic treatments are associated with short- and long-term (immune-related) adverse events (AEs) [7-10]. Furthermore, these AEs have shown to affect physical and psychosocial well-being of patients with melanoma [10-13]. Most prevalent in patients with melanoma undergoing immunotherapy with ICIs are cancer-related fatigue (CRF) and emotional distress, affecting both health-related quality of life (HRQoL) and clinical outcome to immunotherapy [8,14-16]. Efforts to address CRF include exercise recommendation, psychosocial support, mindfulness-based interventions, and yoga, showing positive effects on fatigue, emotional distress, and HRQoL [14,15,17-23].

Insufficient monitoring and reporting of AEs can exacerbate side effects, possibly leading to more frequent hospital visits and admissions [24-26]. Electronic symptom monitoring has shown to be associated with improved clinical outcomes such as survival and HRQoL in patients with cancer undergoing chemotherapy [27-30]. One way to improve patient care in immunotherapy could therefore involve regularly gathering patient-reported outcomes (PROs), such as symptom information, using patient-reported outcome measures (PROMs) through eHealth tools [31-34]. Furthermore, using biometric sensors could potentially detect symptoms and track physical activity in outpatient oncology settings [35,36]. To date, evidence of the effect of eHealth tools monitoring patients with melanoma on treatment with ICIs is scarce. One study showed that an electronic PROMs tool could not reduce the number of severe AEs, although it did increase HRQoL [34,37].

Health apps have also the potential to fulfill patients' requirements for information and support, especially concerning symptom control and supportive services [38,39]. Furthermore, web-based programs and eHealth apps have incorporated nonpharmacological well-being interventions, such as promoting physical exercise, providing psychoeducation, mindfulness-based interventions, and yoga, to address CRF, showing encouraging outcomes [40,41]. By providing a combination of remote symptom monitoring, nonpharmacological well-being interventions, and information provision through an eHealth tool, patients believe this will positively affect their HRQoL and symptom burden [39].

Based on these insights, we previously developed a Cancer Patients Better Life Experience (CAPABLE) mobile app. CAPABLE is an extensively tested eHealth app as part of the EU Horizon 2020 program, designed to offer educational material, supportive care, remote symptom monitoring, and well-being interventions [42], initially for patients during and after ICIs, but open to treatment changes to targeted therapies. Development involved a user (patient)-centered design process in order to improve system usability and user acceptance [43]. The aim of this study was to explore the effect of CAPABLE on patient-reported outcomes, specifically fatigue and other HRQoL domains, compared with a matched historical control group receiving standard care [44].

Methods

Setting

The CAPABLE study was a prospective, exploratory, pilot study in which a cohort that received the CAPABLE smartphone app and a multisensory smartwatch (intervention) was compared with a historical prospective cohort that did not receive the CAPABLE app and smartwatch (control group). CAPABLE was registered as a medical device trial according to the Medical Device Regulation, article 62. A detailed description of the design of the pilot study and the design and development of the CAPABLE app was published previously [44]. Development and content was frozen during the trial. The CAPABLE app

XSL•FO
RenderX

was used in its final operational state for the first time in a trial setting during this study, although preliminary prototype testing was done during system development. Briefly, participants included in the study were provided with the CAPABLE mobile app and a multisensorial smartwatch (ASUS VivoWatch 5 HC-B0) during the first 6 months of treatment with ICIs. The mobile app consisted of 3 main components; first, facilitating symptom and mental well-being monitoring, second, providing educational material, and finally, providing well-being interventions through goal setting and demonstrating the well-being intervention activity through a video or text and figures. The symptom monitoring functionality was used "as needed." When a patient experienced a symptom, they were able to enter this into the CAPABLE app, upon which the decision support system managed the symptom [44]. No regular or static symptom monitoring was prompted by the app; however, the health care professional (HCP) monitored the symptom input coming from the patients on a daily basis and the information was included and discussed in clinical encounters. The well-being interventions could be executed from the home environment, and include a 30-minute walk, deep breathing practice, imagery training, physical activity of stretching, and strengthening exercises, Hatha Yoga or Nidra Yoga videos, or Tai Chi practice videos. The smartwatch collected data on heart rate, sleep (stages, hours, and performance), and physical activity, although data from the smartwatch were treated as ancillary data and not used for real-time symptom monitoring, decision support, or diagnosis. Over the course of the pilot study, participants were asked to complete PROMs at 3 time points. Results of the intervention (CAPABLE) group were compared with participants of 2 previously collected control groups (patient-reported outcomes in high risk and advanced melanoma patients cohort [PRO-MEL]; NL75996.031.20 and PROMs collected in clinical practice), which were 2 similar prospectively collected cohorts with the same inclusion criteria, but treated following standard of care and following the same follow-up schedule. PROMs in clinical practice were collected starting August 2024 and is still ongoing at the time of study. In addition, the PRO-MEL cohort was a prospective cohort that started inclusion in May 2021 and collected additional PROMs, as also collected in the CAPABLE cohort.

Ethical Considerations

The Medical Ethical Committee NedMec (Amsterdam, the Netherlands) granted ethical approval (reference 22 - 981/NL81970.000.22). The trial was prospectively registered at ClinicalTrials.gov (NCT05827289). Ethical approval also included the (secondary) use of data collected in the PRO-MEL and PROMs in clinical practice cohorts. Privacy and confidentiality protection was covered in the Medical Ethical Committee approval by a large data protection impact assessment. The study has not been amended during the course of the trial. Compensation to participants was not provided, except for the temporarily use of the smartphone and smartwatch used in the study.

Recruitment

During a 6-month inclusion period, from April to October 2023, participants were recruited through their treating HCP and the CAPABLE research team recruited in an oncology-specialized center in Amsterdam, the Netherlands. The target sample for feasibility end points of this pilot was to include 36 patients, corresponding to 60 eligible patients and a 60% inclusion and compliance rate in the inclusion period [44]. Eligible participants had histologically confirmed stage III or IV melanoma and planned to start treatment with ICIs (anti–programmed-death 1 with or without anti–cytotoxic T-lymphocyte associated protein 4) according to standard clinical practice. Furthermore, participants had to be >18 years of age, had a sufficient understanding of the Dutch language, and were able to use a smartphone.

Data Collection

Included patients were asked to use the CAPABLE app and smartwatch for a minimum period of 3 months and a maximum period of 6 months after start of treatment with ICIs. CAPABLE installation on mobile phones and baseline measurements took place after signing informed consent and before or during first ICI infusion. Research data were collected at baseline (T0), 3 months (T1), and 6 months (T2) after start of treatment by providing the participants a set of questionnaires. Clinical data (eg, staging, treatment details, and demographics) were extracted from the medical record during the study. PROMs data were stored and managed in ALEA (FormVision) [45]. Data generated through the CAPABLE app were stored on an internal secured drive.

To investigate the primary end point of this study, fatigue, the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire-Core 30 (QLQ-C30) was used [46], a questionnaire developed to assess the quality of life of patients with cancer. Responses to this questionnaire range from 1 (not at all) to 4 (very much) and are linearly transformed into a functioning or symptom scale ranging from 0 to 100, with higher scores representing more experienced symptoms or a higher functioning, respectively. Primarily, the changes in fatigue over time in the intervention cohort were compared with the changes in fatigue over time in the control cohort. The validated fatigue scale of the QLQ-C30 is constructed out of 3 questions in the QLQ-C30 questionnaire, "Did you need to rest?", "Have you felt weak?", and "Were you tired?". To explore secondary outcomes of this study, other domains of the EORTC QLQ-C30 were investigated (functioning and other symptom scales), as well as changes between the CAPABLE and (matched) control group when looking at the EuroQol 5D (EQ-5D-5L) [47], Functional Assessment of Cancer Therapy-Melanoma (FACT-M) [48], and EORTC Quality of Life Questionnaire-Information 25 (QLQ-INFO25) [49].

Feasibility outcomes were investigated throughout the course of this pilot study by exploring the inclusion and compliance rate of the CAPABLE app users. Recruitment rate was calculated as the percentage of patients included in the study out of the patients screened for eligibility. Patient compliance was calculated as the percentage of patients completing the

XSL•FO
RenderX

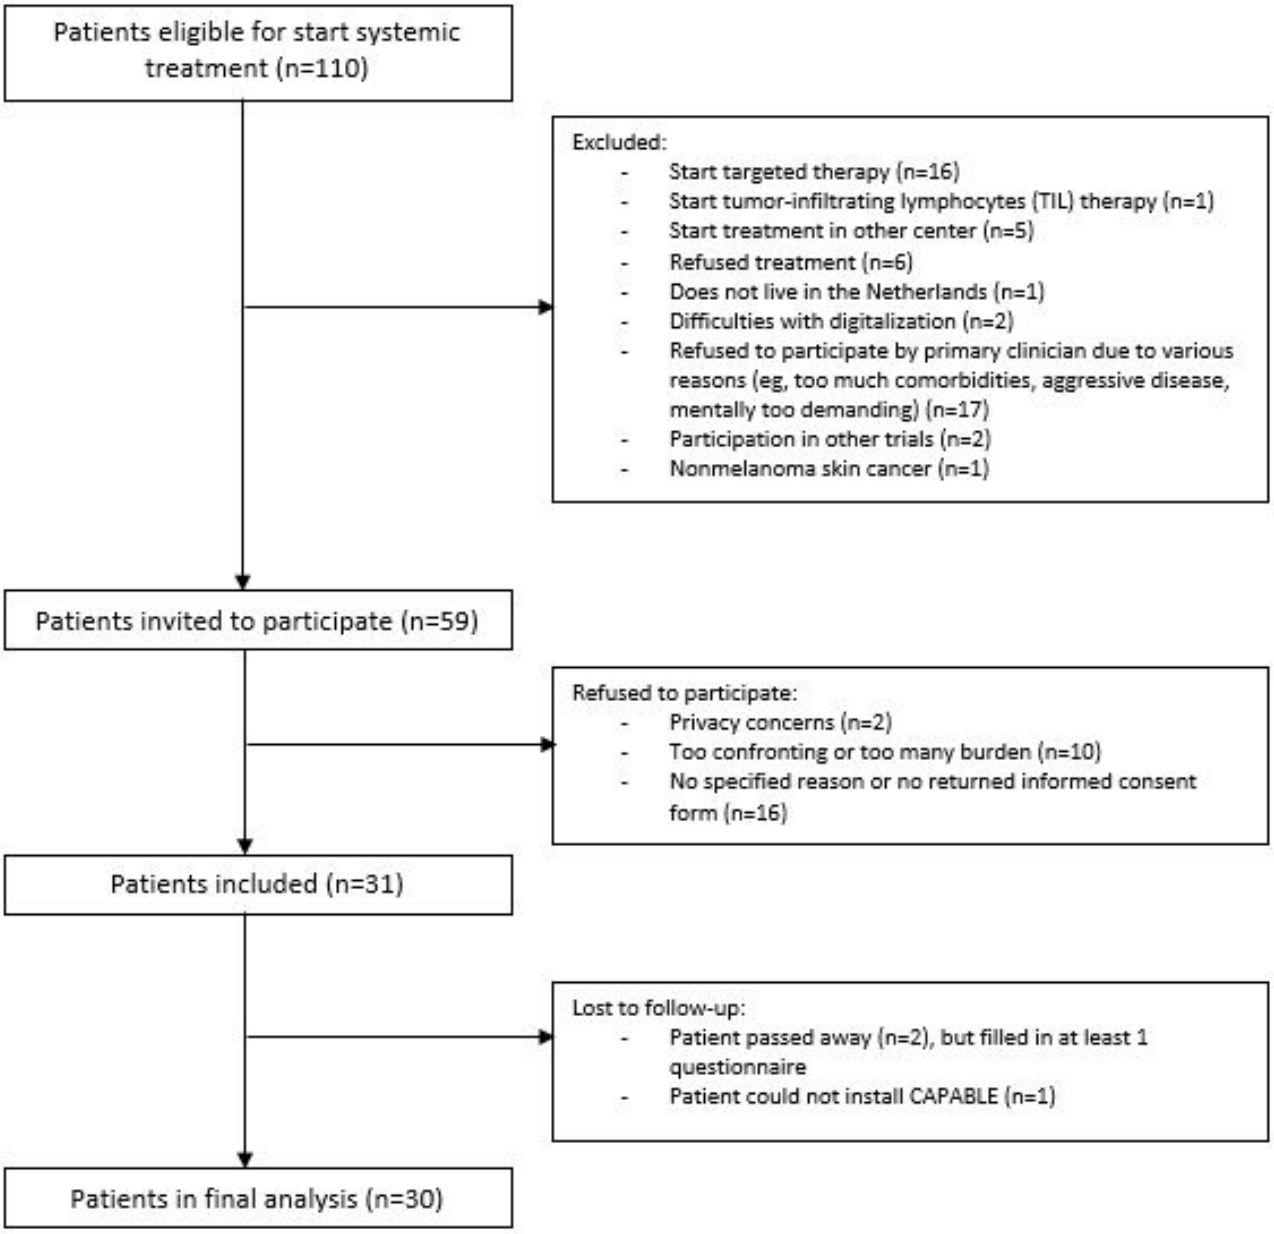
questionnaires per follow-up moment. Finally, patient retention was calculated as the percentage of patients adhering to the CAPABLE mobile app for 6 months (ie, ≥1 interaction with any of the functionalities within the follow-up period). Patient engagement with the app was presented by descriptive data on the use of the symptom reporting and well-being intervention functionalities. Extensive data collection methods and corresponding figures and tables are described in the previously published study protocol [44].

Data Analysis

Patients that completed at least 1 PROM over the course of the study were included in the final analysis. Because of low inclusion in the (control cohort) PRO-MEL study, matching was done on a control group composed of patients from both the PRO-MEL and PROMs in clinical practice cohort who filled in the EORTC QLQ-C30, FACT-M, and EQ-5D-5L according to the same follow-up schedule. Patients in the CAPABLE cohort were individually matched 1:2 with patients in the control cohorts based on sex, age, and tumor staging. To compare information needs (QLQ-INFO25) between the CAPABLE cohort and controls, no matching was performed, and comparison consisted of the entire PRO-MEL cohort to increase statistical power and be able to interpret results.

Descriptive statistics were calculated to provide information about the patient population, feasibility, and engagement with the CAPABLE app. For the purpose of this study, mean scores for fatigue and other QLQ-C30 domains were calculated and presented according to current guidelines [50]. To compare the mean fatigue scores and other HRQoL outcomes between the group receiving the CAPABLE intervention and the control group at each individual time point, independent sample *t* tests were used. To analyze the differences in all outcomes on different time points between the CAPABLE cohort and matched controls over time, linear mixed effects models were used. Statistical models were adjusted for age, sex, tumor stage, time, and baseline scores (with an interaction term between time and cohort). A 2-tailed *P* value<.05 was considered statistically significant, although *P* values in this pilot setting were not powered to provide much information due to the small sample size. Therefore, this study mostly focused on clinically relevant differences according to Cocks et al [51]. Similar methods were used for analyzing the EQ-5D-5L, FACT-M, and QLQ-INFO25.

Missing items from the questionnaires were imputed according to corresponding EORTC guidelines [50]. The scale scores of the EORTC QLQ-C30 were set to missing if fewer than half of the items on a given scale were answered. Where at least 50% of the relevant scale scores were present, the missing values were replaced by the mean of the present values. We applied the same strategy to the other questionnaires as no other guidelines are available for those. Statistical analyses and matching procedures were done using Stata version 15 (StataCorp) [52].



Results

Overview

In total, 110 patients were screened for eligibility for the CAPABLE trial in the 6-month inclusion period (Figure 1). Main reasons for noneligibility were the start of targeted therapy instead of ICIs (n=16) or the patient not being invited for inclusion by the treating physician's decision (eg, aggressive disease, comorbidities, symptomatic brain metastasis, low health literacy, and mentally too demanding; n=17). Eventually, 59 out of 110 (54%) patients were contacted to participate. Most of the contacted patients who did not return a consent form did not specify a reason (n=16). Reasons specified for not participating in the pilot study included privacy concerns (n=2) and the expectation that the burden would be too high (n=10). Of the 31 included patients, 1 did not manage to install the CAPABLE app before T1. A total of 30 patients were taken into consideration for the statistical analysis, although 2 patients died due to progressive disease before reaching T2. In total, 297 patients (70 from the PRO-MEL cohort and 227 from the PROMs in clinical practice cohort) were eligible for individual matching. This yielded 56 patients that were matched 2:1 to the CAPABLE cohort. Thus, a group of 86 patients was included in the analysis of the EORTC QLQ-C30, FACT-M, and EQ-5D-5L. Since data on the EORTC QLQ-INFO25 were only available in the PRO-MEL cohort, the entire PRO-MEL cohort (n=70) was used in the comparison with the CAPABLE group (n=30) for these secondary end points.

XSL•FO
RenderX

Figure 1. Cancer Patients Better Life Experience (CAPABLE) study inclusion flowchart.

Both cohorts were equally balanced in terms of age, sex, and tumor stage, due to matching (Table 1). Median age of the CAPABLE cohort was 65 (IQR 55 - 72) years. Females represented 61% (19/31) of the included participants, and approximately half the participants had stage IV disease (17/31, 55%). Most patients received anti-PD1 monotherapy in the CAPABLE and matched control group (19/31, 61% and 37/56, 66%, respectively). In the matched control group, 21% (12/56) of patients received targeted therapy after therapy switch, compared with 7% (2/31) in the CAPABLE group, but this difference was not statistically significant (P=.07).

[c]PD-1: programmed-death 1.

[d]CTLA-4: cytotoxic T-lymphocyte associated protein 4.

[e]ICI: immune-checkpoint inhibitor.

Fatigue

The trend in unadjusted fatigue over time was similar between the CAPABLE group and the matched controls although fatigue seems to increase less in the CAPABLE cohort (Figure S1 in Multimedia Appendix 1). A 5-point difference was shown in baseline fatigue. The CAPABLE group had lower fatigue score on baseline compared with the matched controls (mean 18.4, SD 21.7) compared with the matched controls (mean 23.4, SD 19.4; *P*=.28), increasing to a difference of 8.2 points at month 3 (mean 23.0, SD 25.2 vs mean 31.2, SD 24.1; *P*=.17) (Table S1 in Multimedia Appendix 1). When correcting for sex, age, stage, time, and baseline scores, an adjusted difference in fatigue of −5.09 (95% CI −15.20 to 5.02; *P*=.32) for the CAPABLE group at month 3 was observed (Table 2). Although this result was not statistically significant, this difference was considered a small, clinically relevant difference. At month 6, a nonsignificant and nonclinically relevant difference was shown between the 2 groups (β=−2.32, 95% CI −12.81 to 8.16; *P*=.66).

Health-Related and Melanoma-Specific Quality of Life

A significant difference in baseline scores was observed between the 2 cohorts for most of the HRQoL domains measured by the EORTC QLQ-C30 (Table S1 in Multimedia Appendix 1). On all functioning scales except cognitive functioning, the CAPABLE group reported better function in terms of both statistical significance and clinical relevance, with mean baseline differences ranging from 8.5 in social functioning (*P*=.11) to 12.0 in role functioning (*P*=.07) (Table S1 in Multimedia Appendix 1). After adjusting for covariates in multivariable regression analysis, no statistically significant nor clinically relevant changes on any of the HRQoL domains were observed between the CAPABLE group and matched controls at either month 3 or month 6 follow-up (Table 3).

XSL•FO
RenderX

Table . Adjusted mixed effects linear regression analyses on different health-related quality of life (HRQoL) outcomes as measured by the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire-Core 30 (QLQ-C30) between Cancer Patients Better Life Experience (CAPABLE) group and matched controls over time. Analyses are adjusted for age, sex, stage, and baseline scores.

	CAPABLE × month 3	−3.37 (−8.78 to 2.04)	.22	—
	CAPABLE × month 6	1.19 (−4.40 to 6.80)	.68	—

[a]Results presented are adjusted βs coming from interaction between cohort and time. Matched controls at baseline are reference group.

[b]Not applicable.

Similar baseline differences were observed in melanoma-specific quality of life as measured by the melanoma subscale (MS) and melanoma surgery subscale (MSS) of the FACT-M. Melanoma-specific quality of life showed a significant baseline difference between the CAPABLE group and matched controls when looking at both the MS (mean 57.5, SD 5.3 vs mean 50.4, SD 8.3; *P*<.001) and the MSS (mean 28.1, SD 4.4 vs mean 22.4, SD 6.3; *P*<.001). Mean scores did not change much over time in both cohorts (Table S3 in Multimedia Appendix 1). When adjusted for sex, age, tumor stage, time, and baseline scores, there were also no significant changes in melanoma-specific quality of life between both cohorts over time (Table 4). Utility scores of the EQ-5D-5L yielded similar results in terms of mean scores, and when adjusted for all covariates, no effect of CAPABLE was seen compared with matched controls (Table S3 in Multimedia Appendix 1; Table 4). However, HRQoL as measured by the visual analog scale, was significantly higher for the CAPABLE cohort compared with the matched controls on month 3 and month 6 when corrected for sex, age, and stage of disease (B=10.28, 95% CI 1.45 - 19.11, *P*=.02 and B=11.50, 95% CI 2.08 - 20.92, *P*=.017, respectively).

Information Needs

Overall, information provision as reported by the EORTC QLQ-INFO25 was significantly lower in the control cohort on both baseline and month 6 (Table S4 in Multimedia Appendix 1). When adjusting for age, sex, and baseline scores, no separate domains showed significant improvements of the CAPABLE cohort. However, information satisfaction was significantly higher in the CAPABLE cohort (B=8.71, 95% CI 1.54 - 15.88; *P*=.02) (Table 5).

Table . Adjusted univariable mixed effects linear regression analyses on information domains between CAPABLE group and PRO-MEL controls. Analyses are adjusted for age, sex, stage, and baseline scores.

Information domains[a]	β (95% CI)	*P* value
Disease	3.38 (−5.49 to 12.25)	.46
Medical tests	9.35 (0.22 to 18.48)	.05
Treatment	1.59 (−6.89 to 10.06)	.71
Other services	2.46 (−7.28 to 12.19)	.62
Different places of care	−2.19 (−14.04 to 9.67)	.72
Things you can do to help yourself	−6.12 (−15.54 to 3.30)	.20
Satisfaction with information received	8.71 (1.54 to 15.88)	.02
Overall the information has been helpful	3.69 (−4.77 to 12.14)	.39

[a]Controls are reference group.

Feasibility

Because of project time constraints, only 31 of the planned 36 patients were included in this study. In total, 59 patients were eligible for study participation, resulting in a recruitment rate of 53% in the set period, whereas the planned recruitment rate for reaching the feasibility end point was 60%. However, patient compliance and patient retention remained high in the patients that were included. Patient compliance to the PROMs at baseline was 98% (30/31), at T1 was 90% (27/30), and at T2 was 79%

XSL•FO
RenderX

(22/28). Finally, 27 out of 31 (87%) patients adhered to using the CAPABLE app until at least T1, which dropped to 24 patients (77%) using the app at T2. Furthermore, 2 of those patients died because of rapidly progressive disease during the trial. Adherence to smartwatch use was lower with only 43% (13/30) usage at T2 due to smartwatch issues. In total, 27 individual problems with the CAPABLE app and smartwatch were reported during the trial, mostly in the first 3 months of usage. Almost half of patients (14/30, 47%) reported at least 1 problem with the CAPABLE app or one of its functionalities. The majority of reported problems were related to login issues (7/20, 35%), smartwatch problems (communication between app and discomfort of the smartwatch; 8/20, 41%), and problems with the symptom reporting workflow (3/20, 15%).

Engagement With the System

Concerning the symptom reporting functionality, 18 out of 30 patients have actively used the CAPABLE app and reported at least 1 distinct symptom or symptom episode (range 1 - 7) (Figure S2 in Multimedia Appendix 1). In total, 20 distinct immune-related AEs were reported through the CAPABLE app, with reports of 33 grade 1, 28 grade 2, 17 grade 3, and 3 grade 4 symptoms according to the mapped Common Terminology Criteria for AEs version 5 (Table S5 in Multimedia Appendix 1). Symptom episodes ranged from 1.5 days for headache to 149.6 days for muscle pain (Table S6 in Multimedia Appendix 1).

Engagement with the well-being interventions was on average lower than symptoms reporting (Table S7 in Multimedia Appendix 1). Interventions were not prescribed by HCPs and were free to use by the patients. The intervention related to taking a walk was the most often used, with 327 execution times, reported by 9 distinct patients. Some patients used the other interventions infrequently. Furthermore, 8 out of 30 patients used the interventions more than 5 times (range 8 - 213). Interventions that were used infrequently were mainly used during the first weeks of enrollment, suggesting that the interventions were tried out at the start of the pilot. The walking intervention was executed throughout the course of the pilot study, with more engagement in summer than in fall and winter (October-December).

Discussion

Principal Findings

The aim of this pilot study was to explore the effect of the CAPABLE mobile app on patient-reported outcomes, specifically fatigue, in patients with melanoma starting ICIs, compared with a historical control group receiving standard care. Our results showed no significant adjusted differences on fatigue and other HRQoL domains between the CAPABLE cohort and matched controls during the first 6 months of treatment. However, although not statistically significant, we did find that the CAPABLE cohort reported a smaller relevant increase in fatigue at month 3 follow-up compared with matched controls. Furthermore, information satisfaction was significantly higher in the CAPABLE users. The secondary goal of this study was to show patients' acceptance and feasibility of the CAPABLE app. With an observed recruitment rate of 53%, our feasibility end point of 60% was not met. A third of the patients refused to participate because study and questionnaires were expected to be too burdensome. Furthermore, HCPs did not feel comfortable including patients in the study because they expected it to be too burdensome for some patients (based on oral feedback). Furthermore, technology barriers might have played a role, as observed in other studies with eHealth apps [53].

We observed a significant baseline difference in almost all the HRQoL domains between the CAPABLE cohort and matched controls, suggesting a selection bias. Although matched on baseline characteristics, HRQoL domains in the CAPABLE group are clinically relevantly and significantly higher than in the matched controls. Therefore, results obtained in the CAPABLE group could have been influenced by the phenomenon "regression towards the mean," as improvement of HRQoL was almost impossible to achieve [54]. However, this phenomenon looks like it occurred in all HRQoL domains, except for fatigue, as we see an improvement only in fatigue for the CAPABLE cohort, although not statistically significant. This observation also underscores the importance of including patients with lower HRQoL in interventions designed to improve this outcome, for example, by minimizing the expected burden of participation [55].

Several studies have shown the benefits of eHealth on CRF. Supporting the small (nonsignificant) difference found in fatigue in our study, a meta-analysis done on 9 studies showed a statistically significant beneficial effect of eHealth interventions on CRF [23]. Furthermore, these eHealth tools were mostly designed to target CRF solely and did not have the multimodal aspects of our CAPABLE app. Furthermore, we were not able to disentangle which specific functionality was responsible for possible changes in fatigue, or if it was a combination of all functionalities. In addition, our sample size was not large enough to provide statistical significance; our pilot study was designed to provide descriptive statistics and focused largely on clinical relevance [51].

A similar study in Denmark, with electronic symptom monitoring carried out in patients with metastatic melanoma starting treatment with ICIs yielded improved HRQoL in the intervention group, as measured by the FACT-M and EQ-5D-5L [34,37], although the differences Tolstrup et al [37] obtained were also not clinically relevant. The Danish study was a randomized controlled trial (RCT) and had an active weekly symptom-monitoring component by their HCP; components of the trial that could have influenced the results compared with passive HCP monitoring in our real-world single-arm setting [56,57].

Information satisfaction was significantly higher in the CAPABLE cohort compared with the control group. Studies done on information provision through eHealth tools in the Dutch cancer care are still conflicting [58]. For example, in an RCT investigating a web-based eHealth app to support multiple cancer patient groups, improvement of knowledge was not reached [59]. However, another study showed that higher information satisfaction might contribute to patient knowledge and decision involvement [60]. Therefore, an eHealth tool, such

XSL•FO
RenderX

as CAPABLE, might still support patient knowledge and shared decision-making.

Results of our study might have been influenced by barriers when integrating and implementing eHealth into clinical practic. Although the CAPABLE system was developed using all relevant stakeholders, the CAPABLE app was not integrated in our electronic health record, causing our HCPs to work with 2 different systems, leading to resistance. In-depth results of user experience and usability research done in HCPs still need to be analyzed, but verbal feedback suggested this was a large barrier for monitoring patients with this app. To date, successful implementation and use of digital health interventions remains limited worldwide by integration into electronic health records, impairing the possible positive effect of such interventions [53]. Second, an existing challenge in digital health interventions research is the recruitment of target populations in need of such interventions [53,61,62]. Both not reaching our feasibility end point of 60% and high HRQoL baseline scores (probably because of selection bias) confirm this challenge. Consequently, results of this study need to be interpreted with caution and future research should make more effort into recruitment strategies including weaker populations, as well as considering health literacy. Furthermore, efforts are needed to reduce patient burden in this type of studies, both in terms of intervention as with research questionnaires, as it is essential to include all patients with serious health conditions [55].

Limitations

Several limitations of this study need to be considered when interpreting the results. Our sample size was too small to prove significant differences on HRQoL outcomes. Because of time constraints of our project, whose main focus was the design and development of the system, inclusion period was short and only 31 patients out of the anticipated 36 were included. Second, most of the control group was collected during the COVID-19 pandemic, which might have influenced HRQoL outcomes in these patients. However, a study done by van de Poll-Franse et al [63] showed that the crisis might have affected well-being of general population more than in that of cancer patients. In addition, another negative aspect of the COVID-19 pandemic was related to some delays in the software development for the CAPABLE eHealth app in an already-restricted project timeframe, which might have resulted in an increase in app issues reported by patients. While in-depth usability outcomes of this study have yet to be analyzed, we observed a relatively high proportion of technical problems during our study and we gathered multiple areas of improvement from verbal feedback from patients, which could have affected the results. Another limitation of the study was our decision to use a matched historical control cohort rather than an RCT. An RCT would have allowed better isolation of the effect of using the app. However, use of the historical cohort allowed us to recognize and characterize the participation bias in the intervention participants. This bias may have contributed to the lack of a clinically relevant effect in our main outcome.

However, a large strength of this study has been that CAPABLE was developed with co-design of patients and HCPs, following user-centered design principles, starting with explorative interviews and undergoing 3 testing rounds. Furthermore, our study was conducted in the real-world setting of the pilot trial; included patients were treated according to clinical practice. The CAPABLE app was added as a monitoring and coaching system tool and could intervene in management of patients after severe symptom reports. Due to the real-world setting of this trial, results on PROs, feasibility, and engagement with eHealth might be more generalizable to real-world patients compared with results found in clinical trials.

Future and larger studies could benefit from including patients more inclusively in terms of low health literacy and social economic status. Inclusion criteria should be broadened to reduce ceiling effects at baseline. Furthermore, the setting of this pilot study might have played a pivotal role, as we included patients in a dedicated cancer and melanoma center with a lot of ongoing clinical trials and other intervention studies and also standard care including easily accessible specialized nurse practitioners.

Conclusion

In our small, nonrandomized study we were unable to show that mobile-based coaching and follow-up affected HRQoL significantly, although results suggest a small clinical improvement of fatigue at 3 months follow-up in the app users. Ceiling effects due to large baseline differences might have caused the impact of CAPABLE to be negligible for patients with higher baseline HRQoL. CAPABLE resulted in significantly higher information satisfaction compared with controls. Although the feasibility end point of 60% was not met, adherence to the system was high. Further optimization of CAPABLE, taking into account patient-related and technology-related barriers is needed before future investigation in an RCT and might influence HRQoL end points. Furthermore, when aiming at personalized patient and survivorship care, further optimization and prospective investigation of eHealth tools is warranted.

Acknowledgments

This work was supported by the European Union (EU)'s Horizon 2020 research and innovation programme (grant agreement No 875052). The Cancer Patients Better Life Experience (CAPABLE) system was developed during the first 3 years of an EU project funded under the Horizon 2020 Research and Innovation Programme. CAPABLE is a 4-year project coordinated by the University of Pavia, Italy, and carried out by 12 partners in Europe and Israel. We like to thank all the partners and participants involved in this and previous CAPABLE-project studies.

Abstract

Background: The rising number of cancer survivors and the shortage of health care professionals challenge the accessibility of cancer care. Health technologies are necessary for sustaining optimal patient journeys. To understand individuals' daily lives during their patient journey, qualitative studies are crucial. However, not all patients wish to share their stories with researchers.

Objective: This study aims to identify and assess patient experiences on a large scale using a novel machine learning–supported approach, leveraging data from patient forums.

Methods: Forum posts of patients with colorectal cancer (CRC) from the Cancer Survivors Network USA were used as the data source. Topic modeling, as a part of machine learning, was used to recognize the topic patterns in the posts. Researchers read the most relevant 50 posts on each topic, dividing them into "home" or "hospital" contexts. A patient community journey map, derived from patients stories, was developed to visually illustrate our findings. CRC medical doctors and a quality-of-life expert evaluated the identified topics of patient experience and the map.

Results: Based on 212,107 posts, 37 topics and 10 upper clusters were produced. Dominant clusters included "Daily activities while living with CRC" (38,782, 18.3%) and "Understanding treatment including alternatives and adjuvant therapy" (31,577, 14.9%). Topics related to the home context had more emotional content compared with the hospital context. The patient community journey map was constructed based on these findings.

Conclusions: Our study highlighted the diverse concerns and experiences of patients with CRC. The more emotional content in home context discussions underscores the personal impact of CRC beyond clinical settings. Based on our study, we found that a machine learning-supported approach is a promising solution to analyze patients' experiences. The innovative application of patient community journey mapping provides a unique perspective into the challenges in patients' daily lives, which is essential for delivering appropriate support at the right moment.

Introduction

Colorectal cancer (CRC), the third most common cancer in the Netherlands significantly impacts the health of individuals [1]. Supportive care involves adopting a person-centered care approach, intending to offer individuals affected by cancer the essential services required to address their informational, emotional, social, and physical needs and concerns throughout the entire patient journey [2,3]. Understanding the needs and concerns of those affected by this disease during their patient journey is crucial for improving patient outcomes and quality of care [4]. Several survey and qualitative studies involving

XSL•FO
RenderX

CRC survivors offer valuable information about the needs and perceptions of patients [4-7]. However, these survey- and qualitative studies are limited by sample size, labor-intensive processes, and could lead to socially desirable answers [8]. Efforts were made to include vulnerable populations who may not be accessible through focus groups, ensuring a more comprehensive understanding of diverse patient perspectives [9]. In the last decade, patient web forums have emerged as valuable platforms for individuals to openly share their experiences and thoughts related to CRC, providing unique insights into the social, physical, and emotional aspects of their patient journey [10,11]. These forums offer different opinions compared with traditional patient experience data collection methods, such as questionnaires and interviews.

While patient community forums contain a wealth of information, the analysis of the extensive unstructured data within these forums poses a considerable challenge [12]. Traditional manual qualitative analysis by human experts is time-consuming, labor-intensive, and lacks scalability, making it impractical to analyze the sheer volume of patient-generated unstructured content. Machine learning techniques offer a potential solution to address this challenge. This enables the automated processing and analysis of textual data, allowing for the efficient extraction and interpretation of large amounts of patient forum posts [13,14].

Our primary objective is to assess patient experiences using a novel machine learning–supported approach and data from patient forums. To achieve this, we used patient community journey mapping to better understand the experiences throughout the patient journey [15]. This is a machine learning-driven approach, that uses web-based patient forums as input data and is processed through topic modeling. By gaining insights into these patient experiences, we can shape future patient journeys such as remote monitoring systems to be aligned with current patients' needs.

Methods

Ethical Considerations

Ethical approval was given by the human research ethics committee of the Delft University of Technology (ID 2596). Informed consent was not required since the data used in this study were sourced from publicly available forums, in accordance with institutional guidelines. The data were accessed and analyzed in accordance with the terms of service and privacy policies outlined by the platform hosting the data. As the ethics committee suggested, all data used in this study were anonymized by removing all direct and indirect identifiers (eg, names, location, and user ID) to prevent potential privacy issues within our data set. Confidentiality was strictly maintained during data collection, analysis, and reporting to ensure that no identifiable information was disclosed.

In order to assess patient experiences using machine learning–driven analysis, this study used systematic data collection, advanced topic modeling techniqu and cocreation sessions with domain experts to interpret and validate identified clusters. The Consolidated Reporting Guidelines for prognostic and diagnostic machine learning modeling studies checklist can be found in Multimedia Appendix 1.

Data Source

To enable research, we used forum posts of patients with CRC scraped from the Cancer Survivors Network USA, an open-source patient community platform. The web-based platform provides support, education, and advocacy for patients affected by CRC that includes current patients, former patients, families, and caregivers. The posts are written with the intention of asking questions to peers and health care providers, as well as forsharing experiences among peers [16]. The initial CRC discussion thread (ie, main posts, comments, and replies) has remained active on the public platform since the year 2000. No distinctions were made between main thread posts and replies to posts.

The data collection involves 2 main steps: first involves using Selenium WebDriver to gather the URLs of discussion pages, and second, using BeautifulSoup to extract data from the HTML elements while keeping sensitive information secure.

Data Analysis (Topic Modeling)

Information about the personal (health) status of patients, which could be directly or indirectly identifiable, was excluded from the analysis. Topic modeling, a machine learning algorithm was used to recognize patterns in the platform data. Nonnegative matrix factorization (NMF) was used as a topic modeling technique to analyze the data set and identify topics with weighted keywords [17,18]. The number of topics was determined by evaluating topic coherence scores and model stability [19,20]. Model stability was assessed using Jaccard similarity to reduce the overlap of topics. Human evaluation was used to ensure that the output contains diverse and distinctive topics, without topics unrelated to patient experiences. This evaluation was conducted by 4 researchers to select the number of topics that yield the most diverse and distinctive clusters.

Interpretation of Data Analysis (Qualitative Analysis)

To comprehend each topic, researchers meticulously read and analyzed the top 50 most relevant posts and top 20 related keywords. The most relevant posts and keywords had the highest dominant topic score identified by the algorithm, indicating they were most closely associated with the topic. The algorithm efficiently identified the most relevant posts and keywords within each topic by using Term Frequency–Inverse Document Frequency to calculate the importance of each term in relation to each document [21].

Clusters

The identified topics were grouped into clusters for topics that revolved around similar concerns. Irrelevant topics (eg, those related to platform-specific issues) were excluded. The frequency of discussions on each topic was recorded by counting the number of posts associated with each topic.

Creation of Patient Community Journey Map

This study uses patient community journey mapping to visually present the identified patient experience topics. The creation of

XSL•FO
RenderX

the patient community journey map began with the conduction of 2 interviews with CRC medical doctors to outline the patient journey and its distinct phases such as diagnosis and follow-up of a patient with CRC.

The results of the interpreted topics were deliberated in an in-person cocreation session involving domain experts [22]. The cocreation session took place in the Erasmus Medical Centre in March 2023 and lasted 3 hours. The interdisciplinary team of domain experts reviewed and discussed the outputs comprehensively. The team comprised 2 oncological surgeons, 2 surgical oncology PhD candidates (MD), and an epidemiologist with an interest in oncological research. A total of 3 out of 5 participants have over 20 years of work experience, indicating a high level of expertise. During the cocreation session, clusters from the NMF results were interpreted, and feedback was provided on the generated interpretations. This process ensured a thorough examination and validation of the identified clusters within a clinically relevant context. During this session, the same domain experts also reviewed the patient community journey map. The identified topics were positioned on the journey map, with allocation to specific phases of the patient journey. Distinctions were made regarding whether each topic was taking place at a “hospital” or “home”setting.

Results

Data

A total of 294,166 posts were extracted from the patient forums of the Cancer Survivors Network USA. The posts on the website were created between the year 2000 and 2022. However, 212,107 posts were analyzed, as the remaining 82,059 posts were excluded through topic modeling.

Topic Modeling

Using NMF topic modeling, the topic coherence score, and model stability did not provide clear insights as the coherence score consistently declined. Therefore, human evaluation was required. Initially, 40 and 50 topics were considered the best amount of topics. Subsequently, the cut-off of 45 topics was also reviewed. Ultimately, 50 topics were chosen as the number that provided the most diverse and distinctive topics. This was confirmed by examining keywords and the most relevant posts for each cluster. Additionally, one topic bin identified 82,059 posts as unclassifiable," which could not be categorized into any of the 50 topics.

Identified Patient Experience Topics and Patient Community Journey Map

A total of 50 topics were identified with the use of NMF topic modeling. Thirteen topics were excluded as they were unrelated to patient experiences, such as platform use and expressions of gratitude. The data export of the relevant topics is shown in Table 1. These are the key patient experiences found in our study.

A total of 10 clusters were derived from 37 topics. The patient community journey map, shown in Figure 1, serves as a visual guide to navigate through the nuanced dynamics of patient experiences.

The topics in the home context have a more emotional content, as emotionally charged keywords such as “confused,” “bad,”and “worried” are more often discussed. Conversely, the hospital context is marked by the clinical terminologies “drug” and “node.” This reflects the distinct atmospheres characterizing discussions in different contexts.

The clusters commanding the highest share of posts are “Daily activities while living with CRC” (38,782, 18.3%) and, “Understanding treatment including alternatives and adjuvant therapy” (31,577, 14.9%) underscoring their important role in shaping the experiences of CRC survivors. Patients expressed significant concerns about test results, as indicated by the 14.1% of posts within cluster 4. As shown in Figure 1, “Understanding treatment including alternatives and adjuvant therapy” is a cluster that goes through almost the entire journey, while the “Daily activities while living with colorectal cancer,” is more in the home context and starts later in the follow-up.

XSL•FO

Table . Overview of the clusters derived from the topics and their keywords.

Clusters and topics, (n, %)[a] (N=212,107)	Top 20 keywords	Number of posts[b], n
Cluster 1: Experience around medical professionals' opinion (9756, 4.6%)		
Doubts about treatment options from medical professionals	'doctor', 'oncologist', 'surgeon', 'told', 'patient', 'system', 'cell', 'wrong', 'reason', 'medical', 'asked', 'office', 'immune', 'trust', 'kill', 'testing', 'medicine', 'appointment', 'clinic', 'recommend'	5043
Suggestion to look for a second medical opinion	'care', 'second', 'opinion', 'ask', 'port', 'onc', 'put', 'taken', 'nurse', 'center', 'forget', 'top', 'first', 'team', 'comfortable', 'third', 'schedule', 'getting', 'question', 'hospital'	4713
Cluster 2: Understanding treatment including alternatives and adjuvant therapy (31,577, 14.9%)		
Patients share their research about alternative therapy options from websites and articles	'answer', 'information', 'might', 'research', 'alternative', 'therapy', 'study', 'perhaps', 'available', 'patient', 'consider', 'website', 'based', 'benefit', 'article', 'option', 'approach', 'internet', 'current', 'specific'	7854
Making treatment decisions for the future with regard to the best outcome and path	'best', 'wish', 'wishing', 'decision', 'health', 'possible', 'whatever', 'future', 'choice', 'outcome', 'decide', 'path', 'upcoming', 'regard', 'situation', 'advocate', 'choose', 'action', 'simply', 'circumstance'	4759
Listing type, side effect, regimen, and effectiveness of drugs	'side', 'effect', 'drug', 'folfox', 'round', 'cycle', 'dose', 'vitamin', 'week', 'oxaliplatin', 'avastin', 'reaction', 'irinotecan', 'affect', 'rash', 'onc', 'cell', 'regimen', 'session', 'effective'	8768
Sharing experience on using traditional Chinese medicine to manage health	'well', 'known', 'fairly', 'usual', 'responded', 'recall', 'crc', 'chinese', 'handling', 'version', 'correctly', 'content', 'deserved', 'treating', 'referring', 'nicely', 'handled', 'spelling', 'managing', 'tolerated'	3610
Share experiences and recommendations for supplements and medication	'congratulation', 'definitely', 'tried', 'experience', 'mentioned', 'suggestion', 'type', 'helped', 'mention', 'medication', 'interested', 'speak', 'form', 'help', 'suggest', 'using', 'supplement', 'suggested', 'detail', 'order'	2854
Sharing information about and experiences regarding clinical trials	'new', 'find', 'look', 'looking', 'awesome', 'forward', 'trial', 'start', 'working', 'step', 'move', 'hearing', 'hard', 'pic', 'yet', 'clinical', 'finding', 'meeting', 'hopeful', 'totally'	3732
Cluster 3: Surgery experience (9540, 4.5%)		
Sharing experience around radiofrequency ablation for the liver	'congrats', 'procedure', 'success', 'huge', 'liver', 'proud', 'shrink', 'treat', 'entire', 'tumor', 'ablation', 'option', 'rfa', 'candidate', 'location', 'status', 'shrinkage', 'inoperable', 'surgical', 'afterwards'	4979

XSL•FO
RenderX

Clusters and topics, (n, %)[a] (N=212,107)	Top 20 keywords	Number of posts[b], n
Sharing negative experience about resection in liver and lung	‘day’, ‘liver’, ‘resection’, ‘mets’, ‘every’, ‘met’, ‘pump’, ‘lung’, ‘ahead’, ‘week’, ‘couple’, ‘following’, ‘open’, ‘two’, ‘operation’, ‘followed’, ‘throughout’, ’single’, ‘complication’, ’section’	4561
Cluster 4: Experience regarding the test results (including being worried and confused) (29,984, 14.1%)		
Sharing negative emotions and experiences to live with colorectal cancer (CRC): overwhelmed, confused and scared, especially for the tests and screenings	‘like’, ’sound’, ‘wonderful’, ‘plan’, ‘place’, ‘picture’, ’show’, ‘meet’, ‘report’, ‘looked’, ‘absolutely’, ‘really’, ‘pick’, ‘button’, ‘familiar’, ‘machine’, ‘pretty’, ’smart’, ’silly’, ‘compare’	3873
Being worried about upcoming scans and results	‘great’, ‘result’, ‘idea’, ’scan’, ‘number’, ‘option’, ‘curious’, ‘present’, ‘follow’, ‘considering’, ‘treated’, ‘recurrence’, ‘appendix’, ‘initial’, ‘cea’, ‘mop’, ‘peritoneal’, ‘assuming’, ‘base’, ‘reliable’	3210
Share their outcomes (clear or not) from scanning and caring about how frequently they scan	‘year’, ‘month’, ‘ago’, ‘clear’, ‘last’, ‘three’, ‘two’, ‘free’, ’scan’, ‘colonoscopy’, ‘end’, ‘past’, ‘every’, ‘four’, ‘clean’, ‘date’, ’six’, ’safe’, ‘behind’, ‘later’	4293
Describing a stressful experience in a blood test; worry about the numbers in the result	‘everyone’, ‘word’, ‘blood’, ‘test’, ‘kind’, ‘wait’, ‘worry’, ‘fine’, ‘check’, ‘waiting’, ‘count’, ‘normal’, ‘wanted’, ‘level’, ‘concern’, ‘checked’, ‘else’, ‘low’, ‘high’, ‘appointment’	5048
Being worried and confused about odd scan results in liver, lung, and lymph	’scan’, ‘tumor’, ‘liver’, ‘node’, ‘lung’, ‘removed’, ‘radiation’, ’stage’, ‘lymph’, ’spot’, ’showed’, ’spread’, ’small’, ‘pet’, ‘biopsy’, ‘remove’, ‘mets’, ’surgeon’, ‘recurrence’, ‘week’	13,560
Cluster 5: Experience with side effects (26,152, 12.3%)		
Sharing their experience on managing the side effects of treatment	‘cold’, ‘nausea’, ‘taking’, ‘help’, ‘water’, ‘drink’, ‘warm’, ‘pill’, ‘infusion’, ’sleep’, ‘mouth’, ’sore’, ‘med’, ‘oxy’, ‘gave’, ‘fatigue’, ‘mum’, ‘nasty’, ‘appetite’, ’sleeping’	8341
Negative feelings of hair loss due to cancer treatments	’stuff’, ‘hair’, ‘funny’, ‘hate’, ‘bad’, ’suck’, ‘lose’, ‘cut’, ‘fall’, ‘wear’, ‘crap’, ‘lost’, ‘really’, ‘made’, ’stand’, ‘head’, ‘weird’, ‘losing’, ’strange’, ‘air’	5122
Feeling uncomfortable due to the obstipation	‘pain’, ‘control’, ‘nothing’, ‘relief’, ‘med’, ‘bowel’, ‘issue’, ‘breath’, ‘walking’, ‘walk’, ’scar’, ‘deep’, ‘kidney’, ‘causing’, ‘blockage’, ‘problem’, ‘intestine’, ‘tube’, ‘hospital’, ‘hernia’	6414

Discussion

Principal Findings

This study delves into the daily experiences of patients using data from a web-based platform, applying topic modeling as a tool to efficiently analyze and interpret large volumes of patient-driven daily life experience data. We analyze patient experiences (eg, struggles, tips, and coping strategies) reported on a platform to better understand patient needs. This understanding of patients' needs has positive potential for future care path development such as information provision or psychosocial support in remote patient monitoring. The use of machine learning techniques in analyzing qualitative data holds significant promise to improve various aspects of health care. This includes optimizing patient care, by using advanced methods such as using symptom checkers to guide patients to the most suitable care journeys and support disease diagnosis. This approach will ultimately lead to patient-centered care to support and empower patients.

The identified clusters in this study align with findings from previous qualitative and survey research, emphasizing the potential to optimize the use of machine learning in qualitative studies of health care in the years to come [4,23]. Based on our analysis, it becomes evident that patients exhibit a notable interest in actively participating in discussions with other CRC survivors to exchange experiences regarding the daily challenges of living with CRC. This underscores the crucial role of social support and the dissemination of pragmatic, day-to-day coping strategies within the broader patient community. This theme aligns with observations from a systematic review detailing the experiences of CRC survivors, where the significance of coping and addressing functional limitations emerged as a central theme [23].

The cluster with the highest share of posts (cluster 10; 38,782, 18.3%) revolves around the challenges associated with resuming daily activities while living with CRC. This substantial volume of posts highlights the significant impact of this particular aspect on the experiences of CRC survivors, as well as the needed change in patients' mindset (cluster 8; 26,379/212,1087, 12.4%). The systematic review of survivorship experiences further supports these findings [23]. The alignment between these dominant themes in the posts and the insights from the qualitative literature underscores the robustness of our findings [24]. These findings emphasize the importance of integrating

XSL•FO
RenderX

comprehensive support mechanisms to facilitate the successful reintegration of patients into their daily lives.

On the platform, patients frequently engage in discussions centered around understanding treatment options (cluster 2; 31,577, 14.9%), highlighting its significance as a key topic. This observation aligns with the qualitative study conducted by van Deursen et al [4], where participants similarly emphasized the need for more information regarding their treatment. It is noteworthy that patients on the platform also frequently express concerns regarding test results (cluster 4; 29,984, 14.1%). This anxiety and fear of recurrence are recognized as common concerns among cancer survivors [25], highlighting the potential to offer valuable support in addressing this. Additionally, the positive outcomes associated with the interaction with family, as reported in the systematic review [23], further underscore the importance of familial support within the context of patient experiences in our findings [26].

A novel finding from our analysis was the open expression of patients' sentiments regarding the opinions of medical professionals (cluster 1; 9756, 4.6%). Not completely surprising as this is possibly due to the reluctance of patients to express negative feelings in a setting where researchers are present, such as focus groups or interviews. Furthermore, qualitative studies primarily concentrate on the follow-up phase, excluding discussions on the experiences of surgery and the subsequent recovery phase. These aspects might provide valuable insights into the comprehensive journey of patients.

The Added Value of Machine Learning to Support the Understanding of Patient Experiences

To reflect on our approach, topic modeling allows extraction from a vast pool of large-scale patient data. The alignment of our study with existing literature is indeed promising. Additionally, topic modeling offers a novel approach by sparing patients the burden of active participation in qualitative studies. Rather than focusing on a single aspect, as is often the case in conventional studies, this method presents a broader spectrum of patient experiences beyond specific questions from researchers. Notably, topic modeling relies on patient-driven data, in contrast to a physician-driven approach. This method's replicability allows seamless comparisons between various medical conditions. This not only contributes to a more extensive comprehension of diverse experiences but also facilitates the identification of commonalities and distinctions of different medical conditions. For example, we explored the present method with patients with pulmonary fibrosis and found comparable experiences to those with CRC, their increased focus on treatment options highlights the distinctive challenges inherent to their specific condition (unpublished data). Given the large data sets on forums, we can quantify patients' experiences with the implementation of topic modeling. This complements the challenges of focus groups and interviews, where the ability to quantify and prioritize findings is limited. As patients' experiences change throughout their journey, the simplicity of using topic modeling remains a flexible and efficient approach for understanding patients' experiences and priorities in the era of remote monitoring [27]. It offers a convenient and adaptable method, without burdening patients [28].

Limitations

Using stories from patients who prefer to share their experiences on a digital platform introduces a risk of selection bias. It is essential to address the potential overexpression of emotion in our findings as the platform primarily captures narratives from individuals who are willing to share their experiences on the web. However, it should be recognized that these individuals represent the intended user group for new care path developments such as remote monitoring support approaches. Patients who are not feeling well, patients who do not have access to the internet, or reserved patients may be less inclined to engage in web-based discussions and might be underrepresented [29]. To complement this, in previous research, we conducted interviews with vulnerable patient populations to ensure their perspectives were included in our understanding of patient experiences [9]. Similar themes such as the need for information provision, concerns about test results, and challenges in reintegrating into daily life were found in this study. Additionally, our approach demands a significant investment of human labor and time to interpret the meaning of topics after generating groups of topics. Thus, exploring another artificial intelligence technique to interpret patient experiences is a promising direction. As an example, a large language model, a pretrained model, can be used to interpret and summarize large quantity textual data [30]. The use of machine learning, even in the part where we used human experts' knowledge, is a promising area to labor-effectively understand the patients' experience while having the least safeguarding support of human validation. Another limitation is the lack of direct involvement of patients with CRC in the co-design or review of the map. We plan to address this in the future as this can provide valuable insights. However, the primary purpose of this method is to enhance the methodology while minimizing the burden on patients. To overcome this limitation, we sought input from highly experienced medical professionals' perspectives. Three of these experts possessed more than 20 years of medical and research experience, specifically with patients with CRC.

In future research, efforts should be directed towards further refining machine learning techniques with the ultimate aim of minimizing or eliminating the need for human involvement, as this will enable more frequent monitoring of patient experiences and thereby facilitate responsiveness to those experiences. Addressing the nuanced interpretation of emotions in patients remains a challenge for artificial intelligence systems. A promising direction is the automatic interpretation of patient-reported outcome measures using machine learning and NLP. Patient-reported outcome measures offer structured data that can improve AI's ability to understand emotional nuances. This approach aims to improve remote patient monitoring, reduce the burden on health care professionals, and identify those who face psychosocial challenges [31]. This approach not only empowers patients in managing their health but also leads to a proactive and personalized approach.

XSL•FO
RenderX

In conclusion, topic modeling and the use of patient forum data offer a robust and efficient approach to understanding patients' experiences in their daily lives. This approach reveals the challenges patients encounter in their daily life such as getting back to daily activities and the need for understanding their treatment. This study not only provides a comprehensive overview of patient experiences through web-based platforms but also highlights the potential for improving patient monitoring systems. This machine learning technique of identifying patient experiences contributes to a more efficient way of building value-based health care. By integrating these insights into the development of remote monitoring solutions, a patient-centered approach can be created that not only addresses medical concerns but also caters to the broader spectrum of challenges individuals face in their daily lives.

Acknowledgments

We extend our gratitude to all the individuals who shared their experiences on the Cancer Survivors Network USA, an open-source patient community platform. This provided valuable insights for this study. Generative artificial intelligence was not used in the writing process.

Abstract

Background: Survivorship care plans (SCPs), ie, personalized health care plans for cancer survivors, can be used to support the growing group of melanoma survivors throughout their disease trajectory. However, implementation and effectiveness of SCPs are suboptimal and could benefit from the involvement of stakeholders in developing a user-centered design.

Objective: The aim of this study was to identify the ideal SCP for patients with melanoma in terms of functions and features to be included according to different stakeholders and to explore their underlying motives.

Methods: In total, 3 cocreation sessions were organized with mixed samples of stakeholders, ie, patients with (a history of) melanoma (n=4), health care providers (HCPs) active in melanoma care (n=3), and IT specialists active in hospital IT departments (n=6). They were invited to compose their ideal melanoma SCP based on potential functions and features identified from prior qualitative research. These functions and features belonged to one of the four main categories of survivorship care (SSC): (1) information and education, (2) identification and treatment, (3) oncological follow-up, and (4) coordination. Participants were invited to explain their motives for including functions and features. Ideas were shared between stakeholders, and interaction was promoted. Descriptive statistics were used to determine the ideal SCP per stakeholder group. To analyze underlying motives, all cocreation sessions were audio-taped, transcribed verbatim, and analyzed in a thematic content analysis.

Results: With regard to their ideal SCPs, all stakeholders added functions from all 4 SSC categories. Patients assembled a rather compact SCP with category 2 on *identification and treatment* being most important. Both HCPs and IT professionals constructed a somewhat larger SCP, with category 3 on *oncological follow-up* being the most important aspect and HCPs also focusing on category 4 on *coordination*. As for the motives behind their ideal SCP compositions, patients predominantly added functions based on their personal experiences or experiences from fellow patients, whereas both HCPS and IT professionals based their compositions primarily on their respective areas of expertise: HCPs related their additions to their roles as medical practitioners; for example, in providing a complete treatment plan and obtaining informed consent, while IT professionals' contributions were mainly influenced by feasibility and privacy concerns.

Conclusions: This cocreation study provides insights into stakeholders' ideal melanoma SCP and the motivations behind them. Considering the diversity in both the preferences and underlying motives regarding SCP composition between patients, HCPs, and IT specialists, it is crucial to develop a broad SCP that extends beyond traditional SCP content, emphasizing personalization. In addition to continued stakeholder involvement, efforts should be focused on addressing potential feasibility and privacy issues to ensure the SCP meets both patients' and HCPs' needs.

KEYWORDS

cocreation; survivorship care; psycho-oncology; supportive care; motives; melanoma; cancer survivor; melanoma care

Introduction

In recent years, the prognosis of melanoma, one of the most aggressive forms of skin cancer, has significantly improved due to advancements in innovative treatments such as immunotherapy and targeted therapy [1]. With an estimated worldwide total of 325,000 new cases in 2022, increasing to an expected total of 510,000 new cases in 2040 [2], this results in an expanding cohort of melanoma survivors, ie, individuals living with or beyond melanoma [3]. To ensure that patients get the necessary support throughout their treatment trajectory and assist them in resuming life thereafter, it is important to provide them with effective survivorship care (SSC) [4].

SSC can be divided into four main categories [4,5], namely (1) information and education, (2) identification and treatment, (3) oncological follow-up, and (4) coordination (Textbox 1 [4,5]). Survivorship care plans (SCPs), personalized health care plans for cancer survivors, have an important role in the delivery of SSC, traditionally mainly regarding categories 1 and 3 of SSC (Textbox 1) [4]. However, notwithstanding their potential benefit for both patients and health care providers (HCPs) and the recommendation of their use in clinical guidelines, the present implementation and effectiveness of SCPs seem to be suboptimal [6-8]. Until now, most SCPs have been static, paper-based documents, while patients have shown a preference for dynamic, electronically accessible formats that permit alterations and accessibility for all stakeholders [8]. Personalization, an essential element of SCPs, has often been overlooked, despite evidence emphasizing the importance of tailoring SCPs to accommodate the diverse information needs among patients [9]. However, these findings are mostly based on evaluations of the SCP subsequent to its implementation and based on the feedback of 1 single type of stakeholder. Indeed, while stakeholder engagement seems critical for effective implementation [10], involvement of key stakeholders like patients and HCPs during SCP development has been limited until present [8,11]. The specific needs of patients with melanoma and their HCPs regarding the content of melanoma SCPs have been explored previously [12], which showed that while both stressed the importance of adequate information throughout the disease trajectory and personal oncological follow-up, different opinions existed regarding psychosocial support and coordination of care. However, the reasons why they consider these elements important and why their opinions differ remain unknown. Thus far, only the needs of users have been investigated, with developers' perspectives yet to be examined, even though this could provide valuable insights into the feasibility of desired content.

An approach to integrating the diverse perspectives of all stakeholder groups, ie, patients, HCPs, *and* IT professionals (future developers), is to engage them in a cocreation process [13,14] that encourages their direct involvement in SCP development. Cocreation allows stakeholders to be active partners in the development of innovations, as opposed to objects of study, resulting in products and services that people want and need [15,16]. Therefore, the objective of this study is to investigate the ideal SCP in terms of functions and features to be included per stakeholder group and to explore the motivations behind these preferences through a cocreation process. The findings of this study will serve as a basis to design a user-centered, practically feasible SCP that is tailored to the needs of stakeholders and thereby more easily integrated in clinical practice.

Textbox 1. The 4 main categories of survivorship care.

- *Information and education* about the disease, its treatment, and the possible early and late effects.
- *Identification and treatment* of the disease and therapy effects on all possible domains (ie, physical and psychosocial, including work- and insurance-related).
- *Oncologic follow-up* with surveillance for cancer progression, recurrences or second cancers.
- *Coordination* between all health care providers involved in the care process, to make sure the survivor's health needs are met.

Methods

Setting

This study was part of a regional project in which a digital and personalized melanoma SCP will be developed that will be linked to the patients' electronic health record and provided to patients from diagnosis onwards to help them deal with all disease and treatment-related impacts [17,18]. This project takes place in the region Rijnmond, the Netherlands, and forms a collaboration between 1 academic (Erasmus Medical Center) and 3 non-academic hospitals (Albert Schweitzer Hospital, Francicus Gasthuis & Vlietland, and Maasstad Hospital), in which, like internationally [7], SCPs are not yet routinely provided [6]. The project consists of multiple phases—from needs assessment to implementation—in which cocreation is used to develop an SCP that is adapted to all stakeholders' needs [13].

Study Design

In this study, qualitative research methods in terms of cocreation sessions were used to gain an in-depth understanding of the preferences of all stakeholders involved [19]. Conducting cocreation sessions allows both the end users, ie, patients and HCPs and developers, ie, IT specialists, to collaborate in the SCP design process to reduce the gap between research and implementation [13,14].

XSL•FO
RenderX

The COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [20] were used in reporting this qualitative study.

Participants and Recruitment

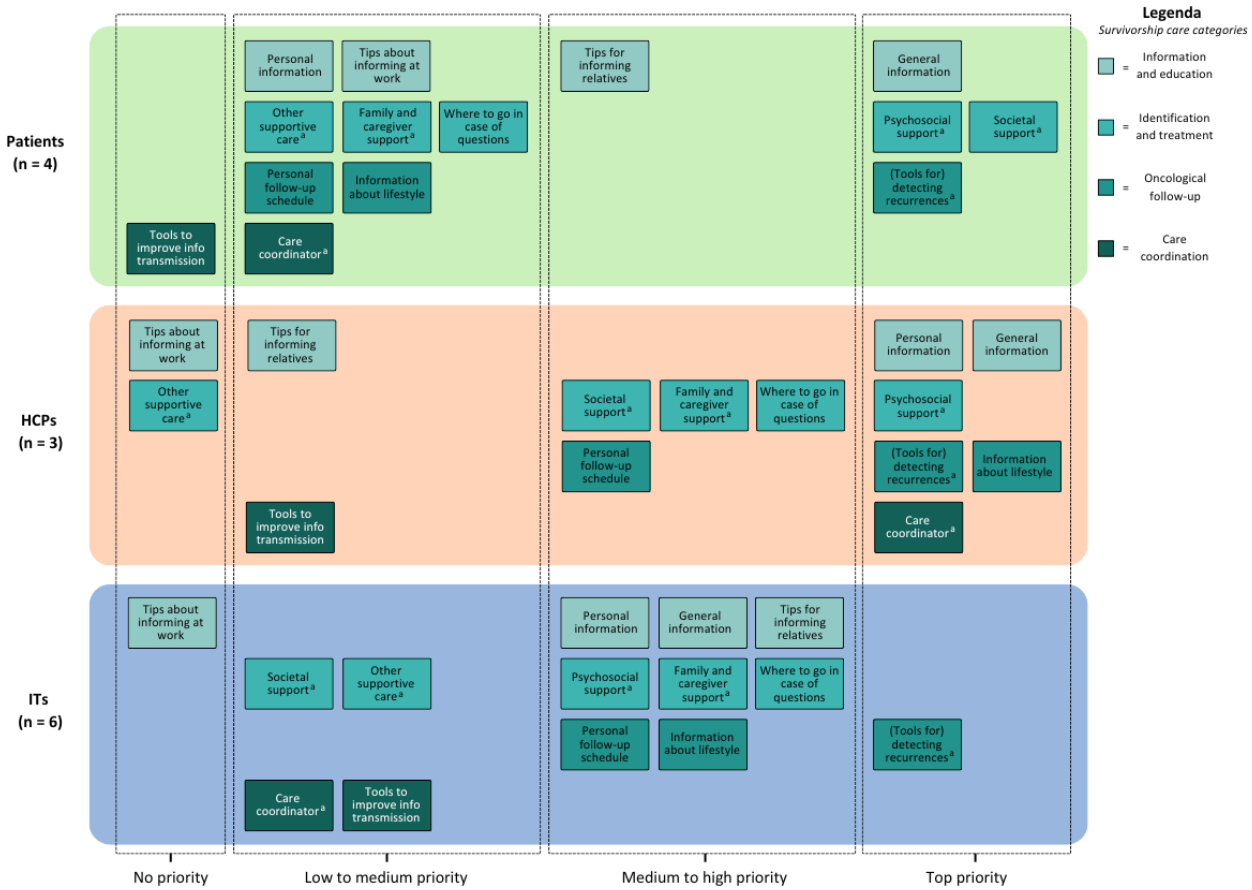
Eligible participants were patients with (a history of) cutaneous stage I-IV melanoma; HCPs involved in both primary, secondary, and tertiary melanoma care such as dermatologists, oncologists, surgeons, general practitioners, and nurse practitioners; and hospital-based IT professionals, for example, those working in organizational aspects of IT in health care and eHealth (future developers of the SCP). We aimed to recruit an equal number of patients, HCPs, and IT professionals to ensure a balanced cocreation session in terms of perspectives to be included and to explore the motives in these perspectives. All patients had to be treated in and therefore under follow-up in, and both HCPs and IT professionals had to be affiliated with one of the 4 participating hospitals. To select participants, first patients and HCPs that participated in prior qualitative research and/or had given consent to be contacted (again) for participation in a follow-up study were invited to participate. IT professionals as well as the remaining patients and HCPs were approached through the professional networks of the researchers. All potential participants received information about the study by email or by phone. Our aim was to recruit ±15 participants, in which we follow prior research (eg, Vandekerckhove et al [21]). In the end, 19 participants signed up, and based on their availability and eventual willingness to participate, a total of 3 mixed cocreation sessions with 4-5 participants were organized, with a total of 4 patients, 3 HCPs, and 6 IT specialists. No financial compensation was given for participation.

Cocreation Sessions

Input for the cocreation sessions was based on prior in-depth qualitative research, in which SSC needs of a total of 50 patients with stage I-IV melanoma and 24 HCPs were explored [6,17,18]. In total, 23 interview- and 8 focus group transcripts were re-analyzed for the purpose of this study using Nvivo version 12/R1, to identify potential functions and features of a melanoma SCP. *Functions* represent the overarching areas in which support can be provided, while *features* are tools to deliver that support. First, all transcripts were coded to identify patients' and HCPs' needs regarding SSC (including SCPs) by 2 researchers (JB, a female medical master student and a female health care management master student), which was then checked and complemented by 2 other researchers (NK, a female medical doctor, and KT, a female academic researcher in health care innovation and cocreation). The resulting SSC needs were reformulated as 44 potential features of an SCP by the research team (first reformulation by JB and a female health management student, under supervision of NK and KT, which was then discussed in the multidisciplinary research team including NK, ML, JB, KT, and a medical student until consensus was reached). Subsequently, an exploratory literature review was conducted to assess completeness, which did not reveal any new features. Subsequently, the features were structured according to the 4 main categories of SSC [4,5], as presented in Textbox 1, and further divided into 14 potential functions. Using this classification, the 44 potential features of a melanoma SCP were presented to the participants of the cocreation sessions (see Multimedia Appendix 1).

As a result of the national restrictions placed in response to the COVID-19 crisis, the 3 cocreation sessions were held online via Zoom in May 2021. All sessions took approximately 90 minutes and were moderated by JB and NK (experienced in moderating group discussions) and a health care management student, who were all not directly involved in melanoma care.

During the cocreation sessions, a PowerPoint presentation was used to present potential functions and features, and participants were invited to individually create their "ideal SCP" by placing their preferred features in a box. Subsequently, participants had a plenary, semistructured discussion in which they were encouraged to share their ideas about the ideal SCPs by sharing their screens. They were invited to elaborate on their motives for (not) including certain functions and features, and discussions arose. At the end of the sessions, the moderators questioned the participants about under-discussed features. All cocreation sessions were audio-taped, and participants were invited to hand in their filled-in sheets.



Data Analysis

All 3 audio-recordings were transcribed verbatim in anonymized form and were analyzed using Nvivo version 12/R1. Descriptive analyses were used, using Microsoft Excel, to determine the ideal SCPs of the different stakeholder groups based on the filled-in PowerPoint sheets and on comments they made during the sessions. For each function and feature, it was determined by how many percent of the participants they were included. Subsequently, all functions were categorized into "top," "medium to high," "low to medium," or "no priority" based on the following criteria: 100% of respondents adding the function to their ideal SCP was defined as "top priority," 50%-99% as "medium to high priority," 1%-49% as "low to medium priority," and 0% of respondents adding the function to their ideal SCP was defined as "no priority"; see also Figure 1. Based on this figure, we then described the ideal SCP par stakeholder group and the similarities and differences between them.

Second, underlying motivations of all participants for including functions and features in their ideal melanoma SCPs were analyzed in a thematic content analysis [22]. As a first step of the analysis, all transcripts were coded based on the functions and features within the 4 main categories of SSC, as previously mentioned (Textbox 1), by 2 researchers (JB and a health care management master student). This was checked and complemented by a third researcher (medical master student). Next, within these categories, underlying motives for composing the ideal SCPs were explored. Motives of each stakeholder group to include (or exclude) a specific function or feature in the SCP were openly coded by one researcher (JB), which was checked and complemented by a second researcher (NK). The next phase of analysis consisted of axial coding, in which the open codes were clustered in concept motives and links between motives and stakeholder groups were made in order to investigate the differences and resemblances between the ideal SCPs for patients, HCPs, and IT specialists. The resulting overview was discussed within the multidisciplinary research team until consensus was reached (JB, NK, ML, and KT).

Figure 1. Overview of composed ideal SCP per stakeholder group in terms of functions added per main category of SSC. For an overview of all functions, including their corresponding features, see Multimedia Appendix 1. [a]Information about and referral to reliable and up-to-date information and tools regarding this topic. HCP: health care provider; SCP: survivorship care plan; SSC: survivorship care.

Ethical Considerations

This cocreation study was part of a larger project, of which the study protocol was submitted to, and approved by, the Medical Ethics Committee Erasmus MC. After reviewing the protocol, the committee concluded that the Medical Research Involving Human Subjects Act (Dutch abbreviation: WMO) did not apply to this study (MEC-2020-0197). Written informed consent was obtained from all participants involved in the cocreation sessions and they were informed that they could withdraw at any point during the study. Participants did not receive any compensation for participation in this study.

Results

Participant Characteristics

The characteristics of the 13 participants in the cocreation sessions as well as the compositions of all 3 sessions can be found in Table 1.

XSL•FO
RenderX

Table 1. Characteristics of participants per cocreation session.

Participant	Gender	Stakeholder	Experience or expertise	Care setting
Session 1				
1	Female	Patient	Melanoma stage IV	Secondary or tertiary care
2	Female	IT professional	Assistant professor in organizing aspects of IT in health care	Tertiary care
3	Male	IT professional	Information management and IT advisor	Tertiary care
4	Female	IT professional	Clinical informatician and data protection officer[a]	Secondary care
Session 2				
5	Male	Health care professional	General practitioner	Primary care
6	Female	IT professional	Information manager in research and innovation	Secondary care
7	Female	IT professional	Clinical informatician: information advisor and architect, (application) implementation lead	Secondary care
8	Male	Patient	Melanoma stage I/II	Secondary care
Session 3				
9	Female	Health care professional	Oncological surgeon	Tertiary care
10	Female	Health care professional	Oncological nurse practitioner	Secondary care
11	Female	IT professional	Information manager	Tertiary care
12	Male	Patient	Melanoma stage IV	Secondary or tertiary care
13	Male	Patient	Melanoma stage IV	Secondary or tertiary care

[a]Having a partner with melanoma.

Ideal SCPs and Underlying Motives

In Figure 1, an overview is provided of the composed ideal SCPs per stakeholder group, followed by an in-depth description of their underlying motives for (not) including certain functions and features. All results are discussed per category of SSC (Textbox 1), and all motives are provided from the participants' perspectives.

Ideal SCPs

Overall, patients assembled the smallest SCP; for them, fewer functions were of medium to high, or top priority compared to the other 2 stakeholder groups. For patients, category 2 focusing on identification and treatment was most important. They primarily included general information and support for themselves, tips on how to inform their relatives, and information about (tools for) detecting recurrences. On the other hand, both HCPs and IT professionals constructed a somewhat larger SCP with more functions being of medium to high, or top priority, with category 3 focusing on oncological follow-up being the most important aspect. HCPs added more information about (personal) follow-up for the patient, including (tools for) detecting recurrences. Furthermore, they added both general and personal information, as well as support for both the patient and their family and caregivers. Additionally, they included information about a care coordinator. IT professionals, on the other hand, considered (tools for) detecting recurrences particularly important to add, and they included extensive information about the patient's (personal) follow-up, both personal and general information, along with support for the patient and their family and caregivers.

Underlying Motives Per Stakeholder Group

For each stakeholder group, motives for (not) including certain functions and features are discussed below per main category of SSC and can be found in Table 2. For readability, results are provided on the function level, which are **bold**. Submotives are in *italics.*

Motives and submotives	PT[a]	HCP[a]	IT[a]
To prevent (irrelevant) information overload		1, 3	3
To prevent taking away hope	1		1[b]
Preventing unnecessary development			
SCP is not the right medium		2	4
Similar tools already exist	3	3	3
Function is applicable in general, not for melanoma specifically			1, 3
Lack patient need for function	3		
Taking feasibility and privacy into account			
Function is unfeasible			2, 3, 4
Privacy issues are more severe than the importance of including the function and its relevance for patients			3

[a]The numbers correspond with the main category of SSC to which the functions belonged and for which submotives were provided, namely (1) information and education, (2) identification and treatment, (3) oncological follow-up, and (4) coordination.

[b]Submotives for (not) including functions provided solely by an IT professional with a partner with melanoma.

Motives of Patients

The most important category for patients was category 2 (identification and treatment). Patients included **psychosocial support**, **societal support**, and **where to go in case of questions** because it would *help them* in *dealing with psychosocial issues*. Furthermore, they indicated that the SCP should contain information about and referral to (reliable and up-to-date information about) **psychosocial** and **societal support** because patients recognized the existence of such issues *based on their personal experiences* and because they *empathized with other patients' (diverse) needs.*

> *Of course it's all very individual.. One person might struggle with their mortgage, while another might not have financial issues due to their illness. […] And chatting with fellow patients for example, peer support, can be helpful for many people, although I personally don't have the need for it.* [Patient, male]

Patients included **general information** and **tips for informing relatives** from the second most important category, namely category 1 (information and education), because they valued being *informed* and *prepared* and to help them *deal with their psychosocial issues*. They indicated that the ideal SCP should provide **general information** that is *reliable* and *understandable* since much of what is currently included in, for example, the patient portal is too medical and written in "doctor's language." According to them, providing this information within the SCP could potentially prevent both patients and their relatives from searching for (incorrect) information on websites.

> *I did a lot of googling myself during the years I was under treatment, and at some point, you end up on really unpleasant websites where you're practically told that you'd be better off not living, and five years later, here I am. I found that very distressing, and it always made me very sad. So, I would like people to know how to find their way to the right information.* [Patient, female]

Tips or **information about informing relatives** could also *help them deal with psychosocial issues*, for example *with the (lack of) understanding of others.* A reason considered for not including functions from this category in their ideal SCP, such as specific parts of **general information**, was to *prevent getting distressed*; they emphasized not to add specific information, such as treatment effectiveness, because, *in their experience*, it *took away their hope.*

Being informed, prepared, and empowered were important motives to include **(tools for) detecting recurrences**, a **personal follow-up schedule**, and **information about a healthy lifestyle** from the third category (oncological follow-up), as was *dealing with their psychosocial issues*, which they did when *empathizing with other patients' needs*. Furthermore, patients stressed that adding information regarding **(tools for) detecting recurrences** could *improve their self-management skills, alleviate their concerns*, and (thereby) *prevent unnecessary consultations*. Motives not to include functions from this category (eg, **information about a healthy lifestyle**) were that similar functions or tools already exist so that *unnecessary development could be prevented*.

Functions in the fourth and last category (coordination), like information regarding a **care coordinator**, although less important in their ideal SCP, were added *based on their own experiences* since they missed an *easily accessible contact point* during their disease trajectory.

Motives of Health Care Providers

HCPs added functions from category 3 (oncological follow-up) to *inform*, *prepare*, and *empower patients*. More specifically, they indicated that the ideal SCP should include information about/referral to **(tools for) detecting recurrences** to *meet patients'* as well as *relatives' information needs*, *improve patients' self-management*, and *alleviate their concerns.* Altogether, this could *prevent unnecessary consultations. Meeting patients' information needs* and also *improving their melanoma outcomes and health in general* were reasons for adding **information about a healthy lifestyle**. Furthermore,

XSL•FO
RenderX

HCPs indicated that offering this information is needed in order *to provide* patients with *a complete treatment plan*, which they did *based on their expertise*. However, others mentioned that *similar tools already exist* and therefore did not add this function to the SCP. A **personal follow-up schedule** including background information was added by HCPs to *meet patients' information needs* and *to provide structure for them.* On the other hand, a reason for not including this background information was also mentioned, namely *to prevent (irrelevant) information overload.*

Identifying and providing support for or treating psychosocial issues were motives mentioned by HCPs for adding **psychosocial support** from category 2 (identification and treatment) to their ideal SCP. They did this *based on their expertise* and when *empathizing with patients' needs*. Other reasons mentioned for adding this function were to *provide reliable information* (preferably by linking it to existing trustworthy resources) that is up-to-date and to *provide an accessible contact point* for patients. Furthermore, HCPs indicated that information regarding and/or referral to **societal support** should be added to meet patients' *information needs* since questions regarding financial and work-related issues arise from diagnosis onwards. **Family and caregiver support** was added by the HCPs to *provide a complete treatment plan* for the patient and their loved ones and to *meet the relatives' information needs*, the latter being important as heredity is a topic that elicits many questions. HCPs indicated that by better informing relatives, *unnecessary consultations* could be *prevented*. Lastly, **where to go in case of questions** was added by HCPs to *provide structure for patients* and to help them find the right person to turn to among the many HCPs involved in their illness and treatment journey.

> *That the patient actually has some idea of where to go for which question, so they don't get lost in the maze of various professionals.* [Health care professional, male]

Similarly, regarding category 4 (coordination), they added information regarding a **care coordinator** to *provide an accessible contact point* for patients and their relatives. They also did this *to alleviate patients' concerns*, which is something that such a contact point could do. In addition, they considered this information important to ensure that the patient had a sense of having somewhere (or someone) to turn to for questions and uncertainties.

Functions from the first category (information and education) that were added to the ideal SCP of HCPs were both **personal** and **general information**, and they included them to *meet the patients' information needs, to provide understandable information, to help patients remember provided information,* and *to support them in (treatment) decision-making.* They mentioned that patients often forget important **personal information** about their received diagnosis and treatment options, but also **general information regarding** what certain treatments (effects) entail, and they considered it important to assist them in retaining this information. In general, HCPs *based this on their expertise* and indicated they should provide this information in order *to obtain informed consent.*

> *You're supposed to tell them what you're going to do, what the side effects are, what the chances are that it will work; make it clear what the patient can choose. Only then can they give informed consent. So, whether you're going to perform surgery or provide immunotherapy, this is the information you must share.* [Health care professional, female]

Motives of IT Professionals

Category 3 (oncological follow-up) was the most important category in the ideal SCP of IT professionals. They added information regarding **(tools for) detecting recurrences** based *on their own experiences* and when *empathizing with patients' needs.* Furthermore, *to improve patients' self-management skills, to alleviate their concerns*, and *to provide an accessible contact point* were also mentioned as motives for including this function. IT professionals indicated that they thought patients could have worries and uncertainties around potential recurrences and that support regarding these worries, which is also *feasible*, should be provided to them. While *empathizing with patients' needs,* they indicated that a **personal follow-up schedule** including background information should be added *to meet patients' information needs*. However, *taking feasibility and privacy into account,* they mentioned that while they considered adding background information feasible, they foresaw several *privacy issues* for including a **personal follow-up schedule** that *were more severe than the importance of including and the relevance of* this information.

> *For privacy regulations, I deliberately left those things out because otherwise, it makes it quite challenging when it comes to an appointment calendar or something similar. If you manage it yourself, it's fine, but if it has to come through the hospital information system, then you have to integrate with that, and it becomes really tricky from an IT and privacy standpoint.* [IT professional, female]

They added **information about a healthy lifestyle** for patients with melanoma when *empathizing with* and *to meet their needs*, as well as *to improve melanoma outcomes*. Reasons for not including this information were that *having a healthy lifestyle is applicable in general, to prevent (irrelevant) information overload* and because *similar tools already exist*.

IT professionals added functions belonging to category 2 (identification and treatment) *based on their expertise* and, more specifically, because they considered them *feasible.* In addition, they added **psychosocial support** to *provide support for or treat psychosocial issues* and *to improve patients' self-management*, which they *based on their own and others' experiences.* They added **family and caregiver support** to *meet patients' and relatives' information and support needs* and *to provide a complete treatment plan*. Some included information about **where to go in case of questions** to provide clarity for patients; although some of them questioned its feasibility, they thought *its importance and relevance for patients outweighed the potential privacy issues.*

XSL•FO
RenderX

> *I think that if you can have patients fill in information like, 'I have this general practitioner, I go to that hospital with that specialist, and these are the other health care providers involved,' and alongside that, a general guide saying, 'For these kinds of questions, contact your GP,' I think that can provide more value. But when you want to retrieve that information automatically, it becomes challenging.* [IT professional, female]

For others, these *potential issues* made them consider this function *unfeasible*, and they did not add this to their ideal SCP.

Informing, *preparing*, and *empoweringpatients* were reasons mentioned by IT professionals to include functions like **personal** and **general information** from category 1 (information and education). They added them *to meet* both *patients' and relatives' information needs, to provide understandable* as well as *reliable information*, and to, at the same time, *help patients deal with the lack of understanding of others*. **Tips to inform relatives** were added by the IT professionals to *meet relatives' information needs* and to *help patients deal with a lack of understanding of others*, which they did *based on the experiences* they gained *from others*. They considered adding these functions (**personal** and **general information** and **tips to inform relatives**) *feasible* as *based on their own expertise* and when *empathizing with patients' needs*. Reasons for not adding functions like **general information** included considering them *not applicable to melanoma specifically* and to prevent this general information from *taking away hope*.

IT professionals considered category 4 (coordination) least important. Nevertheless, they added functions (**care coordinator** and **tools to improve information transmission**) from this category *based on their own and others' experiences* and based on *their expertise*. They also provided motives for not including functions from this category; they indicated that according to them, the *SCP is not the right medium* to include **tools to improve the information transmission between HCPs**, a function that they also considered *unfeasible* to realize.

Discussion

Principal Findings and Comparison With Prior Work

The aim of this study was to gain insight into the ideal SCPs according to relevant stakeholder groups and to explore their motivations behind adding them. Patients composed a rather compact SCP, mainly focusing on category 2 on identification and treatment, including both information and support for themselves, with their motives being primarily based on their personal experiences and needs. HCPs and IT professionals constructed more comprehensive SCPs, with category 3 on oncological follow-up being the most important one, and HCPs additionally focusing on category 4 on *coordination*. When looking at their underlying motives, they all aligned with their respective areas of expertise: HCPs related their additions mainly to their roles as medical practitioners, such as providing a complete treatment plan and obtaining informed consent, while IT professionals' contributions were mostly influenced by feasibility and privacy concerns.

In light of our findings and prior research focusing on other types of cancer (eg, colorectal and gynecological [23-25]) than melanoma, it is evident that patients place considerable emphasis on *identification and treatment of disease and therapy effects* (category 2), perceiving the SCP mainly as an informational and supportive tool. Thereby, patients' unmet needs are related to their commonly faced challenges such as psychological distress, anxiety, depression, long-term and late effects, as well as the fear of recurrence. As a result, they express a need for a more comprehensive supportive care approach that includes nonmedical information, like peer support, financial guidance, return-to-work strategies, and psychological resource information [17,26-28]. Moreover, the emphasis on category 2 in our results underscores the importance of broadening traditional, current SCP content, which predominantly targets categories 1 and 3 on *information and education* and *oncological follow-up* [4]. Patients agreed that functions from category 2 (eg, psychosocial and societal support) are indeed essential for effective SSC, as it would both help them deal with certain issues and prevent searching for incorrect information online and related distress. Integrating (referrals to) this information in the SCP also allows all to be centralized in one place, instead of spread over paper-based information and web-based resources given to them by various HCPs. Despite patients' agreement on category 2, their opinions differed on other functions. For example, some accentuated the need for general information (category 1, information and education) and more specifically on treatment effectiveness, but others felt that knowing this might negatively influence their hope toward a positive outcome. A reason for this may be found in patients' motives for the composition of their ideal SCP, which were predominantly based on their personal, specific experiences with the disease and the knowledge they gained when they were affected and treated [29]. In addition, our findings align with previous research showing that providing certain information might be beneficial for some patients but can trigger fear among others [8,9], and thereby further underscore the importance of personalizing the SCP's content [30,31]. To adequately tailor the SCP to each patient's individual needs, future research should investigate ways for SCP tailoring, possibly through patient profile definition or integrating artificial intelligence (AI) methodologies. In addition, further quantitative research should follow to investigate the actual impact of our results on both SCPs' implementation and effectiveness in clinical practice, for example, through a classic randomized controlled trial or partially randomized patient preference trial, the latter incorporating patient preferences in the process of randomization [32].

HCPs and IT professionals, in contrast, mainly based their ideal SCP preferences on their professional expertise. HCPs primarily related their choices to their clinical knowledge and roles as medical professionals and indicated what is needed to provide patients with a complete treatment plan and in order to obtain informed consent. IT experts offered more practical reasons, predominantly concerning feasibility and privacy issues, thereby including perspectives the end users may have insufficient knowledge about [29,33]. Both HCPs and IT professionals regarded *oncological follow-up (category 3)* as most important. Within this category, information about (tools for) detecting

XSL•FO
RenderX

recurrences was added unanimously. This corresponds with previous literature that identified fear of recurrence as a prevalent psychological concern among melanoma survivors [6,17,34], and offering information and support concerning this has been shown to alleviate the intensity of such fears [35]. In the context of the ongoing digital health transformation and the workforce challenges in health care [36,37], AI offers promising solutions. AI could help in assessing skin abnormalities and thereby detecting recurrences in the future [38]. Although physicians have concerns about AI tools' accuracy and potential health inequality risks, it could lead to fewer unnecessary consultations, cost reductions, and improved care pathways [39]. As a result, improving SSC practices regarding *oncological follow-up* could also facilitate advancements in category 4 on *care coordination*, a topic that HCPs in our study also deemed important. This suggests that the HCPs viewed the SCP as a care coordination tool, which could potentially address areas for improvement that were stressed in previous literature [40].

The feasibility and privacy concerns highlighted by IT professionals were particularly related to functions deemed vital to end users, ie, patients and HCPs, such as an overview of where to go (category 2), a personal follow-up schedule (category 3), and tools to improve information transmission between HCPs (category 4). Although legitimate, particularly given the patients' unmet needs, it is important to investigate how to adequately address these issues. Suggestions put forth to mitigate some of these concerns included providing only the patients' specialist's name rather than their comprehensive contact information and linking the SCP to the electronic patient portal instead of incorporating a personal follow-up schedule directly within the SCP. However, since the use by HCPs in clinical practice and thereby the SCP's implementation could be facilitated by linking it directly to the electronic health record [6], which has been shown feasible before [41], it should be investigated how to overcome these privacy concerns.

The above discussion suggests that HCPs, patients, and IT professionals attribute different but complementary roles to SCPs. Whereas HCPs view SCPs primarily as a coordination tool, patients stress their informational and supportive roles, and IT professionals see them as a data-sharing tool that must function in a safe and reliable manner. These differing perspectives can be explained by the organizational structure of melanoma care, including SSC, which is organized in networks with centralization of administration of systemic treatments across the Netherlands. In the Rijnmond Region, it operates from a "shared-care model" [42], where HCPs lead the network and its coordination while patients are positioned at the receiving end of care, thus receiving care, information, and support. From this point of view, the role of IT professionals in relation to SCPs is to ensure that coordination, information sharing, and support are conducted in a reliable manner.

Recommendations for Future SCP Developers

The future SCP that we envision based on our results should address all the above roles, functioning both as a comprehensive information tool—facilitating the safe and reliable linking and sharing of information of multiple stakeholders through its digital aspect and connection with the patient's electronic health record—and as a means to improve the coordination of melanoma care. Being better informed and supported will likely enhance patient empowerment, allowing them to take a more active role in managing their disease and treatment coordination and thereby facilitating shared decision-making [43,44], rather than merely being passive recipients of care. Thus, future developers should create SCPs that contain functions and features with both personal and general information, information about/referral to reliable information on psychosocial and societal support for patients, as well as information on lifestyle and tools for detecting recurrences, and with functions and features that facilitate care coordination. This SCP can and should be further personalized, depending on patients' and HCPs preferences, by adding additional functions and features such as a personal follow-up schedule, information on where to go in case of questions [12], tips for informing relatives, and support for them.

Strengths and Limitations

The main strength of this study is its inclusive approach to cocreation. Unlike many other cocreation studies that often engage only 1 stakeholder group, typically patients [45,46], or more recent at most 2 (patients and HCPs [47,48]), our study uniquely incorporated IT professionals. Whilst they are not the primary users of SCPs [4], their involvement proved invaluable as they offered crucial insights into the development process, particularly highlighting feasibility and privacy concerns. Moreover, we actively engaged all stakeholders from the inception of the SCP development rather than limiting their participation to its evaluation, as seen in, and of which the importance was stressed in, previous literature [7,33]. Furthermore, this cocreation approach aligns with the current shift toward value-based health care, endorsing the principles of patient partnership and shared decision-making [49]. Such an approach empowers the target audience and other stakeholders to shape the outcome actively, ensuring that the final SCP aligns closely with their needs and preferences. Moreover, the composition of our sessions with mixed groups fostered mutual learning and encouraged interactive discussions [13,14,50]. These elements collectively enhance the likelihood of the tool being widely accepted, facilitating more effective implementation and practical effectiveness.

A limitation of our study was its regional sample, which raises questions about the transferability of our findings. However, since melanoma care is uniformly organized in networks throughout the Netherlands, we expect that our results will be applicable outside our region and possibly to other countries if melanoma care is similarly organized. However, to reach an optimal, inclusive SCP, perspectives and needs of patients with varying levels of (health) literacy, socio-economic status, and backgrounds should also be investigated and incorporated. Another aspect warranting attention is the inclusion of an IT professional being a relative of a patient with melanoma. Even though we believe their experiences did not greatly affect the composition of IT professionals' ideal SCP, it could be interesting to further investigate relatives' perspectives on ideal SCPs and their underlying motivations for it. Based on previous literature, we know that relatives of cancer survivors can encounter significant challenges and have unmet needs

XSL•FO
RenderX

throughout the patients' disease trajectory [17,51,52] and are therefore sometimes even included in the definition of a cancer survivor [3]. Lastly, our participant pool only included patients who had finished their treatment for some time. Since retrospective experiences might differ from those of patients currently undergoing treatment, it is important to focus on this latter group in future research, ensuring a complete understanding of patients' SSC needs throughout the whole disease trajectory.

Conclusions

This cocreation study provides insights into stakeholders' ideal melanoma SCP and the motivations behind them. Considering the diversity in both preferences and underlying motives regarding SCP composition between patients, HCPs, and IT specialists, it is crucial to develop a broad SCP that extends beyond traditional SCP content, emphasizing personalization. By understanding the motives and considerations of patients and HCPs in shaping their ideal SCPs, which we were able to elicit through the interaction and discussion between different stakeholders, thoughtful design can optimize patient care and support throughout the survivorship journey. At the same time, keeping the practical requirements of IT professionals in terms of feasibility and privacy in mind is important to ensure the ideal SCPs can be realized. In addition to continued stakeholder involvement, efforts should be focused on addressing the potential feasibility and privacy issues, particularly those related to personalization, to ensure the SCP meets the needs of both patients and HCPs.

Acknowledgments

This study is part of a larger project that is multi-sponsored by Bristol Myers Squibb (BMS), Merck Sharp & Dohme (MSD), Novartis, and Pierre Fabre. However, the sponsors were not involved in the design of the study, data collection, data analysis, manuscript preparation, and/or publication decisions. The authors thank all patients, HCPs, and IT professionals for sharing their experiences and particularly for their openness during the cocreation sessions. Furthermore, the authors thank Esther Bijl for helping with the data collection and analysis.

Authors' Contributions

NK, ML, JB, and KT designed the study. NK, JB, MW, and KT performed the patient selection. NK and JB performed data analysis under supervision of ML and KT. NK, ML, JB, and KT interpreted the data. NK and KT wrote the first version of the manuscript, and all authors revised the following versions of the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: Survivors of childhood cancer are at risk of medical, psychological, and social late effects. To screen for their risks, receipt of consistent, cancer-specific follow-up care is crucial. However, <50% of survivors attend their aftercare, and only 35% of them recognize that they could have a serious health problem. The use of mobile health (mHealth) is a promising form of intervention to educate, connect, and empower survivors of childhood cancer on the importance of follow-up care.

Objective: This study aimed to use co-design to identify the priority components to include in an mHealth intervention with young adult (aged between 18 and 39 years) survivors of childhood cancer and health care providers.

Methods: This study was conducted between January and November 2022 in Canada and used patient-oriented research methods. Participants were recruited through local or provincial long-term follow-up clinics, using convenience sampling from patient partners who assisted in recruiting survivors across geographical areas in western, central, and eastern Canada, and social media outreach (X, formally known as Twitter; Facebook; and Instagram). Qualitative descriptive data (focus group interviews) from survivors of childhood cancer and health care providers (individual interviews) were gathered. We analyzed the collected data

XSL•FO
RenderX

using reflexive thematic analysis and verified it through member checking techniques through an online community engagement event.

Results: We conducted with patient partners 5 online (Zoom) focus groups with 22 survivors of childhood cancer (mean age 29.19, SD 4.78 y). We conducted individual telephone interviews with 7 health care providers. Participants identified five priority areas to be included in an mHealth intervention: (1) connections, (2) education and information, (3) engagement, (4) personalization, and (5) resources. Results were shared with and validated by survivors of childhood cancer, their families, health care providers, and academic researchers as part of a community engagement event. Small and large group discussions were facilitated to allow participants to review and discuss the accuracy of the themes derived regarding the core components to be included in mHealth. A graphic recording artist visually captured key ideas from the event. A subset of the participants also completed a web-based satisfaction survey, and responses indicated that the community engagement event was generally well received.

Conclusions: Results from this study have provided the necessary foundation to progress in intervention development. The next step of this multiphased project is to build an innovative and accessible mHealth intervention prototype that is based on the identified core components and is grounded in an established conceptual framework for co-design of mHealth.

Introduction

Follow-Up Care for Survivors of Childhood Cancer

Due to advances in treatment and supportive care, the survival rate for pediatric cancer (age 0-19 years) now exceeds 80% [1]. In turn, the number of long-term survivors of childhood cancer has grown exponentially, with more than 45,000 survivors living in Canada today [2]. While this is encouraging, survivors of childhood cancer are at a lifelong risk of developing medical, psychological, and social late effects due to their cancer treatment [3]. By the age of 50 years, nearly 100% of survivors develop one or more chronic health conditions, many of which are disabling or life-threatening [4,5]. This prevalence suggests an important need for early screening and intervention of late effects to improve longer-term outcomes for this group considered vulnerable.

Consistent, cancer-specific follow-up care is associated with better long-term outcomes, including earlier identification of late effects or secondary cancers and minimized risk of morbidity and mortality [6-8]. However, less than 50% of survivors of childhood cancer attend long-term follow-up clinics [9,10]. Known barriers to attending follow-up care in Canada include limited knowledge of late effects and recommendations for follow-up care, treatment factors (eg, diagnosis and type of treatment), distance from cancer-specific follow-up clinics, and sociodemographic factors (eg, minority status and male sex) [7,10]. Furthermore, only 35% of survivors recognize that they could develop a serious health problem [11]. Young adults (aged between 18 and 39 years [12]) survivors of childhood cancer are especially at risk of not receiving consistent long-term follow-up care due to their unique developmental stage. Specifically, this is a critical and dynamic time during which major transitions occur, including greater autonomy, independent living, and financial independence, as well as a period of increased mental health concerns and risk-taking behaviors [13]. The transition from pediatric to adult health services is also particularly challenging and may result in diminished engagement in follow-up care [14].

Mobile Health Intervention for Survivors of Childhood Cancer

Development of innovative interventions is needed to better educate and engage survivors of childhood cancer in their follow-up care. An ideal intervention would meet survivors where they are, be accessible outside of formal follow-up care programs, account for the sociocultural context of survivors [15], and ultimately address the distinct needs and challenges of this population. Mobile health (mHealth) refers to the use of wireless technology in medical care to deliver health education. mHealth has shown potential to educate patients about preventative health care [16]. Furthermore, mHealth may serve to break down some of the geographic barriers and issues related to accessibility faced by survivors of childhood cancer residing in more remote or rural regions [17]. Given the widespread use of smartphones among young people [18], mHealth has the potential to address the unmet psychosocial and health care needs of young adult survivors of childhood cancer. Therefore, the use of mHealth is a promising new form of intervention to educate, connect, and empower survivors of childhood cancer on the importance of cancer-specific follow-up care.

mHealth interventions targeting young adult survivors of childhood cancer are in their infancy [19,20]. A systematic review of eHealth and mHealth interventions in pediatric cancer lends support for the feasibility and acceptability of technology-based approaches to improve outcomes of children with cancer. However, evidence of the effectiveness of interventions targeting specific outcomes (eg, emotional distress and health behaviors) remains mixed [19]. Limitations of existing interventions include restrictions to single-site pretest-posttest designs, a failure to consider an iterative process to intervention development, and a lack of engagement with patients as partners in the co-design of these programs, and intervention components must be guided by survivors' priorities [21]. Engaging patients as partners is a feasible and efficient way to conduct clinical research, as they are considered experts through their own lived experiences [21]. Research shows that patient engagement in health research has many benefits,

XSL•FO
RenderX

including higher participation rates, design of study protocols with more relevant outcomes, and more meaningful and accessible means of disseminating research to study participants and community members [21]. However, survivors are seldom included in the development of interventions directed at improving knowledge of the importance of long-term follow-up care. Therefore, co-designing with survivors of childhood cancer in addressing their own barriers to attending follow-up care may be a promising means to enable survivors of childhood cancer to understand and engage in their follow-up care and maximize their outcomes. There is also limited research that incorporates health care provider perspectives [22,23]. Health care providers that deliver follow-up care to survivors of childhood cancer may offer complementary insights on the mHealth intervention development in the context of Canadian health care systems.

Current Research

The overarching goal of this research was to co-design an mHealth intervention with young adult survivors of childhood cancer, as well as health care providers that deliver follow-up care to this population. In this research, we refer to co-design as a meaningful engagement with end users in the entirety of the research process [24]. In addition, our research approach adhered to the best practices outlined by the Strategy for Patient-Oriented Research (SPOR) of the Canadian Institutes of Health Research (CIHR) [25].

As a foundational step toward mHealth intervention development, we conducted a qualitative study to understand and identify the priority components to be included in an mHealth intervention that can engage, educate, and empower survivors of childhood cancer on the importance of attending their follow-up care. Subsequently, we validated the results by seeking feedback from multiple informants, including survivors, caregivers, health care providers, and researchers, through a community engagement event.

Methods

Overview

This study was conducted as part of a larger, multiphased project regarding survivors of childhood cancer and their follow-up care experiences [26,27]. We used patient-oriented research and qualitative descriptive study design. Qualitative description is a qualitative research framework that provides detailed experiences directly from participant perspectives [28]. This study design is well suited for health sciences research because it captures broad insights and helps address key clinical and health care services questions [29].

Study data were collected and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) electronic data capture tools hosted at the University of Calgary. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources [29,30].

Ethical Considerations

Ethics approval for this study was granted by the Health Research Ethics Board of Alberta—Cancer Committee (HREBA.CC-20-0248). As this project involved human participants, informed consent was obtained from all participants. Data collected were deidentified before data analysis. Participants were compensated for their time in the study (refer to the Procedure section for compensation details).

Patient and Public Involvement

In line with best practices of CIHR SPOR [25], we have reported the background, objectives, methods, and results of this project based on the checklist from the Guidance for Reporting Involvement of Patient and the Public Short Form [31]. Patient partners were involved as coresearchers throughout the project, including study design, recruitment, data collection, interpretation of results, and knowledge dissemination. Patient partners were compensated financially for their time.

Participants

Survivors were eligible to participate in the qualitative study if they were (1) currently aged between 18 and 39 years, (2) diagnosed with cancer before the age of 18 years, (3) at least 5 years after diagnosis and/or 2 years after treatment, and (4) currently living in Canada. Health care providers were eligible to participate in the study if they were (1) delivering clinical care to survivors of childhood cancer, (2) practicing for >5 years, and (3) currently living in Canada.

Participants were eligible to participate in the community engagement event if they were (1) survivors of childhood cancer as defined earlier, (2) parents or caregivers of survivors of childhood cancer, (3) health care providers that provide follow-up care to survivors of childhood cancer as defined earlier, or (4) researchers of childhood cancer survivorship.

Recruitment

Several strategies were used to recruit individuals from diverse sociodemographic backgrounds as part of the larger, multiphased project [26]. First, survivors and health care providers were informed about the study by their local or provincial long-term follow-up clinics, where they were given the option to complete a consent-to-contact form and subsequently invited to participate by the study team. Second, patient partners assisted in recruiting survivors across geographical areas in western, central, and eastern Canada. The practice of patients recruiting patients to integrate diverse patient perspectives is supported by the principle of inclusiveness according to the CIHR SPOR framework [25]. Third, social media outreach was used, including X (formerly known as Twitter; X Corp), Facebook (Meta Platforms), and Instagram (Meta Platforms). This strategy involved recruiting through patient and young adult cancer advocacy groups and communities by sharing study graphics (eg, Childhood Cancer Survivor Canada and #AYACSM).

Participants that completed other phases of this project were invited to participate in this qualitative study. Participants that participated in other phases of the project, as well as those who did not participated in the project, were all welcome to attend the community engagement event.

Procedure

We conducted 5 online focus groups with survivors of childhood cancer on Zoom (Zoom Communications Inc) between March and July 2022. Focus group discussions lasted approximately 90 minutes. Eligible participants were contacted and provided with a link to consent to the study on the web through REDCap. They were then provided with a Zoom link and date for the focus group. Participants were compensated with a CAD $25 (US $17.91) e-gift card for their participation. Similarly, we conducted telephone interviews with health care providers who followed the same consent process as survivor participants. Each interview lasted 15 to 20 minutes. Health care providers were also compensated with a CAD $25 (US $17.91) e-gift card for their participation.

We hosted a half-day online community engagement event via Zoom in October 2022. The event was cofacilitated by 2 academic researchers (FSMS and SHJH) and 2 patient partners (RD and IR). A collaborator from a digital technology company, Cambian, attended the event to provide input from a feasibility and usability standpoint. Cambian specializes in providing collaborative health care information services. A graphic recording artist from Fuselight Creative attended the event to visually capture central and representative ideas generated from the community event. Fuselight Creative is a visual facilitation company that specializes in the strategic use of graphic recording to enhance interactive engagement and learning in community events.

Eligible participants were asked to register for the event and provide their email address to receive the Zoom link. Registered participants provided verbal consent to partake on the day of the event on the web via Zoom. Participants were compensated with a CAD $25 (US $17.91) honorarium for their participation in the community engagement event. Likewise, patient partners (RD and IR) were compensated for their cofacilitation of the event.
