For the qualitative study, survivors completed an initial questionnaire regarding their sociodemographic background, including age, sex, gender, relationship status, family composition, and race and ethnicity. Survivors also completed questions regarding their clinical history, such as their diagnosis, age at diagnosis, type of treatments received, and number of years after treatment. Health care providers completed a similar questionnaire to survivors regarding their sociodemographic background, as well as questions regarding their professional experiences, including the number of years practicing and years of experience delivering care to survivors of childhood cancer.

Interview Guide

Survivors engaged in an online focus group discussion, guided by a semistructured interview guide exploring the development of an mHealth intervention for survivors of childhood cancer to optimize their engagement in follow-up care. Questions were codeveloped with patient partners and centered on the development of content (eg, “What are your thoughts on creating a platform for survivors?”), education (eg, “What type of information would you want included?”), communication (eg, “Would you want an opportunity to interact with other survivors and/or healthcare providers?”), and engagement (eg, “What are some features that could help you engage in your follow-up care?”) related to the mHealth intervention.

Health care providers engaged in an individual telephone interview. The same set of semistructured interview questions was administered, with wording modified to reflect the health care providers’ perspective on the same topic. The complete set of questions asked during the focus groups can be found in Multimedia Appendix 1.

Small and Large Group Discussions

As part of the community event, participants engaged in interactive small and large interactive group discussions. Facilitators posed semistructured questions on the accuracy, representativeness, and resonance of the themes conceptualized from the data. During small group discussions (3-4 participants per group), differences in perspectives were discussed in the presence of an observer who was a member of the research team. The observer’s role is to ensure equal participation among members and that no one individual or group’s views are dominant over others. The observer takes notes, facilitates the flow of conversation and turn-taking among participants, and shares a summary of key discussion points with members to ensure the accuracy of notes taken. Key discussion points from the small group sessions were subsequently integrated into the larger group discussion (all participants) to achieve consensus, facilitated by 2 main facilitators (SHJH and FSMS) and 2 patient partners (RD and IR). Large group discussions were facilitated using interactive media features, including a Google Jamboard, Mentimeter, and polling on Zoom.

Satisfaction Survey

Participants completed a web-based questionnaire within 1 week following the event. Questions were derived and adapted from the Public and Patient Engagement Evaluation Tool [32]. Participants were asked to rate the extent to which they agreed with statements regarding their experience at the event, using a 5-point Likert scale (1=strongly disagree and 5=strongly agree). Questions were centered on participants’ understanding of the nature of the workshop (eg, “I had a clear understanding of the purpose of this community workshop”), as well as whether the workshop met the stated objectives described herein. We also solicited feedback from participants using an open-text response format.

Analysis Plan

Sociodemographic information gathered from participants was summarized using descriptive statistics and analyzed with SPSS (version 28.0; IBM Corp). Qualitative descriptive data gathered from focus groups and interviews were audio-recorded, transcribed verbatim, and deidentified. Transcripts were subsequently analyzed using reflexive thematic analysis [33]. Reflexive thematic analysis is a theoretically flexible analytical approach used to identify patterns of meaning and conceptualize them into themes. This type of analysis is commonly used in qualitative description studies [34]. In total, 5 researchers

XSL•FO
RenderX

(SHJH, BH, RD, KM, and HW) conducted the analysis according to the steps outlined by Braun and Clarke [33]. First, researchers read the transcripts several times to familiarize themselves with the data. Next, researchers developed a preliminary coding framework and coding book. Each researcher independently coded the same transcript and met as a team to compare coding choices and ensure alignment in the interpretation of the codes. Following this, the remaining transcripts were each analyzed by 2 researchers. Theme abstraction took place iteratively among the researchers by meeting regularly to discuss and review each researcher's interpretations. Any differences in theme abstraction were reconciled through open dialogue until a consensus was reached. Data analysis was supported using NVivo (version 14; Lumivero) [35], a qualitative data management software. Multimedia Appendix 2 includes a reflexivity statement from all researchers involved in the thematic analysis.

Member checking, also known as response validation, is a validation technique used in qualitative health research and has been recognized as a method of rigor to enhance the trustworthiness of qualitative data [36]. Member checking was conducted with multiple informants, including survivors, caregivers, health care providers, and researchers, through an online community engagement event. Member checking was achieved through multiple methods, including small and large group discussions, satisfaction surveys, and graphic recording throughout the community engagement event.

Results

Participant Characteristics

In total, we conducted 5 online focus groups with 22 survivors of childhood cancer, with a range of 4 to 6 participants present per focus group. The mean age of survivors was 29.19 (SD 4.78) years. Over 95% (21/22) of survivors indicated that their assigned sex was female and likewise that their gender identity was female. Most survivors (19/22, 86%) identified as White. Survivors came from 6 provinces, most prevalently from Alberta (10/22, 46%), Ontario (5/22, 23%), and Nova Scotia (4/22, 18%). Most survivors (18/22, 82%) lived in an urban geographical region. Survivors reported a history of leukemias (11/22, 50%), lymphomas (6/22, 27%), and solid tumors (5/22, 23%) as the most common diagnoses. The average age at diagnosis was 10.59 (SD 5.45) years, and the mean time off treatment was 17.45 (SD 6.81) years.

We conducted individual telephone interviews with 7 health care providers. In total, 6 health care providers indicated that their sex assigned at birth was female and that their gender identity was female. All health care providers identified as White. Health care providers included 3 registered nurses and 4 allied health professionals. All health care providers had experience delivering care to survivors of childhood cancer; 29% (2/7) of the participants had between 1 and 5 years of experience, 43% (3/7) of the participants had between 5 and 10 years of experience, 14% (1/7) of the participants had between 10 and 15 years of experience, and 14% (1/7) of the participants had >15 years of experience. Health care providers were from Alberta (2/7, 29%), British Columbia (3/7, 43%), Manitoba (1/7, 14%), and Ontario (1/7, 14%). All health care providers reported residing in urban regions. A summary of participant demographic characteristics is provided in Table 1.

Priority Components to Be Included in an mHealth Intervention for Survivors of Childhood Cancer and Health Care Providers

Connections: Establishing Connections Is a Top Priority

Survivors' Perspective

Survivors spoke of the importance of being able to connect with other survivors because they feel validated by those who understand that the cancer journey does not end when treatment ends and that, in fact, the cancer experience is lifelong (quote 1). Survivors also felt that the ability to communicate with other survivors on mHealth would allow them to establish a sense of community through a shared experience and shared understanding of having been impacted by cancer (quotes 2 and 3). Survivors specified that such a connection could be a therapeutic process as well as an opportunity to provide peer support (quotes 4 and 5). Survivors also discussed the possibility of being able to connect with their health care provider through additional means outside of clinical care (quote 6). Finally, survivors emphasized that being able to establish these connections with other survivors of childhood cancer as well as health care providers was a means of self-empowerment and self-advocacy because they could take control of their own care and experiences (quotes 7-9).

Health Care Providers' Perspective

Health care providers also recognized the importance of connecting survivors with one another. Health care providers shared that these social connections are likely to mitigate feelings of isolation for survivors in their cancer experience and, in turn, empower them to engage in their follow-up care (quotes 10 and 11). Health care providers also expressed a desire to connect with other health care providers across Canada for the opportunity to consult and learn from one another about pertinent matters in delivering follow-up care for survivors of childhood cancer (quote 12). In addition, health care providers shared that being able to connect with survivors (eg, navigating appointments and/or scheduling), as well as with primary care providers, may be a useful feature to incorporate in mHealth to enhance the efficiency with which they deliver follow-up care (quote 13; Textbox 1).

XSL•FO
RenderX

Textbox 1. Theme, subthemes, and representative quotes from survivors (n=22) and health care providers (n=7) on the development of an mHealth intervention to enhance follow-up care. This textbox covers theme (1), "connections: establishing connections is the top priority."

Survivors' perspective

- Connecting with other survivors feels validating because not everyone understands the cancer journey and that it is lifelong.
  - Quote 1: "...I think in just hearing others communicate about their experiences to speak to the volume and importance of it's not done after, we're not done after treatment, it's a lifelong thing that we'll always re-engage in at various points in time in different ways." [S6F2]I
  - Quote 2: "...the idea of a platform is really great, especially when you think about people's readiness to engage in that kind of stuff...So having that available when people are ready to engage gives them access and gives them a sense of control about when they are actually feeling they need that support versus when you have that follow-up first talk..." [S6F2]
  - Quote 3: "And you can be surrounded with people that do care about how you're feeling and how you're doing but no one knows what it's like. So being able to connect to people that have gone through the same things as you, that can validate your feelings and all of that..." [S4F5]
- Connecting with other survivors can help create a sense of community.
  - Quote 4: "Almost kind of like meet-up where you could get a bunch of survivors together and like, all go for coffee or something and we'll just hang out and talk about our stories or like how we're moving forward with our lives or what's going on...I think it would be really cool to see something on a bigger scale that's perhaps all the way across the country or just something along that line, as well as having resources." [S4F3]
  - Quote 5: "And also, maybe an option to talk to people who have been through the same thing, but not talk about cancer at all...Build up a bigger community around it without feeling super nervous or weirded out by it." [S4F3]
- Connecting with health care providers may help ensure a shared understanding of what occurs at follow-up care and increase access to health care providers.
  - Quote 6: "When I said, 'I am anxious about ABC' or like, 'XYZ happened to me in my life,' did they hear that or did they just say, 'Worried about cancer but looks good. Goodbye,' like I want to know that they had the same thing. And it would be lovely to have some kind of ability to keep on top of that or keep track of that whether that be some variation of like there's a passport where it's just like, 'We had this conversation on this date' and then I know for future that it has been brought up or it has been talked about." [S1F4]
- Self-advocacy is integral to being a survivor of childhood cancer, and teaching people how to empower themselves through connections and knowledge is key to their health care.
  - Quote 7: "They put you kind of, you're more involved in the whole process if you have really easy access to all the information. Like [participant 3] was saying about her binder, and how she's sort of being involved in the process with keeping track. I think that just helps you feel like you're taking control of your own health. And it's like, that would help engagement." [S2F1]
  - Quote 8: "I think for some of us who are a little more like question shy when it comes to like speaking to doctors, like I know, I often find myself listening and not asking. I think maybe including information on how to like advocate for yourself as a patient would be important." [S3F3]
  - Quote 9: "I'm not 100 percent sure on how this would fit in with the platform yet, but I think that something in aftercare that is kind of missing that might be beneficial in kind of helping people to be able to advocate and engage in their care a little bit more is like—I don't know if it's the first appointment you ever have when you go to adult care or the last one or somewhere in-between." [S3F4]

Health care providers' perspective

- Health care providers recognize that connecting survivors with other survivors is a priority. These social connections can potentially help mitigate feelings of isolation and empower them to engage in their follow-up care.
  - Quote 10: "Yeah well, I agree with the idea of a platform, it helps people to move from kind of the more insular cancer experience to broadening and connecting in the community and identifying what they have in common with other people because I think that would help people and with the focus on mitigating of effects." [HP2]
  - Quote 11: "Really help them with like social opportunities because a lot of them are so isolated socially. Some of them have a really hard time making friends, because they don't like, it's not like a muscle memory they learned in high school. Like where they don't—they just have a hard time knowing how to make and maintain friendships. So that I think would be a useful sort of like, a place where people like me, across the country, could refer to get people connected socially." [HP5]
- Health care providers want to connect with other health care providers to discuss, ask questions, and share expertise.
  - Quote 12: "No. I think one interesting thing too is that we, as a long-term follow-up group, have a Canadian group that we talk about. Like we need every, say, quarterly online and discuss, you know, different issues and what are you doing here? What are you doing here? So, I think having that expertise, Canadian expertise of those groups would be good. So, you know, when this is up and running it would be great if that was presented at our group. Like, you could join our email Zoom, and you know, get everyone on the same page of engagement." [HP6]

XSL•FO
RenderX

- Health care providers indicated that navigating appointments and scheduling with survivors and communication with primary care providers may be useful features.
  - Quote 13: "So, I don't know if adding the primary care information and being able for them to amend it as it changes. I don't know if there's a functionality where when they see an update, they could forward that to their primary care provider. I mean I'm thinking really big here and I know it's nearly impossible to do but, you know, there must be a way to maybe get things together even if it means, you know, they have to physically show it to their primary care provider when they go for their next visit." [HP1]

Education and Information: Having a Cancer History Profile Can Be Useful

Survivors' Perspective

Features that provided information on and tracking survivors' cancer history were some of the most prevalent themes discussed by survivors. Specifically, survivors emphasized the importance of having their cancer treatment history summarized in the form of a cancer profile, along with information regarding the type of follow-up care they receive, a summary of their follow-up care visits, and a summary of past and current medications and treatments (quote 14). Participants highlighted several benefits of this feature in an mHealth intervention, including being able to recall their medical history during appointments with new health care providers, establishing a shared understanding between survivors and health care providers, addressing any gaps in communication, and making their follow-up care more accessible (quotes 15 and 16).

Health Care Providers' Perspective

Health care providers identified a need for a cancer profile so that information such as treatment history (eg, cumulative doses and exposures) can be summarized in 1 hub (quote 17). Furthermore, health care providers indicated that a cancer profile may serve as an effective tool to communicate with survivors about their follow-up care, including the importance of screening for late effects, provided that the cancer profile can include a summary of potential risks of late effects related to diagnosis and treatment (quote 18). Similarly, health care providers explored the possibility of linking updated survivorship guidelines to a cancer profile, which may be informative for survivors of childhood cancer (quote 19; Textbox 2).

Textbox 2. Theme, subthemes, and representative quotes from survivors (n=22) and health care providers (n=7) regarding the development of a mobile health (mHealth) platform to enhance follow-up care. This textbox covers theme (2), "education and information: creating a personalized cancer profile would be helpful."

Survivors' perspective

- A treatment summary can help with communicating with health care providers at follow-up care visits and remembering treatment history details.
  - Quote 14: "Yeah, I mean, I feel like, earlier like I was saying, I have that binder which I feel like is kind of like a one stop shop. But if that was in a digital form, I feel like that would be, that would be useful. Some sort of platform where, yeah it would have some sort of resource thing, but customized to what treatment you had, what drugs specifically you were on. Something that would have—even when you go to aftercare, a digital version of your test results as well. That way it's stored there and there's a history you can refer back to." [S3F1]
- Being able to track and view the history of follow-up care visits would make care more convenient, transparent, and accessible.
  - Quote 15: "...I guess a lot of things are getting more digital now so just being able to have access to records, maybe possible notes of previous visits you had. So, something just to refer to would be very convenient." [S1F1]
  - Quote 16: "...let's say if you want to refer back to a visit that you did a couple of years ago, have some notes that you can kind of refer to. Other than, kind of see how you've improved. And I think that would just help to refer back and then see how it's progressed, from any concerns from past follow-ups." [S1F1]

Health care providers' perspective

- A treatment summary can help health care providers consolidate information and inform treatment planning.
  - Quote 17: "I think that making sure that it has like a comprehensive treatment summary, and by that, I mean...like the significant cumulative doses, that they know what complications that they have, and then the things at risk. But I think the number one thing on the very first page after their treatment summary would be the very practical things you have to do, echoes, when's your next test due; and to also make sure that they have a primary care physician" [HP1]
- A cancer profile may help health care providers communicate the importance of understanding and screening for late effects for survivors of childhood cancer.
  - Quote 18: People have to be prepared kind of for the long haul without knowing exactly what the long haul is. But for some people we have a fairly good idea that they will like pretty significant cognitive or physical disabilities depending on what they've gone through. So, the challenge of figuring out how to help people with that process as it evolves." [HP2]
- Linking updated survivorship guidelines to a cancer profile may be informative for survivors of childhood cancer.
  - Quote 19: "I think it could be linked to the survivorship guidelines somehow but that the less we put and the most important stuff that we put in that will actually make it useful." [HP1]

XSL•FO
RenderX

Engagement: Issues Related to Accessibility and Health Equity Impact Survivors' Engagement in Their Follow-Up Care

Survivors' Perspective

Survivors discussed the challenges related to accessing their follow-up care, referring to the ease of reaching and using health care services, and how these barriers reflected issues related to health inequities that some experience. For example, survivors felt that all survivors requiring follow-up care should be able to access their follow-up care, and yet, disparities exist in this regard (quote 20). Survivors spoke about their difficulty in accessing follow-up care due to geographic barriers, especially for those that reside in more rural or remote communities (quotes 21-23). In addition, survivors shared that features such as appointment reminders, accommodation provided for transportation, and being able to ask questions to health care providers in an mHealth intervention may be ways that can help increase access to their follow-up care (quote 24).

Health Care Providers' Perspective

Health care providers recognized that health inequities exist in the current service delivery of follow-up care to survivors of childhood cancer and highlighted the need to make mHealth easily usable and accessible (quote 24). Health care providers also identified practical strategies that can help survivors engage in their follow-up care, such as displaying a list of the upcoming appointments on mHealth or outlining follow-up care in a stepwise fashion so that survivors that face cognitive effects of their treatment can be accommodated and supported in their engagement with follow-up care (quotes 25 and 26; Textbox 3).

Textbox 3. Theme, subthemes, and representative quotes from survivors (n=22) and health care providers (n=7) on the development of an mHealth intervention to enhance follow-up care. This textbox covers theme (3), "engagement: issues related to accessibility and health equity impact survivors' engagement in their follow-up care."

Survivors' perspective

- Appointment reminders, flexibility, and accommodations for transportation are ways to increase access and engagement to follow-up care.
  - Quote 20: "I would love to have an appointment at a certain time and for the appointment to be like within one hour of that time rather than that's the only thing on my day because I might be pushed four or five hours. And I understand like oncology is a field that does have emergencies and things happen and yes, like those precedent absolutely. But when I'm coming there just to get a rubber stamp that said I've done it and they've already looked at my blood work, where it definitely could've been a phone call, but I was spending my whole day in clinic instead, those are the things that would make it easier for me to engage more with my follow-up rather than treat it like a check box." [S3F1]
- Health inequities exist, and people from remote or rural communities have a harder time accessing their follow-up care. Telehealth mitigates some of these challenges but not all.
  - Quote 21: "But aside from that a lot of the more helpful things to engage with follow-up are things that unfortunately, unless you're building a city from scratch, are very hard to accomplish. I would like to be near my area, I would like more my follow-up is being happening, I would like for there to either be parking or public transport that is easy to access and get me there. All of those things." [S1F4]
  - Quote 22: "And if that's something that, like I said out here, it was shocking to live the reality that health equity is a dream, not a reality in Canada as much as we want it to be. Because like people in [city], the health care here is, it's just not accessible, it's brutal...I mean, I think Zoom and all of the telecommunication stuff will really help now, hopefully where people are more open to doing these sorts of things virtually, rather than having to drive four hours to [city], that sounds horrible." [S4F5]
  - Quote 23: "But just, if there was something that could address that for people who maybe can't access care where they live remotely, and they can actually be connected with practitioners or—yeah, I don't know. I think that's all I wanted to say about the app." [S3F5]
- Being able to communicate with the health care team and ask questions may help increase access to follow-up care.
  - Quote 24: "I also think a message feature would probably be efficient because I think of like, if I have to call the clinic sometimes that can be a little bit of a hassle with my phone tag. But if I knew that on the App, I could just send a message saying something like, 'appointment needs to be changed,' whatever. 'Can you give me a call?' Or even just being able to do it that way completely would be useful." [S3F1]

Health care providers' perspective

- Health inequities exist, and access to care can be increased by showing survivors how to navigate mHealth and making mHealth readily available.
  - Quote 24: "I think that, if I had to be very sort of realistic, I think that making sure that they have things to access is the most important. I still think that that probably would be like a big barrier to building this if we had to add that functionality [to the mHealth platform]." [HP1]
- There are practical strategies that may help survivors of childhood cancer engage in their follow-up care.
  - Quote 25: "But I think the number one thing on the very first page after their treatment summary would be the very practical things you have to do, echoes, when's your next test due." [HP1]
  - Quote 26: "Yeah, just that transition to adulthood thing of helping people see what are the normal kinds of tasks that people learn to become adults; so that's kind of more concrete for them. Perhaps break some of those tasks down into concrete steps so it's not so overwhelming." [HP2]

XSL•FO

Resources: Providing Personalized Resources Can Help Enhance the Survivorship Experience, Psychosocial Well-Being, and Reproductive Health

Survivors' Perspective

Survivors highlighted the need for resources specific to the unique needs of cancer survivorship, highlighting that personalization helps normalize the experience of survivors of childhood cancer (quotes 27 and 28). Survivors also expressed a desire for more mental health resources. They readily endorsed the impact of diagnosis and treatment on their social, emotional, and mental well-being, especially wanting to know more about the notion of posttraumatic growth and posttraumatic stress in survivorship (quotes 29-30). Survivors also highlighted major gaps in resources dedicated to reproductive health, even though there is a negative impact of cancer treatment on fertility and family planning (quote 31). Survivors also noted that educational resources to support survivors' transition back to school are largely absent (quote 32). Finally, survivors discussed the importance of being able to access resources that are up-to-date and reflect recent advances in science and research (quote 33).

Health Care Providers' Perspective

Health care providers identified, as a priority, the need for resources dedicated to survivorship experience, financial assistance, and health care transitions (quote 34). They also identified a gap in psychosocial and educational supports (quote 35). Moreover, health care providers spoke of the need for better resourcing to help survivors understand and navigate their fertility and family planning (quote 36). Finally, health care providers discussed the importance of being able to share resources that are updated and reflect advances in research and science (quote 37; Textbox 4).

XSL•FO
RenderX

Textbox 4. Themes, subthemes, and representative quotes from survivors (n=22) and health care providers (n=7) on the development of an mHealth intervention to enhance follow-up care. This textbox covers theme (4), "resources: providing tailored resources can help enhance the survivorship experience, psychosocial well-being, and female and reproductive health."

Survivors' perspective

- Offering resources on the unique survivorship experience can help to normalize being a survivor of a childhood cancer.
  - Quote 27: "And like it would be nice to have a platform where you can exchange stories and have some of those anxieties assuaged of like this isn't a unique to you experience, it's a unique to the childhood cancer experience. Like there are other people who went through the same thing." [S1F4]
  - Quote 28: "But I think that maybe people would like to access, maybe there's testimonials from people. If it's about people feeling like it normalizes their situation." [S3F5]
- Mental health resources are lacking. Survivors are interested in better understanding the impact of diagnosis and treatment on their social, emotional, and mental well-being, including experiences of posttraumatic growth and posttraumatic stress.
  - Quote 29: "But what I was going to say was, I would say like social, emotional, mental health resources, just that larger I think important too. Or even contacts specifically connected to the aftercare clinic with relation to those. Whether it be social work, or child and youth, depending on the age, that type of thing." [S3F4]
  - Quote 30: "So, I think education maybe around mental health, what certain terms might mean like post-traumatic growths, what is that? Or post-traumatic stress disorder, or survivor's guilt, education content around what kind of complications could pop up for people that have had cancer treatment as a pediatric patient." [S7F2]
- Resources on female and reproductive health of survivors of childhood cancer is inadequate. Survivors would like to be better educated and equipped with the impact of diagnosis and treatment on their female and reproductive health.
  - Quote 31: "I was never told any—I had to ask if I was going to be able to have kids. It was never brought up to me. But I mean, I don't know, I only had chemotherapy. So, I don't know if radiation has something to do with that, but yeah, they've never brought it up." [S2F5]
- Knowing what accommodations and modifications are available to survivors of childhood cancer in their learning and education would be a helpful guide.
  - Quote 32: "I think maybe for deciding where this is for me, at home schooling. Because I know when I was going through treatment they had to—I skipped out like a year and a bit. So, yeah, I guess just resource things or places to refer to, to kind of continue that education if you're not able to be in class." [S1F1]
- Survivors would like resources that are updated and reflect advances in research and science.
  - Quote 33: "...just what's the most up to date evidence, because I think it's constantly evolving, so I think that's a huge piece of that information need and education need. I think it also helps you problem-solve, too, when things come up and you're 'is this normal?' And then you go to research and it's 'yeah, 20 percent or more end up with mental healthcare needs. OK, it's not abnormal for me to be feeling this way or for me to have this challenge.' So, I think there's a normalization element to having information that can support you in navigating follow-up care, for sure." [S6F2]

Health care providers' perspective

- Resources dedicated to the survivorship experience, financial assistance, and health care transitions are priorities.
  - Quote 34: "So, if we can figure out parking, just sort of if you think about another practical suggestion, how do you engage, if you need financial assistance with parking or travel, links to some resources that might be helpful. Not that there's not many, but just sort of how to eliminate barriers." [HP4]
- Health care providers identified a major gap in psychosocial and educational supports.
  - Quote 35: "Well, the big mental health ones I think is key, mental health, like the, I know [location] Health Services have their, has their cope, hard, coping in hard times kind of link or something, just those would be I think standard, would be helpful to have that. And even counselling specific, psychosocial counselling, counselors that are, identify, have experience in working in this area. Private ones would be helpful, although, yeah, and then just financial resources as well too, just links to that. I know, you could kind of there's a whole bunch of different ones I'm sure that you could link there, but the counselling, vocational supports." [HP4]
- Better resourcing is needed to help survivors of childhood cancer understand and navigate their fertility and family planning.
  - Quote 36: "You know some common big things that, not so much for our young patients for our adolescent and young adults, I do think that sort of resources about fertility and family planning needs to be somewhere in there because I think that that's something that some patients whether it be cultural or just personal can't openly ask, and I think that we'll agree that that's probably the most complex late effect that we deal with from a physical and mental-health perspective. I think that that—I don't know if it has to be something on its own, but I wish we could be better at telling a young person that, you know, family planning is different for everybody and that there are different ways to have families and the definition of family is changing every day. So, I don't know if that part is just—if I won $10 million I would put the money toward fertility salvage in survivors; that's what I would do." [HP1]

XSL•FO
RenderX

- Health care providers would like resources that are updated and reflect advances in research and science.
  - Quote 37: "Also, a place where they could see where there's a change in practice, like how often we do echoes or, you know, new recommendations for vaccinations, you know, like the very specific stuff that they, you know—flags or alerts I think would be helpful." [HP1]

Personalization: There Is a Need for Personalized Features on mHealth, Including Consideration of Survivors' Readiness; Emotional Impact of Accessing Follow-Up Care; Privacy; and Right to Accurate, Moderated Information

Survivors' Perspective

Survivors highlighted several important considerations to help personalize the mHealth intervention. For instance, survivors described the importance of providing options so that survivors can feel that they have a choice in when and how they wish to navigate mHealth in their cancer journey (quotes 38 and 39). Furthermore, survivors discussed the emotional impact of accessing their follow-up care, highlighting that the survivorship experience is diverse and that they want to be able to establish their own boundaries in accessing their follow-up care and cancer history through mHealth (quote 40). In addition, survivors discussed the importance of incorporating privacy features to protect their identity and health information, whether that is from their family members and/or other members of the mHealth community (quotes 41 and 42). Finally, survivors recognized that, while they would value being able to communicate with other survivors in a forum on mHealth, there is a need to modulate all communication to ensure that any information or resources shared are accurate and not to be mistaken with professional recommendations (quote 43).

Health Care Providers' Perspective

Health care providers expressed their concern for any information that survivors receive that is not communicated directly from a health care provider (quote 44). They expressed a desire to ensure that survivors receive accurate knowledge and resources to support their follow-up care (quote 44). Health care providers also shared their concern for the limited capacity of current health care providers in being able to support the growing population of survivors (quote 45; Textbox 5).

XSL•FO
RenderX

Textbox 5. Themes, subthemes, and representative quotes from survivors (n=22) and health care providers (n=7) on the development of an mHealth intervention to enhance follow-up care. This textbox covers theme (5), "personalization: there is a need to account for personalized features, including survivors' readiness; emotional impact of accessing follow-up care; privacy; and right to accurate, moderated information, in accessing mHealth."

Survivors' perspective

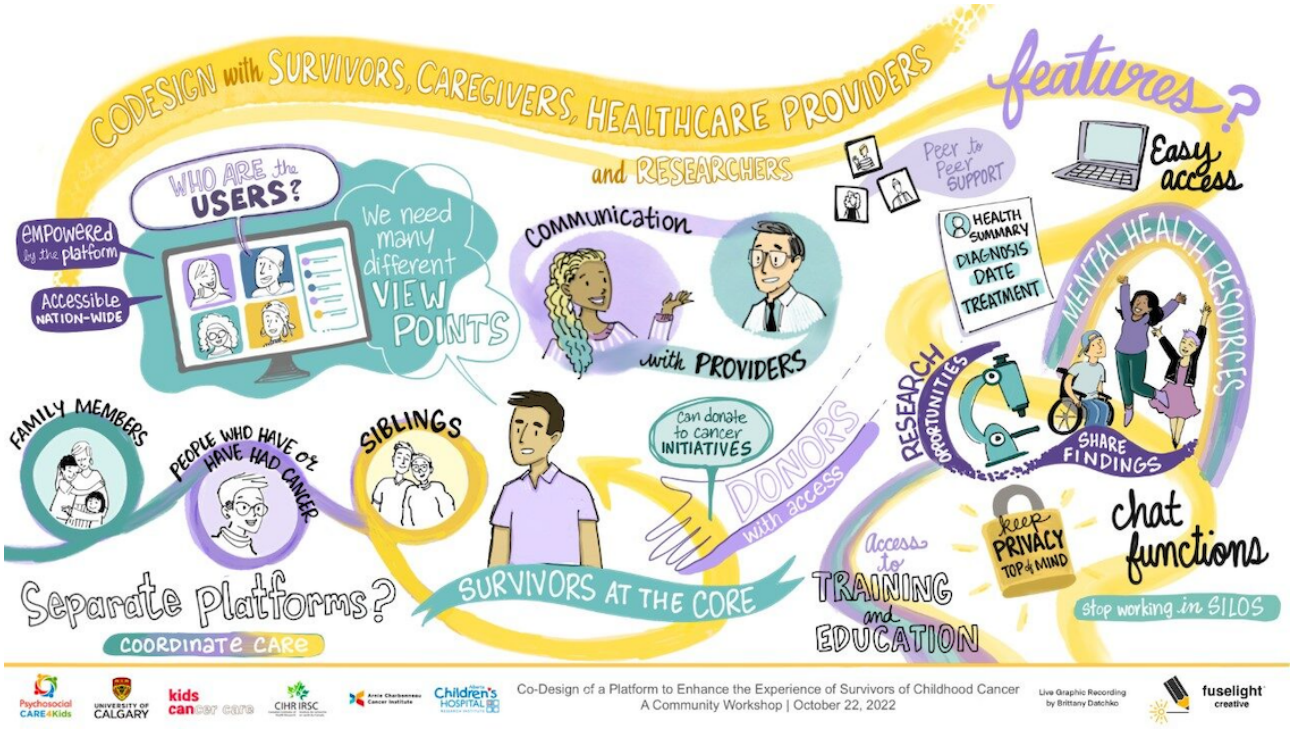
- Being able to choose when to access, and have control over access, mHealth is an important feature. Not all survivors feel ready or want to engage in their mHealth at all times.
  - Quote 38: "And I don't think that it should be alert based, or maybe if there's a way that you opt out of alerts, because I think that that would be probably a stressor, when you're at work, and you like, 'Ping. Have you thought about cancer today?'" [S3F5]
  - Quote 39: "...the idea of a platform is really great, especially when you think about people's readiness to engage in that kind of stuff. Oftentimes...I wasn't ready at first to engage with other youths at that time. It took some time, and it actually was, I made my closest friendships with other survivors five years post, maybe even more than that. So, it was—I was quite defended from that, but there was a readiness there, that I was ready to do that, but it came at an appropriate time. So having that available when people are ready to engage gives them access and gives them a sense of control about when they are actually feeling they need that support versus when you have that follow-up first talk, it's 'hey, here are the resources available to you, have at them when you need them,' and that can be a little intimidating." [S6F2]
- For survivors, there is an emotional impact to accessing their follow-up care. These experiences are diverse, and survivors want to be able to establish their own boundaries in accessing their follow-up care and cancer history.
  - Quote 40: "But my concern with peer support has always been that the people who tend to gravitate toward looking for support, are people who aren't doing well. And so, I don't want to go or be part of something that becomes a co-rumination." [S2F5]
- Establishing privacy features is important for survivors to protect their identity and health information from their family and others.
  - Quote 41: "And I think it's not just me that you're kind of targeting with a platform like this, it's also especially for people who might be younger and still living at home. You're now getting the whole family. Because, with iPads and phones and emails and all these things now, if folks are still living at home, their parents may also be seeing these notifications." [S4F5]
  - Quote 42: "I'd love to meet up with other individuals that have shared my experience one on one or even in a small group setting like this, whether it be like an optional pen pal thing through the platform where you could talk one on one. And, you know, if you wanted to talk to them through video that is your choice but make something so it's secure so you're not giving out personal information if you don't want to." [S4F5]
- It is important that any communication on mHealth is moderated and not to be mistaken with medical or professional advice.
  - Quote 43: "...I do kind of feel as though there might need to be some sort of like regulation on what is said. As much as like 100 percent lived experiences and what people have gone through is so important and can be relayed, but I just would also worry that things would be maybe not communicated clearly and I would just worry that like, 'Oh, someone said that high dose vitamin C treatments at this random clinic did something.' And just that is the only like little thing in my ear that's saying like just be careful is all." [S3F5]

Health care providers' perspective

- Any information shared with survivors of childhood cancer needs to be properly communicated by a health care provider.
  - Quote 44: "You know I think it's a good idea to have some sort of platform where survivors can [pause] I can't think of the right word, that they can look at and give them information. I do sometimes think I worry if they get information without back-up to discuss it and all, like you can't just tell somebody, 'You're going to be infertile' and not go through it all, you know, discuss your options and that sort of thing. That's what I'm thinking from that perspective. [HP3]
- There is a concern for the capacity of health care providers to be able to serve the growing population of survivors of childhood cancer.
  - Quote 45: "I mean, yeah, it's, like I said, the big piece is just increasing capacity and then, yeah, looking at, if we're going to continue on this trend in terms of survivorship. And if we're looking at having the seeing people indefinitely within [location], I don't know if that's the case, then what's the future hold...That's what my concern is, is that we're really, are we really providing the best service possible if we're, we have these volumes and we just don't have the staff to really provide that support, that's my main concern, I guess, where are things going and is there going to be capacity to support it." [HP4]

Validating Findings Facilitated Through Community Engagement

A total of 31 participants, including survivors of childhood cancer (n=10, 32%) and their caregivers (n=2, 6%), health care providers (n=6, 19%), researchers (n=11, 35%, including 2 patient partners), and collaborators (n=2, 6%) participated in the community engagement event to review and verify the qualitative results gathered.



Small and Large Group Discussions

Participants endorsed the accuracy of themes derived regarding the core components to be included in mHealth. Participants explored additional contexts in the development of an mHealth intervention, including considerations for family members (eg,

XSL•FO
RenderX

families and siblings) and the practicalities of preserving privacy and confidentiality on a technology-based intervention. Participants also reported feeling heard through the graphic recording process. The final graphic recording is shown in Figure 1.

Figure 1. Graphic recording of the community engagement event on October 22, 2022. Illustration completed by Fuselight Creative.

Satisfaction Survey

Some participants (8/22, 36%) completed a web-based questionnaire assessing participant engagement at the event. On average, participants *strongly agreed* that they felt that their views were heard (mean 5.00, SD 0.00) and that they were able to discuss their views freely (mean 4.71, SD 0.45). Participants also strongly agreed that they felt they had enough information to contribute to the topics discussed (mean 4.71, SD 0.35) and that a wide range of views on the topics were shared (mean 4.71, SD 0.45). Participants *mostly agreed* that they had a clear understanding of the purpose of the community workshop (mean 4.14, SD 0.35). In addition, participants were asked to indicate the extent to which they agreed that the community engagement event objectives (ie, to co-design mHealth, to engage with others, and to provide feedback on study results) were achieved, and their responses ranged from *mostly* to *strongly* agreed (mean scores ranging from 4.00 to 4.71, SD scores ranging from 0.45 to 0.83). Importantly, participants *strongly agreed* that they felt confident that the input provided through this event would be incorporated by the study team. A summary of participant responses is reported in Tables 2 and 3.

Table 2. Participant responses to community engagement event evaluation (n=8)[a] for section 1 (overview of the workshop)[b].

Overview of the workshop	Responses, mean (SD)
"I had a clear understanding of the purpose of this community workshop."	4.14 (0.35)
"I had enough information to contribute to the topics discussed."	4.86 (0.35)
"I was able to express my views freely."	4.71 (0.45)
"I felt that my views were heard."	5.00 (0.00)
"A wide range of views on the topics discussed were shared."	4.71 (0.45)

[a]A total of 8 attendees, including 4 survivors of childhood cancer, 1 caregiver, 2 family members, and 1 researcher, completed the evaluation.

[b]Attendees were asked to rate the extent to which they agreed with statements in this table, using a rating scale where 1=strongly disagree and 5=strongly agree.

XSL•FO
RenderX

Table 3. Participant responses to community engagement event evaluation (n=8)[a] for section 2 (workshop objectives)[b].

Workshop objectives	Responses, mean (SD)
"To describe the preliminary results from the study on improving follow-up care for survivors of childhood cancer."	4.14 (0.83)
"To co-design a platform for survivors of childhood cancer that is agreed upon within this community."	4.00 (0.76)
"To engage with other core community members (health care professionals, researchers, families, and caregivers)."	4.71 (0.45)
"I am confident that the input provided through this community workshop will be used by the CARE4Kids team at the University of Calgary."	4.71 (0.45)

[a]A total of 8 attendees, including 4 survivors of childhood cancer, 1 caregiver, 2 family members, and 1 researcher, completed the evaluation.

[b]Attendees were asked to rate the extent to which they agreed that the objectives listed in this table were achieved, using the rating scale where 1=strongly disagree and 5=strongly agree.

Discussion

Principal Findings

It is important that survivors of childhood cancer receive routine health care follow-up, yet many survivors do not understand the importance of their follow-up care or have limited knowledge on their need for follow-up care. Our study aimed to amplify the voices of young adult survivors of childhood cancer in identifying the priority components to be included in an mHealth intervention that can help educate and engage survivors in their long-term follow-up care.

Our approach was unique in using co-design and a qualitative research framework and adhering patient-oriented research principles to engage in mHealth intervention development [21,37]. We uniquely incorporated perspectives from survivors of childhood cancer and health care providers that deliver cancer-specific follow-up care. Patient partners collaborated with our team over the entirety of the research process, including study design, recruitment, data collection (ie, cofacilitation of focus groups and interviews), interpretation of results, and knowledge dissemination. Furthermore, a community engagement activity was cofacilitated with patient partners to enhance the validity of qualitative descriptive data gathered.

Limited mHealth interventions have been created *with* survivors of childhood cancer despite its rising potential to improve health [38]. Most efforts have focused on patients who are on active cancer treatment. For instance, a systematic review indicated a positive effect of mHealth interventions on improving the health-related quality of life of adult patients with cancer [38]. Other studies have explored delivering a survivorship care plan and an app for enhancing self-management for adolescents and young adults [39]. Few studies have effectively engaged in the co-design of mHealth, and even less work has been conducted with young adult survivors of childhood cancer in this regard, as well as with health care providers. Therefore, our work provides important and novel insights from the perspectives of individuals with lived experience of cancer and health care providers regarding their follow-up care experiences. Specifically, results shed light on the priority areas necessary to increase knowledge of and engagement in follow-up care for survivors of childhood cancer, establishing a critical foundation in mHealth intervention development.

In total, 5 major themes were conceptualized as the priority components of the mHealth intervention. Many of the themes are consistent with the existing literature on the unmet needs of survivors of childhood cancer. For example, survivors and health care providers from our study identified a lack of knowledge of diagnosis and treatment, as well as associated late effects, for survivors. These results are consistent with past work showing that most survivors of childhood cancer fail to recognize their risk for developing a serious health condition [11,40]. Furthermore, previous research indicates that survivors of childhood cancer need a better way to learn about and engage in their own health information [10,41]. Indeed, our findings indicate a need for advanced means to deliver follow-up care knowledge, such as the use of a mobile app or website, as well as the need for creative features to enhance the follow-up care experience, such as reminders for appointments and a cancer profile to consolidate health history information.

Another notable theme generated was the need for more education and support during health care transitions. This builds on an extensive body of literature on health care transitions for young adults impacted by cancer [42]. There are cancer-specific risks and health care needs of survivors of childhood cancer that are distinct from those with other chronic illnesses [43]. Therefore, our research lends further support for the importance of personalized care for young adult survivors during their health care transition from pediatric to adult health care, one that prioritizes educating survivors on their potential late effects related to their diagnosis and treatment, as well as the utility of engaging in consistent surveillance to promote longer-term optimal outcomes.

Survivors expressed some hesitation toward having regular access to their cancer history information and therefore discussed the importance of being able to have choice and control in how they navigate mHealth. These findings are consistent with existing work documenting experiences related to posttraumatic stress experienced by survivors [44] and the importance of prioritizing a trauma-informed approach in intervention development.

Several other themes were generated from this study that are novel and relevant to building an mHealth intervention for survivors of childhood cancer. Survivors and health care providers emphasized the importance of establishing connections with other survivors and health care providers. These results likely reflect a sense of disconnect that survivors experience and a desire to broaden opportunities for meaningful connections. Indeed, survivors spoke about the need to explore their identity beyond their cancer journey. Taken together, these

XSL•FO
RenderX

results are consistent with past work documenting that adolescents and young adults with cancer experience substantial psychosocial challenges, including peer and family relationships and personal growth stresses [45]. Likewise, health care providers echoed the importance of cultivating connections among survivors to address feelings of isolation on their cancer journey. Importantly, health care providers also highlighted a desire to connect with other health care providers that provide follow-up care across Canada, emphasizing the importance of connecting with and consulting one another to stay informed of current concerns and practices in survivorship. Few studies have addressed the unmet needs of health care providers in delivering follow-up care to survivors of childhood cancer [23]. Our study provides unique insight of both survivors and health care providers, offering a more contextualized understanding of how to improve follow-up care from multiple perspectives.

Issues related to accessibility of follow-up care and health equity were a prominent finding from our research. These outcomes contribute to our understanding of some of the geographic barriers faced by survivors from rural or remote regions, as reflected in our study sample. Developing an mHealth intervention will aim to address these barriers by connecting survivors to their follow-up care through technology. However, barriers to health care are complex and dynamic and require consideration of factors beyond the individual, including health care providers and health care systems factors, to alleviate health disparities [46]. Therefore, further work is needed to capture the complete and intersecting effects of accessibility factors, as well as other inequities faced by survivors of childhood cancer, on their receipt of high-quality health care. These are important considerations in intervention development to ensure that the burden of change is not placed solely on survivors of childhood cancer but rather recognized as a systemic problem that requires multilevel intervention.

Our research incorporated a response validation technique, member checking, to enhance the rigor of qualitative data gathered. Previous qualitative work using member checking lacked detail and discussion in the implementation of the technique. Absence of this reporting may be confounded by epistemological and methodological challenges [36]. In this research, we conducted a comprehensive assessment and report of member checking using a multiinformant, multimodal approach to strengthen the credibility and validity of data gathered. The strength of this approach is to demonstrate the true and iterative process that we took to achieve consensus among researchers and those with lived experiences in the research process. Our goal with this undertaking is to enhance the transparency, accessibility, and replicability of best practices in qualitative health research.

Limitations and Future Directions

We review several important limitations to be considered when interpreting the results of this study. A major strength of this research was leveraging technology for participation (ie, online focus groups and community engagement). This meant an increase in accessibility to those residing in remote or rural regions. However, reliance on technology also meant that participants from lower levels of income, or some individuals from geographically more remote or rural regions of Canada, may face greater barriers to participating because they are less likely to have access to technology. Future research incorporating community outreach, phone-based participation, or compensated travel to the local context can help to mitigate this challenge in research recruitment. Input on how we can account for potential technological limitations in reaching individuals from more remote or rural regions of Canada will be important as we build the intervention.

Research shows that a diversity of perspectives drives innovation [47]. Participants from our study offered important insights into accessibility issues that contribute to health inequities for survivors of childhood cancer. However, our sample nonetheless lacked representation and voice from individuals from diverse backgrounds (eg, diversity in ethnicity, gender identity, sex, language use, and geographic regions) and/or who are not engaged in their follow-up care. We recognize that a potential bias of our sample is that most of our sample reported attending their follow-up care. We are missing the voices of individuals who are not engaged in their care at this time, and future research leveraging purposive sampling of those not regularly attending their follow-up care would offer us important insights into the barriers they face in attending care. In addition, there is a notable disparity in gender representation of participants, with 86% (19/22) of participants identifying as female gender. Studies have found that female gender predicted attendance to follow-up care, such that female participants were more likely than male participants to attend follow-up care [48]. This bias in our sampling reinforces that our findings reflect the views of those who are attending their follow-up care. In addition, there are many factors that contribute to a lack of gender representation in cancer research, including researcher bias, gender stereotypes, and unequal social opportunities [49]. Importantly, a review of gender representation trends in psychosocial survivorship research showed that there is a trend toward a more balanced representation of men and women over a 15-year period (2007 and 1992) [49]. Taken together, our skewed sample indicates an important need to continue to engage with survivors from equity-deserving groups, particularly given the increasing diversity of the Canadian population.

Research shows that members of equity-deserving groups face significant barriers to accessing high-quality and accessible health care [50,51]. Without knowledge of the perspectives and experiences of these individuals, we are missing critical information that can help to address health disparities and, in turn, bring greater awareness to the importance of follow-up care surveillance and attendance for those from underrepresented and underserved communities. Implementation of safe, inclusive, and culturally responsive recruitment strategies is needed to increase representation in pediatric cancer research [52].

Finally, this study solicited feedback from participants and other important parties to enhance the credibility and validity of the results. We demonstrated rigor of data by using a multiinformant and multimodal approach to achieve consensus. However, the response rate for completing the satisfaction survey for our community event was 36%, so responses gathered on patient engagement may not be representative of feedback from most attendees. Another limitation of our community engagement

XSL•FO
RenderX

event is that we did not determine whether attendees included those who previously participated in the focus groups and interviews. Therefore, the feedback gathered at the community event may be influenced by participants' familiarity with the study. Future research establishing and implementing a comprehensive and systematic evaluation of patient and public engagement is necessary to strengthen the rigor of our evaluative framework and enhance patient engagement and research.

The next step of this multiphased project is to build an innovative and accessible mHealth intervention prototype based on the core components identified and grounded in an established conceptual framework for co-design of intervention development. Results from this study have provided the bedrock to progress in our development of an mHealth intervention for survivors of childhood cancer to enhance their knowledge of and engagement in their follow-up care.

Conclusions

In this study, we identified core components to be included in an mHealth intervention to increase the knowledge of and enhance follow-up care engagement for survivors of childhood cancer. We engaged in a rigorous and iterative co-design process with survivors of childhood cancer and health care providers. We incorporated a community engagement event to validate our findings with a broader audience of community members. Findings will inform the next phase of our multiphased, co-design project, ultimately aiming to improve follow-up care and long-term outcomes for survivors of childhood cancer.

Acknowledgments

The authors acknowledge Sharon Paulse and Annette Flanders for their support and insights on the recruitment process. This study is supported by funding from the Strategy for Patient-Oriented Research of the Canadian Institutes of Health Research Catalyst Grant, Alberta Children's Hospital Research Institute, and Kids Cancer Care. Abstract

Background: Young adult survivors of childhood cancer are at risk for late and long-term effects from their treatment, and less than 1 in 5 obtain risk-based care in adulthood. Transitioning young adult survivors from pediatric, parent-driven care to adult, self-driven care is a challenging process during which young adults face multiple barriers. Intervening during this period may facilitate better transition readiness. For this purpose, we previously developed the Managing Your Health (MYH) web-based intervention, which showed initial feasibility and acceptability; however, young adult participants wanted to access the intervention through a mobile app.

Objective: We used an iterative, cocreation design process to translate, build, and evaluate the usability of the MYH web-based intervention into a mobile app to be used in a future peer-mentoring educational intervention.

Methods: In phase 1, we conducted key informant workshops with 3 stakeholder groups to understand target users' needs and expectations related to the content and design of the mobile app. In phase 2, we conducted usability testing with young adult survivors of childhood cancer to evaluate the app's usability and subjective appeal.

Results: Participants in the key informant workshops (n=13) agreed that the content of the proposed app matched the barriers faced by young adult survivors of childhood cancer. Participants provided suggestions about the design of the app, including content and features, although there were mixed views about the inclusion of gamification features. Usability testing participants (n=25) rated the app highly on measures of technology acceptance, usability, and aesthetic appeal. Participants' qualitative comments suggested that they found the app to be useful, easy to use, and likable or familiar relative to other existing apps. Participants suggested a variety of features to enhance the app, including adding features to enhance usability and reformatting certain aspects of the app to enhance interactivity and feedback to the user. Suggestions with uniformly positive reports were used to refine the app, while suggestions with mixed enthusiasm were not prioritized in refining the app.

Conclusions: We engaged target users of an educational app in an iterative app design process to create a product that would meet the needs and expectations of those users. Results suggested that the app was generally viewed as acceptable, useful, and visually appealing. Common suggestions for improvement, such as reformatting quizzes to enhance interactivity and provide feedback regarding correct answers, were used to refine the app. The refined app will be used in the future intervention efficacy trial.

KEYWORDS

self-management; peer mentoring; cancer survivorship; long-term follow-up care; usability testing

Introduction

Proper transition from parent-guided pediatric care to self-managed adult care is crucial for young adult survivors of childhood cancer. Nearly all cancer treatments can cause late effects that can occur months or even years after the treatment; these issues are specific to the type of treatment received [1,2]. Additionally, regardless of cancer type, childhood cancer survivors are at risk for greater morbidity and early mortality than their peers without a history of cancer. It is estimated that between 60% and 90% of childhood cancer survivors will develop at least 1 late effect, a quarter of which may be severe, disabling, life-threatening, or fatal [2-6]. To manage these late effects and to avoid additional complications, survivors of childhood cancers require lifelong survivorship care based on their treatment history and relevant risk factors. Unfortunately, less than 1 in 5 adult survivors of childhood cancer obtain risk-based care [7]. In fact, a recent survey found that only 27% of these individuals had a medical visit related to their cancer or treatment in the 2 years before the survey, and only 41% planned to complete such a visit in the subsequent 2 years [8].

The suboptimal usage of risk-based care is due, in part, to the challenges of transitioning to adulthood, a process that is demanding for all young adults (aged 18-29 years), regardless of cancer history. During this developmental period, young adults experience competing demands and milestones, such as leaving the childhood home, initiating a career, completing higher education, becoming financially independent, and starting a family [9,10]. However, in addition to these normal milestones, young adult survivors of childhood cancer must transition from pediatric-oriented care, which is typically managed by parents, to adult-oriented care, a setting in which the expectation is that the young adult survivors themselves manage their own health care.

There are many barriers to this transition from pediatric to adult care. Ideally, this transition would be treated as a *process* that occurs throughout adolescence. During this process, childhood cancer survivors would receive developmentally appropriate education regarding overall health management and lifestyle behaviors, as well as develop skills in communication, self-efficacy, medical self-management, and decision-making [11,12]. However, there are well-documented challenges in this process, which create poor transition readiness among young adult survivors of childhood cancer [3,13]; this suboptimal readiness can lead to inadequate follow-up or disengagement from care, which can exacerbate the impact of late effects on childhood cancer survivors' lives [11].

To improve transition readiness among young adult survivors of childhood cancer, we developed a web-based self-management and peer-mentoring intervention [14]. Although young adult survivors of childhood cancer who participated in a randomized feasibility trial found the intervention to be feasible and acceptable, participants overwhelmingly preferred accessing intervention content through a mobile app [14]. These participants also wanted increased interactivity within the intervention modules, which could be accomplished through an app. Thus, we planned to develop the Managing Your Health (MYH) mobile app, to be deployed in a future iteration of the MYH intervention.

Digital health interventions, such as mobile apps, that promote, prevent, treat, and maintain health are a popular tool to use with young adults, aged 18-29 years [15]. Young adults are digital natives; almost 100% of this population uses the internet, with nearly 21% of this population accessing the internet using only a smartphone [16]. Due to the ubiquitous nature of digital tools in this population, meeting the needs of young adults who have been affected by cancer has become a popular target for digital health interventions [15,17,18].

Yet, *delivery* of digital resources does not automatically equate to *use* among this population. One of the best practices for developing digital health tools, such as mobile apps, involves soliciting input from or cocreating with the target audience of the app [19,20], especially among cancer survivors [14,17,18,21]. Working with potential users to create any digital health intervention increases the intervention's personal relevance to the target user group and can better meet the community's unique needs [17,22]. Additionally, potential users' perceptions of the app's usefulness, usability, appeal, and ease of use can be predictive of use among the target group [23-26]. As digital natives, young adults also expect well-designed, functional digital tools [27,28].

Therefore, we aimed to design a user-friendly app, "MYH 2.0" through 2 phases of work. The first phase used key informant workshops to inform the creation of the MYH 2.0 mobile app, and the second phase used usability testing to understand potential participants' perceptions of the app's design and usability.

Methods

Phase 1

Overview

To inform the app's design and content, we used a 2-phased approach. In phase 1, we conducted focus-group style workshops with 3 groups of key informants and individual interviews with 2 consultants.

Recruitment

We included 3 key informant groups in the workshops, and recruitment methods varied based on participant type. Young adult survivors of childhood cancer were recruited through the mailing list of a long-term follow-up clinic at a National Cancer Institute–designated cancer center in the northeastern United States. Participants were eligible if they (1) had been diagnosed with any cancer between the ages of 0 and 21 years, (2) were between the ages of 18 and 29 years at the time of consent, (3) were treated in a pediatric cancer setting, (4) were at least 2 years from completing their cancer treatment, and (5) were able

XSL•FO
RenderX

to speak and read English. Participants were excluded if they had a documented or self-reported cognitive delay that would prohibit completing the study or self-managing their health care.

Recruitment of health care providers and advocates occurred through the study team's professional networks. To be eligible, participants had to be able to speak and read English.

Procedure

We conducted 3 key informant workshops, with participants assigned to a workshop based on their participant group. That is, young adult survivors of childhood cancer participated in one workshop, childhood cancer advocates participated in the second workshop, and health care professionals participated in the third workshop. The study team leader (KAD), a PhD-level researcher, and the app developer (JM) cofacilitated all workshops. Individual interviews were also conducted with an oncologist and a primary care provider who served as consultants to the research team. Due to the ongoing COVID-19 pandemic, all sessions took place via Zoom (Zoom Communications) in October 2021. These sessions were recorded, and they were, on average, an hour long.

The sessions focused on both generative (ie, brainstorming features, functions, and contexts of use) and reflective (ie, responding to preliminary designs) exercises and questions. Group moderators designed the sessions with guidance from the Liberating Structures framework [29]. Specifically, the moderators invited all participants to contribute, tried to balance participation levels among different participants, and tracked how time was allocated to different portions of the sessions [29].

Measures

Using an online survey, participants completed basic demographic measures following their participation in the workshops. Young adult survivors' age, race, diagnosis, age at diagnosis, and time since diagnosis were all collected, while professionals and advocates only provided information about their professional roles.

Data Analysis

To analyze our key informant workshops, we relied on a text and topic summary approach [14,30]. This approach was selected because it matched the goal of the workshops: identifying strategies for turning the MYH website into an MYH app. Thus, we first transcribed each Zoom session. Then, members of the qualitative analysis team (KLR and 2 trained coders [Ivelisse Mandato and Melanie Spruill]) coded participants' discussions into two primary categories: (1) reflections on the content of the existing program and (2) suggestions for improvement. Codes were then grouped to understand the overarching needs of the community relative to the app.

Phase 2

Overview

In phase 2, we gathered feedback on the prototype of the MYH app by conducting individual usability testing interviews with young adult survivors of childhood cancer. These sessions were focused on the acceptance, usability, and subjective appeal of the app.

Recruitment

Eligibility criteria for young adult participants were the same as for the key informant workshops, although participants who had taken part in the key informant workshops were not eligible to participate in the interviews. All participants were recruited through the mailing list of a long-term follow-up clinic at a National Cancer Institute–designated cancer center in the northeastern United States.

Procedure

Before each session, participants received instructions to download the MYH app prototype, developed by Radiant Digital, to their personal phones, but were told that they would be provided with log-in information at the usability session. Both Android (Google) and iOS (Apple Inc) versions were available for download. Zoom sessions were conducted individually by 1 trained interviewer, an MS-level project manager on the study team (KLR). Interviews took place in May and June 2022. All sessions were recorded and were, on average, 47 (SD 5.74) minutes in length.

At the start of each session, study consent was reviewed, and participants gave oral agreement to participate. Then, participants were provided with a test username and password. Participants were asked to share their screen via Zoom so that the interviewer could follow along with their app usage. During the session, participants were asked to complete specific tasks within the app, such as logging in, editing a profile, locating certain features, etc, as well as to freely explore the app features. During the directed tasks and the free exploration, participants were instructed to "think aloud" throughout the session. After the session, participants completed a brief online survey with validated quantitative measures described below.

Measures

Participants completed the same demographic information collected from survivors in the key informant workshops, as well as the following measures.

Technology Acceptance Model

Participants' perceptions of usefulness, ease of use, and behavioral intention were measured with items adapted from the technology acceptance model (TAM), which has previously been used to evaluate digital health tools among young adult cancer survivors [23,27]. Response options provided were a Likert-type scale, with 1 corresponding to *strongly disagree* and 5 corresponding to *strongly agree*. Higher scores corresponded to a more positive perception of the app feature.

Participants rated perceived usefulness with 5 items, including "The app will make managing my survivorship journey easier" (α=.76). Perceived ease of use was assessed with 4 items, including "I found it easy to get the app to do what I wanted it to do" (α=.78). Behavioral intentions were assessed with 3 items, including "I think that using the app in my own survivorship journey would be beneficial to me" (α=.80). Finally, use intentions were assessed with a single item: "I intend to use the app in my own survivorship journey."

XSL•FO
RenderX

System Usability Scale

The System Usability Scale (SUS) is a validated measure that consists of 10 items, both positively and negatively worded, assessing the usability of the system [24-26]. The items were measured with a Likert-type scale, with 1 corresponding to *strongly disagree* and 5 corresponding to *strongly agree*.

To create the overall SUS score, the positively worded items were scored by subtracting 1 point from the participant's response. The negatively worded items were calculated by subtracting the participant's response from 5. The sum of the positive and negative items was then calculated and multiplied by 2.5 so that answers would range from 0 to 100. Scores are categorized as good (≥69), acceptable (51-68), or failing (≤50) [25,26].

Visual Aesthetics of Website Inventory

The Visual Aesthetics of Website Inventory – short form (VisAWI-S) was used to assess participants' perceptions of the subjective appeal of the app [31]. The short form consists of 4 items, with each item representing a domain of the full VisAWI. All items were measured with a Likert-type scale, with 1 corresponding to *strongly disagree* and 7 corresponding to *strongly agree*. Higher scores represent a more positive impression of the aesthetics of the app (α=.76).

Specifically, participants assessed the simplicity, diversity, colorfulness, and craftsmanship of the app. Sample items included: "Everything goes together on this app" and "The layout appears professionally designed."

Data Analysis

Qualitative data were analyzed using semantic, deductive thematic analysis [32-34]. Thematic analysis was selected for its iterative approach to the data. First, Zoom sessions were transcribed verbatim. Then, members of the analysis team (Ivelisse Mandato and Melanie Spruill) independently coded one assigned interview. Coders developed their own codes, and then the group met to compare the codes and code definitions developed individually. Audit trails documented these discussions. Each member recoded their assigned interview to finalize the codebook, and then the final codebook was shared with 2 main coders who independently coded each interview. After coding independently, these 2 coders met with the study manager (KLR) to resolve discrepancies using a consensus-building approach. All coding was done using Atlas.ti (Lumivero). All quantitative scale responses were analyzed using SPSS (version 29; IBM Corp). Descriptive statistics (eg, mean and SD) were calculated. We present the quantitative data with the qualitative data with which it best aligns in the Results section of this study.

Ethical Considerations

The Institutional Review Board at Rutgers University approved this study before launch (IRB #Pro2021001514). Participants provided informed consent before their participation. Identifiable information for all participants was stored on the University's enterprise Health Insurance Portability and Accountability Act–compliant cloud system (ie, Microsoft OneDrive), and only authorized team members had access to the information. Once the data analysis was completed, all individually identifiable information was destroyed; the data presented here are deidentified. Each participant was compensated with a US $50 electronic gift card as a thank you for their time.

Results

Phase 1

Overview

We engaged a total of 13 participants, including 7 young adult survivors of childhood cancer, 3 advocates, and 3 health care providers involved in the care of childhood cancer survivors. Young adult survivors were between 23 and 26 years, and they had been, on average, 9 (SD 6.3, range 0-17) years old at diagnosis. There were 2 female and 5 male participants, 3 (43%) of whom identified as racial minorities. In total, 6 of the 7 (85.7%) young adult survivors experienced blood cancers. Time since diagnosis was 15.6 (SD 5.7) years.

The 3 advocates included a patient advocate, a parent advocate, and a nonprofit advocacy organization leader. The 3 health care providers represented the professions of oncology, social work, and psychology. We also individually interviewed 2 consultants on the project (representing leaders in oncology and primary care).

Theme 1: Content Matches Current Barriers

Overall, our key informants found that the content of the MYH program matched the barriers that were salient during the transition period. Both young adult survivors and the health care providers endorsed this theme. Participants found that the content addressed behavioral and psychological (ie, low self-efficacy and feeling "different" from healthy peers), knowledge (ie, the transfer of medical knowledge from parent to adult), and structural (ie, disjointed communication with providers, lack of primary care providers with training in survivorship, and health insurance) challenges.

The advocates suggested adding content relevant to parents and primary care providers. They also suggested adding content that was more tangential to the transition. Given that data collection took place during the COVID-19 pandemic, advocates also suggested including resources specifically for survivors related to staying safe during the pandemic.

Theme 2: Design and Feature Recommendations

All participants, regardless of informant type, rated the subjective appeal of 2 user interface design styles via an anonymous poll during their key informant session. All participants—survivors, providers, and advocates—reported liking the general appearance of both styles, although there was a strong consensus among survivors toward one of the two styles, which was selected for further development.

All participants also offered recommendations for the design and features of the proposed app. Participants recommended designing the app with a simple, easy-to-use interface, offering a checklist of tasks to complete, a glossary of medical jargon, and tools for educating and sharing information with primary care providers. Participants were also highly interested in seeing

XSL•FO
RenderX

tools to help navigate and understand health insurance included in the app, and they also wanted the app to include tools for managing stress.

Health care providers also noted that the needs of young adult survivors of childhood cancers change over time as individuals' health status also changes. For example, fertility may become an important concern when young adult survivors are ready to start a family. Needs may also change as late effects begin or worsen. Health care providers, then, wanted to add "nudges" to remind survivors to return to the app at different points in their lives, especially when certain material becomes more relevant to their life stage (eg, at the time of starting a family).

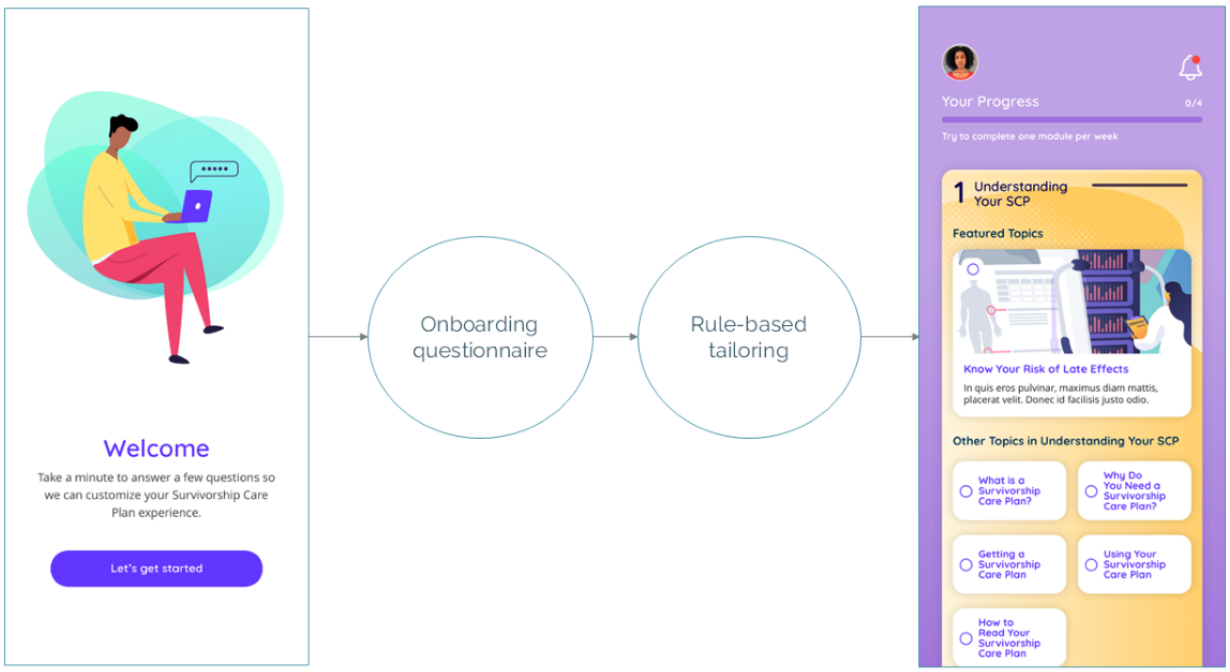
Participants of all key informant groups reported mixed reactions to gamifying the app. Some participants felt that gamification was a helpful feature that could motivate potential users to complete the program, while others felt that adding gamification elements seemed too trivial for the subject matter. In other words, those participants felt that gamification made light of the serious nature of cancer survivorship care. Among potential gamification features, offering completion badges in exchange for finishing content modules was the lowest-rated feature presented.

Data Synthesis: Development of the MYH App Prototype

Using the findings from the key informant workshops, we developed the MYH app. Since informants agreed that the MYH web content was still relevant and applicable to the barriers faced during the transition period and that the MYH web-based intervention was found to be engaging and acceptable, the *content* of the app was largely copied from the existing web-based intervention [14,35]. We retained the 5-module structure of the original, web-based MYH program, with minor content updates to reflect the most accurate health care guidance. Table 1 describes the 5 modules and their associated learning objectives; development of this content is described in the study by Viola et al [14].

Table 1. Modules and learning objectives of the Managing Your Health program.

Module	Module name	Module learning objectives
1	Understanding your survivorship care plan	• Name your diagnosis, treatments received, and risks for late health effects. • Obtain (if needed) and store your survivorship care plan. • Identify any health screenings you need going forward and how often you need them.
2	Taking charge (of your healthcare)	• Identify your strengths and weaknesses regarding self-management tasks. • Discuss the value of establishing and maintaining a relationship with your primary care provider. • Explain your health insurance coverage. • Identify strategies for overcoming any barriers to obtaining care.
3	Thoughts and feelings	• Discuss strategies for coping with uncertainty. • Name the 5 steps of problem-solving. • Identify your own feelings about being a survivor and requiring lifelong care. • List effective strategies for dealing with stress and managing your time.
4	Getting support	• List the ways family involvement in your care is helpful. • Identify specific tasks for which you would like to assume more responsibility. • Discuss strategies for negotiating responsibility for care with your family. • List effective communication strategies.
5	Staying healthy	• List recommendations for physical activity and determine if you are getting enough exercise. • Describe healthy nutrition and sleep habits. • Identify the benefits of avoiding risky alcohol and substance use. • Discuss safe sexual health practices. • Name ways to stay sun safe and protect your skin.



The Radiant Digital team built the app's architecture using STRAPI, an open-source, node-based content management solution. Because no protected health information was to be collected during the individual usability interviews, the parallel architecture for processing and retaining protected health information was not integrated into the app at this stage.

Based on the key informant workshops, we created a list of design and feature priorities. We used the survivor-informants' preferred design style as the base of the app's aesthetic design. During this phase, we prioritized the development of features that had clear, uniform support from our key informants. For example, because our key informants were ambivalent about gamification during the workshops, we did not include this feature.

Our key informants uniformly expressed a desire for content to be tailored to their personal needs and experiences. To highlight content of high relevance to each user, we created an onboarding survey to welcome users to the app and assess their current needs or interests across the topics covered in the modules. Responses to the onboarding survey were used to reorder content and highlight key, personally relevant subtopics within each module. Users retained access to all content, but certain subtopics were highlighted for review based on responses. For example, the onboarding survey asks users about their confidence in following their survivorship care plan. Reporting low confidence would highlight the relevant subtopic. Figure 1 illustrates how the onboarding questionnaire used rule-based tailoring to highlight key subtopics within each module.

XSL•FO
RenderX

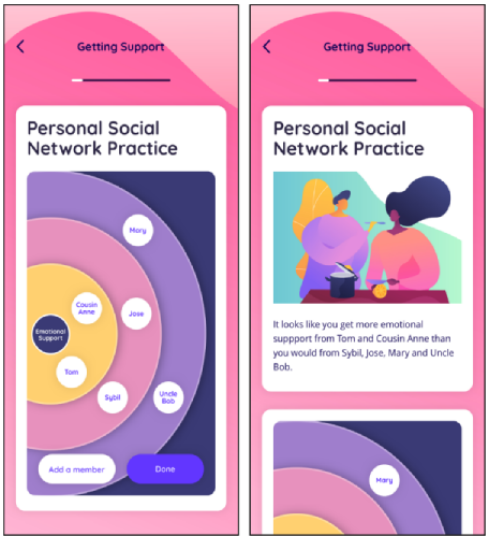


Figure 1. Rule-based tailoring was used to highlight relevant subtopics based on user responses to the onboarding questionnaire.

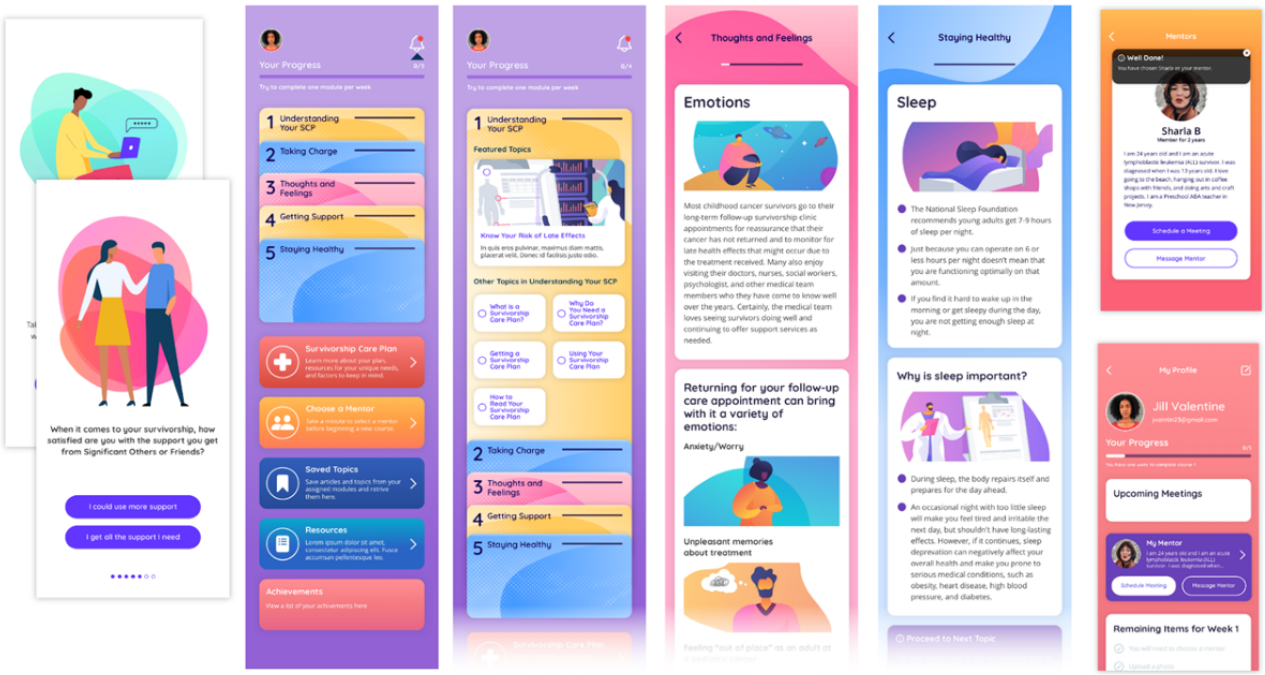
Our key informants also uniformly expressed a desire for interactive features. To accomplish this, we added "quizzes" and "Just Checking In" surveys within each content module that focused on evaluating knowledge of the content presented or encouraging self-reflection on how the content applies to their own lives. Where knowledge acquisition was the focus, such as with learning health insurance terms, "quizzes" were used to test knowledge and provide corrective feedback as needed. Where self-reflection was the focus, "Just Checking In" surveys used a combination of questions with multiple response options and open-ended responses to encourage self-reflection. For example, module 3 discusses coping strategies, and the "Just Checking In" survey asks users to check the coping strategies that work well for them and select a coping strategy to practice.

We also added an interactive activity aligned with one or more learning objectives to each module. For example, in module 4: *Getting Support*, we added a personalized social network builder that allows young adult survivors to visualize who in their social network offers support along various support domains (eg, emotional, practical, and informational). The tool allows participants to place support members in an inner, middle, or outer ring that corresponds to frequency and effectiveness of support interactions with the named social network member as a way to actively reflect on their social support, instead of reading text about it (refer to Figure 2 for screenshots of the activity).

Figure 2. Interactive "Personal Social Network" exercise within the Managing Your Health app.



XSL•FO
RenderX

We also recognized the importance of privacy and confidentiality within the app. We added profile management features to ensure that young adult survivors felt in control of their information and personal goals. Users decide what information they want to put into the app, and notifications alert users to re-engage with the app without providing any specific, identifiable user information.

In-app progress tracking also had uniform support among our key informants, so we added a progress tracker so that young adult survivors could see and understand how each module fit within the whole program. An overview of the overall design and content of the app is illustrated in Figure 3.

Figure 3. Screenshots demonstrating the onboarding survey, dashboard layout, sample module content, and mentor features of the Managing Your Health app prototype.

Phase 2

Overview

Interview participants (n=25; Table 2) were young adult survivors of childhood cancer. Participants, on average, were in their early to mid-20s (mean age 24.08, SD 1.91 years), and they were between 5 and 24 years since diagnosis (mean 13.56, SD 5.51 years). Participants were primarily diagnosed with blood cancers (n=18, 72%). More than half identified as male (n=15, 60%), and a little more than three-quarters of participants identified as Hispanic White (n=3, 12%) and Non-Hispanic White (n=16, 64%).

XSL•FO
RenderX

Table 2. Usability interviews participant demographics (n=25).

Demographics	Value
Age, mean (SD)	24.08 (1.91)
Age at diagnosis, mean (SD)	10.45 (5.44)
Years since diagnosis, mean (SD)	13.56 (5.51)
Sex, n (%)	
Male	15 (60)
Female	10 (40)
Ethnicity, n (%)	
Hispanic	3 (12)
Non-Hispanic	22 (88)
Race, n (%)	
Hispanic White	3 (12)
Non-Hispanic White	16 (64)
Non-Hispanic Black	2 (8)
Non-Hispanic Asian	3 (12)
Non-Hispanic more than one race	1 (4)
Cancer site	
Blood	18 (72)
Central nervous system	4 (16)
Neuroblastoma	1 (4)
Sarcoma	2 (8)

Most user feedback was positive, indicating high acceptance and high perceived usefulness of the app. Three primary themes that were identified were (1) useful and easy, (2) likeable and familiar, and (3) suggested changes and improvements.

Theme 1: Useful and Easy

Participant interviews highlighted the usefulness of the *content* and *features* of the app (refer to Table 2 for an overview of the themes with additional exemplar quotes). They found the module that would allow participants to create a step-by-step, personalized action plan to be particularly helpful. Two of the most liked features explained how to make an appointment with a primary care physician and how to navigate health insurance; these features also came with interactive components with which users could practice by applying their knowledge. For example, participants commented on the utility of the app, providing a sample script to follow in making a health care appointment. One participant said:

> *I like the fact that you're able to print out the form [script]. It kind of tells you what to say and then you can just print it out. It's cool! Normally I get nervous trying to like make sure I say everything perfectly. I'm so used to my mom making appointments for me.* [Non-Hispanic Black female, 20 years, leukemia]

Participants also described how the in-app insurance term glossary and example labeled insurance card were helpful. One participant remarked:

> *This is probably the most confusing part of being on your own medical plan. This is a nice summarization; I feel like it can be overwhelming for new plan users. It can get all confusing about premiums, deductibles, copays – all that stuff – these are definitely the toughest topics.* [Non-Hispanic White male, 26 years, neuroblastoma]

Participants also found the content of the app *easy to digest*, which likely contributed to perceptions of the app's usefulness. Participants noted that the personable presentation of the content was positive, and the use of videos and images to supplement and further explain written information was also noteworthy. For example, one participant said:

> *I like how you guys have videos cause sometimes I don't know what I have to do. Reading it is one thing, also seeing it is much better.* [Non-Hispanic White female, 26 years, leukemia]

Participants' quantitative results reflected their overall comments about the app (Table 3), which was perceived as useful (mean 4.49, SD 0.40). Participants thought that using the app would be beneficial to them (mean 4.55, SD 0.45), and they reported strong intentions to use the app if available to them (mean 4.44, SD 0.65).

XSL•FO
RenderX

Table 3. Usability interviews illustrative quotes by theme.

Theme	Definition	Exemplar quotes
Useful and easy	The *content* and *features* of the app were perceived as useful to managing survivorship and easy to use	• "I thought that that was particularly very good, kind of like a little breakdown of how you could talk to your doctor about it, because it's not easy doing it for the first time when you're on your own. So especially after you had a mom or dad helping you out for most of your life" [Hispanic White male, 23 y, lymphoma] • "I thought it was a good amount of information and broke down what we need to know, while taking those steps to take [sic] care of your health yourself. Especially with the insurance information and then breaking down hot to get a doctor's appointment, what to do, what to say. 'Cause I feel like that is probably anxiety producing for people who haven't done it before" [Non-Hispanic White female, 25 y, leukemia] • "And yeah, just understanding these what these simple terms mean, because I feel like, like for example, like coinsurance, copay, like I feel like, sounds, similar people could get confused, so having this laid out like a little glossary. Very helpful and then I like the card explanation. I'd like your medical card. I feel like sometimes when I fill out information like I'm going to like a new Doctor for the first time or whatever. I always have to make sure. Oh that's my like member ID number whatever. And this kind of clearly explains what it what, so that's helpful" [Non-Hispanic Asian male, 21 y, leukemia] • "I like that it really, really emphasizes the ones that were relevant to me" [Non-Hispanic Black male, 25 y, leukemia] • "It makes it easy to kinda identify the important key points, and if it is too long, there is a good chance I just wouldn't read it. and so I liked how it kinda broke everything up into a little sections" [Non-Hispanic Asian male, 25 y, lymphoma] • "I think it's really- I like how it's designed and like how you're not seeing too much all at once. Like you're going page by page with the modules that feels very like digestual with the information" [Non-Hispanic White female, 25 y, leukemia] • "Anything that's like short and sweet information like this is nice … even though it's multiple paragraphs - I'd rather have a short decent paragraph rather than a long. Because I've googled stuff and then you get a three page paper and I'm like never mind" [White male, 23 y, leukemia]
Likeable and familiar	The *design* and *aesthetics* of the app were perceived as likeable and familiar to potential users	• "This kind of reminds me too – I have a meditation app – and this is kind of how they list all their different options of meditation classes you can take, which I think is why I was just clicking" [Non-Hispanic White female, 22 y, brain tumor] • "It was good, it's very well laid-out, it's very clear. It reminds me of Duolingo, which is pretty good" [Non-Hispanic White male, 27 y, lymphoma] • "So overall, really easy to use, accessible and I feel like definitely a lot of people will find this helpful and useful" [Non-Hispanic Asian male, 21 y, leukemia] • "I thought it was good and was very user friendly, was easy to use. No, I like it, I like how vibrant and user friendly and engaging it is" [Non-Hispanic White female, 24 y, lymphoma] • "Based on my hour using this, I can't think of a better design myself. It's simple – maybe some people like more complicated looking apps but I like how it's simple and easy" [Non-Hispanic White male, 26 y, neuroblastoma] • "I think it's super easy to use, I am very comfortable using it, very comfortable navigating. I don't think it's any more difficult than any app that you're going to be using on the entire market" [Non-Hispanic White male, 23 y, leukemia]

XSL•FO
RenderX

Theme	Definition	Exemplar quotes
Suggestions and improvements	Participants suggested both *content* and *layout* additions to increase the app's relevance to survivorship care	• "The last portion when it's asking you about the things you don't like about the provider – what is the point of that? I feel like it didn't give you any feedback. You know it's just asking you how comfortable you are with your provider and then it's just like- kind of leaves it there" [Non-Hispanic White male, 26 y, lymphoma] • "Since I just mentioned that all that information is kind of sensitive to keep on the phone, I was thinking ...this might be kind of tedious for people, I was think if you could like...log in to see just that part, or something, login like a hospital, I don't know...." [Non-Hispanic White male, 22 y, brain tumor] • "When you say like type, rather than type may it would just come up with a calendar, right? That would probably be helpful, especially if you can sync it to your phone calendar, although that might be kind of a big ask. I don't really know if that's easy to do or not, or if at least just, you know, pull up the date right?" [Non-Hispanic Asian female, 26 y, leukemia] • "For this app, I would turn on push notifications where it would go on my phone and say 'you still have things to complete for Week 1. Complete them so you can move onto Week 2'" [Non-Hispanic White female, 22 y, brain tumor] • "Yeah, I do like the bullet points… I feel like there's- you could add more [info] for symptoms for primary care" [Non-Hispanic White female, 25 y, leukemia] • "Ok when I choose the wrong answer, it still looks the same as to if I were to choose the right answer. I feel as if I chose the wrong answer, it will be really helpful to maybe have a text box at the bottom saying "incorrect"- just saying like "incorrect" and giving the definition to what I chose that was incorrect. And the correct answer to have definition again, just so I kind of reread it" [Non-Hispanic Black female, 20 y, leukemia] • "I would want to I guess explain more on why that's the answer. And like why it's not the answer I chose" [Hispanic White female, 23 y, sarcoma] • "Because it's the same color or font as the number of two years, so it feels like they're equally as important, but I feel like the name is more important than how long they've been a member. So maybe italicize member for two years and bold the name" [Non-Hispanic Black male, 25 y, leukemia]

Overall, participants found the app to be applicable and useful to their survivorship experience, providing them with interactive resources that they could use again, increased the applicability of the app's content and features. Table 4 shows the ratings of the TAM among usability interview participants.

Table 4. Technology acceptance model ratings among usability interview participants (n=25).

Subscale and item[a]	Mean (SD)
Perceived usefulness (α=.76)	4.49 (0.40)
The app will be useful to help me manage my survivorship journey	4.64 (0.49)
The app will make managing my survivorship journey easier	4.64 (0.49)
The app will help me to understand the survivorship topics I'm interested in	4.44 (0.58)
The app will help me in my interactions with doctors, insurers and others	4.28 (0.68)
The app will help me to manage my own survivorship self-care	4.44 (0.58)
Perceived ease of use (α=.78)	4.53 (0.43)
The process of learning to use the app was easy for me	4.72 (0.46)
I found it easy to get the app to do what I wanted it to do	4.40 (0.65)
I found the app to be clear and understandable	4.44 (0.58)
I found the app to be easy to use	4.56 (0.51)
Behavioral intentions (α=.80)	4.55 (0.45)
I think that using the app in my own survivorship journey is a good idea	4.52 (0.51)
I think that using the app in my own survivorship journey would be beneficial to me	4.56 (0.58)
I have a positive impression about using the app	4.56 (0.51)
Use intentions	
I intend to use the app in my own survivorship journey	4.44 (0.65)

[a]All items were measured with the following: 1=*strongly disagree* through 5=*strongly agree*. Higher scores meant more positive perceptions of the feature.

XSL•FO
RenderX

Theme 2: Likeable and Familiar

Participants were highly satisfied with the design of the app—the layout and the aesthetics. They felt the design was *likeable and familiar*, and there was a clear reciprocal relationship between the 2 components of this theme; that is, the likeability and familiarity of the app seemed to contribute to and reinforce each other in participants' minds.

Participants liked that the app was well-organized, accessible, and user-friendly. They perceived that the layout and navigation particularly exemplified these adjectives. For example, one participant said:

> *The flow of the app is actually one of the things I really like the most. I think it just works very well, in a lot of the different ways. A lot of different pages will segue into each other kind of seamlessly … I don't think anyone will have any issues using it. It's very well laid out.* [Hispanic White male, 23 years, lymphoma]

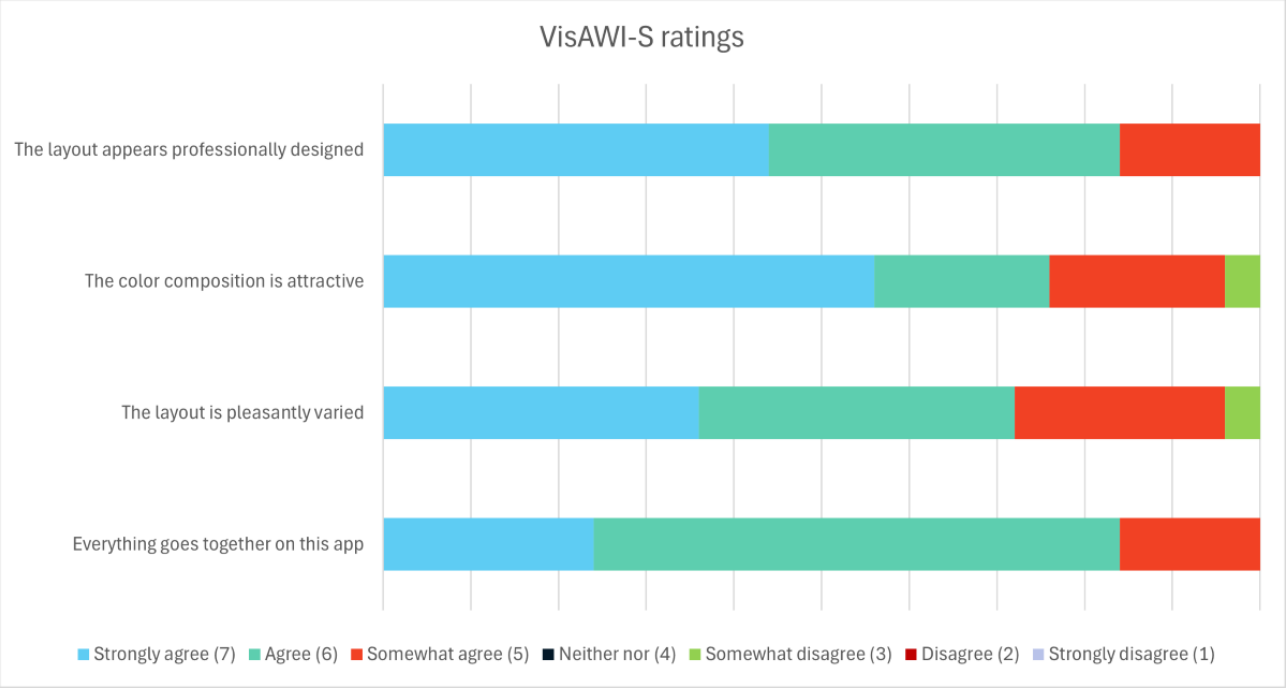
A second participant described the layout:

> *I love the layout, how it's just kind of … It's organized.* [Non-Hispanic Black female, 20 years, leukemia]

A third participant discussed how it was beneficial to have multiple touch points for the same information:

> *I like things being in two places. So, if I misremember … [the information] being in a very similar format so it makes it kind of a catch.* [Non-Hispanic Black male, 25 years, leukemia]

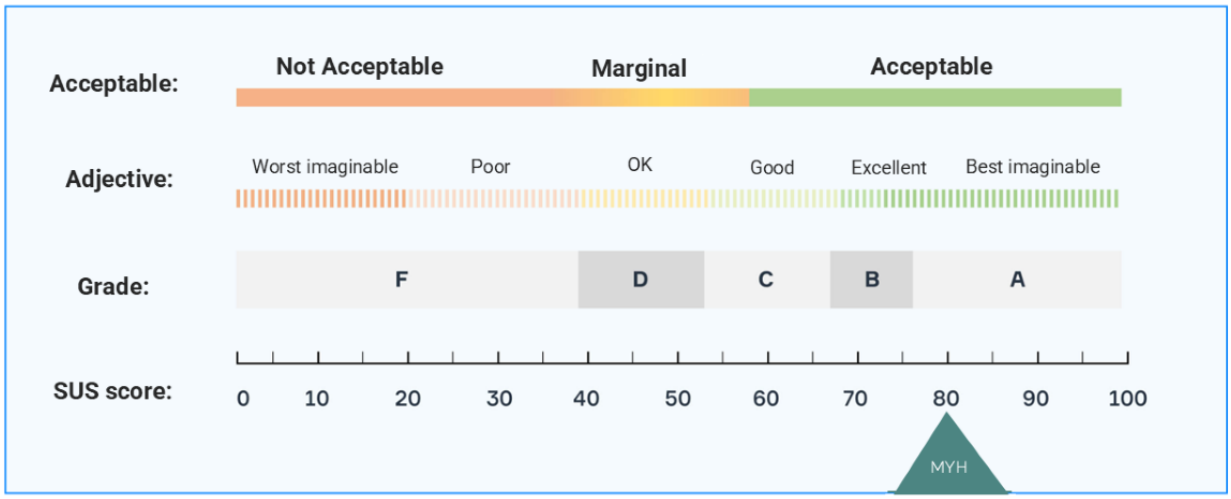
In other words, participants appreciated how the app was designed and how it functioned.



Additionally, several participants compared the design of this app to other apps widely available in the app store, such as the language-learning app Duolingo. These design similarities created a sense of familiarity among our participants; that is, the overall aesthetic and navigational design of our MYH app reminded participants of other mass-market apps. Participants' sense of familiarity with the app seemed to increase the likability of the MYH app, as participants felt more confident in their ability to navigate the app and take full advantage of its features—all key components of the SUS measure. For example, one participant said:

> *It was pretty easy – when you [the interviewer] asked me to do something I felt like I knew pretty roughly. Like I know that little box with the pencil is an edit button so if you're on your profile I knew it would be to edit my profile.* [Non-Hispanic White male, 26 years, neuroblastoma]

Thus, one important component of participants' positivity toward the app was a design that was like other mass-market apps.



Again, participants' quantitative results reflected their qualitative comments. The app was perceived as visually appealing (mean 6.15; SD 0.86) and easy to use (mean 4.53, SD 0.43; Figure 4). Participants' overall usability rating on the SUS was 80.3 out of 100 (SD 11.55), which can be categorized as "Excellent" (Figure 5).

Figure 4. Participants' perceptions of the subjective appeal of the MYH app. VisAWI-S: Visual Aesthetics of Website Inventory – short form measured on a 1 (strongly disagree) through 7 (strongly agree) scale.

XSL•FO
RenderX

Figure 5. Participants' ratings of the Managing Your Health app on the System Usability Scale (range 0-100). MYH: Managing Your Health; SUS: System Usability Scale.

Theme 3: Suggested Changes and Improvements

Finally, participants described suggested changes and improvements that they wanted to see in the app. This theme referred to *content* (eg, unnecessary features and desired additions) as well as *layout* (eg, formatting changes).

Participants' suggestions addressed a range of functionalities that they thought would make the app both more useful and easier to use. For example, multiple participants wanted to integrate a calendar feature within the app. For example, one participant said:

> *Maybe there should be like a calendar function where you can, you know when your appointments are, you can put them on this one app and you are not juggling between your calendar app, or email, it would kinda be centralized in here [the app].* [Non-Hispanic Asian male, 25 years, lymphoma]

A second participant (Non-Hispanic White female, 26 years, medulloblastoma) suggested integrating a medication list within the app so that survivors could easily report which medications they were taking at appointments because it would be "just an easier way to help them [other survivors] manage their medicines," while a third participant (Non-Hispanic White female, 26 years, leukemia) wanted a to-do list integrated in the app so user could notate "what you need to ask your doctor or what symptoms you are having." These features were suggested as ways to consolidate the information that our participants felt they needed to have on hand—often from their own experience of follow-up care—but the app did not currently include.

Participants also suggested changes to the *formatting* of the app's content. This feedback varied, although multiple participants requested reformatting the quizzes throughout the app's modules. For example, one participant said:

> *Yeah, I probably prefer like if I were to get the answer wrong, it would like highlight it in like a red color. Just show me that it's wrong and then I could click on something and then like and something pops up and it just kind of gives an explanation on why your answer was wrong and then like what's the correct answer.* [Non-Hispanic Asian male, 21 years, leukemia]

Participants wanted to understand *why* they missed quiz questions, further indicating the usefulness of the app's content. They asked for incorrect answers to be more easily identifiable, and they wanted explanations. To our participants, these formatting changes would help them learn—and internalize—the content so that they could use it in their lives.

Other formatting suggestions included making the app more inclusive. One participant suggested adding,

> *…some sort of gender-neutral sign in the middle … because it's like 'man and woman' but that's not very inclusive of members of the trans[gender] community or [the] non-binary community.* [Non-Hispanic White female, 24 years, lymphoma]

Overall, participants gave both positive quantitative and qualitative feedback about the content and design of the app; this feedback suggested high usefulness and ease of use among this population.

Discussion

Overview

In this study, we developed and evaluated the content and usability of the MYH app. The app is one component of a proposed transition-readiness intervention for young adult survivors of childhood cancer. The purpose of the intervention is to promote effective transition from parent-guided pediatric survivorship care to self-guided adult survivorship care through interactive, personalized educational content within the app and a peer mentor to connect with on videoconference outside of the app. Overall, our participants quantitatively and qualitatively reported that the MYH app contained content that was relevant and useful to their experience as young adult survivors of childhood cancer and was visually appealing and easy to use.

XSL•FO
RenderX

Principal Findings and Comparison With Previous Work

We implemented an iterative design process to ensure that app development met the needs and expectations of our target users, young adult survivors of childhood cancer. Engaging target users early in the design process, especially for the purpose of understanding their specific needs and wants, is essential for the implementation and uptake of mobile health technologies [36,37]. Additionally, in a previous study with young adult survivors of childhood cancer, the acceptability of a survivorship health management app was positively and moderately correlated with app engagement [38].

Participants in the phase 1 key informant workshops affirmed that the content in the MYH program matched the barriers faced by young adult survivors of childhood cancer. Participants were also highly satisfied with the preliminary designs for the app, especially the proposed features intended to help navigate the complexities of health insurance coverage. Health insurance is consistently a source of stress for young adults, regardless of cancer history, and studies have demonstrated that people in this age group have low knowledge and self-efficacy [39,40]. Childhood cancer survivors are also more likely to experience financial hardships [41,42]. The insurance navigation feature is just one example of how the unique needs of young adult survivors of childhood cancer were met by the content of the app.

Participants provided mixed feedback about gamifying the app, which came as a surprise given previous literature suggesting that gamification can increase engagement and goal achievement in cancer survivors [21,43,44]. Additionally, gamification elements have been positively associated with intrinsic need satisfaction, such as autonomy competence, motivation, and relatedness [45]. However, there is a lack of clear efficacy data in relation to gamification for disease self-management among this population; among interventional apps that include gamified elements, efficacy studies are rarely designed or adequately powered to understand the effects of gamification on study outcomes, leaving the question of whether it is the gamified design or another element driving efficacy [46-48]. Since increasing engagement is often stated as the primary rationale for including gamified elements among other eHealth tools—and the tailored, interactive features of the MYH app could spur such engagement—we decided to develop the app without any additional gamification elements, such as point rankings, completion badges, and so on [48].

Usability testing sessions with 25 young adult survivors of childhood cancer established high acceptance and perceived the usefulness of the app. Participants' qualitative feedback during the sessions related to three categories: (1) useful and easy, (2) likeable and familiar, and (3) suggested changes and improvements.

Overall, participants' qualitative comments indicated that they found the content of the app to be useful in their survivorship journey and easy to understand. Participants also found the design and navigation of the app to be likeable and familiar (ie, similar to the design of other apps they already use). These qualitative remarks aligned well with quantitative scores across the TAM and VisAWI-S measures, which indicated that most participants agreed or strongly agreed that they perceived the app as visually appealing, useful, and easy to use. High ease of use was also evident from participants' ratings on the SUS, which was higher than the industry average of 68 across a wide range of apps [49,50]. Since perceived usefulness is a key driver of technology use, especially among this population, this feedback is encouraging for future use of the MYH app [17,23].

Our participants provided the most enthusiastic feedback about features that could help them manage their survivorship care; they also proposed additional app features based on their real-life experience of accessing survivorship care. Because these comments primarily focused on enhancements to the existing app features rather than limitations or irrelevant features, it seems that participants already saw the MYH app as a feasible and usable tool through which to manage their survivorship care. Additionally, young people can be overwhelmed by the sheer amount of information available online and want to be able to quickly find information that is relevant to their unique situation [51]. As demonstrated by their responses, participants in our study were most drawn to features that they would use and were most likely to suggest features that they wished they had available to them earlier in their transition process. Taken together, these findings echo previous research emphasizing the importance of personalized information and resources within digital health tools [19,20], especially for cancer survivors [14,17,18,21].

Limitations

This study, like all studies, is not without limitations. First, despite our attempts to recruit a diverse group of participants, most participants in both the key informant workshops and the usability interviews predominantly identified as Non-Hispanic White, which may indicate that our findings do not reflect the opinions of all young adult survivors of childhood cancer. Second, we recruited our sample primarily from one National Cancer Institute–designated cancer center in the northeastern United States, although our advocates in the key informant workshops were from various parts of the country. This may also limit the applicability of our findings to all young adult survivors of childhood cancer, especially those who come from other parts of the country. Third, to move quickly through the app development, our key informant workshops relied on a text and topic summary approach to data analysis, which may have obscured additional nuances within the data. Finally, data collection occurred during the COVID-19 pandemic (ie, October 2021-June 2022), which may have altered participants' views on salient features and needs in unknown ways.

Future Directions

Based on the feedback provided in the individual usability interviews, the team designed and implemented several changes to the functionality, layout, and content of the app. The team also added both backend architecture and functionality to manage any potential security concerns, including a PIN sign-in and industry-standard security.

Because previous testing established the high feasibility and acceptability of the MYH program (ie, the intervention modules

XSL•FO
RenderX

and the peer mentor), conducting a randomized controlled efficacy trial of the program is a critical next step in contextualizing and translating the results presented here [35]. Due to the relative homogeneity of the sample in the design phase, as presented here, recruiting from multiple sites across the country was prioritized in the design of the efficacy trial, which is currently underway.

Conclusions

We engaged young adult survivors of childhood cancer in an iterative cocreation process to ensure that the MYH app reflected the needs and expectations of the target population, as is best practice in developing mobile health technologies for specific populations [17,22,36,37]. The key informant workshops and usability testing demonstrated that the MYH app is useful, visually appealing, and easy to use among young adult survivors. While participants rated the proposed design and features highly, they also had many—and varied—suggestions for content and layout improvements that would enhance the existing app. These results were used to refine the app for further efficacy testing.

Acknowledgments

We would like to acknowledge the work of our 2 qualitative coders of the usability sessions: Ivelisse Mandato (BS) and Melanie Spruill.

Generative artificial intelligence was not used in generating any portion of the content presented in this manuscript.

Abstract

Background: Male breast cancer (MBC) is an uncommon disease. Few studies have discussed the prognosis of MBC due to its rarity.

Objective: This study aimed to develop a nomogram to predict the overall survival of patients with MBC and externally validate it using cases from China.

Methods: Based on the Surveillance, Epidemiology, and End Results (SEER) database, male patients who were diagnosed with breast cancer between January 2010, and December 2015, were enrolled. These patients were randomly assigned to either a training set (n=1610) or a validation set (n=713) in a 7:3 ratio. Additionally, 22 MBC cases diagnosed at the First Affiliated Hospital of Guangxi Medical University between January 2013 and June 2021 were used for external validation, with the follow-up endpoint being June 10, 2023. Cox regression analysis was performed to identify significant risk variables and construct a nomogram to predict the overall survival of patients with MBC. Information collected from the test set was applied to validate the model. The concordance index (C-index), receiver operating characteristic (ROC) curve, decision curve analysis (DCA), and a Kaplan-Meier survival curve were used to evaluate the accuracy and reliability of the model.

Results: A total of 2301 patients with MBC in the SEER database and 22 patients with MBC from the study hospital were included. The predictive model included 7 variables: age (hazard ratio [HR] 1.89, 95% CI 1.50 - 2.38), surgery (HR 0.38, 95% CI 0.29 - 0.51), marital status (HR 0.75, 95% CI 0.63 - 0.89), tumor stage (HR 1.17, 95% CI 1.05 - 1.29), clinical stage (HR 1.41, 95% CI 1.15 - 1.74), chemotherapy (HR 0.62, 95% CI 0.50 - 0.75), and HER2 status (HR 2.68, 95% CI 1.20 - 5.98). The C-index was 0.72, 0.747, and 0.981 in the training set, internal validation set, and external validation set, respectively. The nomogram showed accurate calibration, and the ROC curve confirmed the advantage of the model in clinical validity. The DCA analysis indicated that the model had good clinical applicability. Furthermore, the nomogram classification allowed for more accurate differentiation of risk subgroups, and patients with low-risk MBC demonstrated substantially improved survival outcomes compared with medium- and high-risk patients (P<.001).

Conclusions: A survival prognosis prediction nomogram with 7 variables for patients with MBC was constructed in this study. The model can predict the survival outcome of these patients and provide a scientific basis for clinical diagnosis and treatment.

KEYWORDS

male breast cancer; specific survival; prediction model; nomogram; Surveillance, Epidemiology, and End Results database; SEER database

Introduction

Male breast cancer (MBC) is an infrequent type of malignancy [1,2]. The incidence of MBC accounts for less than 1% of all breast cancer (BC) instances, and MBC accounts for 0.31% of all BC cases in China [3-5]. The incidence of MBC varies by region and ethnicity, with higher rates observed in Africa, North America, and Australia, and the lowest rates are observed in Asia [6]. In China, there are only 4 cases of MBC per million people, but this figure has been increasing gradually in recent

XSL•FO
RenderX

years [6]. Due to the low incidence of MBC, current research on BC primarily focuses on female patients [7]. Therefore, the current treatment for MBC is based on the guidelines for treating female BC [8]. However, MBC possesses unique tumor, molecular, and clinicopathological characteristics, and no consensus has been established regarding its diagnosis, treatment, and assessment of prognostic risk factors. A previous study revealed that the median age at diagnosis for BC in men is 67 years old, which is 5 - 10 years later than that in women [9]. Despite this, the overall survival of MBC is significantly lower than that of female BC, largely due to late diagnosis [10].

The TNM (tumor, extent of spread to the lymph nodes, and presence of metastasis) staging system is the most commonly used clinical instrument to evaluate the prognosis of individuals with cancer [11-13]. However, in MBC, the limited amount of breast tissue and the frequent involvement of the chest wall at early stages reduce the prognostic value of TNM staging [14]. Many studies have demonstrated that factors such as age, tumor type, and other factors significantly influence the prognosis of BC [15,16]. Compared to using the clinical stage alone, comprehensive multivariate models can provide numerical estimates of practice-specific risk and the accuracy of prognostic predictions for patients with cancer [17]. Therefore, various clinical medical records need to be combined to construct a prognostic model for MBC, thus enabling a more accurate judgment of the prognosis of patients and an accurate, individual evaluation of the prognosis of patients.

Current clinical approaches for constructing risk prediction models include the nomogram, a scoring system, and other methods, which can serve as a guide for clinical decision-making and individualized treatment [18-20]. The nomogram, as a straightforward and intuitive prediction tool with strong predictive ability, has the advantages of accurate predictive ability and calibration ability, and it has been widely used in prognosis research [21-23].

This study aimed to identify the prognostic indicators of patients with MBC by using the Surveillance, Epidemiology, and End Results (SEER) database; establish a predictive model on the basis of the independent predictors of overall survival; and internally and externally validate the model to guide clinical staff in evaluating the prognosis of patients more accurately and formulating more personalized diagnosis and treatment plans. We present the study in accordance with the TRIPOD reporting checklist.

Methods

Data Sources

The SEER database collects information on new cancer cases and survival rates from 18 population-based cancer registries, which currently cover approximately 30% of the US population [22]. Clinical data on male patients with pathologically confirmed BC from 2010 to 2015 were gathered using the SEER database to establish a training set and an internal validation set. Data from patients with MBC admitted to the First Affiliated Hospital of Guangxi Medical University between 2013 and 2021 were used for the external validation set of the model. Clinical data for MBC were retrospectively collected from the hospital database, and follow-up information was obtained through telephone interviews. Patients with missing follow-up data or other essential clinical information were excluded.

Patient Inclusion and Exclusion Criteria

The criteria for patient inclusion were as follows: (1) male patients; (2) an *International Classification of Diseases for Oncology, Third Revision* code; (3) breast as the primary site; and (4) complete survival data. The exclusion criteria were (1) missing clinical information, including TNM staging and tumor laterality; (2) unknown demographic characteristics, such as age at diagnosis and marital status; and (3) instances without records of follow-up (0-month survival time code). The enrolled patients were randomly assigned in a 7:3 ratio to two sets: a training set and an internal validation set. The training set was used to develop the prediction model, and the internal validation set was used for internal validation. The data obtained at the hospital were applied for external validation.

Variable Selection

The outcome variable in this study was overall survival. The selection of predictor variables was informed by previous reports in the literature. The variables collected included year of diagnosis, age, marital status, pathological grade, breast subtype, estrogen receptor, progesterone receptor, human epidermal growth factor receptor 2 (HER2), American Joint Committee on Cancer stage, chemotherapy, surgery, radiotherapy, duration of follow-up, and death.

Follow-Up of Patients

Male patients with BC were followed up by telephone in the hospital, and the follow-up ended on June 10, 2023. The index used for follow-up was overall survival time, with the outcome event being mortality.

Statistical Analysis

Data analysis was conducted using the R software version 4.1.1 (IBM Corp). Percentages were used to represent categorical variables, and the χ^2 test or Fisher exact test was used to compare the baseline characteristics of the training set, internal validation set, and external validation set. The Kaplan-Meier model was applied to describe the overall survival curve, and the log-rank test was used to evaluate the disparities in survival among various subgroups of each variable. First, variables that had a significance value of $P<.05$ in the univariate analysis were chosen to be incorporated into the multivariate Cox proportional hazard model to obtain variables affecting the survival of patients with MBC. Second, stepwise regression was performed based on the Akaike information criterion. The nomogram prediction model was constructed using R software (via the *rms* and *survival* R packages) to assess the influence of risk factors on the overall survival of patients with MBC. Predictions were made for the 1-, 3-, and 5-year overall survival rates of patients with MBC by constructing the nomogram.

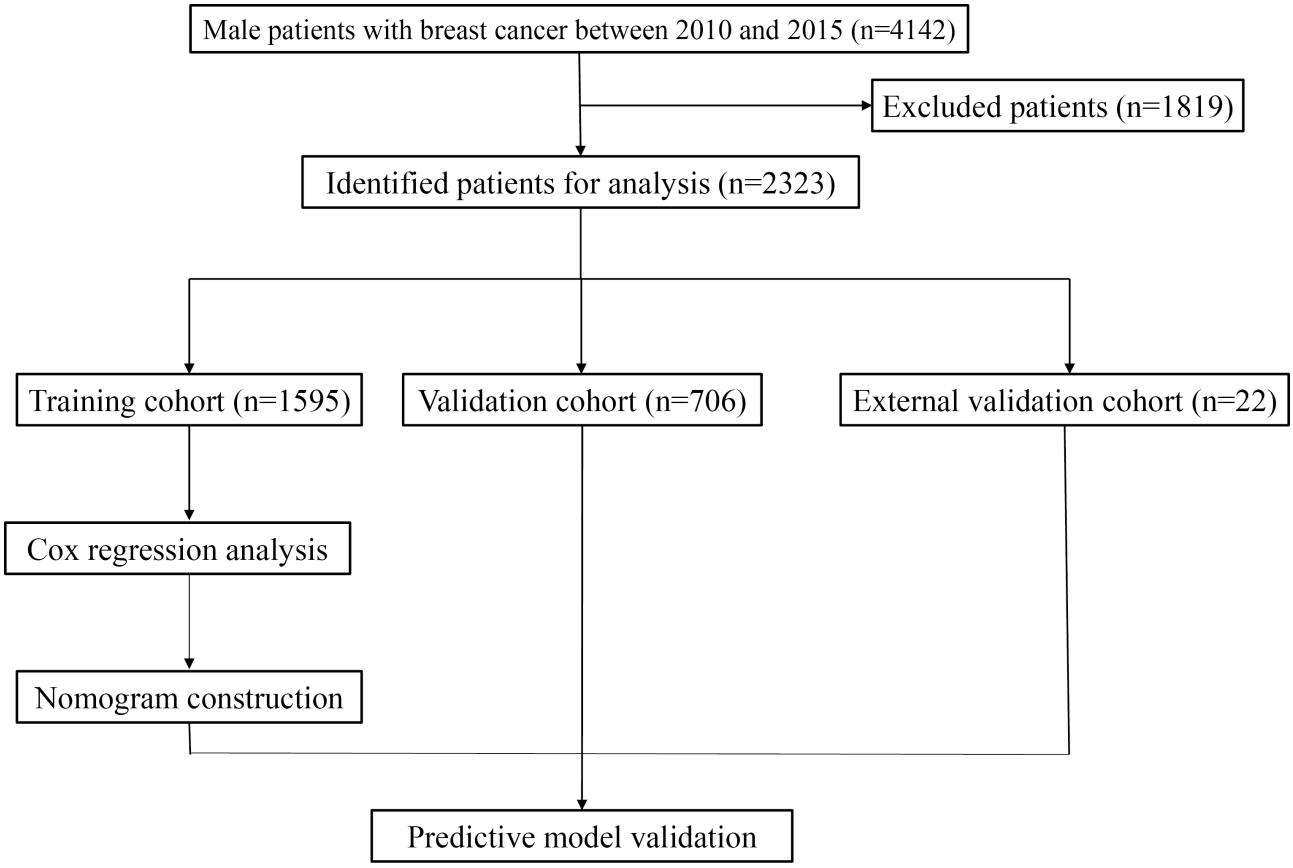
The performance of the nomogram was evaluated through internal and external validations. Bootstrapping was used to perform 1000 instances of resampling to internally validate the predictive performance of the nomogram to ensure the stability

XSL•FO
RenderX

and reliability of the model's performance. The discrimination of the nomogram was assessed using the Concordance index (C-index) and receiver operating characteristic (ROC) curve. A calibration curve was created to assess the degree of calibration of the nomogram to ensure its accuracy and reliability. Furthermore, decision curve analysis (DCA) was conducted using *ggDCA* in the R package, to evaluate the clinical utility and application value of the nomogram. Finally, X-tile software (version 3.6.1, Yale University School of Medicine) was used for risk stratification on the basis of the total score of the nomogram for each individual. An α level of .05 was used.

Ethical Considerations

The data used in this study were extracted from a publicly accessible SEER database. This study was reviewed and approved by the Medical Ethics Committee of the First Affiliated Hospital of Guangxi Medical University (2023-E320-01). During the follow-up, informed consent was obtained orally from individual participants included in the study, and the investigator explained the purpose of the study to the patient or caregiver. Participants were also made aware of their right to withdraw at any time without penalty or prejudice to their future care, a principle that was strictly adhered to throughout the study period. In addition, participants who completed the survey received a complimentary disease knowledge resource as a token of appreciation and compensation for their participation, All participants' information was confidential, and each patient was assigned an ID to keep the study data and results anonymous.



Results

Patients' Baseline Characteristics

Figure 1 depicts the screening procedure in the SEER database. In accordance with the inclusion and exclusion criteria, a cohort of 2301 eligible patients with MBC was selected from the SEER database and randomly divided into a training set (n=1595) and an internal validation set (n=706). A total of 22 patients with MBC were chosen from the institution to serve as an external validation set. Significant variations in age were observed among the 3 groups in relation to demographic characteristics (P=.01). The proportion of older men in the SEER database (training set: 1180/1595, 74%; internal validation set: 505/706, 71.5%) was substantially greater than that in the external validation set (9/22, 41%). Significant differences were found in chemotherapy, lung metastasis, breast subtype, and HER2 status among the 3 groups (all P<.05). The proportion of men with breast cancer who received chemotherapy was higher in the external validation set (17/22, 77%) than in the SEER database (training set: 601/1595, 37.7%; internal validation set: 257/706, 36.4%). The incidence of lung metastasis in patients with MBC in the external validation set (3/22, 14%) was higher than that in the SEER database (training set: 49/1595, 3.1%; internal validation set: 24/706, 3.4%). There was a high prevalence of luminal A among men, with rates of 86.7% (1379/1595) and 85% (607/706) in the training set and internal validation set, respectively, as well as 41% (9/22) in the external validation set. A notable detail is that a significant portion of the total population exhibited a HER2-negative status accounting for 88.6% (1413/1595) in the training set, 87.5% (618/706) in the internal validation set, and 59% (13/22) in the external validation set. Table 1 displays the demographic and clinicopathological characteristics.

[f]HER2: human epidermal growth factor receptor 2.

The data of 22 male patients diagnosed with BC in the study hospital were collected. Statistically significant differences were observed between the two groups in terms of age, T stage, chemotherapy, breast subtype, and HER2 status (P<.05). In the unit set, ≤60 years old, T_2 stage, receiving chemotherapy, luminal B, and HER2-positive status accounted for a greater proportion of patients with MBC. The clinicopathological characteristics of the SEER set and the unit set are provided in Multimedia Appendix 1.

Univariate and Multivariate Cox Regression Analysis

Cox regression risk analysis was applied to conduct univariate and multivariate survival analysis for the patients with MBC in the training set. The findings indicated that age (hazard ratio [HR] 1.89, 95% CI 1.50 - 2.38), marital status (HR 0.75, 95% CI 0.63 - 0.89), T stage (HR 1.17, 95% CI 1.05 - 1.29), clinical grade (HR 1.41, 95% CI 1.15 - 1.74), surgery (HR 0.38, 95% CI 0.29 - 0.51), chemotherapy (HR 0.62, 95% CI 0.50 - 0.75), and HER2 status (HR 2.68, 95% CI 1.20 - 5.98) were risk variables for the survival of patients with MBC (all $P<.05$; Table 2).

Table . Univariate and multivariate analysis of male breast cancer risk factors in the training set.

Variable	Univariate		Multivariate	
	HR[a] (95% CI)	*P* value	HR (95% CI)	*P* value

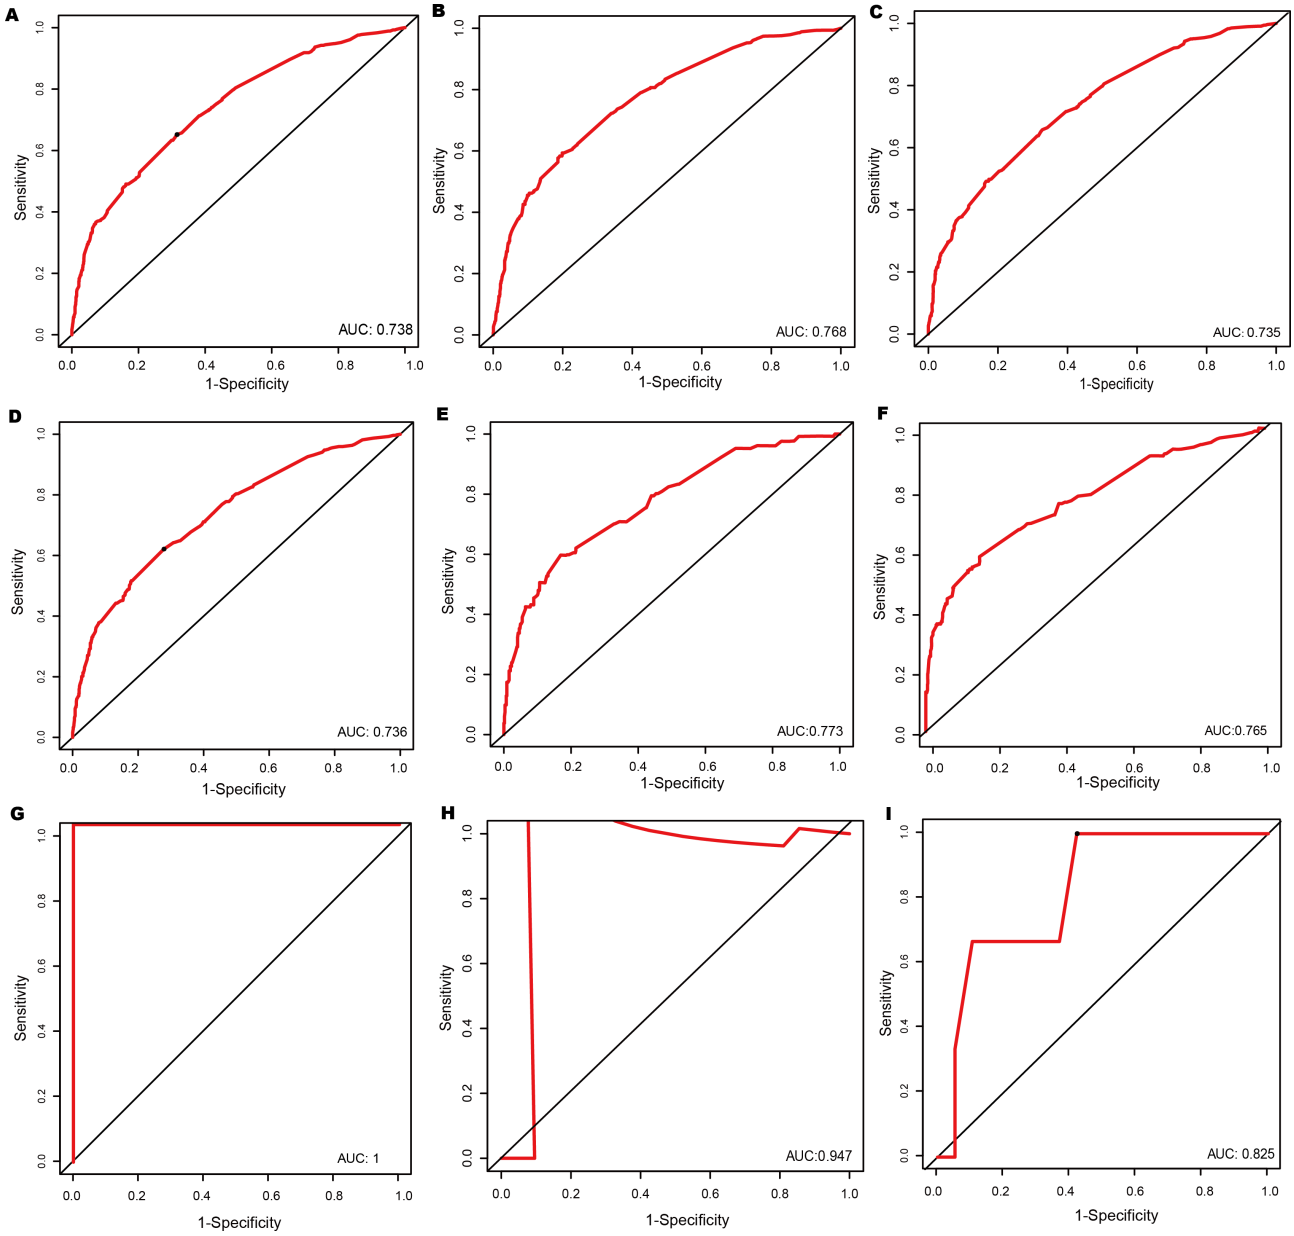
Construction and Validation of Nomogram

The construction of a nomogram for the overall survival prognosis of MBC was based on the results of the Cox regression analysis conducted on the training set. This analysis identified 7 variables that were subsequently used in the development of the nomogram (Figure 2). The nomogram demonstrated that clinical stage and surgery were the primary vital risk variables that affect the survival outcomes of patients with MBC. The total score could predict the 1-, 3-, and 5-year survival rates of patients with MBC by summing the scores of each variable.

XSL•FO
RenderX

Figure 2. Nomogram for predicting 1-, 3- and 5-year overall survival in patients with male breast cancer. HER2: human epidermal growth factor receptor 2; T: tumor.



The discrimination ability of the nomogram was evaluated in this study by using the ROC curve and the C-index. The area under the curve values of the nomogram at 1-, 3-, and 5-year survival probabilities had excellent discrimination efficacy in the training set (Figure 3A-C). The area under the curve values in the internal validation set were 0.736, 0.773, and 0.765 (Figure 3D-F), and the external validation set values were 1, 0.947, and 0.825 (Figure 3G-I). The C-index of the training set was determined using the bootstrap method, and the C-index of the external validation set was 0.72, 0.747, and 0.981 for the at 1-, 3-, and 5-year survival, respectively, indicating that the nomogram exhibited a favorable discriminatory capability in the American and Chinese populations.

The calibration curves were used to evaluate the consistency of the nomogram. The findings indicated a high degree of uniformity between the predicted and observed probabilities of survival in the training set (Figure 4A-C) and internal validation set (Figure 4D-F).

The DCA curve demonstrated that the nomogram exhibited superior performance in terms of net clinical benefit and predictive accuracy for 3- and 5-year survival outcomes in the training set (Figure 5A) and internal validation set (Figure 5B).

Nomogram Prediction Score Risk Stratification

Finally, risk stratification was conducted by calculating the nomogram total score of each individual in the training set (Table 3). After the cut-off values were determined using X-tile software, all patients with MBC were divided into 3 groups: low-risk group (points≤93), medium-risk group (93<points≤117), and high-risk group (points>117). The survival curves of each risk group were depicted using the Kaplan-Meier model in the training set (Figure 6A) and internal validation set (Figure 6B). A log-rank test was used to compare the differences between the groups to assess the accuracy of risk stratification on the basis of the nomogram score.

Discussion

Principal Findings

In this study, we developed a nomogram to predict survival in MBC based on the SEER database and validated it using both an internal validation dataset from this database and an external validation cohort from a single center. We identified 7 independent risk factors and incorporated them into the nomogram to predict the survival of patients with MBC. The results of both internal and external validation demonstrated that the nomogram exhibited good accuracy and discriminative power, confirming the robustness of the prediction model.

MBC has a low incidence and is a rare malignancy [24]. However, MBC exhibits a delayed onset, presents as a more advanced disease, and has a less unfavorable prognosis than female BC [25]. Due to its rarity, MBC is often overlooked in clinical practice. The assessment of prognosis in MBC holds considerable importance for facilitating the implementation of comprehensive treatment strategies. This study used the clinical data of 1595 patients with MBC from the SEER database to establish a nomogram for prognosticating the survival in MBC. The bootstrap method was used for internal validation, and external validation was performed in the hospital cohort. The ROC curve, C-index, and calibration curve were used to assess the discrimination and reliability of the nomogram. Additionally, the clinical benefit and application value of the nomogram were evaluated using the DCA curve. The findings demonstrated that the nomogram can accurately and individually predict the survival outcomes of patients with MBC. This predictive tool holds the potential for informing clinical decision-making and guiding the development of appropriate diagnostic and therapeutic strategies.

Previous studies analyzed the influencing factors of MBC survival by using univariate and multivariate Cox proportional hazards regression models [26,27]. Compared with traditional multivariate regression, least absolute shrinkage and selection operator (LASSO) regression is widely regarded as a superior approach for variable selection owing to its ability to mitigate model complexity, minimizing overfitting by incorporating a loss function or a penalty term into the objective function. In this study, the LASSO regression algorithm identified 7 variables (age, surgery, marital status, T stage, clinical stage, chemotherapy, and HER2 status) as factors that are associated with the prognosis of MBC. This detail has also been recognized in other studies [9,28]. Based on the aforementioned variables, a nomogram prediction model that significantly enhanced the clinical applicability within various clinical scenarios was developed. The nomogram exhibited good discrimination, consistency, and clinical validity in the training set and validation set. It may guide clinical decision-making for these patients more effectively.

Age was identified as a significant risk factor for the survival of patients with MBC in the nomogram, and individuals aged over 60 years had higher mortality, consistent with prior studies [28,29]. This finding may be related to the presence of more comorbidities in older patients [28]. Surgery and chemotherapy are essential for determining the prognosis of patients with MBC who are undergoing treatment, a finding that is similar to that of previous studies [30-32]. A recent study conducted by Wang et al [33] indicated that patients diagnosed with MBC who received surgery or chemotherapy exhibited a more favorable prognosis than individuals who did not undergo these treatments. The prognostic significance of marital status was observed, with unmarried patients exhibiting a poorer prognosis [34-36]. The reason for this result may be that unmarried patients with MBC experience more significant psychological distress, including feelings of sadness and anxiety, compared to married patients [37], and they may demonstrate greater adherence to treatment regimens [38], which could improve cancer management. Additionally, this study provided evidence to support the notion that the T stage and clinical stage are prognostic indicators for MBC [39,40]. Among the 7 parameters in the nomogram, the clinical stage showed the most significant influence on overall

XSL•FO
RenderX

survival, and patients with stages III and IV MBC had the worst prognosis. One study in Serbia showed that low initial disease stage and low tumor grade are independent predictors of a good prognosis in patients with MBC [41]. In addition, having a HER2-positive tumor is widely acknowledged as a significant prognostic factor for MBC, and this observation has been corroborated by other investigations [42-44].

In this study, the average age of onset of Chinese patients with MBC may be younger than that of patients in the SEER database, which is similar to the onset characteristics of female patients with BC [45]. In addition, the hospital exhibited a higher proportion of patients in the early T stage than the SEER database. The proportion of patients undergoing chemotherapy was significantly greater than that in the SEER database, contributing to the favorable prognosis observed in Chinese patients with MBC.

Constructing a nomogram for the survival of patients with MBC can be beneficial for medical staff to intuitively analyze the weight of risk factors and the corresponding survival probabilities of patients. These survival probabilities can be used as a basis for stratification. The patients were classified into 3 groups: low-, medium-, and high-risk. For example, a patient with MBC that is over 60 years old, is married, has undergone surgery and chemotherapy, has a T grade of T_2, has a tumor stage of II, and has a HER2-positive tumor, would have a total score of approximately 105, belonging to the medium-risk group for survival. Therefore, the medical staff should take relevant measures to timely manage and improve the prognosis of this patient. In clinical practice, the proposed model can be used to determine and evaluate the survival rate and prognosis of patients with MBC. This approach aims to provide personalized and accurate survival rate and prognosis and then develop targeted clinical decisions for patients with MBC.

Strength and Limitations

Our study has the following strengths. First, the existing prognostic models for BC have a focus on female BC, and little focus has been given to MBC. The study aims to develop a prognostic model specifically for this group. Second, the SEER database included a large and diverse cohort, ensuring robust and representative results. In addition, external validation using datasets from our own hospital further confirmed the model's accuracy and generalizability.

However, this study has some limitations. First, as a retrospective study, it is subject to selection bias. Second, important variables, such as endocrine therapy, BMI, and the cellular proliferation marker Ki-67, are not included in the SEER database, which may limit the accuracy and effectiveness of the nomogram. Finally, the external validation sample size in this study was limited, including only retrospective data from a single health care institution, and the predictive ability of the model for the Chinese population needs to be further verified using a large sample of data.

Future Directions

Future studies should consider incorporating data from multicenter cohorts to increase the sample size, thereby enhancing the accuracy and generalizability of survival prediction models for MBC. By collecting data from diverse geographic locations, researchers can ensure that the model captures a broader range of clinical variables, improving its robustness and applicability. Additionally, prospective cohort studies should be conducted to externally validate the model in real-world clinical settings and assess its practical utility in daily clinical decision-making for MBC. Furthermore, integrating additional datasets that include critical variables, such as BMI and the cellular proliferation marker Ki-67, would further strengthen the model's predictive power.

Conclusion

In summary, a nomogram was developed using 7 variables to predict the prognosis of patients with MBC, and age, surgery, marital status, T stage, clinical stage, and HER2 status were identified as independent risk factors for predicting the survival of patients with MBC. Internal and external verifications proved that the model has good accuracy and reliability. Thus, it could serve as an accurate and individualized tool that clinicians could use for decision-making.

Acknowledgments

The authors thank all the patients and institutions for participating in the study, especially for the open access to the SEER database.

Abstract

Background: Patients with cancer need coordinated care for both treatment and concurrent health conditions. This requires collaboration among specialists when using telemedicine services, emphasizing the importance of care continuity.

Objective: This study aimed to explore the effects of cross-sectorial video consultation involving oncologists, general practitioners, and patients with cancer on patients' perceived coordination of care, compared with usual care.

Methods: This study describes the primary outcomes from a 7-month follow-up of patients in the Partnership Project, a randomized clinical trial. Patients in the intervention group were randomized to receive a "partnership consultation," a shared video consultation with an oncologist, general practitioners, and the patient, in addition to their usual care. Questionnaires were completed for both groups at baseline and 7 months to assess the primary outcome, "global assessment of inter-sectorial cooperation," from the Danish questionnaire "Patients' attitude to the health care service." The questionnaire also included 2 single items and 5 index scales, examining patients' attitude toward cooperation in the health care system. Change in perceived global coordination from baseline to 7 months was compared between intention-to-treat groups using generalized estimating equations in a linear regression model.

Results: A total of 278 participants were randomized with 1:1 allocation, with 80 patients receiving the intervention. Further, 210 patients completed the questionnaire at baseline, while 118 responded at 7-month follow-up. The estimated difference in the primary outcome between usual care (−0.13, 95% CI −0.38 to 0.12) and intervention (0.11, 95% CI −0.11 to 0.34) was 0.24 (95% CI −0.09 to 0.58) and not statistically significant (*P*=.15).

Conclusions: Low rates of intervention completion and high levels of missing data compromised the interpretability of our study. While we observed a high level of global assessment of coordination, the estimated intervention effect was smaller than anticipated, with no significant difference in perceived coordination between control and intervention groups. Future studies should explore strategies like patient incentives to increase response rate and improve the evaluation of this innovative health care model.

Introduction

Health care systems increasingly use digital technology to improve quality of health care services across a spectrum of medical issues including critical conditions like cancer [1]. Notably, over the past 2 decades, there has been a growing deployment of telemedicine technologies, making a transformative shift in how health care is delivered and experienced [2].

XSL•FO
RenderX

Patients with cancer have distinctive medical requirements, including both cancer therapy and treatment of concurrent health conditions [3]. Addressing these needs involves engaging various specialties and health professionals, using specialized telemedicine care services, and ensuring continuity of care throughout and after cancer treatment. This necessitates a higher level of care coordination [4]. However, both patients and health care providers face challenges in coordinating care and communication patterns, as evidence by logistic issues such as technological problems which hinder effective telemedicine practices [5,6]. To mitigate such challenges, shared care models have been proposed as a promising approach [7]. These models allow patients to benefit from the expertise of specialists, while maintaining the care through the primary care providers. By bringing together the patients, general practitioners (GPs), and oncologist in a shared video consultation, telemedicine offers a powerful solution to improve care coordination. A recent study further supports the benefits of telemedicine as its ability to improve care coordination, and better management patients' health needs through enhanced communication [8]. Therefore, efforts to assist patients with cancer have shifted toward patient-centered communication approaches [6], so that over time, such approaches for these patients are rapidly expanding and diversifying [9]. Based on a previous study, these approaches may have varying impact on patients' outcomes and perceptions [9]. Furthermore, application of such approaches in combination with virtual consultations may have diverse effects on outcomes, as they may interact differently with each patient's unique health needs. This aligns with the health care providers' perspective, who advocate patient-centered approaches in cancer care [9]. Despite such widespread advocacy, there is limited consensus on definition and methods to achieve patient-centered care [9].

A previous meta-analysis on cancer care coordination suggests that implementation of cancer-care coordination approaches resulted in positive changes in majority of measured outcomes (eg, overall patients' experience on cancer care, quality of end-of-life care, etc). The study recommended the development of new intervention models and care coordination strategies to enhance patients' self-management [10]. Notably, none of the studies included in this meta-analysis applied a virtual intervention mode [10].

We hypothesized that virtual shared models involving specialists, primary care providers, and patients could more effectively address optimal outcomes for patients with cancer [3]. Hence, this study aims to investigate the effects of a shared video consultation including oncologists, GPs, and patients with cancer on the patients' perceived coordination of care.

Methods

Study Design

This study is a randomized controlled trial entitled "The Partnership Project' (PSP)" [11]. The protocol and details of the study have been published previously [11-13]. This paper now presents the primary outcome based on a 7-month follow-up survey on patients' participation in a shared video-based consultation.

Participants and Setting

All newly diagnosed patients with any type of cancer receiving treatment with chemotherapy for the first time at the Department of Oncology, Lillebælt Hospital, University Hospital of Southern Denmark were invited for the study. The eligibility criteria were age above 18 years, proficiency in speaking and reading Danish, and having an estimation from an oncologist indicating a survival time of more than 7 months.

Multimedia Appendix 1 provides an explanation of the initial sample size that was previously published [14]. Since patient inclusion matched the predetermined sample size, the trial was ended.

Usual Care

The control group was randomized to receive "usual care" in terms of standard information exchanging between the department of oncology and primary care. This involved sending an electronic summary letter to the GP after each visit to the department of oncology. GPs and the hospital can communicate by phone if needed. In addition, patients may reach out to their GP or a designated coordinator at the department of oncology.

Intervention

Patients in the intervention group were randomized to receive a "partnership consultation," which was a shared video consultation involving an oncologist, GP, and patients with cancer, alongside their "usual care." GPs were contacted only after obtaining patients' consent, and the GP had the option to refuse participation. Three to 6 weeks in advance, the sessions were scheduled during regular clinic hours. Patients were given the option to choose either the GPs' office or the oncologist's office for their consultations. In case the patient preferred to sit by the GP, the video consultation took place in that way, with the oncologist alone in his or her office at the hospital. GPs or oncologists may have had more than 1 patient in the intervention group. However, we do not have specific information about the individual oncologist for each patient in our database. The consultations were chaired by an oncologist within 12 weeks from the time of inclusion. Before the consultation, oncologists and GPs received information including a consultation guide with themes that may be relevant (Multimedia Appendix 2). Typically, the oncologist was assisted by an oncology nurse. A summary of the consultation was recorded in the hospital electronic patient record, shared with the GP, and accessible for the patient at an online portal (sundhed) for medical reports in Denmark.

Three to 6 weeks in advance, the sessions were scheduled during regular clinic hours. Patients were given the option to choose either the GPs' office or the oncologist's office for their consultations. In case the patient preferred to sit by the GP, the video consultation took place in that way, with the oncologist alone in his or her office at the hospital.

GPs or oncologists may have had more than 1 patient in the intervention group. However, we do not have specific information about the individual oncologist for each patient in our database.

XSL•FO
RenderX

The consultations were chaired by an oncologist within 12 weeks from the time of inclusion.

Prior to the consultation, oncologists and GPs received information including a consultation guide with themes that may be relevant (Multimedia Appendix 2). Typically, the oncologist was assisted by an oncology nurse.

A summary of the consultation was recorded in the hospital electronic patient record, shared with the GP, and accessible for the patient at an online portal (sundhed.dk) for medical reports in Denmark.

Randomization and Blinding

Following informed consent, patients were assigned in a 1:1 ratio through block randomization, with block sizes and sequences known only to the REDCap (Research Electronic Data Capture; Vanderbilt University) [15] data manager from our collaboration partners. The allocation was transparent for the patients, GPs, and oncologist. However, during baseline data collection, patients in the intervention group and enrolling nurse were kept blind of the randomization.

A project nurse at the research unit in the department of oncology conducted the randomization process and enrolled patients in the study following the patients' consent. Neither patients nor their GPs and oncologists in the intervention group were blinded to the patients' allocation status. Data analysts remained blinded to the allocation. GPs of patients in the control arm were not formally informed until they received the survey.

Primary Outcomes and Instruments

Patients were asked to complete questionnaires at baseline, and after 4 and 7 months. Upon arrival at the department of oncology, patients received information, a consent form, and a paper-based baseline questionnaire, which outpatient nurse collected after enrollment. Follow-up questionnaires were sent electronically using REDCap [15], which securely managed distribution and response collection. However, patients could request paper-based follow-up with prepaid return envelope.

An overview of primary and secondary outcomes can be found in Multimedia Appendix 3. The primary outcome included the single item "global assessment of inter-sectorial cooperation," which was part of the Danish questionnaire "Patients' attitude to the health care service" [14]. The English questionnaire "The patient cancer diary" [16] served as the basis for the 26-item Danish questionnaire. The adaptation was done based on interviews with Danish cancer patients and caregivers [17] and the English questionnaire template [16]. The questionnaire was chosen because it measures the study's aim, patients' perceptions of cross-sector cooperation, and has previously been used in a Danish cancer study [14]. Single items were scored on a 5-point Likert scale from strongly agree (1) to strongly disagree (5). The "not relevant" category was coded as missing.

This questionnaire comprises also 2 other single items and 5 index scales (secondary outcome; Multimedia Appendix 3), examining patients' attitude toward the cooperation in the health care system. There is no manual available for the questionnaire; however, 2 papers have been published that describe the validation and usage of the questionnaire [14,17]. For the 5 subscales, at most 1 missing was replaced by the mean of the other items in the corresponding subscale. A subscale was coded as missing if more than 1 single item in the scale were missing. The direction of the answer scale varied depending on the item. For instance, in the case of the primary outcome, a low score indicated a positive attitude toward the question, while for secondary outcomes (eg, global feeling of left in limbo), a high score indicated a positive attitude. However, for analysis purpose, all items were aligned so that a higher value indicated a positive attitude toward the questions. Primary and secondary outcomes were measured at the following time points: baseline, 4, and 7 months after baseline. Coding was done separately for each time point.

Other Parameters

Demographic data for patients including age, gender, education, marital status, having child, work status, comorbidity, diagnosis or cancer type were assessed through questionnaire which was completed by patients at baseline.

Deviation From the Protocol in Statistical Analyses

As outlined in the published protocol [11], the original statistical analyses plan aimed to conduct a simple group comparison at 7 months using *t* tests or Wilcoxon rank-sum tests. However, a deviation from the initial analysis strategy was decided due to the large amount of missing data associated with the primary variable at 7 months.

Definition of Intervention and Control Groups for Analysis

The main analysis strategy followed the intention-to-treat (ITT) approach, defining groups by random allocation (control and intervention). As a second approach, we defined 2 as-treated grouping approaches. First, we split the intervention group by degree of intervention fidelity: 1 group had the intervention as defined by protocol, the second did not receive the intervention due to technical issues, while the third did not receive the intervention for other reasons. Then, as-treated $group_1$ (AT1) comprised patients completing the video consultations; this group was compared with patients who did not receive the intervention (randomized to control or $subgroup_1$ or $subgroup_2$). As-treated $group_2$ (AT2) comprised patients with planned video consultations, regardless of completion due to technical reasons (AT1 and $subgroup_1$); this group was compared with patients randomized to controls and $subgroup_2$. As-treated groups were defined post hoc. Unless stated explicitly otherwise, we based the group definition on the ITT approach.

Revised Statistical Analysis

As a first step, we compared the change from baseline to 7 months between the 2 groups, as defined by allocation (ITT), through a linear regression model. This model was applied to measurements at both baseline and 7 months, using generalized estimating equations (GEE) to account for within-patient clusters. Robust variance estimation was used, and the group difference was modeled as time-by-group interaction. Similar estimates were presented for both post hoc and defined as-treated approaches. No additional covariates were considered in this primary analysis. The GEE approach was chosen to ensure

XSL•FO
RenderX

robustness of the statistical methods in the presence of missing data. Analyses specified in the protocol were also reported, restricted to complete cases. A corresponding analysis strategy was followed for secondary outcomes. Data analyses was done using Stata version 17 [18], and the significance level was set at 5%.

Ethical Considerations

Statement Regarding Human Subject Research Ethics Review

The Regional Ethics Committee on Biomedical Research in Denmark (S-20142000 - 138) and the Danish Data Protection Agency (2014-41-3534) peer reviewed and approved the study.

Informed Consent Descriptions

At the Oncological Department, Vejle Hospital, Denmark, outpatient clinic nurses obtained informed consent from patients for the PSP. Patients provided consent to participate in the randomized controlled trial, the video recordings, and the user perspective assessments on the same consent form. The consent forms were securely stored at the Clinical Research Unit, Department of Oncology, Vejle Hospital. The unit of randomization was the patient. Therefore, according to Danish law and the instructions of the Regional Ethics Committee on Biomedical Research, consent from GPs was not required. However, out of courtesy and to show consideration for their workload, oral consent was obtained from GPs when their patients were allocated to the intervention group. Before the study's start, written information about the trial was sent to all GPs in the Region of Southern Denmark. If a GP declined to participate, their patients were not invited to join the study.

GPs for patients in the control group were not contacted and were therefore unaware of their patients' participation in the study until they were asked to complete a questionnaire 4 months after the patients' inclusion.

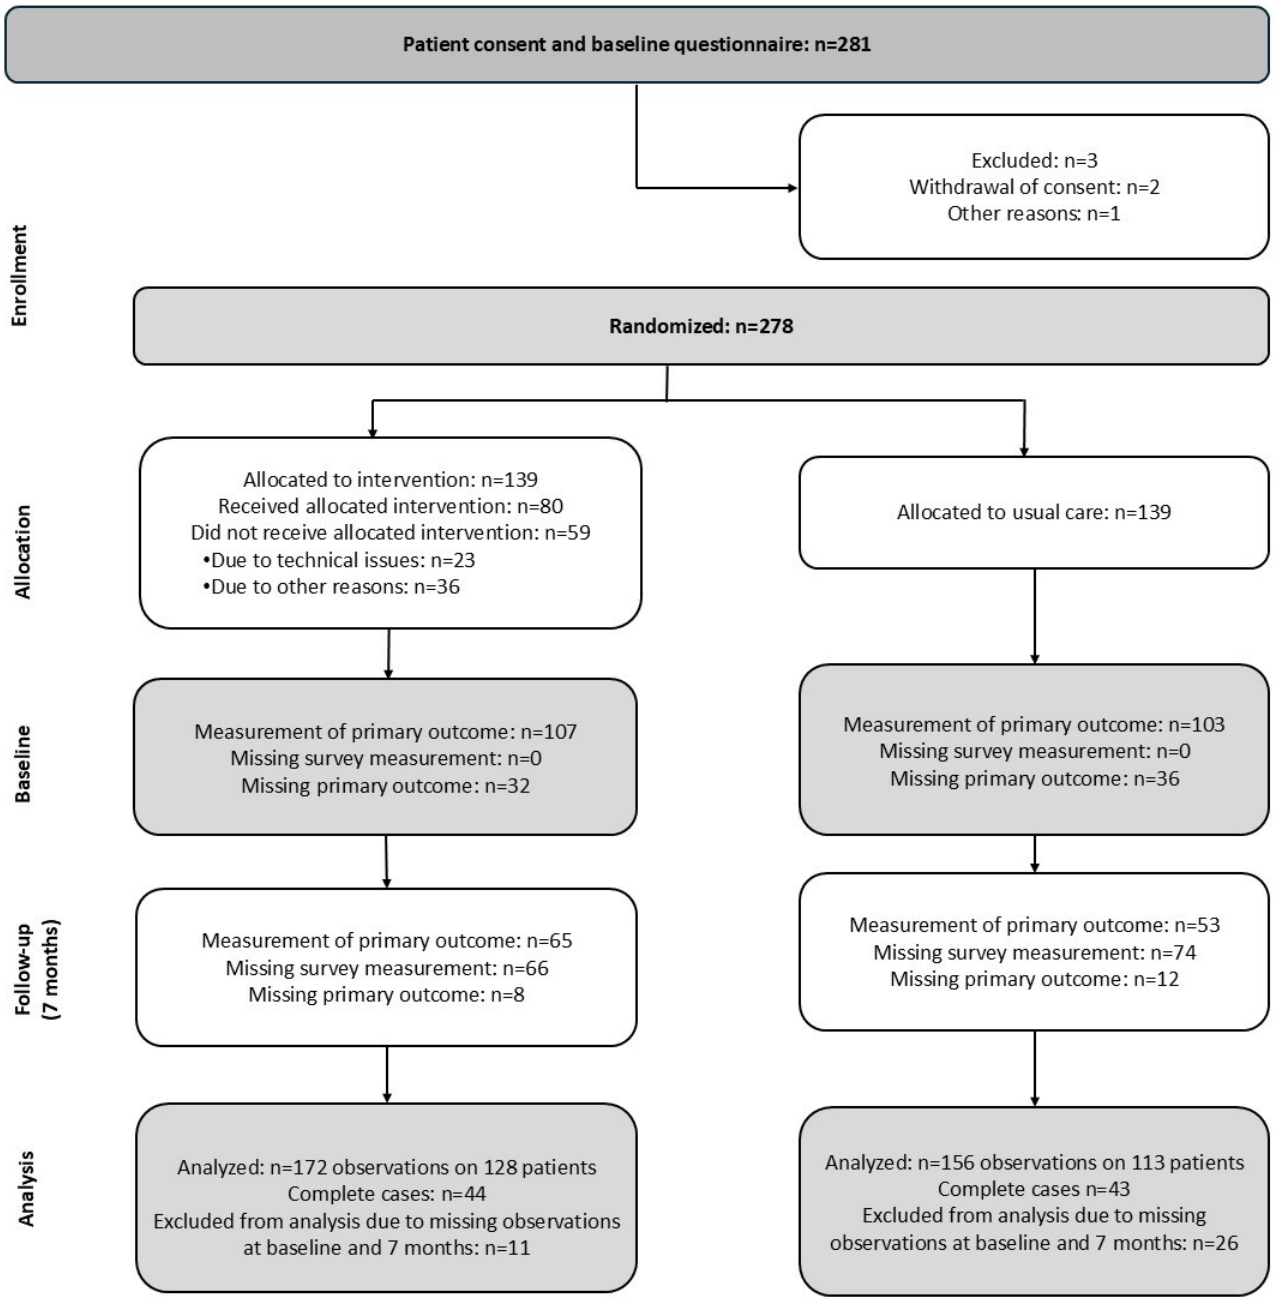
Privacy and Confidentiality Protection Description

Data security in video consultations is essential. Patients demonstrate a high level of trust regarding data security, as they trust the health care staff using the technology. To ensure this trust, all video consultations were conducted on the Region of Southern Denmark's secure videoconference servers using virtual meeting rooms. These servers provide a highly secure connection with no third-party data processing, and meeting rooms could only be accessed by the participating parties. Before a video consultation, patients may have discussed confidential matters, such as alcohol consumption or smoking, which they had not shared with all health care providers. This could place patients in a dilemma. To address this, the intervention guide for oncologists and GPs includes a note to handle such situations sensitively.

Compensation Details

No compensation was provided to patients or oncologists. GPs were reimbursed through the standard payment system of the Region of Southern Denmark for participating in video consultations with a specialist at the hospital. The agreement used existing provisions for cross-sector cooperation and discharge follow-up. GPs received a fee for video consultations based on the time spent: €48 (at the time of the study, the exchange rate was approximately €1=US $1.10; fee number 4670) for up to 30 minutes and €97 (fee number 4669) for consultations exceeding 30 minutes. Therefore, they did not receive any additional payment for participation, nor were they paid by the study for their involvement in the video consultations. Furthermore, GPs were compensated for completing the questionnaires. Payment was provided by the Region of Southern Denmark and corresponded to one module (€18 at the time for the trial), equivalent to the payment for a standard patient consultation in their clinic.

Results



Recruitment and Participant Flow

The patients were included between June 2016 and November 2019. In this study, 281 patients initially agreed to participate. Three patients were excluded due to withdrawal of the consent or other reasons. In total, 278 patients were randomized; 139 patients were allocated to the intervention group and another 139 to the control group. However, due to the following reasons, only 80 patients received the intervention as intended: GP refused participation for 22 patients; in 15 cases, IT failed; and for 8 patients, there were administrative (scheduling) issues. A total of 8 patients died before intervention, 3 patients were too ill, and 3 did not wish to participate in the intervention. See Figure 1 for the CONSORT (Consolidated Standards of Reporting Trials) flow diagram [19] (Checklist 1).

An overview of the GP-patient relationship can be found in Multimedia Appendix 4 to provide additional context.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

Baseline Data

As shown in Table 1, patients in the intervention and control groups had similar baseline characteristics. However, comorbidity was more frequent in the control group (58.3% vs 46.8%) than in the intervention group.

XSL•FO
RenderX

Table . Baseline characteristics of patients in the intervention and control groups.

Characteristics		Total (N=278), n (%)	Control group (n=139), n (%)	Intervention group (n=139), n (%)
Age (years), mean (SD)		65.2 (10.6)	63.8 (11)	66.6 (10)
Sex				
	Male	155 (55.6)	77 (55.4)	78 (56.1)
	Female	123 (44.4)	62 (44.6)	61 (43.9)
Education				
	Primary and upper secondary school	176 (63.3)	85 (61.1)	88 (63.3)
	Further education	76 (27.3)	41 (29.5)	35 (25.2)
	Higher education	16 (5.8)	7 (5)	9 (6.5)
Marital status				
	Single or missing[a]	81 (29.1)	48 (34.5)	33 (23.7)
	Married or residing with a companion	197 (70.9)	91 (65.5)	106 (76.3)
Children living at home				
	No children at home or missing[a]	244 (87.8)	120 (86.3)	124 (89.2)
	Children at home	34 (12.2)	19 (13.7)	15 (10.8)
Work status				
	Employed	89 (32)	46 (33.1)	43 (30.9)
	Public benefits	15 (5.4)	9 (6.5)	6 (4.3)
	Retired or missing[a]	174 (62.6)	84 (60.4)	90 (64.7)
Comorbidity				
	No	132 (47.5)	58 (41.7)	74 (53.2)
	Yes	146 (52.5)	81 (58.3)	65 (46.8)
Diagnosis or cancer type				
	Breast	33 (11.9)	17 (12.2)	16 (11.5)
	Gynecological	13 (4.7)	4 (2.9)	9 (6.5)
	Lung	106 (38.1)	53 (38.1)	53 (38.1)
	Gastrointestinal	110 (39.6)	56 (40.3)	54 (38.8)
	Other	16 (5.8)	9 (6.5)	7 (5)
	Incident cancer (yes or missing[a])	255 (91.7)	126 (90.6)	129 (92.8)

[a]There were less than 3 patients with missing information on marital status, number of children at home or work status, and 6 patients with missing information on incident cancer. These patients were grouped with the indicated categories.

Numbers Analyzed

In Table 2, an overview of the missing data for the primary outcome at different time points in both control and intervention groups is presented. Over time, there was a decline in participation in both the control group (38% at 7 months vs 74% at baseline) and the intervention group (47% at 7 months vs 77% at baseline), based on 278 randomized patients. In the ITT analyses, 172 observations on 128 patients from the intervention group and 156 observations on 113 patients from the control group were included. A total of 11 patients (intervention) and 26 patients (control) were excluded from the analysis due to missing observations at both baseline and 7 months.

A total of 59 participants failed to have the intervention as intended, due to technical problems or other reasons. Based on the subgroup analyses, the subgroup$_1$ had a higher percentage (78.3%) of nonmissing values, which gradually dropped to 39.1%% and 34.8% at the subsequent time points (Table 2). The subgroup$_2$ displayed a comparable pattern of missing data at various time points (83.8%, 35.1%, and 24.3%, respectively).

$Group_2$[f]	139	107 (77)	32 (23)	24	0	77 (55.4)	12 (8.6)	7	50 (36)	65 (46.8)	8 (5.8)	—	66 (47.5)
$Subgroup_1$[g]	23	18 (78.3)	5 (21.7)	—	0	9 (39.1)	3 (13)	—	11 (47.8)	8 (34.8)	<3 (8.7)	—	13 (56.5)
$Subgroup_2$[h]	36	31 (83.8)	6 (16.2)	—	0	13 (35.1)	2 (5.4)	—	22 (59.5)	9 (24.3)	<3	—	27 (73)

[a]Data missing: the primary variable was absent, while other sections might have been answered.

[b]Not relevant: the primary variable was answered as “not relevant”; this is part of the data missing category.

[c]Missing survey: the entire questionnaire was missing for a specific time point.

[d]$Group_1$: randomized as control.

[e]Not applicable.

[f]$Group_2$: randomized as intervention.

[g]Intervention group was divided into the following subgroups based on reasons for not receiving the intervention. $Subgroup_1$: not received intervention due to technical problems.

[h]$Subgroup_2$: not received intervention due to other problems.

Outcomes and Estimations

Table 3 shows patients’ attitudes toward the cooperation between the primary sector and the department of oncology. The estimated within-group changes in the primary outcome between baseline and follow-up were −0.13 (95% CI –0.38 to 0.12) in the control group and 0.11 (95% CI −0.11 to 0.34) in the intervention group. The between-group difference was estimated as 0.24 (95% CI −0.09 to 0.58; *P*=.15). This suggest that, based on perceived global coordination, there was no noticeable differences between the ITT groups from the beginning to 7-month follow-up.

[a]ITT: intention-to-treat approach.

[b]C: control.

[c]Not applicable.

[d]I: intervention.

[e]AT: as-treated groups (AT1 and AT2).

[f]LIMBO: global feeling of left in limbo.

[g]FAM-Global: global support from general practitioner.

[h]FAM-Information: information from general practitioner subscale.

[i]FAM-Care: support from general practitioner subscale.

[j]FAM-knowledge: general practitioners' knowledge regarding treatment subscale.

In the context of the AT1 approach (Table 3), comparing patients who received the intervention with those who did not, the estimated within-group change in the primary outcome between baseline and follow-up was −0.10 (95% CI −0.33 to 0.12) in the control group and 0.17 (95% CI −0.08 to 0.42) in the AT1 group. The between-group difference was estimated as 0.27 (95% CI −0.07 to 0.61; *P*=.12).

For the AT2 approach (Table 3), the estimated within-group change in the primary outcome between baseline and follow-up was −0.09 (95% CI −0.33 to 0.14) in the control group and 0.10 (95% CI −0.15 to 0.34) in the AT2 group. The estimated between-group difference was 0.19 (95% CI −0.15 to 0.53) with the corresponding *P*=.27.

The estimated within-group and between-group changes in all secondary outcomes including 2 single items and 5 subscales showed no significant differences between the ITT groups from the beginning to 7-month follow-up (Table 3).

We also conducted the originally specified analyses on the primary outcomes at 7 months only, comparing intervention and control group in the ITT, AT1, and AT2 approach. The findings are presented in Table 4, showing similar *P* values.

Table . Additional analyses on primary outcomes at 7 months.

Discussion

Principal Findings

This study found that the addition of a cross-sectoral video consultation to usual care did not significantly impact patients' perceived coordination of care. Both intervention and control groups showed high levels of perceived coordination at both time points, with no statistically significant differences over time or between the groups.

Comparison With Previous Work

Based on our knowledge, video consultation has been used for patients with cancer for many years [20]. A recently published systematic review showed virtual consultation over time has been developed and improved in many ways (eg, delivery platforms and stakeholder engagement) [21]. Despite this improvement, comparing our findings was challenging due to the lack of studies on patients' attitudes toward care coordination in multidisciplinary video consultations, which involve patients with cancer, oncologists, and GPs simultaneously.

A newly released scoping review revealed that specialist collaborations with GPs and patients can increase the effective quality of care in the follow-up phase for patients with cancer [22]. This comprehensive review did not report findings on patients' attitudes toward care coordination. Therefore, we believe that in this area, more studies should be initiated to capture a better picture of care coordination from patients' perspective and subsequently enhance the quality-of-care coordination for patients with cancer.

Limitations of the Study

Several limitations should be considered. First, a large percentage of participants in the intervention group did not proceed with the intervention, mostly due to GP refusal to participate, administrative or technical issues. This could affect the generalizability of our findings to the broader population or specific subgroups due to potential selection bias. However, it should be noted that the trial was carried out before the introduction of a standard, clinically available video setup during the COVID-19 pandemic. Since then, the technical aspects of video-based communication in everyday life and health care consultations have improved dramatically [23]. However, challenges related to establishing online meetings, achieving relevant views of all participants, and ensuring efficient sound quality persist. These issues can occasionally make scheduled consultations impracticable [24]. These facts highlight the relevance of the results of "the Partnership Study" and underscore the importance of our learnings for future health care, particularly in adapting the evolving landscape of telemedicine. Second, the low completion rate for video consultation (58%) and high rate of missing data in our study affected the quality of our data, consequently limited our ability to draw definitive conclusion on effectiveness of the intervention. As a result, we focused on addressing challenges encountered. Third, a considerable amount of missing data for the primary outcome at the 7-month time point might impact the statistical power and consequently lead to a lack of significance in our findings. Several factors can be contributed to this issue (eg, the lengthy follow-up period, focus of the process evaluation on the intervention rather than barriers to participants retention, inadequate assessment of the follow-up duration during the pilot test, reliance on survey distribution alone, particularly during COVID-19 pandemic). In addition, it is possible that a ceiling effect influenced the intervention's lack of superiority, as coordination scores were substantially higher, compared with findings from another department [14]. Fourth, the choice of single primary outcome variable that included "not relevant" response option may have constrained the depth of data obtained, because patients who had not experienced collaboration might have selected "not relevant." Fifth, in the as-treated analysis, some patients from the intervention group were combined with patients from the control group, which assumes that the nonreceipt of the intervention was unrelated to individual patients' characteristics. Therefore, our findings should be interpreted with caution. Sixth, the study does not provide insight into why some patients marked the primary outcome as "not relevant." It is possible that these patients had no experience with collaboration at the time of the survey, and this uncertainty limits our understanding of the factors contributing to missing data and how they may influence the study's conclusions. The handling of responses marked as "not relevant" as missing data may not actually capture patients' experiences, that raise concerns about the interpretation of the results (eg, generalizability of findings related to collaboration experiences).

Future Direction

Despite the lack of significant differences on primary and secondary outcomes of care coordination, limitations of our study may have implications for the research community in their future studies. For instance, our findings stress the need for further exploration into structural and engagement factors to strengthen future interventions.

The low completion rate for video consultation may indicate logistical and engagement challenges. Therefore, we encourage researchers in their future similar intervention to implement strategies that enhance patients' engagement and improve data completion rate.

We encountered challenges such as potential power problem in reaching statistical significance. Despite this, we believe it is crucial to delve deeper into these findings and explore underling factors. This could provide valuable insights for development of more effective interventions in future. Findings may also highlight more involvement of patients to address their concerns related to care coordination and consequently enhance their experiences with the health care system. Furthermore, the findings highlight the importance of continually evaluation of health interventions to understand the impacts over time and make timely and necessary improvement, particularly where we have clearly identified specific problems or challenges, like decreased patients' satisfaction.

Conclusion

Our study, conducted before the COVID-19 pandemic, found that the shared video consultation model, involving patients with cancer, oncologists, and GPs, did not result in a statistically

XSL•FO
RenderX

significant difference in patients' perceived coordination of care between the control and intervention groups. We suggest that technical issues impacting the intervention implementation and the potential ceiling effect may have contributed to these results. Therefore, we emphasize the necessity for additional evaluation of the conceptual notion of uniting patients with cancer, oncologists, and GPs, particularly considering the advancements in techniques, the adoption of virtual communication, and the expanding role of GPs in cancer care. Further exploration of specific aspects of care coordination may provide additional insights into areas for improvement in this innovative health care model. This study highlights the complexity of implementing collaborative health care interventions and emphasizes the importance of ongoing evaluation of the intervention to optimize patients' care coordination in cancer management. In addition, future research should focus on evolving trends in virtual communication among professionals and the public, as we think that leveraging post-COVID virtual communications could improve future health care interventions.

Acknowledgments

Financial support was provided by the Danish Cancer Society (R156-A10018-16-S49), the Region of Southern Denmark (14/39009), ML Jørgensen and GunnarHansen Foundation, and the University of Southern Denmark. The sponsors played no role in the planning, design, or implementation of the study. ChatGPT (version 3.5, OpenAI) was used to edit the first draft of the manuscript. However, the next versions were edited and revised by the authors.

Authors' Contributions

TBT and LHJ conceived the study, participated in study design and data collection, and revised the manuscript. JS, JJS, and DGH conceived the study, participated in study design, and revised the manuscript critically. MMS and SW analyzed the data, participated in the interpretation of the results, and revised the manuscript. FB made substantial contributions to the interpretation of the results and wrote the manuscript. All authors commented on and approved the final version of the paper.

Abstract

Background: Radiotherapy (RT) is a crucial modality in cancer treatment. In recent years, the rise of short-form video platforms has transformed how the public accesses medical information. TikTok and Bilibili, as leading short-video platforms, have emerged as significant channels for disseminating health information. However, there is an urgent need to evaluate the quality and reliability of the information related to RT available on these platforms.

Objective: This study aims to systematically assess the information quality and reliability of RT-related short-form videos on TikTok and Bilibili platforms using the Global Quality Score (GQS) and a modified DISCERN (mDISCERN) evaluation tool, thereby elucidating the current landscape and challenges of digital health communication.

Methods: This study systematically retrieved the top 100 RT-related videos on TikTok and Bilibili as of February 25, 2025. The quality of the videos was assessed using the GQS (1 - 5 points) and an mDISCERN scoring system (1 - 5 points). Statistical analyses were conducted using the Mann-Whitney *U* test, as well as Spearman and Pearson correlation analyses, to ensure the reliability and validity of the results.

Results: A total of 200 short-form videos related to RT were analyzed, revealing that the overall quality of videos on TikTok and Bilibili is unsatisfactory. Specifically, the median GQS for TikTok was 4 (IQR 3 - 4), while for Bilibili, it was 3 (IQR 3 - 4). The median mDISCERN scores for both platforms were 3 (IQR 2 - 4 and 3 - 4, respectively), and no significant differences were observed between the 2 platforms regarding the GQS (P=.12) and mDISCERN score (P=.10). On TikTok, 53% (53/100) of videos had a GQS of 4 or higher ("good" quality or better). On Bilibili, 45% (45/100) of videos had an mDISCERN score of 4 or higher, indicating "relatively reliable" quality. Videos produced by professionals, institutions, and nonprofessional institutions had significantly higher mDISCERN scores than those made by patients, with statistical significance (P<.001, P<.001, and P<.01, respectively). Furthermore, the correlations between the number of bookmarks and video duration, with mDISCERN scores, were 0.172 (P=.02) and 0.192 (P=.007), respectively. However, no video variables were found to predict the overall quality and reliability of the videos effectively.

Conclusions: This study revealed that the overall quality of RT-related videos on TikTok and Bilibili is generally low. However, videos uploaded by professionals demonstrate higher information quality and reliability, providing valuable support for patients seeking guidance on health care management and treatment options for cancers. Therefore, improving the quality and reliability of video content, particularly that produced by patients, is crucial for ensuring that the public has access to accurate medical information.

(JMIR Cancer 2025;11:e73455) doi:10.2196/73455

KEYWORDS

radiotherapy; RT; short-form videos; information quality; social media; Global Quality Score; DISCERN score; TikTok; Bilibili

Introduction

Radiotherapy (RT) plays a crucial role in cancer treatment. It uses high-energy radiation to directly target tumor cells, causing DNA damage that inhibits tumor growth and spread. In recent years, advancements in technology have significantly enhanced the precision and effectiveness of RT, making it a vital treatment option for many patients with cancer [1,2]. Modern RT techniques, such as stereotactic radiosurgery and intensity-modulated radiation therapy, enable precise tumor localization while minimizing damage to surrounding healthy tissue. These techniques use computer-assisted treatment planning to ensure optimal radiation dose distribution [3-5]. Additionally, RT can activate the body's immune response,

XSL•FO
RenderX

enhancing the immune system's ability to recognize and attack tumor cells. This not only improves treatment outcomes but also reduces side effects and enhances patients' quality of life [6-9].

As the number of patients with cancer continues to rise each year, cancer treatment regimens, particularly RT, exhibit promising future characteristics [10,11]. As a primary means of obtaining medical information, particularly regarding treatment in the field of cancer, in today's fast-paced society, it is crucial to ensure the quality of videos on short-video platforms. Our research aims to assess the quality of videos providing information related to RT on platforms such as TikTok and Bilibili [12]. As cancer subtypes continue to be explored, treatment modalities have become increasingly diversified [13]. RT, as a core method for cancer treatment, has seen significant advancements globally [1]. With ongoing innovations in the precision and personalization of RT techniques, public awareness of this treatment has also grown [14,15]. China has experienced rapid advancements in the research and application of RT, with a robust body of work emerging in recent years [16]. The integration of technological innovations with clinical practice has continuously enhanced the precision and effectiveness of cancer treatments [17]. The dissemination, promotion, and popularization of RT techniques are crucial for the diagnosis and treatment of various cancers [18].

Despite a marked transition toward electronic health formats, significant disparities in eHealth literacy persist across various populations. These disparities hinder access to health information and services for specific individuals, underscoring the need for targeted interventions to enhance digital competencies and ensure equitable access to eHealth resources [19-21]. People increasingly acquire medical knowledge through web-based channels, including short-video platforms, search engines, and artificial intelligence. To enhance academic rigor, this study focuses on China's most popular short-video platforms, TikTok and Bilibili. Some global short-video platforms, such as YouTube and Instagram Reels, have a level of video quality and reliability that is as unsatisfactory as that of TikTok and Bilibili [22,23]. As a leading global short-video–hosting platform, TikTok boasts a substantial user base across more than 150 countries, with more than 1.026 billion monthly active users in the Chinese market alone. Meanwhile, Bilibili has also experienced significant user growth due to its unique interactive features and rich content [24-26]. Since the advent of 5G technology, the development of social media platforms has accelerated, establishing them as emerging channels for the dissemination of health information [27]. Research indicates that more than 10 million users engage with health and wellness content on short-video platforms, covering various medical fields, including liver cancer, thyroid cancer, gastric cancer, pancreatic neuroendocrine tumors, and other medical fields [26,28-37]. However, discussions surrounding RT remain scarce in the general population, and the quality of information is often inconsistent. Inaccurate information about RT increases the risk of patients with cancer making misleading decisions based on unreliable sources, making it essential to assess the quality of RT-related videos on social media. To our knowledge, no prior studies have systematically assessed the quality of RT-related content on short-form video platforms, highlighting a significant gap that our research aims to address.

To systematically evaluate the quality and reliability of RT-related short videos, this study recorded and organized the top 100 RT-related videos on TikTok and Bilibili. We used the Global Quality Score (GQS) for quality assessment and the modified DISCERN (mDISCERN) tool for reliability evaluation. Additionally, we analyzed the relationships between video quality and various factors, including video source, content, the number of followers of the uploader, video duration, and interaction metrics (likes, comments, shares, and bookmarks). Our research aimed to evaluate the information quality and reliability of short RT videos on Bilibili and TikTok.

Methods

Ethical Considerations

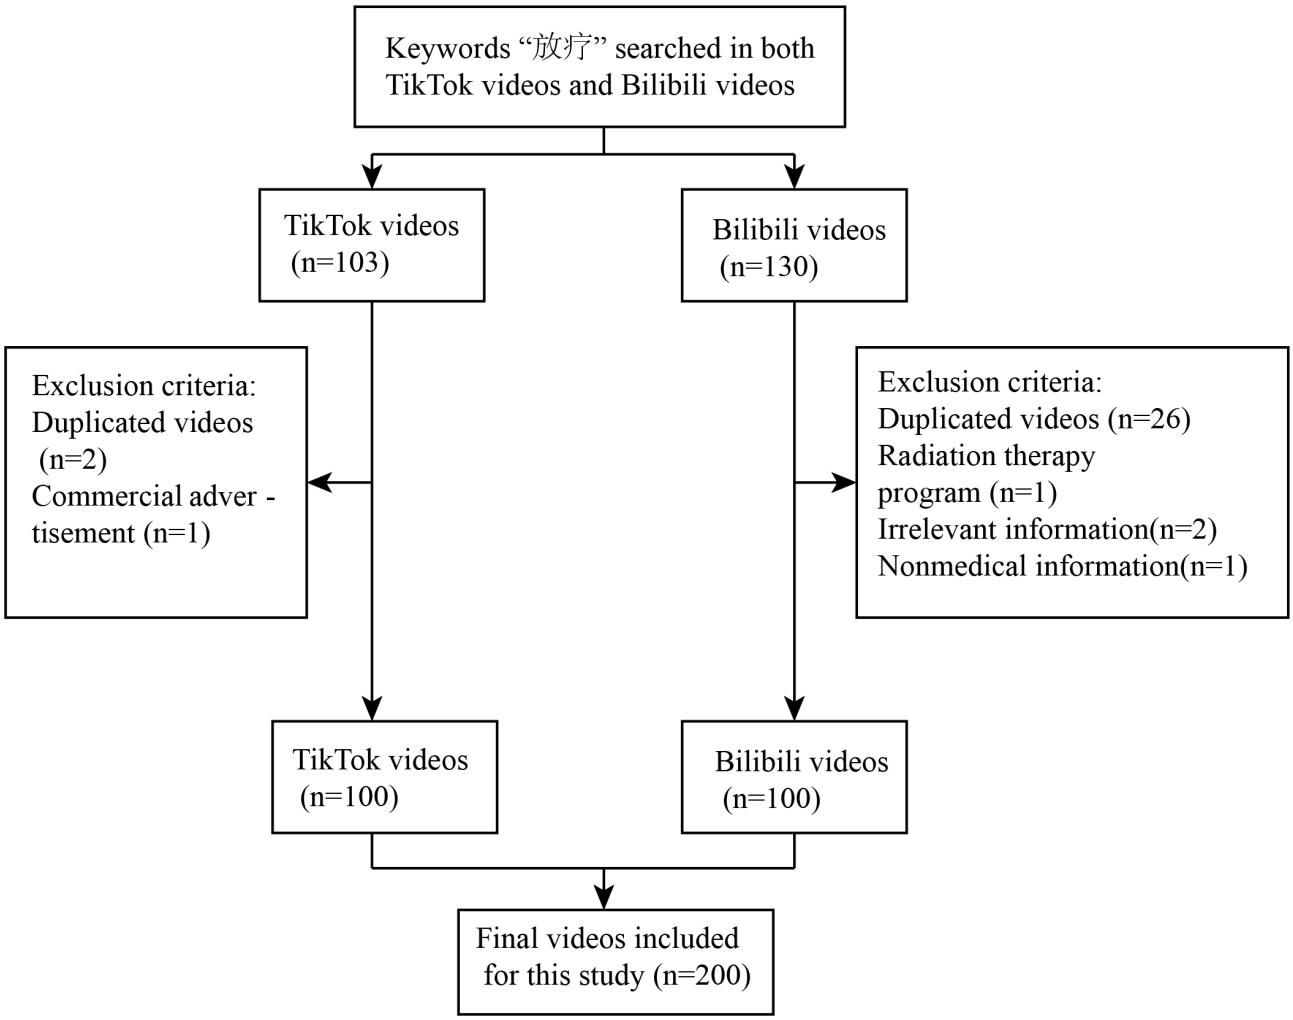
This study involved the analysis of publicly available short-video data from TikTok and Bilibili, which are accessible to the general public. No personal identifying information was collected, and no interaction with individuals occurred; all privacy concerning participants has been preserved. According to the standards proposed by Eysenbach and Till [38], researchers may conduct research in public places or use publicly available information about individuals without obtaining consent. According to the Declaration of Helsinki, this type of research, which uses open-source, publicly available data, does not require ethical approval. Therefore, ethical review was not deemed necessary.

Eligibility Criteria and Information Sources

Videos included in the study must be relevant to RT treatment. The professionals and institutions possess official influencer verification on short-video platforms, indicating that their credentials have been reviewed by the platforms. The content was sourced from 2 prominent Chinese short-form video platforms: TikTok and Bilibili, which are representative of the majority of short-video platforms in China.

Search Strategy and Data Collection

In this cross-sectional study, we conducted a comprehensive search for videos related to RT on 2 prominent Chinese short-form video platforms: TikTok [39] and Bilibili [40], using "radiotherapy" as the primary keyword. The search was conducted on February 25, 2025, and the top 100 videos from each platform were selected based on a composite ranking score [26,41]. This score was derived from a combination of video completion rate (proportion of viewers who watched beyond 5 seconds), like rate (proportion of viewers who liked the video), comment rate (proportion of viewers who commented on the video), follow rate (proportion of viewers who followed the uploader), and upload time. Default settings were applied, including no restrictions on upload duration, video length, or search scope, to minimize selection bias.



To mitigate the influence of personalized recommendation algorithms, 2 independent viewers uninstalled and reinstalled the applications on their devices, using a clone app to create isolated environments. New accounts were registered and logged

XSL•FO
RenderX

in for each platform, ensuring a fresh start for video recommendations. We acknowledge that while this approach may not eliminate personalization, it represents the maximum extent to which patients seeking RT assistance on short-video platforms can be accommodated. Nonmedical videos, duplicates (videos with identical content but different uploaders), videos unrelated to RT, professional RT course videos, and commercial advertisements were systematically excluded until the top 100 videos were identified (Figure 1). Our study limits the number of short videos analyzed on each platform to the top 100, as previous research has demonstrated that videos ranked beyond the top 100 receive very few views, thus having a minimal impact on the study's findings. [26,32,41-45].

The study recorded essential video metadata, including the uploader's username, identity verification status, follower count, and video metrics, such as likes, comments, saves, shares, and duration. Additionally, video content, source, days since upload, presence of background music, and subtitles were documented.

Figure 1. Search strategy and video screening procedure on radiotherapy.

Selection Process

Each video was independently reviewed and assessed by the 2 reviewers (FH and YZ). In cases of disagreement, a third viewer was consulted to reach a consensus (XR). All reviewers are radiation oncologists.

Classification and Assessments of Videos

This study collected and analyzed 100 videos each from Bilibili and TikTok. Each video was meticulously categorized based on its source and content, resulting in four distinct groups for each classification. The source categories included (1) professionals, (2) professional organizations, (3) patients, and (4) nonprofessional institutions. The content categories were (1) personal experiences with RT, (2) educational content on RT, (3) discussions of special cases, and (4) information on RT equipment. Videos from professionals were further classified into (1) radiation oncologists and (2) oncologists. Nonprofessional institutions included (1) science communicators (popular science) and (2) nonprofit or entertainment organizations. Professional organizations referred to official hospital sources or physicians who did not specialize in oncology or RT.

Before evaluating the videos, 2 independent researchers (FH and YZ) reviewed relevant RT guidelines, the GQS, and the mDISCERN tool. The GQS is a widely recognized instrument consisting of 5 criteria, with GQS ranging from 1 to 5, where higher scores indicate better quality of health information videos. The mDISCERN tool was initially developed by Charnock et al [46] to assess written health information and later adapted by Singh et al [47]. Given the medical video context, a modified

XSL•FO
RenderX

version of the mDISCERN tool was used to assess the reliability of the content, better aligning it with the specific context of web-based video content. During the review process, researchers evaluated whether each video met the following criteria: clarity, reliable information sources, robustness and fairness, additional references, and statements of uncertainty. Responses to these criteria were recorded as either “yes” (1 point) or “no” (0 points), and a cumulative score (0 - 5 points) was calculated, with higher scores indicating greater reliability of the health information presented (Table 1). We conducted a sensitivity analysis by creating a composite index based on GQS and mDISCERN scores with different weights. Under these 2 scoring tools, if the scores of the 2 reviewers are consistent, that score shall be adopted; if not, a third reviewer will review them.

Table . Description of the Global Quality Score (5-point scale) and the modified DISCERN for evaluating the quality and reliability of videos with Radiotherapy information.

Cumulative Scale	Level	Interpretative descriptor
Global Quality Score		
1	Poor quality	Specifically, the content is illogical, the narrative flow is poor, and most of the information is missing, making it useless for patients.
2	Generally poor quality	The content logic is poor, although some information is listed, more critical information is still missing, and the use of patients is minimal.
3	Moderate quality	Some vital information is adequately discussed.
4	Good quality and flow	Specifically, the video logic is clear and smooth, covering most of the relevant information, which is helpful for patients.
5	Excellent quality and flow	Specifically, the video logic is clear, and the content is very smooth, which is very useful for patients.
Modified DISCERN		
1	Unreliable	Is the video clear, concise, and easy to understand?
2	Less reliable	Are valid sources cited?
3	Fairly reliable	Was the content presented balanced and unbiased?
4	Relatively reliable	Are additional sources of content listed for patient reference?
5	Reliable	Are areas of uncertainty mentioned?

Statistical Analyses

After conducting a normality test on the data, we determined that it followed a nonparametric distribution. Therefore, descriptive statistics are presented as median (IQR). The Mann-Whitney *U* test was used to assess differences between groups, while Dunn’s Multiple Comparison Test was used for pairwise comparisons. The κ coefficient was calculated to quantify the agreement between the 2 raters. Spearman and Pearson correlation analyses were performed to evaluate the relationships between quantitative variables. A Poisson regression model was used to assess the impact of video variables on predicting video quality and reliability. Statistical significance was defined as a *P* value of <.05. Data analysis and visualization were conducted using R software (version 4.4.1; the R language was developed and is maintained by the R Core Team, and the software is primarily distributed through the Comprehensive R Archive Network) and the Hiplot platform.

Results

Video Characteristics

Based on our keyword search, we identified 200 videos for data extraction and analysis, consisting of 100 from TikTok and 100 from Bilibili. The general characteristics of the videos are illustrated in Table 2. This study used the Mann-Whitney *U* test to compare the video characteristics and associated ratings between the Bilibili and TikTok platforms. The results indicated that TikTok significantly outperformed Bilibili in terms of likes median (1129.50 vs 184.00, $Z=-5.09$ $P<.001$), comments (190.00 vs 23.50, $Z=-5.21$; $P<.001$), saves (281.00 vs 60.50, $Z=-4.27$; $P<.001$), and shares (139.00 vs 28.50, $Z=-4.66$; $P<.001$). Additionally, TikTok had a significantly higher follower count (26,500 vs 6,645, $Z=-3.93$; $P<.001$) than Bilibili.

XSL•FO
RenderX

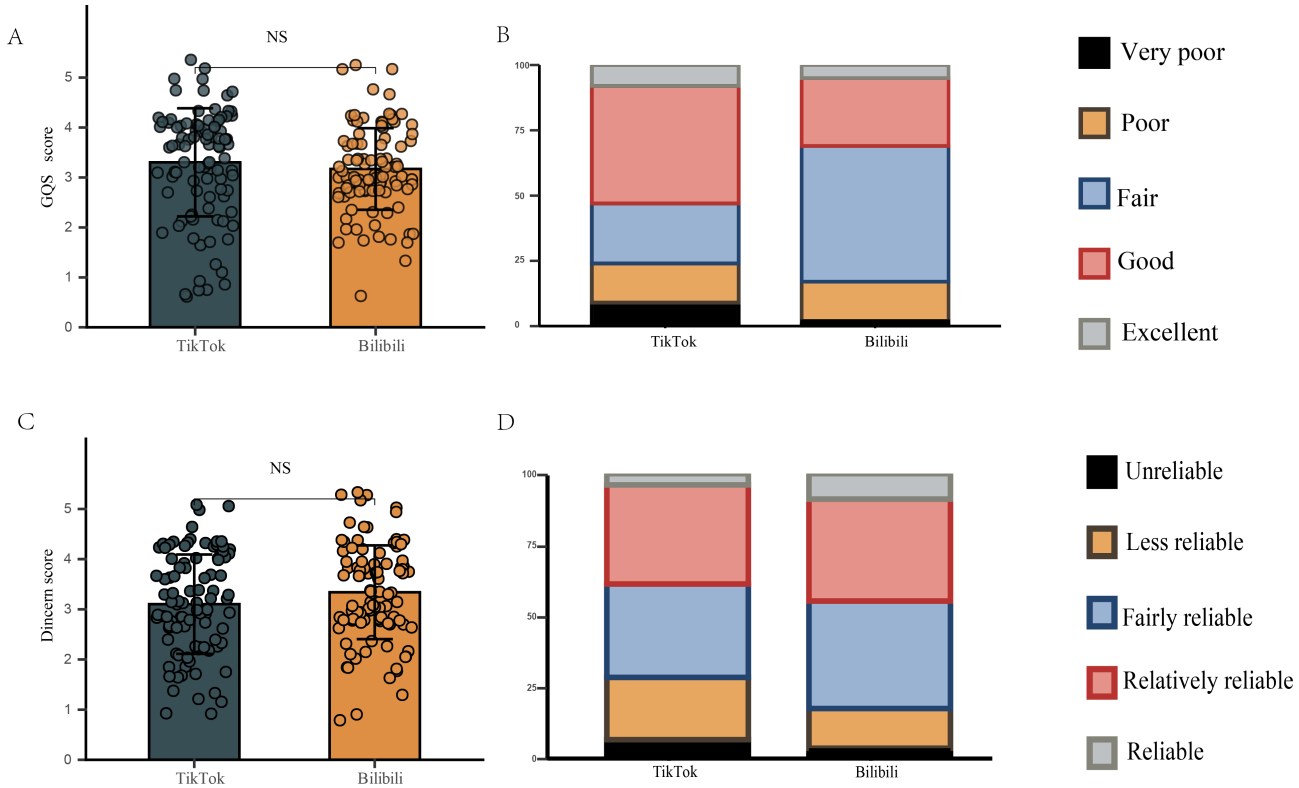
Table . Characteristics of videos on TikTok and Bilibili.

Variable	Bilibili (n=100), median (IQR)	TikTok (n=100), median (IQR)	Mann-Whitney *U* test	*P* value
Likes	184.00 (43.00-97.50)	1129.50 (300.25-3320.25)	*Z*=−5.09	<.001
Comments	23.50 (2.75-107.00)	190.00 (38.00-528.50)	*Z*=−5.21	<.001
Saves	60.50 (13.50-229.75)	281.00 (62.00-936.50)	*Z*=−4.27	<.001
Shares	28.50 (5.00-92.75)	139.00 (21.75-628.25)	*Z*=−4.66	<.001
Fans	6645.00 (307.50-32,250.00)	26,500.00 (7450.75-117,000.00)	*Z*=−3.93	<.001
Days since upload	604.00 (247.75-1030.00)	70.50 (23.50-126.25)	*Z*=−9.89	<.001
Duration	173.50 (95.75-303.25)	71.50 (39.75-129.25)	*Z*=−6.79	<.001
Global Quality Score	3.00 (3.00-4.00)	4.00 (3.00-4.00)	*Z*=−1.57	.12
M score	3.00 (3.00-4.00)	3.00 (2.00-4.00)	*Z*=−1.66	.10

Although Bilibili demonstrated greater activity in terms of days since video upload (604 vs 70.50, *Z*=−9.89; *P*<.001) and video duration (173.50 vs 71.50, *Z*=−6.79; *P*<.001), no significant differences were observed between the 2 platforms regarding the GQS (*Z*=−1.57; *P*=.12) and mDISCERN score (*Z*=−1.66; *P*=.10).

Multimedia Appendices 1 and 2, along with Multimedia Appendix 3, illustrate the sources and content types of videos on TikTok and Bilibili. On TikTok, patients with cancer were the most prolific uploaders, contributing 43% (43/100) of the videos, followed by radiation oncologists (24/100, 24%) and medical oncologists (17/100, 17%). Science communicators exhibited the highest levels of user engagement, with a median of 5048 likes (IQR 3,157 - 79,500), 393 comments (IQR 160.5 - 5005.5), and 1028 saves (IQR 621 - 17,500). In terms of content, the majority of TikTok videos focused on sharing personal experiences with RT (51/100, 51%), followed by educational content on RT (33/100, 33%), discussions of special cases (11/100, 11%), and information on RT equipment (5/100, 5%). On Bilibili, patients with cancer also represented the largest group of uploaders, accounting for 27% (27/100) of the videos, followed by other medical professionals or official hospital accounts (22/100, 22%). Science communicators again demonstrated the highest levels of user engagement. Regarding content, educational videos on RT were the most prevalent, comprising 48% (48/100) of the total.

Video Quality and Reliability Assessments



In this study, we evaluated the consistency between the GQS and the mDISCERN score using Cohen κ coefficient for analysis. The results showed that the κ coefficient for GQS was 0.64 and the κ coefficient for the mDISCERN score was 0.68, demonstrating substantial agreement. We conducted a comparative analysis of the GQS and mDISCERN scores for videos on the Bilibili and TikTok platforms. Table 3 and Figure 2A and B revealed that on the Bilibili platform, 31% (31/100) of users rated videos as “good” (4 points) or higher, compared with 53% (53/100) on TikTok. In terms of mDISCERN scores, Table 3 and Figure 2C and Figure 2D revealed that 45% (45/100) of videos on Bilibili received ratings of “relatively reliable” or higher (4 and 5 points), while TikTok had a score of 39% (39/100). Although there were differences (Figure 1), no significant differences were observed between the GQS and mDISCERN scores of TikTok and Bilibili videos (*P*=.12 and *P*=.10, respectively). Multimedia Appendix 4 indicates that the composite index (GQS and mDISCERN weighted differently) for TikTok ranges from 3.109 to 3.261, while for Bilibili, it spans from 3.187 to 3.323.

Table . Global Quality Score and modified DISCERN scores for TikTok and Bilibili videos related to radiotherapy.

Scale, score	Bilibili (n=100)	TikTok (n=100)	Comparative trend
Global Quality Score			
1 (Poor Quality)	2	9	TikTok
2 (Generally Poor Quality)	15	15	Stable
3 (Moderate Quality)	52	23	Bilibili
4 (Good Quality and Flow)	26	45	TikTok
5 (Excellent Quality and Flow)	5	8	Close
Modified DISCERN			
1 (Unreliable)	3	6	TikTok
2 (Less Reliable)	14	22	TikTok
3 (Fairly Reliable)	38	33	Close
4 (Relatively Reliable)	36	35	Stable
5 (Reliable)	9	4	Bilibili

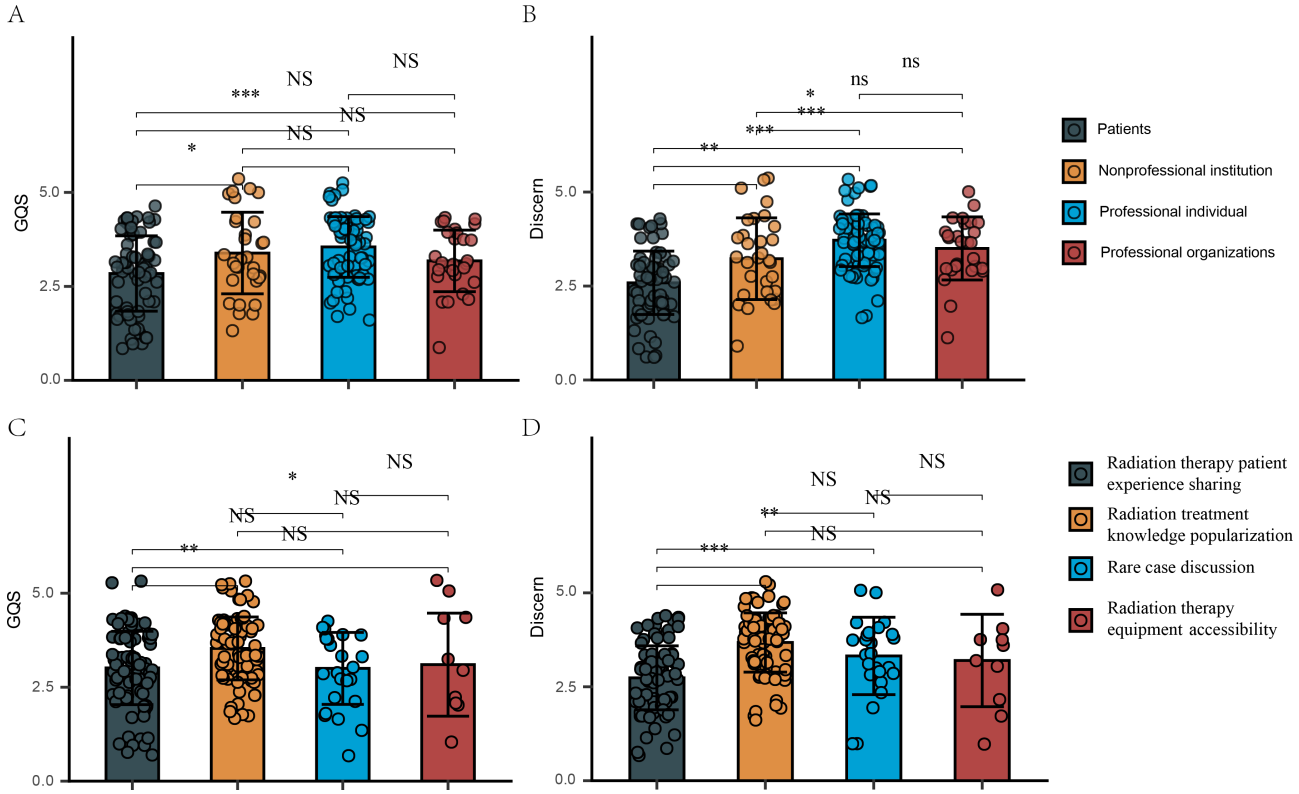

Figure 2. Global Quality Scores, modified DISCERN scores, and quality or reliability distributions of short videos related to radiotherapy on TikTok and Bilibili. (**A**) Comparison of GQS between TikTok and Bilibili videos. (**B**) Proportions of different levels of video quality. (**C**) Comparison of modified DISCERN scores between TikTok and Bilibili videos. (**D**) Proportions of different levels of video reliability. GQS: Global Quality Score; NS: not significant at $P<.05$.

We compared the GQS and mDISCERN scores of videos from different sources and with varying content in Figure 3. Figure 3A revealed that the GQS for professionals and nonprofessional institutions was higher than that for patients ($P<.01$ and $P<.05$, respectively). Additionally, Figure 3C revealed that the GQS for videos focused on sharing radiation therapy experiences and special case discussions was lower than that for radiation treatment knowledge popularization ($P<.01$ and $P<.05$, respectively).

XSL•FO
RenderX

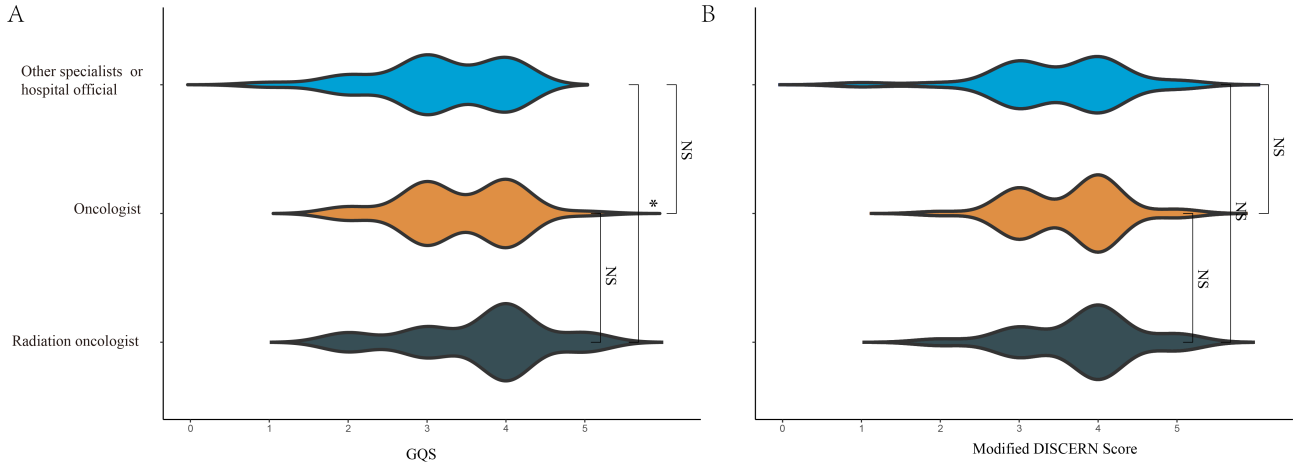

Figure 3. (**A**) GQS from different sources of videos related to radiotherapy (RT). (B) Modified DISCERN scores from different sources of videos related to RT. (C) GQS with different contents of videos related to RT. (**D**) Modified DISCERN scores with different contents of videos related to RT. *P<.05, **P<.01, ***P<.0001. GQS: Global Quality Score; NS: not significant.

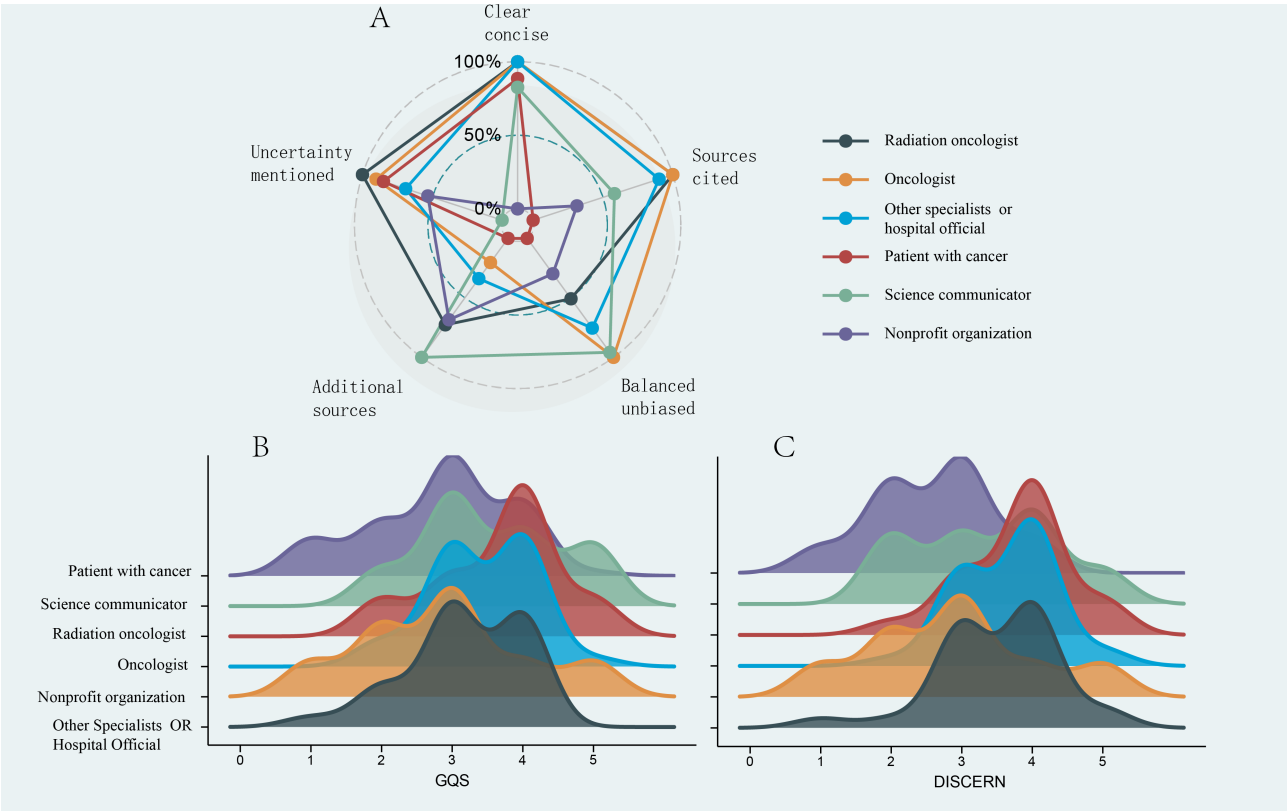
Similarly, Figure 3B revealed that the mDISCERN scores for videos from professionals, organizations, and nonprofessional institutions were higher than those for patients (P<.001, P<.001, and P<.01, respectively), with professionals scoring higher than nonprofessional institutions (P<.05). Furthermore, Figure 3D revealed that the mDISCERN scores for radiation treatment knowledge popularization and special case discussions were higher than those for radiation therapy experience sharing (P<.01and P<.01, respectively).

To further explore whether different types of professionals and institutions affect the quality and reliability of videos, we further categorized the sources into 3 groups: radiation oncologists, medical oncologists, and other physicians or official hospital sources. Figure 4A revealed that the GQSs for videos from radiation oncologists were higher than those from other physicians or official hospital sources (P<.05). However, no significant differences were found among the other source groups (Figure 4B).

Figure 4. Global Quality Scores (A) and modified DISCERN scores (B) of short videos related to radiotherapy uploaded by different professional individuals. *P<.05. GQS: Global Quality Score; NS: not significant.



Next, we compared the content comprehensiveness of different video sources using GQS and mDISCERN scores. As shown in Figure 5A, we evaluated the performance of various video sources across multiple dimensions of content comprehensiveness. Key findings include that all video sources consistently scored low on the uncertainty explanation dimension. Figure 5B and Figure 5C revealed that the radiation oncologists generally achieved higher scores than other sources,

XSL•FO
RenderX

particularly in terms of video quality and reliability. Patients with cancer and nonprofit organizations exhibited lower scores than other sources. Other physicians or official hospital sources displayed moderate performance.

Figure 5. (**A**) Relative strength and balance of mDISCERN scores across different dimensions. (**B**) Overall distribution of Global Quality Scores across different sources. (**C**) Overall distribution of modified DISCERN scores across different sources. GQS: Global Quality Score.

The GQS and mDISCERN ridge plots indicate that none of the video sources achieved perfect scores, highlighting significant shortcomings in the quality and reliability of radiation therapy videos on short-form platforms. This underscores the need for greater attention from professional doctors and experts to improve the quality and reliability of radiation therapy short videos.

Correlation Analysis and Poisson Regression Analysis

Due to the nonnormal distribution of the data, Spearman correlation analysis was conducted to explore the relationships between different video variables. Table 4 and Figure 6 indicated a robust positive correlation between likes and comments (r=0.899; P<.01). Additionally, likes showed significant positive correlations with saves (r=0.880; P<.01) and shares (r=0.763; P<.01). Comments also had a strong positive correlation with saves (r=0.793; P<.01) and shares (r=0.702; P<.01). Notably, days since upload was negatively correlated with likes (r=−0.161; P=.02) and comments (r=−0.203; P<.01). There was a positive correlation between duration and days since upload (r=0.433; P<.01). Furthermore, fans showed significant positive correlations with all interaction metrics: likes (r=0.615; P<.01), comments (r=0.508; P<.01), saves (r=0.495; P<.01), and shares (r=0.442; P<.01).

Figure 6. The correlation analysis of relationships between different video variables.

Using Pearson correlation analysis, the relationships between video features and GQS and mDISCERN scores were examined. The results showed that saves and duration had correlations with mDISCERN scores of 0.172 (P=.02) and 0.192 (P=.007), respectively. However, none of the indicators reached significant levels, as indicated by GQSs (Table 5). Additionally, Table 6 revealed that no significant video variables could predict GQS and mDISCERN scores (all P>.05).

Discussion

Principal Findings

This study systematically reviewed RT-related videos on 2 of the most popular short-form video platforms in China, TikTok and Bilibili, encompassing more than 200 video samples. Overall, the quality of short videos related to RT on both TikTok and Bilibili was found to be unsatisfactory. Although no significant statistical differences in video quality were observed between the 2 platforms (GQS, $Z=-1.57$, $P=.12$; mDISCERN, $Z=-1.66$, $P=.10$), videos produced by professionals or institutions emphasized the dissemination of RT knowledge and techniques, demonstrating higher quality and reliability.

In the field of health care short-video research, various methodologies, inclusion criteria, video variables, sources, and content types are crucial for a comprehensive understanding of the quality and reliability of medical information [48-50]. Some studies share significant similarities with our work, using GQS and mDISCERN tools to assess video quality and reliability, with a focus on platforms such as Douyin and Bilibili, and categorizing video sources into professionals, professional organizations, patients, and nonprofessional institutions [26,32,51,52]. This reflects methodological homogeneity. However, our study introduces methodological innovations by distinguishing between different types of professionals (eg, radiation oncologists and medical oncologists), providing a more nuanced analytical perspective. Notably, most studies have found that videos uploaded by professionals have significantly higher quality than those uploaded by patients, a finding consistent with research on the dissemination of medical information.

Additionally, our study used Poisson regression analysis, indicating that video interaction metrics do not directly predict quality and reliability scores. It must be acknowledged that although some of the Poisson regression models have statistically significant *P* values, the correlations are very weak. For instance, the correlation between the number of saves and duration in the mDISCERN score is only 0.172 and 0.192, which accounts for only a small portion of the variability in the reliability score. Methodologically rigorous, our research ensured data purity through strict retrieval strategies and the removal of duplicate content.

Quality of the Short Videos on RT

However, the characteristics of short-video formats limit the breadth and depth of content. The brief duration and singular presentation style often prevent viewers from gaining a comprehensive understanding, particularly in educational videos where complex topics such as RT may not be adequately explained within a short time frame. Although we have not directly proven this, we believe that video length may correlate with viewers' understanding of RT. Previous studies on medical short videos have demonstrated this [53]. Engagement metrics such as likes, comments, and shares are crucial for increasing the visibility of videos on social media platforms. Studies show that higher engagement can lead to improved algorithmic promotion and rankings by platforms, thereby amplifying the reach of the content [54]. However, many qualified physicians do not receive as much engagement as videos uploaded by patients with cancer or entertainment influencers. The prevalence of patients sharing medical videos on RT may lead to a decline in content quality, resulting in partial and incomplete information. This can easily cause misdiagnosis, negative emotions, and skepticism toward professional doctors, ultimately

XSL•FO
RenderX

leading to delays in treatment and indecision regarding treatment options, which poses serious risks for patients with cancer [55].

The Progress of RT Short Videos

Given the strict professional requirements in the field of RT, we advocate for more video uploaders to seek guidance from qualified RT professionals before disseminating information. In our collected videos, medical professionals certified by TikTok and Bilibili are marked with special indicators, and their credentials can be verified through their respective hospitals' official websites. This enhances the reliability of the videos and fosters greater trust in RT's knowledge among viewers. RT professionals must not only possess a solid medical foundation but also use clear visual metaphors to break down complex processes into coherent and understandable steps. This approach can reduce the monotony of RT short videos and use relatable analogies that connect professional terminology with everyday understanding. Additionally, integrating interactive elements and evidence-based visual aids can significantly enhance viewers' comprehension and retention of medical knowledge, effectively disseminating information within a short time frame.

Practical Significance

This study provides essential empirical evidence for assessing the quality and reliability of RT-related medical knowledge dissemination on short-form video platforms. By systematically analyzing the quality and reliability of RT videos on TikTok and Bilibili, we have highlighted significant disparities in how the public accesses medical information [37,56,57].

Our findings fill a critical gap in the existing literature and offer valuable insights for health care professionals and regulators of short-video content. Notably, China has introduced the world's first health promotion guidelines for scientific communication on short-video platforms, marking a significant advancement in this field [37,58,59].

We recommend that platforms implement stricter content verification policies, including mandatory certifications for health-related content creators and a vetting process by licensed professionals. Additionally, prioritizing content from verified medical experts is essential. We also advocate for digital literacy programs that empower patients to critically assess web-based health information, alongside clear guidelines for content creators to ensure adherence to best practices in medical communication. Engaging stakeholders, including platform developers, health care institutions, and public health agencies, will be crucial in collaboratively implementing these measures and improving public health literacy, ultimately contributing to the advancement of global RT practices.

Future research should explore the effectiveness of different types of RT content, develop more precise assessment tools for evaluating the quality of RT content, and investigate the long-term impacts of short-video platforms on public acquisition of medical knowledge and health behaviors. This study represents a crucial step toward improving the quality of medical information in the digital age, providing a comprehensive framework for addressing challenges in web-based health communication.

Strengths and Limitations

The study demonstrates unique strengths in several aspects. First, the research design systematically evaluated RT-related short videos on TikTok and Bilibili platforms. This approach not only ensures data comprehensiveness but also enhances the representativeness of the research findings. Second, the study conducted a comprehensive assessment of video quality and reliability using the GQS and the mDISCERN tool [26,28,31]. This dual assessment approach increases the credibility of the results, allowing for a more accurate evaluation of video content quality.

In terms of data analysis strategies, this study used nonparametric statistical methods to accommodate the distribution characteristics of the data, ensuring the validity of the analytical results [30]. Additionally, Spearman and Pearson correlation analyses further elucidated the relationships between video features and quality scores, providing deeper insights into the factors influencing short-video content [26]. The application of Poisson regression models offered predictive capabilities regarding the potential relationships between video variables and quality scores, thereby enhancing the depth of the research. Notably, this is the first study in China to analyze the quality of RT-related short videos across 2 social media platforms [60].

However, our study has several limitations that affect the generalizability and external validity of the results. First, the inclusion criteria excluded videos from professional RT courses, meaning that the findings cannot be applied to the quality and reliability assessment of such educational content.

Second, the cross-sectional design of the study restricts the generalizability of the results. Cross-sectional studies provide data at a specific point in time, but they lack long-term observations of trends. Therefore, future research should use longitudinal designs to validate our findings and ensure the stability and reliability of the results. Additionally, the primary focus of this study was on Chinese users, using the Chinese versions of TikTok and Bilibili. Caution should be exercised when applying our findings to other countries and populations, as cultural and social background differences may influence the acceptance and dissemination of video content. Although we selected the top 100 videos from each platform, which represents a small proportion, we believe that this sample is sufficiently representative, as videos beyond the top 100 did not significantly impact the analysis [61-63]. Furthermore, specific subgroup categories (eg, nonprofit organizations and RT equipment promotion) had small sample sizes, which may introduce inaccuracies.

Despite the potential biases that may exist in this study, such as reviewer bias, selection bias, sampling bias, measurement bias, and content bias, we formulated systematic screening criteria. We conducted cross-platform data collection to ensure the diversity and comprehensiveness of the included videos. Furthermore, all reviewers strictly followed the GQS and mDISCERN guidelines for independent scoring, which a third reviewer (XR) subsequently audited, achieving good κ consistency. The final selection of videos not only covers most of the high-quality content on the topic but also possesses good representativeness. Therefore, we believe that the impact of

XSL•FO
RenderX

these potential biases on the research outcomes is negligible, providing a solid foundation for the conclusions of this study. Finally, as an observational study, this research can detect associations only between variables and cannot establish causal relationships.

Conclusions

This study systematically evaluated the quality and reliability of RT-related short videos on 2 major short-video platforms in China, TikTok and Bilibili. By analyzing 200 video samples, we found that the GQS of most videos was unsatisfactory. On the Bilibili platform, 69% (69/100) of the videos received a GQS of 3 or below, while on TikTok, this figure was 47% (47/100). In terms of mDISCERN, the 2 platforms had scores of 55% (55/100) and 61% (61/100), respectively, for scores of 3 or below. Although TikTok outperformed Bilibili in user engagement, there were no significant differences in video quality scores (GQS) and mDISCERN scores between the 2 platforms.

Therefore, we conclude that while short-video platforms have the potential to disseminate medical knowledge, the quality of the content urgently needs improvement. We recommend that relevant platforms and institutions enhance oversight of short-video content to ensure the accuracy and scientific integrity of the information presented. Additionally, encouraging RT professionals to actively participate in creating short videos will help improve public understanding and trust in RT knowledge.

Acknowledgments

The authors sincerely thank all patients with cancer and health care professionals who have been involved in the dissemination of radiotherapy videos on TikTok and Bilibili. Special appreciation goes to the Fifth Affiliated Hospital of Zhengzhou University for their support and collaboration.

Authors' Contributions

FG, YZ, and XL were involved in the acquisition and interpretation of data. FG and YZ were involved in the data analysis and drafting the manuscript. XL critically revised the manuscript. FG, GD, XL, and YZ contributed to the conception and design of the study.

Abstract

Background: The lack of information and awareness about clinical trials, as well as misconceptions about them, are major barriers to cancer clinical trial participation. Digital and social media are dominant sources of health information and offer optimal opportunities to improve public medical awareness and education by providing accurate and trustworthy health information from reliable sources. Infotainment, material intended to both entertain and inform, is an effective strategy for engaging and educating audiences that can be easily disseminated using social media and may be a novel way to improve awareness of and recruitment in clinical trials.

Objective: The purpose of this study was to evaluate whether an infotainment video promoting a clinical trial, disseminated using social media, could drive health information seeking behaviors.

Methods: As part of a video series, we created an infotainment video focused on the promotion of a specific cancer clinical trial. We instituted a dissemination and marketing process on Facebook to measure video engagement and health information seeking behaviors among targeted audiences who expressed interest in breast cancer research and organizations. To evaluate video engagement, we measured reach, retention, outbound clicks, and outbound click-through rate. Frequencies and descriptive statistics were used to summarize each measure.

Results: The video substantially increased health information seeking behavior by increasing viewership from 1 visitor one month prior to launch to 414 outbound clicks from the video to the clinical trial web page during the 21-day social media campaign period.

Conclusions: Our study shows that digital and social media tools can be tailored for specific target audiences, are scalable, and can be disseminated at low cost, making it an accessible educational, recruitment, and retention strategy focused on improving the awareness of clinical trials.

Trial Registration: ClinicalTrials.gov NCT03418961; https://clinicaltrials.gov/study/NCT03418961

(JMIR Cancer 2025;11:e56098) doi:10.2196/56098

KEYWORDS

cancer clinical trials; digital media; social media; infotainment; recruitment; education and awareness; edutainment; public engagement; cancer; lack of information; social media; health information; medical awareness; video series; public audience; low cost; research participants

Introduction

A total of 90% of Americans use social media [1] and over 40% of Americans watch web-based videos daily [2]. Digital media is a dominant source of health information, with 50% to 80% of internet users searching for health information on the web [3-5]. Unfortunately, misinformation and disinformation threaten the quality of health information available [6,7]. Given public interest in accessing web-based health information and the potential public reach, social media offers an optimal opportunity for public health practitioners and health care providers to improve public medical awareness and education

XSL•FO
RenderX

by providing accurate and trustworthy sources of health information. However, the attention span of social media audiences is typically short. Thus, digital content has to be engaging, meaningful, and attention grabbing [8,9].

One specific area of health care that can benefit from such strategies is cancer clinical trials. The lack of information and awareness about clinical trials, coupled with significant misconceptions about them, persist as major barriers to cancer clinical trial participation [10]. Only 3% to 5% of patients with cancer participate in clinical trials and over 50% of Americans report that the lack of awareness and information are major reasons for low participation rates [11-13]. This is the case despite one study reporting that 56% of respondents preferred the internet as a source of information about clinical trials [11].

Infotainment is defined as the delivery of broadcast material intended to entertain, engage, and inform [14]. Examples of this form of media in our culture vary but can include news talk shows, podcasts, and social media influencers. Its use may be a novel way to improve awareness and alleviate misconceptions that act as barriers to clinical trials. Moreover, since many trials close due to the lack of accrual [15], infotainment delivered on social media may be a viable clinical trial recruitment strategy.

The purpose of this study was to evaluate whether a clinical trial promotional video, disseminated on social media, could effectively drive health information seeking behaviors and, as a result, increase awareness about the clinical trial. To accomplish this goal, we instituted a dissemination and marketing process to measure health information seeking behaviors among public audiences on social media.

Methods

Video Development and Content

A clinical trial promotional video represents an underexplored method for engaging with targeted audiences. The trial we chose to feature was Southwest Oncology Group (SWOG) S1501, “Prospective Evaluation of Carvedilol in Prevention of Cardiac Toxicity in Patients with Metastatic HER-2+ Breast Cancer, Phase III.” [16] Collaborating with a clinical trial recruitment and retention specialist from the SWOG, we selected this trial based on its relative ease of understanding and to improve accrual performance. Our research team collaborated with the SWOG Cancer Research Network, a global cancer research community that designs and conducts federally funded clinical trials; The Hope Foundation for Cancer Research, a public charity with the mission of raising and contributing funds for the treatment and prevention of cancer; and Digital Health Networks (DHN), a media production studio and streaming service that specializes in producing, marketing, and distributing health care content and collecting viewership data.

The creation of the video was informed by the World Health Organization (WHO) Strategic Communications Framework [17] and the social cognitive theory [18]. The WHO Strategic Communications Framework asserts that effective health communications should be accessible, actionable, credible and trusted, relevant, timely, and understandable [17]. The social cognitive theory asserts that learning occurs in social contexts where individuals can influence and be influenced by others and their environment [18]. Using the social cognitive theory framework in the context of the health information seeking behavior of social media users, Zhang et al [19] found that (1) information quality, social media platform quality, and user experience have a significant positive effect on emotional arousal; (2) user experience, social support, and emotional arousal have a significant positive effect on self-efficacy; and (3) emotional arousal and self-efficacy have a significant positive effect on social media users’ health information seeking behavior. To this end, we sought to develop high-quality, emotionally engaging digital media that delivers accurate information about a clinical trial, with an embedded URL hyperlink to learn more information from a credible source, on a highly used social media platform to increase awareness about the trial and motivate users to seek additional information.

To ensure the information, language, and imagery provided in the video was medically accurate, a project steering committee, who chose the clinical trial of focus, was formed, consisting of SWOG Digital Engagement committee members, study investigators, and a representative from The Hope Foundation for Cancer Research. The video concept, script, and storyline were initially developed by a research team member who is also a filmmaker; cancer survivor; and long-standing member of the SWOG’s Digital Engagement, Adolescent and Young Adult, and Patient Advocates committees. The outline, script, and questions were submitted to the project steering committee for feedback, and regular communication was maintained throughout the process in multiple feedback loops. Updates were provided during committee meetings and were presented at biannual SWOG group meetings with storyboards, a rough and final cut of the video, and initial project results. This inclusive process encouraged committee members and meeting attendees to provide feedback, ask questions, and be part of the creative filmmaking process. The steering committee viewed the video and gave the final sign off prior to launch.

To engage audiences, the video attempted to parody cliché tropes often seen in pharmaceutical commercials. In our fictional video, Beth, a more relatable portrayal of a woman who is visually worn down from cancer treatment, is watching television and flipping through channels as a highly stylized, cheery commercial for the S1501 study comes on. It is akin to pharmaceutical advertisements commonly broadcast on television. Beth, feeling the side effects of treatment, dozes off but is awakened when she, in disbelief, is interacting with the commercial’s characters and asking the physicians questions about clinical trials and specifically the S1501 study. In this narrative structure, Beth’s role is to serve as a vehicle to convey the pertinent information the study team hoped the audience would learn. In the end, Beth is brought back to her reality. Appearing cautiously interested in the trial, she presumably seeks out further information about it. Video screenshots showing the main character (Beth), a paradoxical patient with cancer, and a scene with clinicians explaining the clinical trial to Beth is provided in Figure 1. The full video is available in Multimedia Appendix 1.

Ethical Considerations

The National Cancer Institute Cancer Prevention and Control Central Institutional Review Board reviewed the recruitment/patient education video (protocol version dated June 6, 2019; study ID: S1501) and granted approval on July 24, 2019. The expedited review was conducted in accordance with the federally defined categories of expedited review stated in 45 CFR 46.110(b)(1)(ii) and 21 CFR 56.110(b)(2). The dissemination strategy was not determined to be human subjects research.

The study protocol and study materials for video 2 were reviewed and approved by the National Cancer Institute Institutional Review Board. We are publishing the results from a marketing strategy to see how it could inform research. The data presented herein represent information collected for the purposes of social media marketing, and we did not collect individual-level data. Rather, we collected population-level data to inform the effectiveness of marketing research. Institution review board approval and informed consent were not obtained as no human subject data were collected on an individual level, no data were obtained through interaction with any individuals, and we cannot ascertain the identities of individuals to whom data the belonged. The data collection was conducted by a medical entertainment company, and instead of keeping the data internal, we are sharing this information with the wider medical audience.

Identifiable individuals have granted consent for the use of their image in this publication.

Dissemination and Marketing Methods

For this work, we disseminated the video on Facebook (Meta) because of its number of users and daily interactions, campaign optimizations, low cost of advertising, analytic capabilities, and sophisticated audience targeting that identifies specific audiences based on users' interests and previous interactions [20]. DHN ran and coordinated the marketing campaign using their Facebook advertising account, and video performance data were captured using Facebook's advertising management platform.

The video ran daily from September 7, 2021, to September 27, 2021. The video length was 5 minutes and 10 seconds long, and the production cost was US $4000. Projects with a similar method would cost significantly more to produce; however, costs were kept at a minimum by filming at three free locations and DHN's in-kind production services, which included directing, editing, color correction, music and graphic licenses, and voice-over narration. The video consisted of two different campaigns. The purpose of the first campaign was to identify the optimal target audience who might be more engaged with the video content. For the first campaign, which was conducted from September 7, 2021, to September 10, 2021, we used Facebook targeting algorithms to disseminate the video to audiences who expressed interests in breast cancer research and to audiences who expressed interest in breast cancer organizations. We compared the engagement (number of views and outbound clicks to the S1501 clinical trial web page) between each group. The audience interested in breast cancer research had greater engagement and was chosen as our target audience for the second campaign, which ran from September 10, 2021, to September 27, 2021. Our second campaign disseminated the video to individuals who met the look-alike audience profile, which is an audience who shared similar indicated interests, characteristics, and behaviors to individuals who were interested in breast cancer research. This technique helped us identify potentially more engaged users who would more likely be interested in our video; this is where we spent the majority of our US $1000 advertising campaign budget.

Measures and Analysis

To evaluate video engagement, we measured four outcomes:

- *Reach* was defined as the number of people exposed to the video during the advertisement campaign.
- *Retention* was defined as the length of time that individuals watched the video. We measured the number of individuals who watched for at least 3 seconds and at intervals of 25%, 50%, 75%, and 100%.
- *Outbound clicks* were defined as the number of clicks on a "learn more button" under the video that was linked to the SWOG Cancer Research Network's S1501 patient information web page.
- *Outbound click-through rate* was defined as the percentage of times viewers saw a video and performed an outbound click.

We calculated frequencies and descriptive statistics to summarize each outcome.

Results

Reach, retention, outbound clicks, and outbound click-through rate are summarized in Table 1.

XSL•FO
RenderX

Table . Educational video engagement outcomes for the S1501 study.

Outcomes	Value
Length	5 min 10 s
Video reach, n	61,456
Length of video watched, n (% retained)	
At least 3 seconds	47,566 (77.4)[a]
25%	226 (0.5)[b]
50%	84 (37.2)[c]
75%	44 (52.4)[d]
100%	34 (77.3)[e]
Outbound clicks, n	414
Percentage increase in visitors	41,300
Outbound click-through rate, n/N (%)	414/61,456 (0.67)

[a]N=61,456.
[b]n=47,566.
[c]n=266.
[d]n=84.
[e]n=44.

In our first campaign, we found that the group interested in breast cancer research performed better with video views and outbound clicks than the group interested in breast cancer organizations (9764 views and 54 outbound clicks vs 2513 views and 25 outbound clicks). This informed our target look-alike audience for the second campaign. The video had a total reach of 61,456 individuals. A total of 77.4% (47,566/61,456) watched at least 3 seconds and among those, 0.5% (226/47,566) watched 25% of the video. The number of viewers dropped at each consecutive retention interval; however, the retention rate increased at each consecutive retention interval past 25%. A month prior to launch, the S1501 patient information clinical trial web page had only 1 visitor. During the 21-day dissemination campaign period, the video received 414 outbound clicks from Facebook to the patient-facing clinical trial page. The outbound click-through rate was 0.67% (414/61,456).

Discussion

Principal Findings

We found that with an active digital marketing dissemination strategy and a very modest marketing budget (US $1000), the video substantially increased health information seeking behavior by increasing visitors to the SWOG's S1501 patient information page from only 1 web page visit the month prior to campaign initiation to 414 web page visits during the campaign. Although research organizations have passively disseminated clinical trial–related content on social media platforms, this very active and intentional campaign to engage with the public is promising as it relates to clinical trial recruitment and illustrates the utility of using engaging digital content coupled with social media marketing as an effective strategy for clinical trial recruitment. Additionally, our study shows that digital and social media tools can be disseminated to specific target audiences at low cost, making it an accessible educational, recruitment, and retention strategy for clinical trials.

Our study shows that the health information seeking behavior of social media users may be impacted by immediate attrition. The average social media video watch time benchmark is 10 seconds, and Facebook's best practices suggest that video advertisements be 15 seconds or less [9]. Considering that the average Facebook video watch time is 4.6 seconds [21], our video (5 min 10 s), which only retained 0.5% of 3-second viewers, illustrates the challenge of delivering important information in a succinct way. In addition to video length and the lack of engagement, another factor that may have contributed to this decline is that although we used Facebook algorithms to target individuals who were interested in breast cancer research and breast cancer organizations, it is plausible that only a subset of these individuals were interested in learning about clinical trials. Interestingly, viewership retention across other intervals was drastically higher (37.2% retention at the 50% interval, 52.4% retention at the 75% interval, and 77.3% retention at the 100% interval). Viewers who watched 25% of the video (1 min 17 s) tended to stay for the duration of the video, suggesting an engaged audience. Although a drop-off in retention is expected, our data suggest that the first 45-60 seconds may be the most instrumental in capturing audiences and maximizing engagement among viewers who are interested in the video topic area. It is noteworthy that the number of outbound clicks (n=414) was substantially higher than the number of people who watched the full video (n=34). This indicates that certain individuals were compelled to seek further health information before they finished watching the video, although we do not know when during the duration of the video that they performed an outbound click. These data show that *completely watching* the video was not necessarily correlated with seeking additional information

XSL•FO
RenderX

(ie, outbound clicks) and further illustrates the importance of delivering compelling and engaging content within the first 60 seconds of video content. Finally, the outbound click-through rate (0.67%) was below the average outbound click-through rates of 0.89% across industries and 0.83% in health care, but above the 0.45% average in science [22,23], which may also provide insight into the level of engagement in the video.

In this burgeoning and ever-evolving social media landscape, digital marketing and its advanced analytical techniques allow researchers to engage with patients and potential trial participants where they are already consuming health information. It also allows for real-time data on what worked well and what did not work well, so that researchers can pivot their tact and capitalize on the most effective strategies to engage with an audience that is more likely to be interested in or eligible for their trials. Although this medium is novel in oncology, social media analytics have proven to be successful in informing engagement strategies for other industries, and future oncology research could benefit from these digital tools.

Comparison to Prior Work

Our research is aligned with limited previous studies that found web-based infotainment videos to be an effective approach in increasing public understanding about science and health care among web-based health information seekers [14,24,25]. One study found that narrative infotainment videos compared to expository videos resulted in more likes by viewers without a university education and better information recall among viewers [14]. Study findings that assess study recruitment with and cost effectiveness of social media advertisement for study enrollment are mixed [26-29]. A recent scoping review reported that 9 (27%) out of 33 studies that used both social media and traditional methods for recruitment to clinical trials achieved or exceeded their enrollment target, and one study reported that social media outperformed other recruitment methods. The review did not specify how many of these studies used video as a recruitment method, highlighting the need for more research to understand if infotainment videos disseminated on social media to target audiences may be a significant strategy for facilitating clinical trial recruitment [24,30].

Limitations

Our study is limited in that we were not the administrators of the S1501 study's public facing web page and did not retain detailed information about visitor activities or characteristics (eg, location, frequency, and time of visit). This limited our ability to ascertain if each outbound click was from a unique or repeat visitor and our ability to understand additional characteristics that may have impacted health information seeking behaviors. We recommend that research teams be the administrators of both outgoing (where the advertisement played) and incoming (where visitors were sent) visitor analytics to maximize data utility. Additionally, our study did not test whether outbound clicks resulted in actual recruitment; therefore, we cannot make assertions that the increase in web page visitors contributed to study recruitment [31]. In addition, our video did not include subtitles in English nor any other language. Since 85% of Facebook users interact with the platform with the sound off [32], future digital media engagement studies should consider the use of language subtitles as this feature might facilitate engagement and accessibility with a larger audience. Another limitation is that our target audience indicators may not have been the most appropriate indicators to capture audiences interested in a specific clinical trial. We cannot ascertain that outbound clicks reached potential participants, as opposed to other individuals who may have been interested in clinical trials (eg, researchers and providers). More specialized or specific targeting (eg, those meeting study criteria) should be used to capture audiences who would most benefit from and be engaged by video media for specific clinical trials. Finally, we tested engagement using only one social media platform. Social media platforms vary in the average length of videos and average video watch times. It is plausible that social media platforms that are more conducive to longer viewing times (eg, YouTube) may have yielded different viewership and engagement outcomes.

Future Directions

Emerging internet technologies and social media are widely used sources for health information. Our study found that infotainment disseminated using social media is a useful and effective approach in relaying complex health information, motivating interested viewers to seek additional health information, and driving public audiences to credible and reliable sources of information. It has promising utility in facilitating recruitment and retention strategies for cancer clinical trials and generating increased awareness about clinical trials among patients and the general public.

Acknowledgments

We would like to acknowledge the Southwest Oncology Group (SWOG) Cancer Research Network, The Hope Foundation for Cancer Research, Digital Health Networks, and Dr Justin Floyd and Dr Monika Leja for supporting this work. This research was supported by funding from The Hope Foundation for Cancer Research and SWOG Cancer Research Network National Institutes of Health/National Cancer Institute (NCI) award U10CA180888 and was also supported by Digital Health Networks. VH is supported by the NCI (K01CA248852, P30CA015704, UGCA286954, and U54CA132381), the American Cancer Society, and the Andy Hill Cancer Research Endowment Fund. Abstract

Background: Breast cancer is the most common malignant tumor and the fifth leading cause of cancer death worldwide, imposing a significant disease burden in China. Mammography is a key method for breast cancer screening, particularly for early diagnosis. Douyin, a popular social media platform, is increasingly used for sharing health information, but the quality and reliability of mammography-related videos remain unexamined.

Objective: This study aimed to evaluate the information quality and reliability of mammography videos on Douyin.

Methods: In October 2023, a search using the Chinese keywords for “mammography” and “mammography screening” was conducted on Douyin. From 200 retrieved videos, 136 mammography-related videos were selected for analysis. Basic video information, content, and sources were extracted. Video content was assessed for comprehensiveness across 7 categories: conception, examination process, applicable objects, precautions, combined examinations, advantages, and report. Completeness was evaluated using a researcher-developed checklist, while reliability and quality were measured using 2 modified DISCERN (mDISCERN) tool and the Global Quality Score (GQS). Correlations between video quality and characteristics were also examined.

Results: Among the video sources, 82.4% (112/136) were attributed to health professionals, and 17.6% (24/136) were attributed to nonprofessionals. Among health professionals, only 1 was a radiologist. Overall, 77.2% (105/136) of the videos had useful information about mammography. Among the useful videos, the advantages of mammography were the most frequently covered topic (53/105, 50.5%). Median values for the mDISCERN and GQS evaluations across all videos stood at 2.5 (IQR 1.63 - 3) and 2 (IQR 1 - 2), respectively. Within the subgroup assessment, the median mDISCERN score among the useful and professional groups stood at 2 (IQR 2 - 3) and 3 (IQR 2 - 3), respectively, surpassing the corresponding score for the unhelpful and nonprofessional groups at 0 (IQR 0 - 0) and 0 (IQR 0 - 0.75; $P<.001$). Likewise, the median GQS among the useful and professional groups was evaluated at 2 (IQR 1.5 - 2) and 2 (IQR 1 - 2), respectively, eclipsing that of the unhelpful and nonprofessional groups at 1 (IQR 1 - 1) and 1 (IQR 1 - 1.37; $P<.001$). The GQS was weak and negatively correlated with the number of likes ($r=-0.24$; $P=.004$), comments ($r=-0.29$; $P<.001$), and saves ($r=-0.20$; $P=.02$). The mDISCERN score was weak and negatively correlated with the number of likes ($r=-0.26$; $P=.002$), comments ($r=-0.36$; $P<.001$), saves ($r=-0.22$; $P=.009$), and shares ($r=-0.18$; $P=.03$).

Conclusions: The overall quality of mammography videos on Douyin is suboptimal, with most content uploaded by clinicians rather than radiologists. Radiologists should be encouraged to create accurate and informative videos to better educate patients. As Douyin grows as a health information platform, stricter publishing standards are needed to enhance the quality of medical content.

Introduction

Breast cancer is the second most common cancer and the fourth leading cause of cancer death worldwide. In 2022, an estimated 2.3 million new cases (11.6% of all cancer cases) were diagnosed, and 666,000 deaths (6.9% of all cancer deaths) occurred, and the number of new breast cancer cases is projected to reach 4.4 million by 2070 [1]. Among women, breast cancer is the most commonly diagnosed cancer, and it is the leading

XSL•FO
RenderX

cause of cancer deaths globally. In 2022, breast cancer accounted for approximately 15.4% of all deaths in global female patients and 6.9% of all cancer deaths [2]. As the second most common cancer in Chinese women, an estimated number of 357,200 new cases of breast cancer occurred in 2022, accounting for approximately 7.4% of total new cancer cases in China and 15.5% of global breast cancer cases [3]. The World Health Organization recently launched the Global Breast Cancer Initiative with the aim of reducing breast cancer mortality by fostering timely diagnosis and adequate treatment and patient management [4]. The 5-year survival rate in patients with early breast cancer is very high; thus, early screening, detection, and treatment are important [5]. Measures used for breast cancer screening in the "Guidelines for breast cancer diagnosis and treatment by China Anti-Cancer Association (2024 edition)" include mammography, ultrasonography, clinical breast examination, breast self-examination, and magnetic resonance imaging. Guidelines recommend that the starting age for breast cancer screening in the general risk population is 40 years. However, for people at high risk of breast cancer, the start of screening may be earlier than the age of 40 years. For those older than 70 years of age may consider opportunistic screening [6]. Mammography is one of the most effective methods for breast cancer screening, especially for early breast cancer diagnosis, and it has been a major contributor to the decline in breast cancer mortality rates [7-9]. At present, there is no nationwide screening program for breast cancer in China. A cross-sectional survey conducted with a convenience sample of 494 Chinese women indicated that participation in screening practices ranged from 27.5% for BSE, 36.4% for clinical breast examination, 23.5% for mammography, and 40% for ultrasonography [10].

With the widespread adoption of internet technology, web-based platforms have become a primary channel for accessing public information. As of June 2023, China's internet user base has expanded to 1.079 billion, with short video users reaching 1.026 billion, representing 95.2% of the total internet population [11]. The short video format has emerged as a dominant force in the new media landscape, due to its low barrier to entry, concise format, and rapid dissemination capabilities, making it one of the most preferred mediums for health information acquisition. While TikTok stands as a global social media giant, operating in over 160 countries with more than 1 billion monthly active users [12], its services are unavailable in China due to internet regulations. Instead, Douyin (the Chinese equivalent of TikTok, literally meaning "shaking sound") has established itself as a national phenomenon, boasting over 750 million daily active users and ranking among the country's most popular applications [13]. The platform's influence on health communication is particularly noteworthy. The Douyin Health Science Data Report indicates that daily health science content reaches more than 200 million users as of March 2023 [14]. This trend is further supported by data from the 2023 Douyin Health Lifestyle New Paradigm White Paper, which reveals that during the first half of 2023, the platform hosted more than 10 million creators specializing in health care knowledge content [15]. Notably, industry reports highlight that 42% of Douyin's user base comprises individuals aged 40 years and older [16], suggesting a significant engagement of mature audiences with health-related content on the platform.

Mammography screening often evokes feelings of anxiety and discomfort among patients, prompting many to seek preparatory information and clarification through social media platforms. High-quality educational videos can serve as valuable resources in this context, potentially contributing to improved health outcomes. Research evidence underscores the effectiveness of video interventions in promoting mammography screening. A study focusing on Chinese immigrant women demonstrated that culturally adapted videos, developed based on the health belief model, significantly enhanced screening intentions, breast cancer knowledge, risk perception, and understanding of mammography benefits [17]. Furthermore, empirical evidence indicates that brief preprocedure video interventions can substantially increase both physician referrals for screening mammography and patient compliance with screening completion [18]. These findings highlight the potential of video-based educational tools in addressing patient concerns and facilitating informed decision-making regarding breast cancer screening.

Despite the growing reliance on social media for health information, significant challenges persist regarding the reliability and accuracy of such content. The diverse backgrounds of content creators and viewers, coupled with the absence of robust verification mechanisms, make it difficult to assess the quality and credibility of health-related information on these platforms [19]. A comprehensive systematic review of reviews revealed that the prevalence of health misinformation on social media ranges from 0.2% to 28.8% [20], posing substantial risks to users. Exposure to inaccurate health information through videos may lead to severe consequences, including delays in seeking appropriate care or even life-threatening situations [21,22]. Previous research has extensively evaluated the quality of health-related content on traditional video-sharing platforms like YouTube and TikTok, covering various medical topics such as cervical spondylosis, gastroesophageal reflux disease, and broken heart syndrome [23-25]. However, the examination of mammography-related video content remains limited. To date, only 2 studies have assessed the quality of mammography videos on YouTube [26,27], both of which identified inconsistencies in the quality of information presented. Notably, no studies have yet evaluated mammography-related content on Douyin, the Chinese counterpart of TikTok. This research gap underscores the need for systematic evaluation of mammography-related short videos on Douyin, particularly considering its massive user base in China. Therefore, this study aims to comprehensively assess the quality and reliability of mammography-related short videos on Douyin by analyzing their characteristics, sources, and content.

Methods

Search Strategy

To minimize the bias introduced by personalized recommendation algorithms, we used 3 tactics: creating a new Douyin account specifically for evaluation, disabling Douyin's personalized recommendations to eliminate differential content

XSL•FO
RenderX

recommendations caused by user habits, and banning access to mobile location services. All videos were viewed without any actions such as downloading, liking, commenting, collecting, or sharing. Evaluation tasks were carried out by 2 qualified radiologists (Chuangying Zhu and HY) from the division of radiology in a tertiary teaching hospital.

The keywords "钼靶" ("mammography" in Chinese) and "钼靶检查" ("mammography screening" in Chinese) were searched in the Douyin app on October 22, 2023, with no limits placed on the release time. Douyin offers 3 ways to filter videos: overall ranking, most recent, and most likes. We used the overall ranking mode to retrieve the top 100 videos because most consumers use this default sorting option. We chose the threshold number of 100 for 2 reasons. First, Douyin's search function takes topic relevance into account; the most relevant mammography videos tend to appear at the top of the results list, and it is difficult to observe any pertinent videos when the results exceed 100. Second, most general health users apply the "least effort" principle when searching for information on the web; they tend to concentrate on the top search results. In this study, we included videos directly related to mammography. The exclusion criteria were videos not in Chinese, videos not related to mammography, duplicate videos, videos shorter than 10 seconds in length, and videos that were unavailable.

Data Collection

A Microsoft Excel spreadsheet was created by a researcher for data collection. Video information analyzed in this study was the identity of the uploader; the duration in seconds; the number of "likes" as indicated by the heart icon; the number of comments, saves, and shares the video received; and the number of days since the video was uploaded.

We divided the videos into 2 main groups according to whether the uploaders were professional or nonprofessional. Professional videos consisted of videos uploaded directly by board-certified physicians, health channels, and hospital channels. Most health channels and hospital videos were narrated by doctors. Nonprofessional videos included those uploaded by patients and other individuals.

Quality and Reliability Assessment

The quality and reliability of the video were evaluated based on the following criteria: the accuracy and comprehensiveness of the content, the clarity and fluency of information delivery, and the overall usefulness of the video to its intended audience.

No validated tools for assessing mammography video content are available in the literature. According to the American Cancer Society recommendations for the early detection of breast cancer [28] and the China Anti-Cancer Association Breast Cancer Diagnosis and Treatment Guide and Standard (2024 Edition) [6], 2 qualified radiologists (Chunmin Zhu and RH) from the division of radiology in a tertiary teaching hospital, with more than 10 years of experience in the radiological profession, developed a completeness checklist to assess the quality of mammography video content (Table 1). The 7 categories cover most aspects of mammography: conception, examination process, applicable objects, precautions, combined other examinations, advantages, and report. A video was awarded 1 point in each domain if it mentioned the content listed in Table 1, resulting in a final score ranging from 0 to 11. A score of 0 indicated that there was no accurate content in any of the 7 earlier-mentioned areas of mammography, whereas a score of 11 indicated that a video contained accurate information in all areas. Videos were then further categorized as useful or unhelpful according to the final score. Videos with a score of 0 were considered unhelpful if they only dealt with personal experiences or testimonies without providing any scientific content, whereas useful videos received a score of ≥1. We used the modified DISCERN (mDISCERN) tool and the Global Quality Score (GQS), previously used in many studies of Douyin, as instruments to assess the quality of information in each video.

XSL•FO
RenderX

Table . Completeness checklist.

Content	Description
Conception	1. Basic principles: mention that a mammogram is done with a machine designed to look only at breast tissue, with low-dose x-rays.
	2. Radiation: mention that mammogram exposes the breasts to small amounts of radiation.
Examination process	3. Remove upper body clothing: mention that the patient must remove clothing above the waist to have a mammogram.
	4. Pain: mention that it might feel some discomfort when the breasts are compressed, and for some women, it can be painful.
	5. Two positions for unilateral breast: mention that x-ray pictures of each breast are taken, typically from 2 different angles.
Applicable objects	6. Age: mention when to start a mammogram and how often.
	7. High risk: mention that women who are at high risk for breast cancer based on certain factors should get a mammogram every year, typically starting before 40 years of age.
Precautions	8. Special period: mention that women who are in a special period, such as preparing for pregnancy, pregnant, or breastfeeding, and those who have undergone breast augmentation surgery need to inform doctor in advance. Mammograms are generally not recommended for pregnant women. It is best to schedule the examination about a week after her period.
Combined other examinations	9. Mention that breast ultrasound and magnetic resonance imaging can help find some breast cancers that cannot be seen on mammograms.
Advantage	10. Mention that mammograms have a great advantage in detecting calcifications.
Report	11. Mention that what is the breast imaging reporting and data system.

The DISCERN criteria are a validated scoring system developed by an Oxford University research team to assess the information quality and reliability of content related to consumer health information on treatment options [29]. The mDISCERN tool was modified by Singh et al [30] and is based on a 5-point Likert scale that examines goals, reliability of information sources, bias, areas of uncertainty, and additional sources. According to the mDISCERN score, the reliability of video content is considered good for a DISCERN score of >3 points, moderate for a DISCERN score of 3 points, and poor for a DISCERN score of <3 points.

The GQS, which was developed by Bernard et al [31], is a 5-point Likert scale used to assess the quality of a video based on the flow of information, completeness of the information presented on a particular topic, and usefulness of information to patients. A GQS of 1 is considered very poor, 2 is considered poor, 3 is considered fair, 4 is considered good, and 5 is considered excellent. The detailed information for mDISCERN and GQS is available on the web as in Multimedia Appendices 1 and 2.

Before starting to score the videos, radiologists first reviewed the official DISCERN and GQS instructions and referred to a simplified Chinese version [32], the latter is more adapted to the Chinese language and culture. To ensure consistency, prescoring discussions were mandatory. After reaching a consensus on the first 20 videos, the evaluators independently reviewed the subsequent entries. The original scores of the 2 radiologists (C Zhou and HY) were independently recorded. The scores of mDISCERN and GQS given by the 2 researchers (C Zhou and HY) were averaged to obtain an overall score, which was then used in the analysis. Any disagreements about the completeness checklist were resolved by consensus.

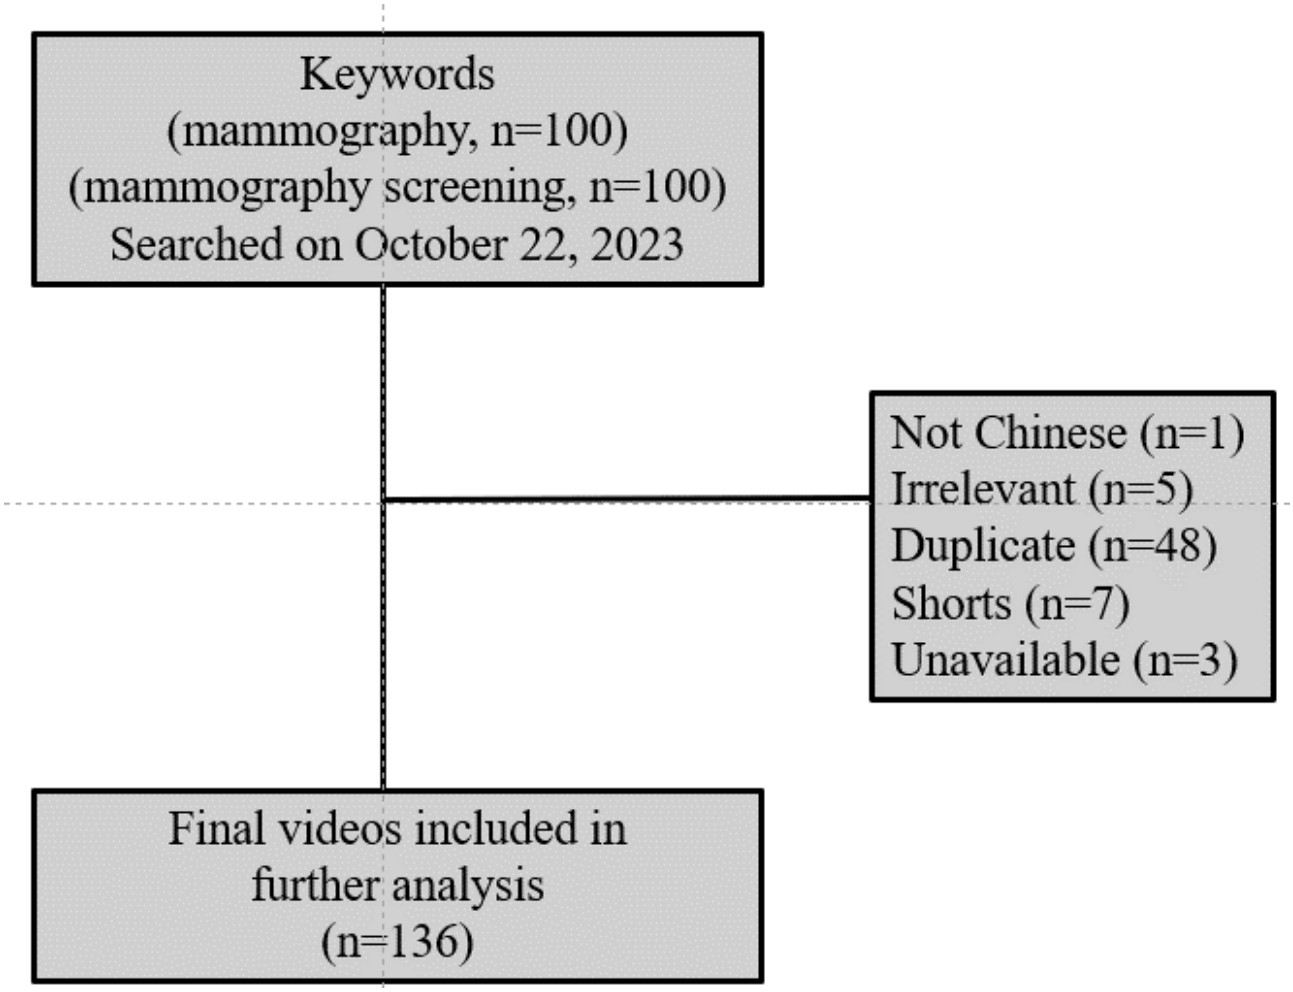
Statistical Analysis

SPSS (version 27.0; IBM Corp) was used for data entry and analysis. Data are summarized as frequency (n) and percentage (%) for categorical variables and median (IQR) for ordinal variables. The normality of the data was analyzed using the Shapiro-Wilk test. Because the data were not normally distributed, the Mann-Whitney *U* test was used to compare the continuous variables between the 2 groups. Cronbach α coefficients were used to calculate the agreement between the 2 researchers. Spearman correlation tests were used to assess relationships between parameters. The correlations were interpreted based on the magnitude of the Spearman correlation coefficient (r), with the following thresholds used as a guide to describe the strength of the relationships: $r<0.1$ is considered a negligible correlation, $0.1\leq r<0.4$ is a weak correlation, $0.4\leq r<0.7$ is a moderate correlation, $0.7\leq r< 0.9$ is a strong correlation, and $r\geq 0.9$ is a very strong correlation. These thresholds were adapted from conventional guidelines for interpreting correlation coefficients, as discussed in the literature [33]. Differences were considered statistically significant at a P value of <.05.

Ethical Considerations

No clinical data, human specimens, or laboratory animals were involved in this study. All information used in this study was obtained from publicly released Douyin videos, and none of the data involved personal privacy. In addition, the study did not involve any interaction with users; therefore, no ethics review

XSL•FO
RenderX



was required. All data were deidentified, and no individual users, videos, or screenshots are identifiable in this manuscript or its supplementary materials.

Results

Video Selection Process

In total, 200 videos were screened, and 136 were included in the study. The 64 excluded videos were 1 video in a non-Chinese language, 5 irrelevant videos, 48 duplicate videos, 7 short videos, and 3 unavailable videos (Figure 1).

Figure 1. Flowchart of videos included in the study.

Video Characteristics

The statistical analysis showed that the mammography videos ranged from 11 to 876 seconds. At the time of this study, the 136 short mammography videos had received 1,788,786 likes, 288,802 comments, 110,224 saves, and 598,393 shares. Each short video received 2 to 256,000 likes, 0 to 81,000 comments, 0 to 21,000 saves, and 0 to 145,000 shares. The most recent video was posted 21 days before the data collection, while the oldest had been on Douyin for more than 3 years. The median duration of the videos was 49.5 (IQR 32.5 - 76.75) seconds; the median indicators of engagement comprised 414 (IQR 155.75 - 1887.25) likes, 50.5 (IQR 20 - 286.25) comments, 56 (IQR 19-201.75) saves, and 61.5 (IQR 12 - 275.75) shares; and the median time since upload was 382.5 (IQR 116.25 - 635.75) days. The characteristics of the included videos are shown in Table 2.

XSL•FO
RenderX

Table . Characteristics of videos about mammography on Douyin.

Characteristics	Median (IQR)	Range
Duration (seconds)	49.50 (32.50 - 76.75)	11 - 876
Number of likes	414 (155.75 - 1887.25)	2 - 256,000
Number of comments	50.50 (20 - 286.25)	0 - 81,000
Number of saves	56 (19 - 201.75)	0 - 21,000
Number of shares	61.50 (12 - 275.75)	0 - 145,000
Days since upload	382.50 (116.25 - 635.75)	21 - 1208
Global Quality Score	2 (1 - 2)	0 - 4
DISCERN score	2.5 (1.63 - 3)	0 - 3.5

Uploader Douyin Account Characteristics

Most of the videos in our sample were contributed by professional users (112/136, 82.4%), while a relatively small proportion were contributed by nonprofessional users (24/136, 17.6%). Among professional users, most videos were created by board-certified physicians, followed by hospital channels and health channels (Table 3). Only 1 imaging physician was involved in the posting of 3 videos. The median video duration was significantly longer (P<.001) in the nonprofessional group and received significantly more comments (P=.004; Table 4).

Table . Proportion of videos by different types of uploaders.

Source	Description	Videos (n=136), n (%)
Professionals	Individuals or mechanisms who describe themselves as health professionals with certification	112 (82.4)
Board-certified physicians	Medical specialist who diagnoses, treats, and manages diseases and conditions related to breast cancer	106 (77.9)
Health channels	Organizations providing health knowledge	2 (1.6)
Hospital channels	Hospital platforms share health care information	4 (2.9)
Nonprofessionals	Individuals who share mammography experiences or medical personnel without certification	24 (17.6)

Table . Analysis of video characteristics by source.

Characteristics	Professional (n=112), median (IQR)	Nonprofessional (n=24), median (IQR)	*P* value
Duration (seconds)	46 (31.25 - 69.50)	96.50 (53 - 132.25)	<.001
Number of likes	382.50 (154 - 1658.50)	641.50 (155.75 - 15,223)	.33
Number of comments	44 (20 - 192.75)	165.50 (42.25 - 2900)	.004[a]
Number of saves	55.50 (19.5 - 182.5)	75.50 (10.25 - 2122.50)	.58
Number of shares	66 (12 - 198.75)	59 (11.5 - 4561.25)	.57
Days since upload	397 (137 - 648.25)	310.5 (78.25 - 611.50)	.66
Global Quality Score	2 (1 - 2)	1 (1 - 1.37)	<.001
DISCERN score	3 (2-3)	0 (0 - 0.75)	<.001

[a]P<.01.

As mentioned earlier, the selected videos were divided into useful and unhelpful groups based on scores of the completeness checklist. Of the 136 selected videos, the number of videos containing useful and unhelpful information was 105 (77.2%) and 31 (22.8%), respectively. Notably, despite uniformity in video days since upload between groups, uploads by unhelpful groups garnered more engagement metrics such as likes (median 6892, IQR 585 - 104,000), comments (median 1305, IQR 130 - 4103), saves (median 748, IQR 53-4381), and shares (median 1056, IQR 50 - 6071) relative to useful group, and this differential attains statistical significance (P<.01 for all; Table 5). Because the number of nonprofessional uploaders in the useful group was small (7/105), we could not compare this group.

XSL•FO
RenderX

Table . Analysis of video characteristics by usefulness.

Characteristics	Useful group (n=105), median (IQR)	Unhelpful group (n=31), median (IQR)	*P* value
Duration (seconds)	46 (31-69)	76 (46-114)	<.001
Number of likes	276 (131.50 - 815.50)	6892 (585 - 104,000)	<.001
Number of comments	35 (17 - 113.50)	1305 (130 - 4103)	<.001
Number of saves	47 (17-107)	748 (53 - 4381)	<.001
Number of shares	48 (10.50 - 158)	1056 (50 - 6071)	<.001
Days since upload	365 (104.50 - 675)	410 (151-538)	.77
Global Quality Score	2 (1.50 - 2)	1 (1 - 1)	<.001
DISCERN score	2 (2-3)	0 (0 - 0)	<.001

Information Content Comprehensiveness

Useful videos were analyzed based on the information they contained. Among all the categories, the advantages of mammography were the most frequently covered topic (53/105, 50.5%), followed in descending order by applicable objects (50/105, 47.6%), conception (47/105, 44.8%), examination process (44/105, 41.9%), combined other examinations (42/105, 40%), report (26/105, 24.8%), and precautions (11/105, 10.5%; Multimedia Appendix 3). Most of these videos (97/105, 92.4%) scored <5 points, and only 1 video received a maximum score of 7.

Video Reliability and Quality

The median (IQR) mDISCERN score and GQS of all videos were 2 (1 - 2) and 2.5 (1.63 - 3), respectively. The Cronbach α coefficients for reliability between the raters were 0.94 and 0.97 for the GQS and mDISCERN, respectively. The mDISCERN score and GQS of the videos in the useful and professional groups were significantly higher than those in the unhelpful and nonprofessional groups (all $P<.001$).

Correlation Analysis

Spearman correlation analysis revealed certain correlations among the characteristics of the videos. The video duration was positively correlated with the number of comments ($r=0.23$; $P=.008$), saves ($r=0.20$; $P=.02$), and shares ($r=0.19$; $P=.02$). Across all videos, Spearman correlation analysis revealed positive and significant correlations among the number of likes, comments, saves, shares, and days since upload ($P<.05$ for each pair).

The GQS was negatively or positively correlated with the number of likes ($r=-0.24$; $P=.004$), comments ($r=-0.29$; $P<.001$), and saves ($r=-0.20$; $P=.02$) as well as with the mDISCERN score ($r=0.65$; $P<.001$). The mDISCERN score was found to be negatively correlated with the number of likes ($r=-0.26$; $P=.002$), comments ($r=-0.36$; $P<.001$), saves ($r=-0.22$; $P=.009$), and shares ($r=-0.18$; $P=.03$). The correlation coefficients (r) reported in this study are generally below 0.39, indicating weak associations. In cases where the correlation coefficients are below 0.1, we consider these to be negligible. We acknowledge that the statistical significance of these correlations may be influenced by the sample size; therefore, we place greater emphasis on the magnitude of the correlation coefficients to better reflect the strength of the relationships. More detailed analytical results are shown in Table 6.

Discussion

Principal Findings

This is the first study in the literature to evaluate Douyin content on mammography videos. According to the findings of 2 independent reviewers (C Zhou and HY), more than three-quarters of the videos were uploaded by professional individuals or institutions, and videos containing content primarily concerned with disease knowledge were of higher quality and more reliable. Nevertheless, the overall quality of the mammography videos was poor according to the completeness checklist, GQS, and mDISCERN score. Additionally, the fact that seekers gave higher ratings to the lower-quality videos than the higher-quality videos suggests that most health viewers are not able to identify poor-quality medical information in videos.

The rapid development of digital technology and the widespread application of mobile intelligent terminals have caused various new media to become important platforms for sharing and exchanging scientific knowledge. This has further expanded the channels through which the public can understand and obtain information, broadening the breadth and depth of knowledge. There was an unprecedented reliance on social media platforms to seek information during the COVID-19 pandemic [34]. Douyin is a representative national short video platform, and

XSL•FO
RenderX

watching videos every day has become a part of many people's lives.

Currently, uploaders who share health information on the Douyin app are required to obtain certification materials that verify their affiliation with tertiary A hospitals as doctors. In our study, approximately 80% of mammography-related Douyin contents were uploaded by professional users. Most of them were clinicians; only 1 was an imaging specialist. These findings show that clinicians in tertiary A hospitals with a high level of expertise are enthusiastic about participating in the popularization of mammography-related information. A previous study also showed that radiology-related content on the increasingly popular social media platform TikTok is mainly posted by nonphysician radiology personnel [35]. In addition, our results suggest that the videos cannot cover all aspects of mammography, which may be due to the limited short length of Douyin videos. Furthermore, the most prevalent content of the videos was the advantages of mammography in detecting calcifications; few videos fully addressed other types of content during the examination. This finding may indicate that most publishers believe that the unique advantage of mammography is to help detect breast cancer at an earlier stage. As radiologists, they may be more likely to focus on pain and positioning or precautions during the examination and have a more accurate understanding of diagnostic reports [36]. Pain and discomfort during mammography may influence participation in screening programs and be detrimental to cancer prevention efforts [37]. More senior radiologists should be encouraged to become involved in mammography popularization. Specialized training and publicity should be provided to meet the public's need for knowledge about mammography.

The current results indicate that the reliability and educational quality of mammography-related videos on Douyin are unsatisfactory, with median mDISCERN and GQS evaluations across all videos stood at 2.5 (IQR 1.63-3), and 2 (IQR 1-2), respectively. This finding is in accord with previous studies that have examined low-quality videos on various health topics and found that this information may not be reliable on Douyin [38,39]. Studies on other video platforms, such as YouTube, also showed that the overall quality of videos providing disease information was poor [40,41]. Because the content of most videos lacks peer or institutional quality review, many may not be subject to quality control and may not be evidence-based; it is therefore not surprising that much of this content is inadequate [42]. Thus, patients should access certified organizations and sites such as those certified with the Health on the Net Foundation Code of Conduct certificate to obtain professional information and avoid being misled by social media. The Health on the Net Foundation Code of Conduct was created as a practical solution to help internet users recognize reliable health-related information on the internet while distinguishing it from potentially erroneous or hazardous content [43]. However, contrary to all these findings, in previous studies of the quality of Douyin videos on children with humeral supracondylar fractures, chronic obstructive pulmonary disease, and cosmetic surgery, the overall information quality and reliability of these short videos were satisfactory in China [44-46]. This might be explained by the assessment instrument's lack of comparability between different disease categories and the bias introduced by the use of different scoring criteria among different researchers.

The results also showed that videos posted by professionals had significantly higher reliability and GQS than those posted by individuals. This finding indicates that ownership is an important element that can be used to assess the reliability of videos. Video content may be considered trustworthy when produced by professionals such as doctors, medical organizations, and health information websites [47]. Unfortunately, our regression analysis revealed that the number of likes, comments, and saves had a weak negative correlation with both the mDISCERN score and GQS. The results showed that lay users had difficulty distinguishing useful information from a large number of videos. A common misconception is that digital information accuracy is directly related to the number of hits or views [48]. There are thousands of health-related videos promoting misleading information that get millions of views, such as videos that disparage vaccinations [49,50]. These results also indicate that effective regulatory measures are needed to control scientifically accredited information. In the future, it would be beneficial to develop an algorithm that ranks videos preferentially uploaded by a trusted medical center or professional. If the public had less access to unhelpful videos, the damage could be less.

Limitations

This study has some limitations. First, this was a cross-sectional study that examined a very small portion of a very large amount of data. The number of views, likes, and dislikes of health-related videos on the internet changes over time. The "snapshot" approach to data collection seems to be the main limitation of this study because the results may vary with the use of different search terms and according to the date and time of the search. Second, because of the limitations of the search criteria, it was not possible to include all video resources that fit the topic of this study. Although we included a relatively small percentage of videos, we considered it to be sufficiently representative, as videos beyond the top 100 have no significant impact on the analysis. Third, we only included videos uploaded on Douyin, which is a Chinese video-sharing platform; thus, the findings may not be generalizable to other social media platforms (eg, YouTube) or to other countries. Subsequent cross-linguistic research is required to fill this gap. Finally, the GQS and DISCERN are subjective assessment tools. Although 2 independent experts (C Zhou and HY) determined the ratings iteratively and used Cronbach α coefficients to quantify the agreement between the 2 raters, subjective differences still cannot be ignored. Looking ahead, future research should include broader cross-linguistic comparative studies, using more appropriate assessment instruments to validate our findings.

Conclusions

According to the findings of our study, a majority of the Douyin videos concerning mammography were uploaded by clinicians and exhibited poor quality and reliability. Patients should not use these videos as the only source of information about mammography because they may lead to misdirected or inappropriate interventions. Douyin is often used to obtain health-related information, and radiologists should be

XSL•FO
RenderX

encouraged to provide useful and accurate videos and to instruct patients appropriately. From the standpoint of preventing and curing breast cancer, there is a need for stricter standards and procedures for video publishing to improve the quality of medical content.

Acknowledgments

The authors thank Angela Morben, DVM, ELS, from Liwen Bianji (Edanz) for editing the English text of a draft of this manuscript.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

The study was designed and planned by RH and Chunmin Zhu. Data collection, results interpretation, and manuscript writing were all carried out by HY and C Zhou. Chuangying Zhu reviewed the work. LH, HW, PC, and SZ contributed to the reagents, materials, and analysis tools. HY and C Zhou drafted the manuscript. Chunmin Zhu and RH reviewed and edited the manuscript. All authors have reviewed and revised the manuscript.

Abstract

Background: Cervical cancer (CC) screening participation remains suboptimal among vulnerable populations in France. This study aimed to develop and evaluate AppDate-You, a chatbot-based decision aid, to support women from socioeconomically disadvantaged areas in the French Occitanie region to make informed decisions about CC screening, particularly human papillomavirus self-sampling (HPVss).

Objective: This study aimed to explore the needs, preferences, and barriers related to CC screening and to design and validate a user-centered, empathetic, and effective chatbot-based decision aid to empower women experiencing socioeconomic challenges in France to make informed choices about HPVss.

Methods: The chatbot was developed following a validated framework for developing decision aids. The process included qualitative research involving online and in-person interviews and focus groups with women and health care professionals, followed by alpha testing with both groups and beta testing with women only. Participants included women (both French and non-French speaking) aged between 30 and 65 years from socioeconomically disadvantaged areas of the Occitanie region and health care professionals (general practitioners, gynecologists, and midwives) working with these populations. AppDate-You was made accessible through WhatsApp and Facebook Messenger, offering text-based and voice-based interactions and multimedia content.

Results: The exploratory phase identified key barriers to screening and digital tool preferences. Prototype testing revealed great satisfaction with the chatbot's performance, educational value, and content quality. Contrary to the expectations of health care professionals, women from diverse backgrounds, including women who were older and socioeconomically disadvantaged, were willing and able to use the tool. Users—even those with limited digital literacy—found AppDate-You innovative, user-friendly, and informative. In the beta testing phase, 80% (12/15) of the participants expressed interest in HPVss. Some limitations were identified, such as the chatbot's occasional repetitive responses and the need for clearer medical terminology.

Conclusions: This study demonstrates the potential for artificial intelligence chatbots to improve access to health education and increase cervical screening intention among underserved populations. The user-centered approach resulted in a tool that effectively meets the needs of the target population.

Introduction

Background

Cervical cancer (CC) remains a significant global health challenge, particularly among vulnerable and underserved populations with limited access to health care resources. While largely preventable through human papillomavirus (HPV) vaccination and regular screening, the effectiveness of interventions is heavily dependent on high participation and coverage rates. However, women experiencing socioeconomic challenges often face numerous barriers to accessing and participating in CC screening and prevention programs [1].

In France, an organized CC screening program was implemented in 2020, using HPV testing for women aged ≥30 years [2]. The program is available via various health care providers, including gynecologists, general practitioners (GPs), midwives, primary care facilities, and hospitals [2]. However, participation in CC screening programs remains suboptimal (59.5%), particularly among certain demographic groups [3]. Women aged >50 years, from socioeconomically disadvantaged backgrounds or underserved areas, or women with chronic health conditions, as well as women covered by supplementary health insurance, have notably lower screening rates [4].

Multiple barriers are responsible for suboptimal screening uptake. These include limited awareness of CC and its risk factors, insufficient understanding of screening benefits, inadequate access to health care services, cultural and linguistic barriers, fear or embarrassment associated with the screening process, and competing life priorities [5]. Addressing these multifaceted challenges is crucial to increasing participation rates and reducing disparities in CC prevention efforts.

To improve participation rates, the French government has issued national guidelines recommending a follow-up reminder at 12 months after invitation for women who do not respond to the initial screening invitation [6]. The reminder includes an HPV self-sampling (HPVss) kit, designed to overcome some of the barriers associated with traditional screening procedures.

A systematic review about values and preferences [7] reported evidence for the acceptability of HPVss regardless of age, income, or the country of residence. Two French randomized controlled trials (RCTs) [8,9] reported that mailing HPVss kits significantly increased participation rates compared to reminder letters alone. One study [8] reported an increase in uptake from 2% to 18.3%, while another study [9] showed an improvement from 11.7% to 22.5% [9]. Despite these promising results, it is important to note that <20% of nonrespondent women submitted the kit when mailed to their homes, indicating persistent barriers to participation [8,9].

There is growing recognition of the potential of decision aids to empower individuals to make informed choices about health care by providing them with evidence-based information [10]. Decision aids are designed to help people understand their different options and make informed decisions aligned with their values and preferences. Traditional educational methods often face limitations, such as inaccessibility, language and literacy challenges, and the inability to tailor information to individual needs [11].

In parallel with the evolution of decision aids, there has been increasing interest in leveraging technology to address health care disparities and improve access to medical information and services. Chatbots have emerged as a potential solution to engage patients and deliver educational content in a conversational format [12]. With their ability to provide 24-7 access to information, interactive and personalized guidance, as well as support, chatbots offer a promising solution to improve health literacy and patient engagement. Numerous artificial intelligence (AI)–based chatbots have been developed to provide cancer screening education, and several studies have demonstrated that users readily embrace these tools, which can serve as an additional source of information for individuals who may struggle to obtain or understand health-related guidance [13]. For example, chatbots have been developed to answer HPV vaccine–related questions [14], to improve colposcopy adherence after abnormal Pap test results in women living in underserved urban areas [15], or to promote HPV vaccination among girls in South Korea [16]. However, our chatbot is the first that aims to increase accessibility to information on cervical screening, with the option of self-sampling, targeted at women from a socioeconomically disadvantaged French area.

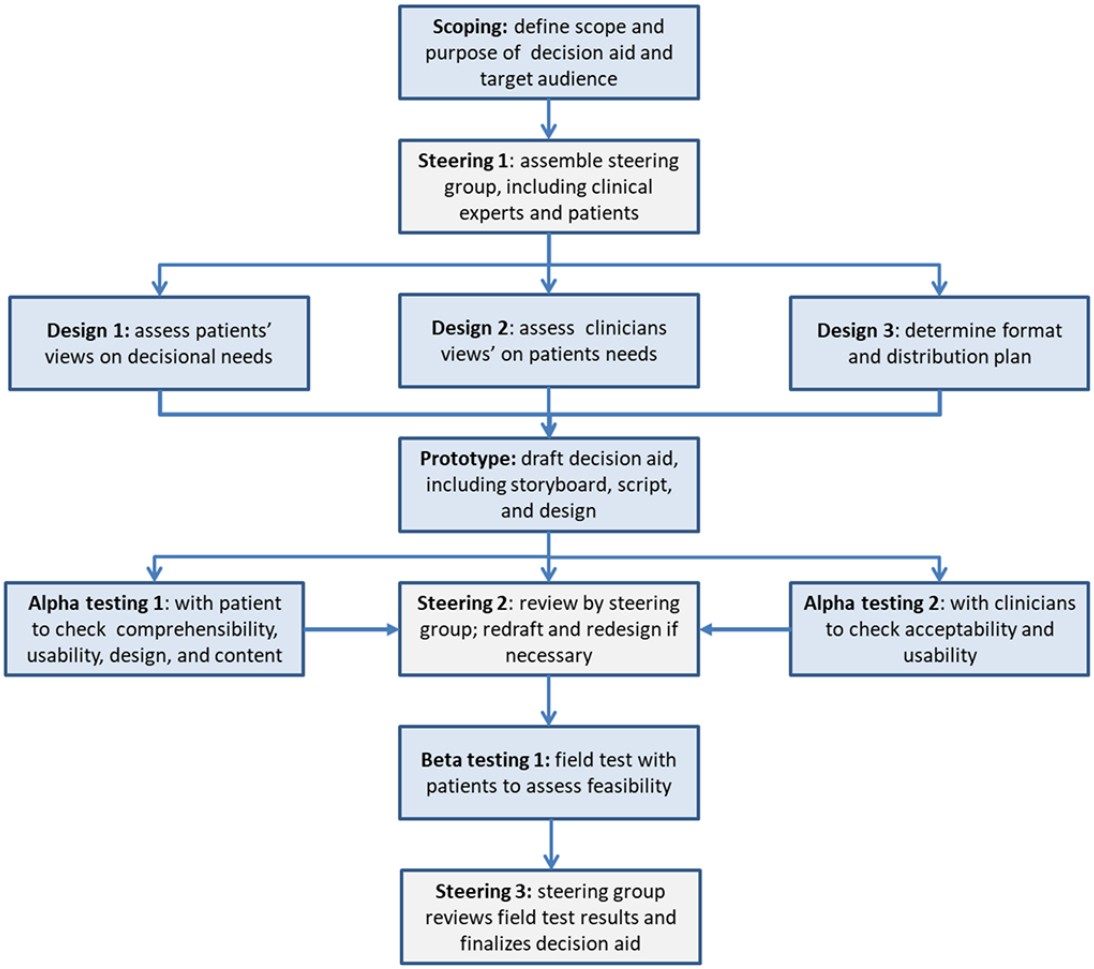
Objectives

Considering the disparities in cervical screening uptake in France (as in many high-income countries) and the increased use of AI tools in health care, it is essential to explore how AI and the novel implementation of HPVss could improve equity in access to cervical screening. This paper focuses on the design and validation of a chatbot-based decision aid, specifically tailored to support women experiencing socioeconomic challenges in the Occitanie region of France to help them make informed decisions about CC screening. By leveraging qualitative research methods, we first aimed to explore the needs, preferences, and barriers faced by this population in relation to CC screening and then to create a user-centered, empathetic, and effective digital tool that can empower these women to make informed choices about HPVss.

Methods

Overview

We followed the structured framework proposed by Coulter et al [17] for developing decision aids, based on the International Patient Decision Aid Standards, which consists of five key steps (Figure 1 [17]): (1) scoping the decision aid, (2) forming a multidisciplinary steering group, (3) designing the decision aid, (4) alpha testing (prototype testing), and (5) beta testing (field testing). We made slight adjustments to this framework to better



XSL•FO
RenderX

suit our specific needs and context while maintaining its core principles. The design phase was meticulously structured to ensure that the decision aid was precisely tailored to meet the unique requirements and preferences of our target population. Notable modifications to the original framework include, first, the decision to exclude a literature review during the initial design phase, focusing instead on directly capturing the needs, preferences, and experiences of the women themselves. This decision was driven by time and resource constraints, as well as our commitment to a user-centered approach. Second, the decision to conduct beta testing exclusively with end users (eligible women), as the chatbot-based decision aid was designed for direct use without support from health care professionals. These adaptations improved the user-centered approach throughout the development process, ensuring that the final product would be highly relevant and accessible to our target population.

We organized the chatbot development process into 3 main operational phases in alignment with the steps proposed by Coulter et al [17], as described in Textbox 1.

Each phase was designed to iteratively refine the chatbot, ensuring it met the needs and preferences of our target population while adhering to the principles of effective decision aid development.

Figure 1. Model Development Process for Decision Aids (adapted from Coulter et al. 2013).

Textbox 1. Phases of the chatbot development process.

- Phase 1: exploratory phase (September 2021 to November 2021)—this phase corresponded to the "scoping" and initial "design" stages of the framework proposed by Coulter et al [17]. We defined the tool's purpose, established our multidisciplinary steering committee (comprising experts in screening, behavioral economics, and digital communication), and conducted qualitative research with eligible women and health care professionals to identify their needs, barriers, and preferences. The findings from this phase informed the initial design of the chatbot.
- Phase 2: prototype testing (June 2023 to July 2023)—this phase corresponded to the "alpha testing" step in the framework. We tested the chatbot prototype with both eligible women and health care professionals, gathering feedback on usability, content design, content comprehension, and acceptability.
- Phase 3: field testing (February 2024 to April 2024)—this phase corresponded to our adapted version of the "beta testing" step and was focused solely on end users. We tested the improved version of the chatbot with eligible women in real-world conditions to assess feasibility.

Technical Development of the Chatbot

The AppDate-You chatbot was developed using the YeldaAI platform with a JavaScript-based architecture, integrating open-source large language models, such as Mistral and Llama, within a proprietary framework. This technical foundation enables natural language understanding, adaptive conversations, and secure hosting on certified Health Data Hosting servers in France, ensuring compliance with the European Union data protection standards.

The chatbot was built to be easy to access and use. Rather than requiring users to download a dedicated app, which participants in phase 1 identified as a potential barrier, AppDate-You was integrated with widely used messaging platforms—WhatsApp and Facebook Messenger. This approach leveraged existing platforms that most participants already had installed on their devices. Users accessed the chatbot by scanning a QR code that immediately initiated the conversation without requiring additional sign-up processes or authentication. Beyond text-based interaction, the chatbot can also process voice queries, adapting to diverse user preferences. Users can send voice messages through WhatsApp or Facebook Messenger, and the chatbot processes these messages and responds in both text and voice formats.

During its development, the project team conducted alpha and beta testing in collaboration with health care professionals and representative user groups. These tests informed refinements in conversational flow, language style, and tone, ultimately shaping a persona that represents a friendly, knowledgeable female health care figure. The deliberate choice of a female persona was based on input from our multidisciplinary steering group and target users, who indicated that women were likely to feel more comfortable discussing cervical screening with a female virtual assistant. Rather than adopting the role of a physician or an authoritative expert, AppDate-You presents itself as “Sarah,” a supportive peer from the medical field who can relate to the users’ experiences and concerns. This persona’s female voice was selected for its calm, reassuring tone that aligns with the chatbot’s overall empathetic design principle. The chatbot can also recognize emotional cues—such as worry or confusion—and responds with reassuring, plain-language statements before delivering factual details about screening procedures.

Privacy and data minimization were central considerations, reflecting the sensitivity of women’s health information. Users are advised not to share personally identifiable details, and any information provided inadvertently is automatically flagged or masked. All conversation logs remain on secure servers, accessible only to authorized personnel for maintenance or aggregated statistical analysis.

Participant Recruitment

Purposeful sampling was used to select participants for the 3 study phases to ensure a representative sample, and those who participated in the first phase were excluded from subsequent phases of the study. This approach was implemented to obtain unbiased feedback throughout the iterative development process and to gather perspectives from a diverse range of women and health care professionals. We recruited women aged between 30 and 65 years residing in socioeconomically disadvantaged areas of the Occitanie region, France. The selection criteria included a range of sociodemographic characteristics: family status, employment status, country of origin, length of residence in France, French language proficiency, digital literacy, education level, and screening history. Recruitment was conducted by an external professional recruitment company and a local nongovernmental organization. Participants were recruited from existing panels, directories, or via the associative network. They were approached by email or telephone.

Health care professionals, including gynecologists, GPs, and midwives, were recruited from the Occitanie region. They were selected to represent diverse backgrounds, specialties, ages, years of experience, geographical locations, experience working with socioeconomically disadvantaged populations, experience in involvement in CC screening programs, and practice settings (eg, private practice, public hospitals, and public community centers).

The Occitanie region is the fourth most populous region in France, with 6.1 million inhabitants [18]. This region faces significant socioeconomic challenges, with an unemployment rate of 8.6% (compared to 6.9% nationally) and a poverty rate of 16.8% (vs 14.4% nationally), with marked disparities between departments [18]. To recruit women from socioeconomically disadvantaged areas, we used the Îlots Regroupés pour l’Information Statistique or Aggregated Units for Statistical Information classification of the French National Institute of Statistics and Economic Studies, which divides the territory into small geographic units of approximately 2000 residents with similar socioeconomic characteristics. These disadvantaged areas are characterized by high unemployment rates, a high proportion of manual workers, low average household incomes, and low education levels (low rate of high school graduates) [19].

Data Collection

Data were collected by 5 interviewers (over the 3 phases) from an external company (BVA Xsight). All interviewers were women, had a master’s degree or a PhD in social sciences, and had previous experience in conducting qualitative research (from 1 to 13 years). The interviewers were employed by the external company as consultants, project managers, or managers of the qualitative studies unit.

Phase 1

The objectives of the first phase were (1) to identify barriers faced by eligible women in participating in CC screening and their perceptions of HPVss, (2) to explore their smartphone use and perceptions of educational e-tools, (3) to identify difficulties faced by health care professionals in recommending CC screening to their patients, and (4) to explore the health care professionals’ perceptions of difficulties faced by their patients from socioeconomically disadvantaged backgrounds. An interview guide was developed based on these 4 objectives. The information gathered from this phase informed the development of the first AppDate-You chatbot prototype.

XSL•FO
RenderX

In total, 5 interviews (average duration: 1 h 30 min) and 2 focus groups (average duration: 3 h) were conducted in person with 15 non–French-speaking women in November 2021. The eligibility criteria included women from the Algerian or Georgian communities living in the city of Toulouse. Participants were recruited through associative networks. To anticipate language barriers, in each interview and focus group, a peer facilitator (a person from the community ensuring translation and understanding) was paired with the interviewer to support the discussion.

In total, 5 interviews (average duration: 1 h) and 2 focus groups (average duration: 2 h 30 min) were conducted online with 15 French-speaking women in November 2021. Eligibility criteria included women belonging to a working-class socioeconomic background, having a level of education no higher than high school graduation, and living in a socioeconomically disadvantaged area.

A total of 20 interviews (average duration: 1 h) were conducted over the phone or online with health care professionals between November and December 2021. Eligibility criteria included health care professionals working in the Occitanie area and being in contact with patients from socioeconomically disadvantaged areas or from ethnic minority groups.

Phase 2

The aim of the second phase was to gather the opinions of women and health care professionals on the prototype, particularly on its acceptability, design and content, ease of use, and their understanding of the educational messages. An interview guide explaining this aim was provided to the participants.

Acceptability was defined as participant satisfaction and positive attitudes toward the chatbot experience, drawing on key constructs from the AI device use acceptance model [20,21]. We assessed this through structured interview questions focusing on ease of use (effort expectancy), user-interface satisfaction, content relevance and perceived usefulness and comfort (performance expectancy), and emotional responses to the interaction. These factors serve as strong indicators of whether women and health care professionals would use the tool.

Eligibility criteria were the following: belonging to a working-class socioeconomic background, having a level of education no more than 2 years beyond high school graduation, and living in a socioeconomically disadvantaged area. Eligible women could be either very comfortable using e-tools or not comfortable at all.

The interviews and focus groups were organized in 3 steps. First, preliminary phone interviews (approximately 20 min each) were conducted to assess women's perspectives on health, CC screening, and smartphone use. Second, participants then engaged with the chatbot over a 5-day period, exploring specific topics related to CC. During this time, they were assigned 5 daily missions through an app designed to ensure comprehensive interaction with the chatbot's content. Participants could also provide feedback and record their observations throughout the interaction period using this app. In addition, participants were encouraged to ask the chatbot further questions. Finally, in-depth interviews and focus groups were conducted to collect detailed feedback about their overall experience.

In total, 8 interviews (average duration: 1 h) and 4 focus groups (average duration: 2 h 30 min) were conducted online with 20 women (2 focus groups involved women who were comfortable with digital tools, and 2 focus groups involved women who were not comfortable with digital tools).

In total, 13 interviews (average duration: 1 h) were conducted with health care professionals (GPs, gynecologists, and midwives). Each participant was asked to assess the chatbot freely, with instructions sent by email.

Phase 3

The aim of the third phase was to gather feedback from eligible women on the use of the chatbot (an improved prototype following the results of phase 2) and particularly to assess its feasibility in real-world conditions. The interview guide was developed to answer these key questions.

Feasibility was defined as a user's ability to access and use the chatbot independently in real-world conditions. We evaluated this through (1) successful completion of initial access steps without assistance; (2) user-reported technical difficulties during the 5-day testing period; and (3) engagement metrics, including average session duration.

Participants were selected based on the following criteria: living in disadvantaged areas of the Occitanie region (specific areas selected based on socioeconomic level), not having participated in CC screening in the last 4 years, and being aged between 30 years and 65 years (the age range for CC screening eligibility in France).

A total of 15 eligible women were sent an invitation letter to participate in CC screening, including a guide explaining how to access the chatbot (via WhatsApp or Facebook Messenger). Women were encouraged to use the chatbot freely over a 5-day period. A facilitator was available to help access the tool if required. Following the testing period, participants were invited to an interview to share their experiences. In total, 15 interviews were conducted.

All Phases

All interviews and focus groups were audio- or video-recorded with consent. Notes were also taken by the interviewers. Participants received financial compensation for their participation (between €30 and €50 [€1=US $1.183; approximate average for 2021] depending on the time spent). Interviewers had no previous relationships with the participants. Participants were informed both in writing and verbally about the aim of the research, as well as the data collection and analysis process, and were asked to sign an informed consent form beforehand. Participants were informed that the interviews and focus groups were conducted as part of a research project aiming to understand their needs and expectations in terms of quality of life and health. The interviews and focus groups were organized online or in person. When in person, they were organized in private dedicated spaces or rooms belonging to the associative network. Besides the participants and the researchers, only the

XSL•FO
RenderX

peer facilitators were present when required. Interviews and focus groups were conducted until enough data were obtained.

Ethical Considerations

This study was approved by the International Agency for Research on Cancer ethics committee (IEC 21-16). All methods were performed in accordance with the relevant guidelines and regulations outlined in the Declaration of Helsinki. All participants provided written informed consent after being informed about the study's aims and procedures. For non–French-speaking participants, a peer facilitator assisted with translation to ensure comprehension of the consent process.

All data were anonymized during analysis. Recruitment information, contact details, audio recordings, and interview transcripts were stored on secure servers with access restricted to the research team and automatically destroyed within 3 months after completion of each study phase. For chatbot testing phases, conversation logs were secured on certified Health Data Hosting servers in France, complying with the European Union data protection standards, and destroyed after completion of analysis for each phase. Users were advised against sharing personal identifiable information during chatbot interactions, and any personal details inadvertently shared were masked in the analysis.

Participants received financial compensation ranging from €30 to €50 (€1= US $1.183), depending on the duration of their participation, to compensate for their time commitment and potential travel expenses.

Data Analysis

The interviews and focus groups were transcribed manually. For non-French recordings, the transcription was completed with the assistance of peer facilitators who participated in the interviews. These peer facilitators provided translation during the interviews and assisted with the translation of recordings during transcription to ensure accurate representation of participants' responses in French while preserving cultural context and meaning. An initial content analysis was performed manually following the method described by Braun and Clarke [22]. This initial analysis was performed by the external supplier who conducted the interviews, involving 3 data analysts who had expertise in qualitative research. The analyses were then reviewed and validated by a senior behavioral economics expert from the external company. An analysis grid was preliminarily developed to categorize participant feedback into themes and subthemes. The focus was placed on the barriers, facilitators, attitudes, and motivations toward CC screening, particularly HPVss, as well as gathering the insights, views, and recommendations from women and health care professionals to enhance the chatbot's design and content. A subsequent deductive analysis was then performed by the first author (ALB) to reorganize identified themes to match our objectives. This second analysis involved selecting the data to inform the key aspects of the chatbot's development, that is, views on HPVss, experiences with the tool, and perspectives on its use.

Participants in the focus groups were organized into numbered groups with different criteria across phases. In phase 1, a total of 4 focus groups were organized by language background: groups 1-2 French-speaking women and groups 1-2 non–French-speaking women. In phase 2, four focus groups were organized by digital comfort level: groups 1 and 3 included women who were not comfortable with digital tools, while groups 2 and 4 included women who were comfortable with digital tools. For individual interview participants, pseudonyms (eg, Esther and Eric) were assigned to protect anonymity while enhancing the readability of direct quotations, in accordance with standard qualitative research practice.

Validity Procedure

The methods used follow recommendations about the validity of results [23]. Credibility was satisfied through the implementation of several systematic procedures throughout our research process. All interviews and focus groups were conducted using standardized guides to maintain consistency across data collection. For non–French-speaking participants, peer facilitators helped translate discussions to ensure accurate understanding across languages. Data triangulation was achieved by comparing perspectives across different participant groups (French-speaking women, non–French-speaking women, and health care professionals).

Authenticity was satisfied by the achievement of interviews and focus groups until a sufficient diversity of perspectives was captured and data saturation was reached. Moreover, our 3-phase iterative development approach served as an additional validation mechanism, as participant feedback directly informed subsequent improvements to the chatbot.

Concerning transferability, comprehensive and detailed explanations about the procedure of the interviews and focus groups have been provided, and the interview and focus group grids (in French) are available upon request.

Finally, concerning confirmability, we used 3 analysts to code the thematic analysis. Investigator triangulation was used through a team-based analytical approach, where multiple researchers from the external company independently coded transcripts before meeting to reach consensus on themes. Regular meetings between our research team and the external company ensured alignment with research objectives throughout the data collection and analysis process.

Results

Participant sociodemographic characteristics are provided in Tables S1-S6 in Multimedia Appendix 1.

Phase 1: Exploratory Phase

Views on HPV Self-Sampling

Health Care Professional Perspective

Self-Sampling Is Easy

Self-sampling was considered simple, easy, and accessible to all women, and without risk of harm or injury to oneself. Self-sampling was perceived as ideal for women with an aversion to gynecological examinations (due to embarrassment). Most health care professionals considered self-sampling to be

XSL•FO
RenderX

in line with present-day practice, as people are used to self-sampling with COVID-19 tests:

> *No, women know how to insert tampons, women clean themselves far too much, as I told you, and far too often on the inside, it's child's play.* [Esther, GP]

Self-Sampling Might Not Be Appropriate for All Women

However, health care professionals reported that self-sampling would not be suitable for all women, specifically women who do not know their own anatomy and women who do not participate in self-testing in general. Moreover, they assumed that older women (regardless of their backgrounds) would not adhere to this procedure:

> *Let's say that the self-test is mainly intended for patients who are already comfortable with their bodies and who are, for example, accustomed to using tampons or menstrual cups or inserting things internally.* [Sophie, midwife]

A lack of interest or willingness among women from socioeconomically disadvantaged areas toward screening campaigns in general was also mentioned by health care professionals:

> *It's generally these women who throw away the mail and who don't really care about it.* [Morgane, midwife]

Self-Sampling Could Deter Women From Consultations

All health care professionals reported that the self-test was a good screening tool to improve screening participation, but it should not replace a clinical examination or the Pap smear test. Instead, self-testing should complement regular follow-up. Some health care professionals perceived the self-test as a competitor and feared that patients would skip necessary clinical examinations:

> *The concern is that they won't have a clinical examination. 'It's ok, I did it at home, it's fine,' it shouldn't become an excuse to get out of doing it.* [Hélène, gynecologist]

Women's Perspectives

Self-Sampling Can Improve Access to Screening

The women did not anticipate any particular difficulties and felt comfortable with the idea of self-sampling. The self-sampling test appeared simple, with only a few steps, and the instructions were considered sufficient. Handling the cotton swab was reported as familiar, as many women had already done a polymerase chain reaction test for COVID-19. The main advantages of HPVss highlighted by women were being reassured between gynecological examinations, saving time, having a solution when it is difficult to consult a specialist, being able to do the test comfortably at home (less stressful), and having an alternative for when they did not want to consult a male health care professional for gynecological procedures:

> *It's good for women who work all day because we don't have much time.* [Zourika, aged 35 y, non–French-speaking woman]

> *Living in Hérault as well, there's an issue, anything gynaecology-related is quite complicated, very long to get appointments, so yes, I support this kind of proposal, and if it really replaces the Pap smear, there's no need to go to the gynaecologist anymore, at my age, she just gives me a Pap smear, sends me the results, and that's it. It can free up places for people who need to be monitored, it's positive.* [French-speaking woman, group 2]

Self-Sampling Can Be Perceived as Complex

For all women, several obstacles could hinder adherence to self-sampling. First, the complexity of the test was often considered too technical. Introducing the cotton swab into the vagina and how to correctly collect a sample before removing it was considered very technical and required expert hands:

> *I don't know if I would do the test, and I'm even rather against it because I prefer to have it done by a specialist because I don't know if I would do it correctly, if I would know what to do to get an accurate result.* [Madina, aged 32 y, non–French-speaking woman]

Second, the fear of hurting themselves was also mentioned by the participants. The test was not perceived as a pleasant moment, and having it carried out by another person seemed to make things easier. However, for some participants, having the responsibility of conducting an unpleasant test on themselves was too demanding:

> *I would also be afraid of hurting myself, of inserting it in the wrong place or damaging something.* [Sophie, aged 39 y, French-speaking woman]

Self-Sampling Is Perceived as Unreliable

Concerns were raised about the reliability of the self-sampling test, as self-sampling is not as deep as samples taken by a health care professional using a speculum. In addition, the risk of a false negative result if the sample was not taken correctly was also expressed by the participants:

> *I would be more inclined to do the first two steps, for the third one I would be afraid of not turning it correctly, I wouldn't trust the result. I'm not convinced. It's the act of inserting it into the vagina and turning it. If they tell me it's positive, I'll consult immediately, if they tell me it's negative, I wouldn't be convinced.* [Magali, aged 48 y, French-speaking woman]

Participants who had regular gynecological follow-up indicated their clear preference for screening to be performed by a health care professional:

> *I prefer to have my doctor do the smear. I don't feel confident doing it myself. I'd rather have a professional who's used to doing it, who knows how to do it, who knows how to do it properly. I would be more comfortable with the results.* [Sophie, aged 39 y, French-speaking woman]

XSL•FO
RenderX

Women Could Miss Out on the Benefits of a Consultation

Without medical supervision, women with positive results might not follow up on additional examinations. The risk of replacing gynecological follow-up with self-testing was highlighted, as some women interested in self-sampling mentioned the possibility of no longer going to their physician:

> *I don't think so, because I have regular check-ups and I tend to bury my head in the sand, what I don't know can't hurt me. I wouldn't do it in addition to my regular check-ups. For those who have difficulty finding a practitioner, it might be a good alternative. I don't think it would be necessary in my case, but it could be useful for other people.* [French-speaking woman, group 1]

Perspectives on the Chatbot Platform

Overview

For both health care professionals and women, the scope of the app was not broad enough. One would not need to consult it often for its current purpose of just CC screening. Consequently, downloading the app did not seem worthwhile to participants:

> *It's a good idea, but would it be an application just for that? An application seems odd, I don't think people will download it just for that. It could be an application but for screenings for different types of cancers, then I'd say yes, the scope is broader.* [Marie, aged 59 y, French-speaking woman]

The Health Care Professional Perspective

Limited Interest in e-Tools in General

Health care professionals expressed limited interest in e-tools in general, but they reported a growing interest among their patients:

> *Often, they talk about it, 'Oh, I have an app, doctor, I'm going to check it,' and it irritates me.* [Hélène, gynecologist]

Health Care Professionals' Preconceptions About Digital Tool Use

Health care professionals expressed some preconceptions about older women and women from disadvantaged areas who might not be interested in e-tools or would not be able to use them:

> *But if you like, the problem with sites is that the people who need it most, if you want to understand things properly, are often people who don't often have a computer or who are a bit limited, you know what I mean?* [Anne Marie, GP]

However, the development of the app and the use of HPVss was supported by all health care professionals, on the following conditions:

- It is specified that a self-sampling test cannot replace a test performed by a health care professional or a clinical examination.
- The app includes a personalized reminder with support mechanisms in place in the event of a positive result.
- The app is extended to other screening programs and includes reminders, information on the screening program, and directories to help women find health care professionals.

User Perspective

Use of the Internet and Smartphones in Daily Life

The women interviewed had at least one smartphone for personal use and most also had at least one laptop. If they had technical problems, they reported no hesitation in asking their children to help them navigate or configure their devices. Non–French-speaking women, who were not familiar with the term "app," confused it with the social media website pages:

> *I use my smartphone for everything, I make my medical appointments, do my shopping list and my online shopping, searches for myself or for the little one's homework, I go on social media.* [French-speaking woman, group 1]

Strong interest in the app and HPVss was expressed by non–French-speaking and older women, who had not consulted a gynecologist for a long time. Less interest was expressed by younger and French-speaking women who preferred to consult their physician directly:

> *I think it's great, a super idea. In Hérault, it is very difficult to get an appointment, it's ridiculous in Montpellier, I have to wait 6 months. We don't have regular follow-ups like we used to have 15, 20 or 30 years ago, now we just go for a Pap smear, so if we can do it at home with the time we need to do it, it's great to be able to do it ourselves.* [non–French-speaking woman, group 2]

All women showed interest in the project to develop the e-tool and use HPVss, provided the following:

- The e-tool is recommended by a trusted source (eg, physician, friend, and family member) or a reliable authority (eg, French Health Insurance).
- The self-sampling test is free of charge, sent to the home with a prestamped return envelope, and results are easily and securely accessible.
- The e-tool provides audio-video tutorials on how to do the self-sampling test, as well as information about cancer, screening, and prevention in the user's preferred language.
- The e-tool provides information beyond CC screening, including broader health prevention topics.
- The e-tool is integrated into commonly used social media platforms for easy access and sharing.

Limited Interest Among Some Women

Some participants reported that they would prefer to consult their health care professional directly, as they were more comfortable doing so and testing performed by a health care professional was more reliable. These women were French-speaking and benefited from regular follow-up:

> *The only thing I'd be interested in is having some kind of follow-up to reminds us, 'Don't forget, it's been 11 months since your last screening, it would be good to make another appointment.' Otherwise, I don't really see the point. If I want information about*

XSL•FO
RenderX

> *the disease, I'd rather talk about it with my gynecologist or my GP.* [French-speaking woman, group 1]

Phase 2: Prototype Testing

Overview

The second phase of the study aimed to gather feedback from health care professionals and women on the prototype. Participants provided feedback on the acceptability, design and content, ease of use, and understanding of the educational messages. The AppDate-You chatbot was made available through WhatsApp, offering text-based and voice-based interactions.

User Experience and Interface Design

All participating women provided positive feedback on the chatbot's performance, highlighting its speed, precision, and reliability in delivering responses. Notably, even participants with limited interest in smartphone apps found the tool accessible and user-friendly. The inclusion of a vocal option was particularly appreciated, enhancing the chatbot's usability. The integration with WhatsApp emerged as a key feature, praised by both women and health care professionals. Health care providers specifically noted the advantage of using WhatsApp as a platform, citing its free availability and widespread adoption among the target population. This choice of platform seemed to remove barriers to accessing the tool and increase the chatbot's potential reach:

> *Very easy, even though I'm usually not very good smartphones, computers, etc., but this was easy.* [Hayat, aged 42 y]

Despite the generally positive reception, usability testing revealed some challenges. A key issue reported by some women was the need to frequently rephrase questions to obtain relevant answers from the chatbot, leading to frustration and an impression of time-wasting. Users also expressed dissatisfaction with repetitive responses, particularly when the chatbot failed to understand queries or lacked appropriate information:

> *A question or two where I had to insist, age-wise, it always gave me the same answer, and then I got no video, no link to a site.* [Christine, aged 45 y]

Educational Value and Content

All participating women reported increased knowledge from using the chatbot, particularly about self-sampling, screening, HPV, and HPV vaccination. Participants expressed interest in using similar tools in the future, highlighting the importance of health care professional validation. Health care professionals agreed with its educational impact, praising the relevance and clarity of the information provided. They described the chatbot's answers as scientifically accurate and easily understandable, highlighting its potential as an effective tool for health education:

> *It's interesting, even fun to have the answers, to be able to chat like that. And so I think it might interest people to have a quick and reliable answer.* [Eric, GP]

> *I would love to use it, especially if you create an app like this, make sure you say that it's verified by healthcare professionals, it is really important.* [Chehrazade, aged 35 y]

Health care professionals appreciated that the chatbot appropriately guided users to seek in-person medical consultations when necessary:

> *Frankly, he can give them information quickly [...] he tells them to go and consult, when to consult a professional, no, frankly I think it can be interesting.* [Olivia, midwife]

Users valued the freedom to ask various questions without feeling embarrassed or judged:

> *Sometimes it can be embarrassing to ask a professional this kind of question.* [Maryline, aged 36 y]

> *I would say discretion. Sometimes some people are afraid of what other people will think.* [woman, group 1]

Users also praised the chatbot's flexibility in handling concise queries regardless of spelling or grammatical errors. The inclusion of links to informative videos was noted as a particularly useful feature, enhancing the educational experience. Importantly, women suggested simplifying complex and technical information through the use of images, illustrations, and infographics, highlighting a preference for visual learning aids to enhance understanding of medical concepts:

> *A diagram yes, that's right, that would have been good.... A diagram would be great.* [Chehrazade, aged 35 y]

> *Both: testimonials and images like we can see in the photo, with drawings, showing the progression, small diagrams.* [Hayat, aged 42 y]

Feedback on HPVss-Related Content

While all women were not aware of HPVss before participating in the study, they all showed a good understanding of the benefits of using HPV self-sampling. This positive feedback was shared by the health care professionals, who mentioned that the HPVss was presented well in the chatbot. However, both women and health care professionals highlighted a lack of clarity for the following aspects. First, the price of a self-sampling kit and reimbursement rates. Second, how to obtain a self-sampling kit (eg, availability in pharmacies, availability online, and necessity for a prescription):

> *I had trouble understanding where you can get the self-test. It said on the Internet. This is not reassuring.* [Woman, group 3]

Third, women were concerned with the lack of clarity about the kit's delivery conditions and (eg, protection of the tube against temperatures, packaging, and deadline to send it) and communication of the test results (eg, confirmation of receipt and waiting times). Fourth, health care professionals were concerned about a lack of information about screening follow-up modalities depending on test results. Finally, women were concerned about the lack of success stories or shared experiences

XSL•FO
RenderX

from other women having used a self-sampling kit, which would serve to reassure them.

In addition, women found that the e-tool put too much emphasis on HPVss in the presentation of screening procedures for CC. They advised that it should be moderated. Health care professionals also insisted on the fact that self-sampling is only one way to get screened and that even if women opt for self-sampling, they should still consult their gynecologists regularly:

> *It felt like it wanted to sell us the self-test.* [Woman, group 3]
>
> *That's all very good, but I think that if all women received their kit at home, they would no longer go to see the gynecologist.* [Léonie, midwife]

Finally, the video presenting the HPVss kit was much appreciated by both women and health care professionals. This video was developed by another French research team working on promoting HPVss. Participants found the 4-minute, 15-second video to be easy to understand, accessible to all, and sufficiently detailed. Health care professionals reported that this format caught their attention and encouraged them to recommend self-sampling to their patients. Some women even mentioned that they learned more about their anatomy while watching the video:

> *It is interesting because it can help people have a better understanding of their internal anatomy.* [Woman, group 4]

However, both women and health care professionals suggested improvements to the video (shortening its length and making it more engaging) and adding step-by-step illustrations of the screening process. Moreover, due to inconsistent display of the video link, some participants never saw the video and consequently lacked understanding of how to use the self-sampling kit:

> *It was too long, you know. I lost interest, I didn't follow all the way to the end.* [Olivia, midwife]

Accessibility and Target Audience

Some health care professionals expressed concerns about the chatbot's reach and target audience. They were worried that the tool might not be accessible to women experiencing socioeconomic disadvantage, especially those with low literacy or without smartphones. They also felt that the tool would only be of interest to young women (aged <30 y) who are comfortable using smartphones, although this concern was not reported by the participating women themselves:

> *For my underserved patients, they don't necessarily have smartphones, so it won't reach everyone. And I have patients who can't read, gypsies for example.* [Marjolaine, midwife]

Phase 3: Field Testing

Overview

The third phase evaluated the improved AppDate-You chatbot prototype for usefulness, feasibility, and acceptability among eligible women. An enhanced version based on phase 2 feedback was made accessible via WhatsApp and Facebook Messenger. This version incorporated rich multimedia content, including illustrations and infographics, covering various aspects related to CC and screening procedures. We also created a new, more concise video explaining how to perform HPVss that was informed by participant feedback from phase 2 and addressed the concerns about length and monotony. This improved visual approach aimed to further simplify complex information and enhance user understanding.

User Experience and Use Patterns

Most participants provided positive feedback on the chatbot's use. In total, 5 participants expressed difficulties accessing the chatbot, and 1 participant requested help from the facilitator to access it. Overall, 93% (14/15) of the participants were able to access the chatbot independently. Participants found the tool easy to use and compatible with their usual online communication platforms, particularly WhatsApp. Interactions with the chatbot were consistently described as straightforward. On average, participants engaged with the tool for about 10 minutes daily, asking between 1 and 3 questions per session. Notably, the topic that generated the most interest among users was the HPVss test:

> *The tool is easy and quick, you don't need to go on forums, look for something related to a very specific issue, and the answers are there, instantaneously, and useful. Like the links.* [Nadhira, aged 58 y]

Despite overall positive feedback, some limitations were noted. A recurring issue was user frustration with the chatbot's tendency to provide repetitive answers to some queries:

> *Minor reproach: There are too many unnecessary images. It's always the same ones over and over again.* [Claudine, aged 45 y]

Educational Value and Content Quality

Participants appreciated the chatbot's content, describing it as diverse, informative, clear, and useful. They reported significant knowledge gained while using the tool, particularly about CC screening:

> *Really useful, I've learned things I didn't know, it's made me want to go for a smear test, although I wasn't aware of it, but now I know why I should do it, and how to go about it. And if it prevents me from getting cancer, it is important.* [Sonia, aged 30 y]

The chatbot effectively raised awareness about CC screening, but some limitations were identified. Users found that the chatbot's answers sometimes did not sufficiently encourage or prompt users to delve deeper into the topics discussed. Moreover, the use of medical terms, particularly abbreviations, occasionally caused confusion. For example, one participant had to search online for the meaning of "HPV," highlighting the need for clearer explanations of medical terminology.

HPVss Perceptions and Impact

The final test revealed a positive perception of the information on HPVss. Moreover, 80% (12/15) of the participants expressed

XSL•FO
RenderX

interest in HPVss when it becomes available. Users perceived HPVss to be a safe, private, easy, and reliable method that provides fast results:

> *It's very practical, it's reassuring to do it at home, it saves time and it makes it easier for many people to get screened and encourages them to do it.* [Ophélie, aged 38 y]

The educational video demonstrating the HPVss steps helped to change women's attitudes toward screening. Several women who were initially hesitant about self-sampling reported feeling more confident after watching the demonstration:

> *It's reassuring because it shows that tests done at home are just as reliable as if they'd been done at the doctor's. They show you how to do it, what position to adopt and, above all, you have to be very relaxed for the test to be carried out properly. And once you've taken the test, you have to send it the same day, by post, to get the results within 15 days.* [Shalini, aged 32 y]

> *The video is really important, without it the subject seems a bit unclear.* [Magali, aged 50 y]

Self-sampling was seen as a potential solution to various barriers, including difficulties in obtaining health care appointments, past negative experiences with professionals, and discomfort associated with examinations performed by professionals:

> *I think it's good for people like me who refuse to go to the doctor.* [Michelle, aged 61 y]

Three women preferred not to use self-sampling due to a lack of confidence in performing the test correctly themselves, fear of self-injury, or a general dislike of self-tests. However, all participants recognized the value of self-sampling for those with limited access to health care or time constraints.

Discussion

Principal Findings

This paper outlines the design and validation phases of a chatbot designed to help women from socioeconomically disadvantaged areas in France to make an informed choice about cervical screening. Our multiphase approach ensured AppDate-You's development as a user-centered, empathetic, and effective digital decision aid. The user-centered design evolved throughout our iterative process that continuously incorporated women's feedback. For example, we added additional videos and infographics in response to suggestions to simplify complex medical information. Women in phase 3 particularly appreciated these user-centered adaptations and found the visual content especially helpful to understand screening procedures. We also removed technical barriers for users with varying digital literacy levels by integrating with widely used messaging platforms and offering voice interaction options. Empathy was achieved through conversational tone and a nonjudgmental approach. Women appreciated the chatbot's ability to provide a comfortable environment to freely ask questions without feeling embarrassed or judged. The effectiveness of AppDate-You was demonstrated through dual validation: users reported substantial knowledge gained and increased likelihood of screening uptake, while health care professionals confirmed the content's scientific accuracy and appropriate guidance in phase 2.

Findings from phases 2 and 3 also demonstrated high acceptability and feasibility of the AppDate-You chatbot among the target population. Acceptability was shown by feedback from both participants and health care professionals on the chatbot's performance, educational value, and content quality across testing phases. Users appreciated its accessibility through familiar messaging platforms, user-friendly interface, and ability to provide scientifically accurate information. Regarding feasibility, most participants accessed and navigated the chatbot independently without technical assistance, engaging with the tool for approximately 10 minutes on a daily basis, with HPVss emerging as the topic that generated the most interest and questions among users. Beyond evaluating the chatbot itself, this research also provided valuable insights on the acceptability of HPVss in France. While the HPVss procedure was perceived as easy and approachable by both health care professionals and the participants, some challenges were identified by participants. Some women mentioned a lack of confidence in using the device correctly and questioned its reliability. Health care professionals expressed a fear of deterring some patients from consultations.

The AppDate-You chatbot was designed to assist women in making informed decisions about HPVss and has garnered positive feedback from both users and health care professionals. Notably, even individuals with limited digital literacy or minimal familiarity with AI found the chatbot to be innovative, user-friendly, and highly informative. Users particularly appreciated the intuitive interface, rapid response times, and the quality of information provided. The incorporation of multimedia elements, such as infographics and videos, proved effective in simplifying complex health concepts and enhancing overall understanding of HPV and CC screening.

Comparison to Previous Work

Our findings showed that the chatbot not only enhanced knowledge about CC screening but also significantly boosted motivation to engage in screening practices. These results underscore the potential of digital interventions to advance and promote health education, especially among populations less engaged in preventive health practices. These promising outcomes are consistent with recent studies, notably the study conducted by Baumgärtner et al [24], which demonstrated that the PROState cancer Conversational Agent chatbot for prostate cancer screening achieved high user engagement and satisfaction while effectively conveying health information and improving understanding of screening processes.

In recent years, chatbots have been increasingly used across the spectrum of oncological care, from early prevention and screening to patient support during treatment for various types of cancer [12]. Evaluations consistently report high levels of user satisfaction and have shown that these tools are effective in key areas, including enhancing patient-centered communication, improving access to cancer-related information, and facilitating better overall engagement with oncological services [12].

XSL•FO
RenderX

Chatbots can be delivered through various channels, with WhatsApp emerging as a particularly valuable platform for health education. Pereira et al [25] demonstrated that WhatsApp-based interventions significantly enhance breast cancer knowledge and serve as a viable alternative to support breast cancer control strategies [25]. Similarly, in our study, WhatsApp was highly appreciated and widely used by the participants, proving to be more accessible than Facebook Messenger. This preference is likely due to WhatsApp's widespread adoption and the greater familiarity it holds among our target women.

Our results are in accordance with international evidence, showing that HPVss is generally acceptable to women, but a lack of self-confidence with collecting a reliable sample can be a barrier to choosing this option [7]. A study conducted in France showed that health care professionals have positive attitudes toward HPVss**.** More precisely, health care professionals indicated that self-sampling could help to remove logistical, organizational, financial, and psychological obstacles [26]. Our study demonstrated similar results; however, our participants also expressed concern that self-sampling could deter women away from consultations and might not be suitable for all women.

Given the current lack of standardization in the development and evaluation processes for chatbot health care tools [27], we adopted the framework proposed by Coulter et al [17] to design our chatbot. This comprehensive approach consisted of 3 key phases: identifying CC screening information needs, conducting user testing, and implementing iterative improvements. By adhering to this systematic process, we significantly enhanced the chatbot's performance and aligned our tool with women's needs before its widespread implementation. The beta testing phase resulted in only minor revisions, indicating the robustness of our initial design and the value of behavioral science and our user-centered approach.

Strengths and Limitations

A notable strength of our study is the thorough approach we adopted to collect opinions and feedback from both women and health professionals. We used a validated framework to develop a chatbot and a range of methods tailored to the specific objectives of each phase, including face-to-face and online interviews and focus groups. This diverse methodological approach ensured a comprehensive understanding of user experiences and preferences, enhancing the robustness and depth of our findings. However, while the sample size was adequate to gather feedback and capture perceptions, it may not be fully representative of the broader population of women in disadvantaged areas of France. We also acknowledge that digital health interventions may not reach all demographic groups equally. Certain racial, cultural, or gender groups might be less likely to engage with AI-based health tools due to technological barriers, language limitations, or cultural preferences for in-person health care. To mitigate these barriers, we implemented several design choices: (1) creating a female virtual assistant named "Sarah," an internationally recognizable name acceptable across many cultures; (2) offering both text and voice interaction options to accommodate various literacy levels; and (3) ensuring the language used was simple and accessible. Despite these efforts, we recognize that some groups may still be underrepresented among users, highlighting the importance of complementary approaches when promoting CC screening.

Future Directions and Implications

A key finding of our study is the divergence between health care professional expectations and women's actual experiences with the chatbot. While professionals anticipated that older women and those from underprivileged backgrounds would struggle with or show disinterest in e-tools, the reality was quite different. These women demonstrated both willingness and ability to engage effectively with digital health solutions. This difference suggests that health care professionals may underestimate patients' ability to engage with and benefit from digital health tools. Several factors could contribute to this misconception. First, health care professionals might be influenced by stereotypes about age and socioeconomic status in relation to technology use. Second, they may lack up-to-date information on the increasing digital literacy across diverse demographics. In addition, the user-friendly design of the chatbot, with its clear interface and engaging content, may have played a crucial role in overcoming potential barriers. These findings have important implications for the development and implementation of digital health solutions. They underscore the need for health care providers to reassess their assumptions about patient capabilities and to involve diverse user groups in the design and testing phases of digital tools.

While AI chatbots show promise in increasing health knowledge and enhancing motivation to adopt health-related behavioral changes, robust RCTs are still needed to draw definitive conclusions about their effectiveness in health care [28]. We plan to conduct a 2-arm cluster RCT to evaluate the impact of our chatbot-based decision aid on CC screening participation rates. The detailed study protocol has been previously published [29]. This trial will provide valuable empirical evidence on the real-world effectiveness of digital interventions in promoting preventive health care behaviors and help to establish their role in improving health outcomes.

In conclusion, our study highlights the potential for AI chatbots to improve health education and promote cervical screening among underserved populations. By leveraging user-friendly digital tools integrated into widely used platforms, we can address potential barriers and enhance health outcomes. Future research, particularly well-designed RCTs, will be essential to validate these findings and refine the implementation of digital health interventions. Our planned RCT will be a critical step toward providing evidence on the impact of chatbot-based interventions on CC screening rates and will contribute to the broader understanding of digital health tools in preventive care.

Abstract

Background: A public involvement group consisting of 4 public contributors with lived experience of cancer diagnosis contributed to 2 cancer research projects that focused on optimizing the diagnostic pathways for patients with suspected cancer. The public contributors have been involved from the start of the projects and were involved in aspects of the design, analysis, and dissemination alongside research and clinical teams. Despite public involvement in cancer research being seen as a key element of the research process, there is still a limited understanding of what works well and how to do it in a meaningful way for both researchers and public contributors.

Objective: This study aims to evaluate the public involvement process in 2 cancer research projects.

Methods: This was a collaborative evaluation with the research team and public contributors jointly evaluating the process. Data were collected throughout the lifespan of the project by public contributors through photovoice, where they collected photos that represented their experiences of involvement. At the end of the evaluation meeting, 2 separate analyses were conducted. First, public contributors reflected on their experiences using a 4-dimensional framework to capture how strong their voice was, how many ways they had an opportunity to be involved, if their feedback was implemented, and if the discussion focused on their priorities. Second, they analyzed the collected photos by organizing them alongside their narratives, explaining their meanings and comparing how they experienced the involvement process.

Results: Narratives from 8 photos illustrate public contributors' experience of involvement in these projects, presenting them in chronological order, showing how their perspectives evolved from not knowing what form the project would take, through understanding foundations and building confidence through being satisfied with the successful projects. Results from the 4-dimensional framework showed that public contributors felt that their voices were strong, and the research and clinical team mostly implemented suggested changes. The discussion focused on topics and issues that were relevant to public contributors. However, how public contributors were involved depended mainly on the research team's decision, and they would have preferred more opportunities.

Conclusions: This study has shown that public contributors can be meaningfully involved throughout the lifespan of cancer research projects. The evaluation demonstrated that establishing a strong relationship and trust between researchers and public contributors helps to ensure that the public contributors' voice is meaningful and makes a difference in the projects. However, it also identified improvements for future public involvement. Researchers should involve public contributors as early as the funding application stage to offer more opportunities to shape research and thus have diverse involvement opportunities at each stage of the research process.

patient involvement; prostate cancer; breast cancer; PPI; patient and public involvement; patient engagement

Introduction

Background

Public involvement has emerged as a crucial element in cancer research, ensuring studies are both patient-centered and impactful. In the United Kingdom, organizations such as the National Institute for Health and Care Research (NIHR) and Cancer Research UK mandate public involvement in funded research to ensure transparency and accountability [1,2]. By actively engaging patients, caregivers, and community members in every phase of a study, from identifying research questions to designing research methods and disseminating findings, the

XSL•FO
RenderX

public voice introduces unique insights that extend beyond traditional clinical or academic perspectives [3,4]. Furthermore, public involvement builds trust between researchers and the communities they serve, leading to improved recruitment, better retention of study participants, and ultimately more meaningful outcomes that reflect real-world needs [5]. Despite these acknowledged benefits, systematic evaluation of public involvement processes and their impacts on research outcomes remains a critical area for further investigation.

We follow the NIHR in the UK definition of public involvement in research as research "being carried out 'with' or 'by' members of the public rather than 'to,' 'about,' or 'for' them" [6]. It is the active partnership between researchers and members of the public, who work collaboratively throughout the research process rather than merely serving as study subjects [7]. These definitions are operationalized by the UK National Standards for Public Involvement, which provides a framework for ensuring that engagement is meaningful, inclusive, and sustainable [8]. The underpinning principles of respect, support, transparency, and accountability have been central to our approach, guiding the integration of public perspectives throughout the research process.

While public involvement is widely regarded as beneficial in cancer research, the literature reveals significant challenges in ensuring that such involvement goes beyond superficial consultation. Scoping reviews in health research indicate that public involvement activities are predominantly advisory and tend to occur during the early stages of research, thereby limiting the influence public contributors have on key decisions [7,9]. Although researchers value public input, integrating lay perspectives on an equal footing with academic expertise can be challenging. Structural aspects, such as the hierarchical nature of academia and the research environment, pose additional barriers to sharing power and influence [10]. Resource constraints further compound these issues; without adequate time and funding dedicated to public involvement, the process can be rushed and superficial, undermining meaningful involvement [4]. Overall, the literature emphasizes the need to continuously reflect on power dynamics, proactively plan public involvement, and create environments where public contributors have genuine influence.

Critical reflection of public involvement from both public contributors' and researchers' perspectives remains limited in the literature. As effective partnerships require careful attention to process, robust evaluations of the processes and outcomes of public involvement are essential [11]. However, many projects do not formally assess the impact of public involvement or report the challenges encountered. Reflecting on both successes and difficulties is critical to strengthening public involvement practice and ensuring that public contributions are genuinely integrated into research. In this context, evaluative frameworks, such as the 4-dimensional theoretical framework developed by Gibson et al [12,13], are invaluable for guiding the evaluation of public involvement in cancer research. We present an evaluation of the involvement of 4 public contributors across 2 cancer research projects.

Background to Evaluated Cancer Research Projects

The public contributor group has been established to support 2 Cancer Research UK-funded projects [14]. They both aimed to optimize the diagnostic pathway for patients with suspected cancer and were conducted in partnership with NHS Fife and NHS Forth Valley in Scotland. The project in Fife introduced the nurse-led diagnostic clinic for suspected urgent prostate cancer referrals. The Forth Valley project implemented direct referrals to secondary care for urgent suspected breast cancer by removing primary care appointments. Both projects, which ran simultaneously, used a hybrid effectiveness-implementation study design with similar research methods, focused on health outcomes, patient experience, costs to the health care system, and the process of implementation. Therefore, the decision was made to share experiences between these 2 projects and organize joint management and governance groups such as this one for public contributors. This paper refers to both breast and prostate interventions as the projects.

The research team comprised academic and clinical researchers with backgrounds in public health, health services research, psychology, and oncology, all with a shared commitment to inclusive, person-centered research. The team had previous experience in participatory methods and a belief in the value of lived experience as a form of expertise. These perspectives shaped the approach to involving the public as active partners and informed the interpretation of findings with a focus on equity, collaboration, and real-world relevance.

Public involvement guidance recommends involving more than 1 public contributor in research [6]. In these projects, the research team decided to involve 4 public contributors. This was based on previous experiences that small groups offer an opportunity for all public contributors to share their opinions, but also to bounce ideas through peer discussion and support. Previous cancer projects showed that 2 [15] or 3 public contributors [16] can meaningfully influence research.

The projects were launched in May 2023. In July, the research team recruited 4 public contributors with lived experience of breast (n=2), prostate (n=1), or another form of cancer (n=1) to the public involvement group. One of them was previously involved in research as a public contributor. None of the public contributors knew each other or the researchers before their involvement. The public contributors were not representative of the general population but rather emphasized the diversity of experiences [17]. This diversity included, for example, previous research experience, type of cancer, age, and whether cancer was diagnosed among other family members. Identifying potential public contributors can be challenging, and engaging with established contacts and cancer charities can facilitate that process [18]. They were recruited through established contacts, charities (eg, Breast Cancer Now), and the 1000 Elders Group at the University of Stirling [19]. Interested members of the public contacted the researcher with a short paragraph about why they were interested in the projects and subsequently met with the researcher to discuss the opportunity further. This meeting was not an interview process, but rather an opportunity for interested individuals to learn more about the projects, the

XSL•FO
RenderX

role involved, and the time commitment required to make an informed decision about becoming a public contributor.

Public contributors contributed in 2 ways. First, they attended management group meetings alongside researchers, clinical teams, and funder representatives. The purpose of the management group was to oversee and manage projects, ensuring the cross-fertilization of ideas across projects and enabling input. These meetings took place approximately every 3 months in person or hybrid. Second, the public involvement group met regularly with the research team. These meetings were online. One researcher was identified as a contact for public contributors through email, and peer support was offered through WhatsApp. Public contributors received £20 (US $27.5) shopping vouchers for attending meetings and were offered reimbursement for travel expenses (public transport or mileage).

During the design stage (May-July 2023), public contributors were introduced to the projects, the implementation plan, and the draft methodology and agreed to terms of reference for the public involvement group. Terms of reference defined the role of public contributors in the projects and their responsibilities (eg, maintaining confidentiality of all project-related information). It also stated the researchers' responsibilities, such as providing support, training, and offering regular updates on the progress of the projects and remuneration process. The terms were presented as draft versions and jointly agreed upon by both sides. Later, public contributors co-developed the theory of change (mapping how each intervention was expected to lead to desired outcomes), capturing patient perspectives and ensuring that the language was inclusive. They also reviewed and revised draft data collection tools and participant recruitment plans. This ensured that all questions in the interview guides and patient questionnaires were written in lay language and easily understandable by members of the public. Public contributors provided additional questions to capture the patient experience or reordered the question order for clarity. The protocol detailing the projects has been published, and public contributors have co-authored it [14].

During the implementation (August 2023-July 2024) and write-up stage (August- November 2024), public contributors acted as critical friends during the management group meetings as both clinical and research teams updated on the projects' progress. During meetings with the research team, they were involved in the initial analysis of staff and patient interviews. This was facilitated by training on how to be reflective when interpreting qualitative data. Thus, public contributors started to reflect on how their experiences impacted their interpretation of data. Table 1 summarizes reflective questions asked around each data segment shared with public contributors. The research team shared initial interviews as the data collection was ongoing, public contributors contributed not only to analysis (eg, developing codes during qualitative analysis) but also identified follow-up questions for future interviews. Later, public contributors were involved in writing policy reports and lay summaries.

Table . Reflective questions shared with public contributors during qualitative data analysis.

Reflective question	Aim of this question
How does this quote make you feel?	Offered space for a public contributor to reflect on the segment and link it with their experience.
Did anything surprise you and why?	Public contributors linked the situation in the segment to the theory of change and assumptions underpinning the project implementation.
Do some parts of this discussion benefit from follow-up questions?	Critical friend feedback if the interviewer potentially captured all relevant information from the participants in that part of the interview.
Should we explore another issue with participants – staff or patients?	Identified areas for future interviews that should be explored.
How would you describe what is going on in this quote?	Public contributors captured keywords that were later used to develop codes for the coding process in NVivo (Lumivero).

The research team and public contributors have developed a close working relationship throughout the research projects to facilitate the evaluation process. Researchers provided a nonjudgmental space and encouraged discussion [20]. This was achieved by having jointly agreed ground rules for each meeting (including evaluation) centering around listening and respecting each other's points of view and being a safe space to share perspectives and experiences. Honesty was crucial to developing trust [21]. Public contributors were constantly kept updated on the research progress through the management group and email updates. It takes time to develop the relationship between researchers and public contributors, but continuous involvement between the same people can facilitate that process [20]. In these projects, public contributors engaged with two key researchers for an 18-month period, thus establishing that connection.

Public contributors attended the Scottish Cancer Conference. One public contributor co-presented with the researcher on the public involvement process alongside initial findings from this evaluation at the Patient and Public Involvement Event. The research team invited public contributors to a thank-you dinner to celebrate the end of the projects.

Evaluation Aims

This paper presents the evaluation of our public involvement process in these 2 cancer projects. The objectives are to: (1) capture the involvement from the perspective of public contributors, (2) understand interactions between public contributors and the research team, and (3) identify what worked well and areas for improvement.

XSL•FO
RenderX

Methods

Design

The decision to evaluate the public involvement in these projects was undertaken jointly by the research team and the public contributors' group in July 2023. It was agreed to be a collaborative evaluation, thus actively engaging public contributors in the evaluation process. Before co-authoring this paper, all public contributors became involved in data collection, analysis, interpretation, and reporting [22]. Principles of collaborative evaluation are similar to, and often used simultaneously with, other participant-oriented evaluation approaches (eg, participatory and utilization-focused evaluation) [22]. These, in turn, show similarities to public involvement in research [23]. Table 2 summarizes the key features underpinning this evaluation. To further ensure the quality of this paper, the Standards for Reporting Qualitative Research [24] are reported in Checklist 1.

Table . Key features of the collaborative evaluation adapted from O'Sullivan [22].

Aspects of collaborative evaluation	How incorporated in this evaluation
Primary evaluation focus	The evaluation aimed to improve future public involvement run by the research team, and those where public contributors would participate.
Evaluation decision-making	Public contributors themselves chose the level of involvement.
Stakeholder roles	Public contributors were partners in the evaluation process and data sources.
Evaluator roles	Roles agreed. PT took the role of the evaluator as the team leader in the evaluation and public contributors were involved throughout the process.
Pre-evaluation clarification activities	Public contributors discussed and agreed on the evaluation aims.
Design	The evaluation was systematic and rigorous, with the process agreed upon at the start of the projects.
Type(s) of data collection	How public contributors' experience was captured was collaboratively agreed upon at the start of the evaluation process.
Type(s) of data reporting	Reporting has been collaboratively agreed upon between the research team and public contributors. Public contributors decided which collected data would be presented in the paper.
Evaluation capacity building	Public contributors learned new skills and became more confident researchers by being involved in the evaluation (alongside skills learned in the projects).
Cultural responsiveness	The research team had previous experience in organizing and evaluating public involvement activities.
Systems and networking considerations	Learnings from the evaluation were used to feed into the broader public involvement strategies and future research projects. This included dissemination of evaluation findings.
Active stakeholder engagement in evaluation implementation	Public contributors were actively involved in all stages of the evaluation and co-authored or co-presented any findings arising from the evaluation.

Data Collection

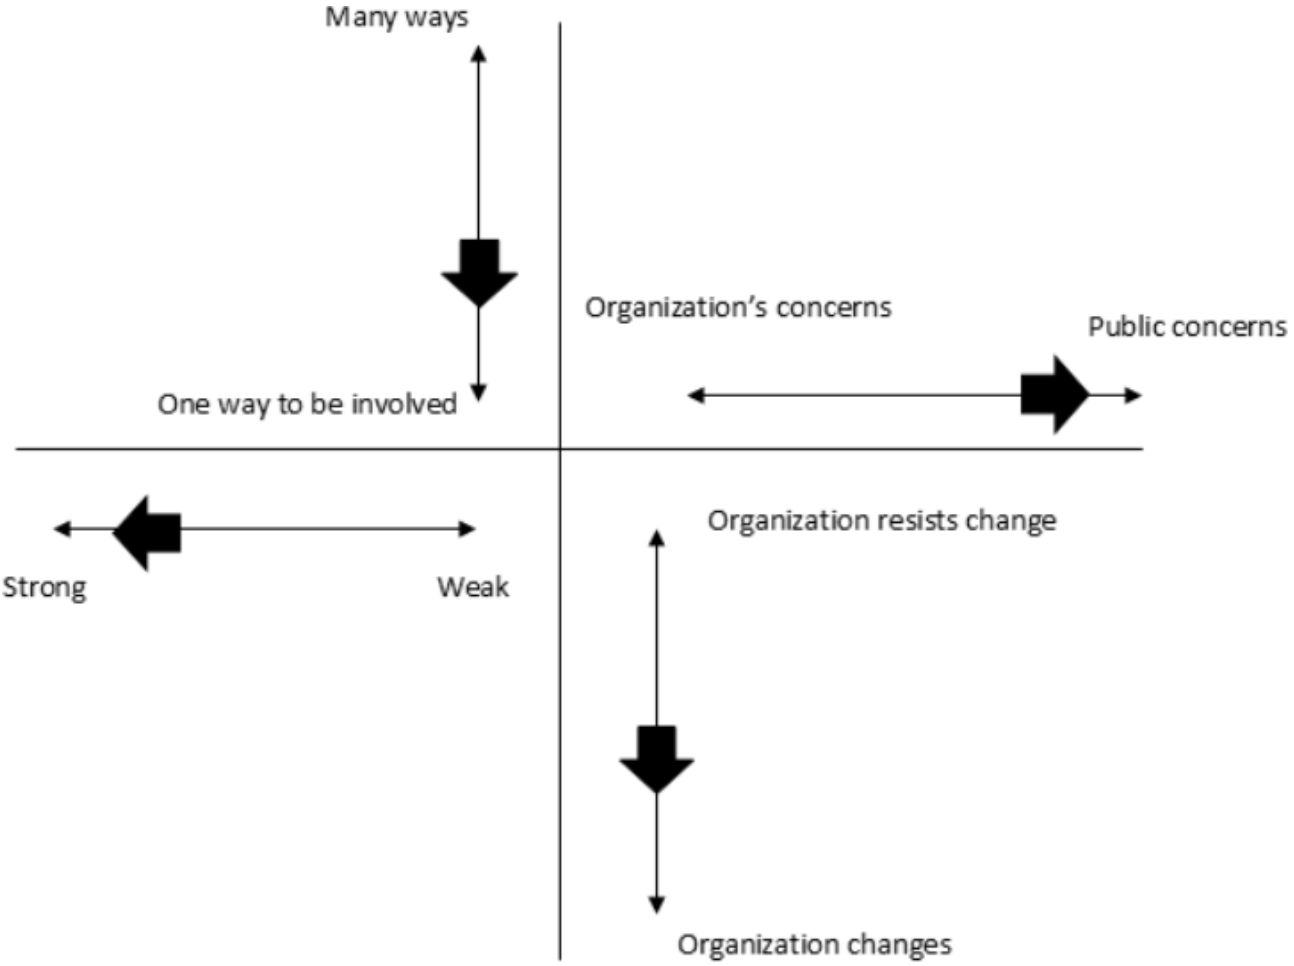
The collaborative evaluation was supported by creative research methods. Creativity has been used successfully in previous public involvement [25] and to evaluate the involvement process [26]. Creativity can offer public contributors a space to reflect on sensitive topics and express in their way their understanding of the world [27], thus providing insights that otherwise would be missed.

Public contributors had the option to choose between two creative methods. First, photovoice [28] and second, photo-elicitation [29]. Both methods entailed public contributors sharing their experiences through photos; they used the photos to symbolize their experiences and described how the images expressed their experiences. In photovoice, public contributors would take and bring their own photos, whereas, in photo-elicitation, the research team offered a choice of images. The photovoice method has been ongoing throughout the project, whereas the photo-elicitation method was available during the evaluation meeting. However, public contributors decided not to use any photos the research team offered; instead, they chose only those they took themselves. Photovoice and photo-elicitation were selected as creative methods due to their scope to capture people's experiences in an empowering way, where public contributors could actively shape data collection and offer space for reflection (both on individual and group levels).

Photovoice methodology guidance outlines 9 steps for using the method, although there is flexibility in how to implement it in each study [30]. Table 3 summarizes how photovoice was approached in this evaluation.

XSL•FO
RenderX

Table . Photovoice steps as outlined by Wang [31].



Photovoice steps	How was it implemented in this evaluation
Select and recruit a target audience of policymakers or community leaders.	Photographs should be shared externally to influence policymakers. The decision was made to share these through academic conferences and peer-reviewed papers targeting those working in cancer research (both researchers and public contributors). Public contributors and researchers co-presented the photos during an academic conference and co-authored this paper.
Recruit a group of photovoice participants.	All public contributors had an opportunity to take part in the photovoice.
Introduce the photovoice methodology to participants and facilitate a group discussion.	Researchers organized a training session on what photovoice is, how photos could be used to describe experiences, and explained the key rules of what kind of photos could be taken. Public contributors were reassured that this is not about becoming professional photographers.
Obtain informed consent.	All public contributors received a consent form and a participant information sheet before taking part in the photovoice. This was separate from the terms and conditions of being involved in the projects as public contributors.
Pose an initial theme for taking photos.	During some of the meetings, the research team brought photos, encouraging public contributors to choose one that represented their experience of the discussion held. This helped to build confidence in how to use photos in the discussion.
Distribute cameras to participants and review how to use them.	Researchers checked if all public contributors had access to a smartphone camera or a professional one.
Provide time for participants to take photos.	Public contributors could take photos anytime throughout the projects and share them with the researcher, who uploaded them to the secure document accessible by all public contributors.
Meet to discuss photographs.	The photographs were analyzed during the evaluation meeting. The discussion helped to establish consensus on how photos represent public contributors' experiences.
Plan with participants a format to share photographs and stories with policymakers or community leaders.	Co-presenting at a conference and co-writing this paper.

Analysis

At the end of the projects, PT, MM, and the public contributors met online on Microsoft Teams to evaluate the involvement process using the 4-dimensional framework [12,13]. The framework was chosen as it offered a comprehensive assessment of the public involvement interactions and captured subjective perspectives among public contributors. Researchers and public contributors had different perspectives of involvement (as those involving and being involved); there were also differences within the groups, as 1 researcher had experience of public involvement in research, as well as 1 public contributor. The four dimensions of the framework are: (1) the strength of public contributors' voice, (2) the number of ways they were involved, (3) if the research team implemented change, and (4) if the focus of involvement was on public contributors' priorities or the research team's. Each dimension was discussed in turn, and experiences were mapped as a group consensus. As the meeting took place online, PT shared his screen during the mapping exercise. PT and MM took notes from the discussion. However, all public contributors had an opportunity to deviate from the group if they wished. The process consisted of public contributors placing themselves on a line with two opposite ends (eg, weak voice vs strong voice in projects) to explain why they had placed their experiences there. The findings were presented as a diagram (see Figure 1) and a narrative way.

XSL•FO
RenderX

Figure 1. Mapped findings within the 4-dimensional framework as based on work by Gibson et al [12,13].

Collected photos were analyzed separately, discussed, and organized in a way that presented the joint experiences of being involved in the projects. Each photo was presented, and the author shared the story behind it, which led to questions from other public contributors and a reflection on how contributors' own experiences related to the one presented. Thus, this offered a more comprehensive understanding of public contributors' experiences. All public contributors agreed jointly on the interpretation of the data through the discussion. Investing time in building trusting relationships from the beginning and throughout the project was helpful for mitigating potential biases, such as social desirability bias and researcher influence during the evaluation meeting.

Ethical Considerations

The ethical approval for this evaluation has been granted by the University of Stirling General University Ethics Panel (15773). The ethical approvals for projects have been granted previously by South Central—Oxford A Research Ethics Committee (NHS Fife, 23/SC/0252) and by East of England—Cambridge East Research Ethics Committee (NHS Forth Valley, 23/EE/0168). As only 4 public contributors participated in the evaluation and they co-authored this paper (alongside other dissemination outputs), their confidentiality was limited. This was discussed with them beforehand and explained in the consent form that all public contributors signed before the start of the evaluation. Participation in the evaluation meeting was reimbursed with a £20 (US $27.5) shopping voucher, in accordance with the established policy for any type of meeting attended by public contributors.

Results

Photovoice

Findings from the photovoice method are presented and discussed chronologically to show how public contributors' experiences with projects have evolved over time. A total of 3 public contributors shared 8 photos throughout their involvement. The public contributor who did not share a photo felt that their experiences were already captured in others, as data collection was ongoing and everyone had access to already shared photos. The group discussed these jointly, and a consensus was reached to share all of them as joint experiences of their involvement.

At the start of their involvement (see Figures 2 and 3), public contributors had to visualize what these projects would look like and what their role would be in this process. Inductions and support from the research team were essential, and building connections with other public contributors was key in establishing the public contributors group.

XSL•FO
RenderX

Figure 2. Photo shared by public contributor.

XSL•FO
RenderX

Figure 3. Photo shared by public contributor.

The daffodil facing outwards is the thought process, visualizing how the project will form. The little bunch of daffodils standing tall reflects that vision coming to fruition with our now formed group! [Figure 2]

I find this photograph of the building of one of the pillars of the Cross Tay road link similar in concept to our project at the moment.

The foundations have been firmly set and we are now reaching out to complete the project.

Once finished many people will benefit from this. There is however still a lot of significant work to do. [Figure 3]

The projects focused on patient diagnostic pathways, and public contributors felt that the path through the woods appropriately represented the pathways being developed (see Figure 4). The imagination of a forest and an uncountable number of trees looked overwhelming—similarly, project plans, expected outcomes, and how these would be delivered felt overwhelming. However, public contributors agreed that the path and direction became more apparent as the projects progressed.

XSL•FO
RenderX

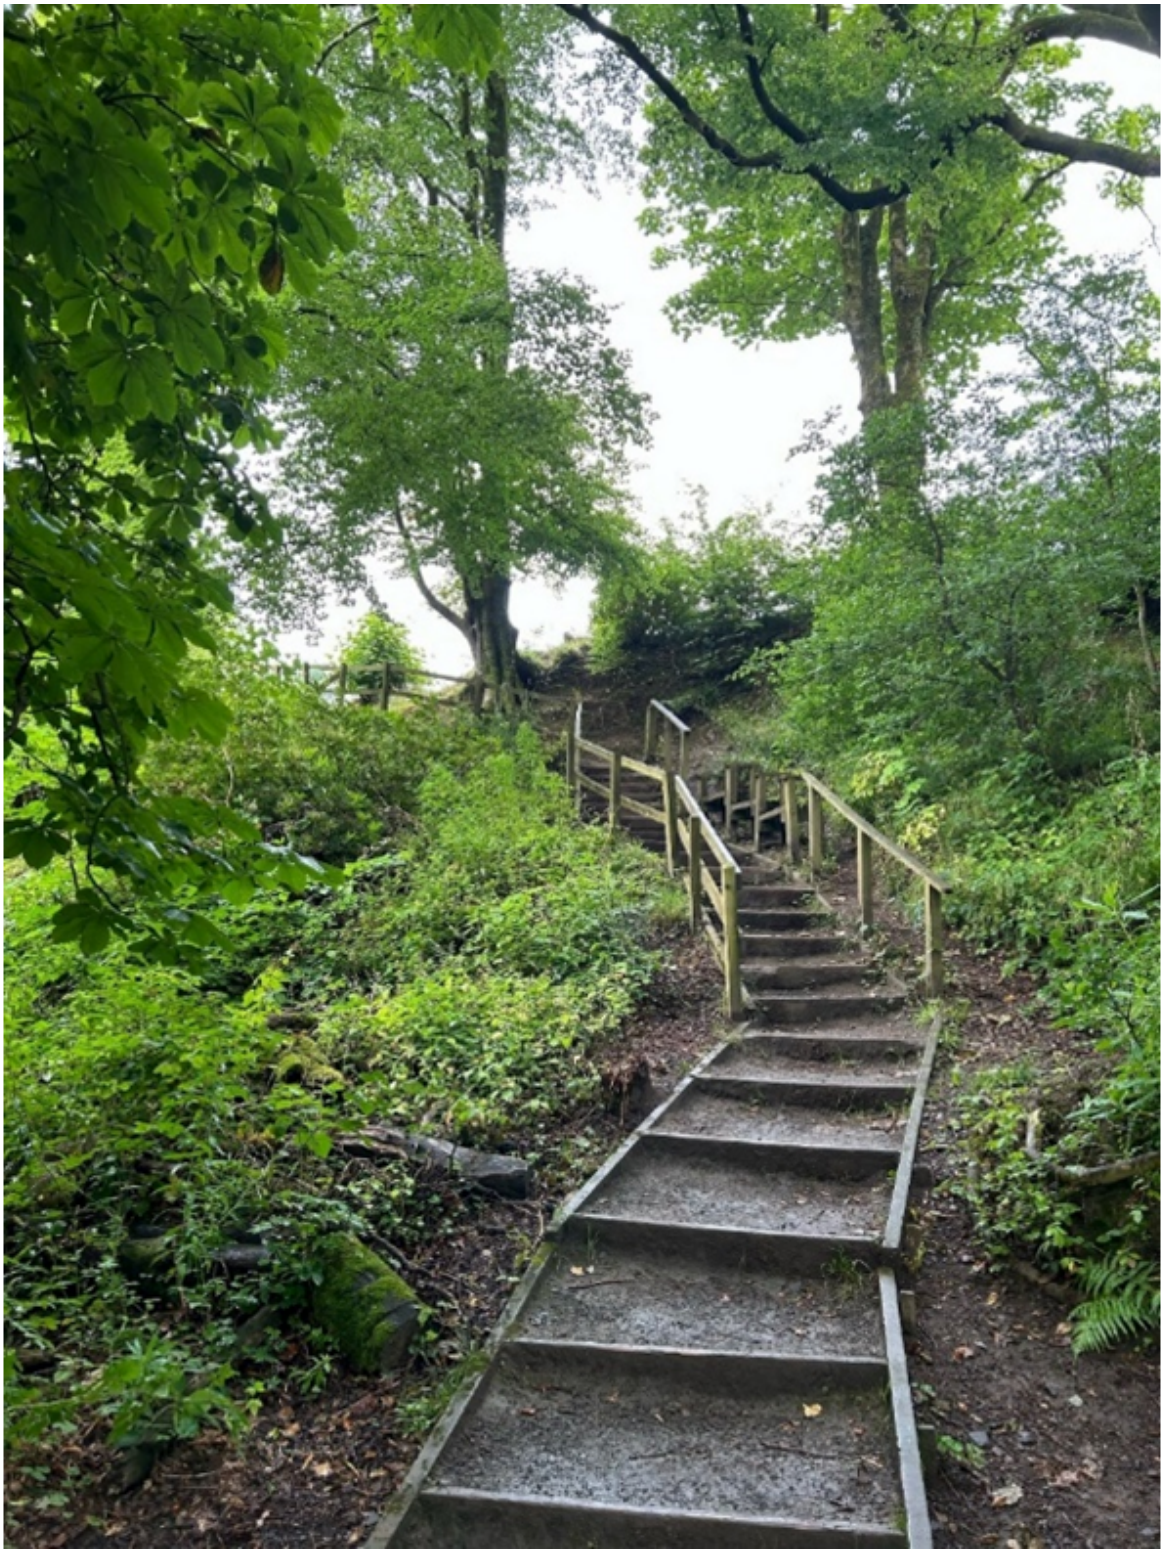
Figure 4. Photo shared by public contributor.

Here is my Photovoice image from Jurmala, Latvia, following our last project conference call:

Sometimes it is difficult to see the "wood from the trees" from information collected but this image reflects to me that patient feedback, from both the Forth Valley & Fife projects, shows us that we are on a good clear path forward. [Figure 4]

The next picture could not be included as it shows people queuing to see a rare type of plane arriving at an airport, and we were unable to obtain consent from those pictured. This waiting for the plane described the public contributor's feelings toward the project. This includes excitement about the change in health care (the new cancer pathways) and uncertainty about when it will fully be implemented and what it will bring to patients. Waiting in the queue also offered a space for reflection on the many small steps and pieces that need to come together

XSL•FO
RenderX



before implementing a change and all the components required to achieve the intended outcomes. This was likened to the necessary procedures required for landing a plane (control tower, weather, runway, pilots, landing equipment, etc). In a way, the people queuing mirrored the progression of the project.

> *I like the image of people waiting by the road- not sure when they will get what they want/need, but an overarching structure is in place to ensure it will arrive at the right time. […] People are anxious to see the plane but it is controlled by a system/pathway that will determine the landing time.*

Being involved in the research was like climbing on steps that had no handrails, so in turn, this approach could be a wobbly climb to start with, but as the public contributors reached the middle, they saw the handrails offer confidence and assistance to make the climb to the top safely achievable (see Figure 5). Being involved in the project felt like a wobbly climb, filled with uncertainty about whether things were heading in the right direction. Each handrail represented the meetings with the project team, where assistance and feedback guided the way. The middle ground of the project has been reached successfully, and there was confidence that the team would achieve the high point (expected outcomes). Public contributors reflected that the collaboration and feedback from the research team acted as stabilizing support, helping the project move forward confidently.

XSL•FO
RenderX

Figure 5. Photo shared by public contributor.

On approach to the steps we see no handrails so in turn could be a wobbly climb to start with but as we reach the middle we see the handrails offer confidence and assistance to make the climb to the top safely achievable.

Thought about the group being formed at the beginning, we have made the middle ground successfully and confident we will reach a high point. [Figure 5]

Public involvement in these research projects had moments of hope in terms of project outcomes helping those going through the cancer diagnostic journey; the following photo of the rainbow (see Figure 6) symbolizes positivity and high expectations for the success of the project. Public contributors expressed their surprise and appreciation for the staff's (clinical, management, administrative, and general practitioner reception teams) reactions to the suggested changes coming from public contributors. They noted their appreciation for the staff's

XSL•FO
RenderX

positivity and adaptability in creating a more patient-centered process and how most staff embraced the change in the pathways.

Figure 6. Photo shared by public contributor.

Here is my Photovoice image on approaching the end of our project together. This photograph was taken recently overlooking Ullapool.

Seeing the rainbow shining over Ullapool amongst the grey background reminds me of the hope that our project will give a better journey to those who have to experience the process of cancer tests and treatments. [Figure 6]

The sunflower photo (see Figure 7) symbolizes the joy of contributing to a successful project. This focused on both personal pride in contributing to these projects and the perception that, thanks to their involvement, the projects have been executed well.

XSL•FO
RenderX

Figure 7. Photo shared by public contributor.

This image reflects the joy in having contributed to a successful project. I am sure future patients will benefit from the changes made. [Figure 7]

The final photo (see Figure 8) is the repeated image of the same bridge, but now completed. The simplicity of the finished bridge is the result of 2 years of meticulous planning, collaboration, and hard work, and is thus like the project's development. The functional purpose of the bridge, connecting people and enabling smoother travel, mirrors the project's aim of optimizing patient pathways, ensuring patients can access care more effectively and efficiently. The bridge metaphor emphasized the importance of the people and resources that contributed to the bridge, which parallels teamwork and collaboration within the projects. Public contributors agreed that the images of the bridge, from its early stages to completion, were a fitting representation of the research process and thus captured the essence of their involvement.

XSL•FO
RenderX

Figure 8. Photo shared by public contributor.

The Cross Tay Project has mirrored our project being built in exactly the same timeframe.

Earlier I sent in a picture of this bridge in progress drawing similarity to our project in that once successfully finished it would provide benefit to patients for years to come.

Both this bridge and our project are now almost complete and will successfully improve the lives of their customers/patients.

Congratulations on a successful project. [Figure 8]

The 4-Dimensional Framework

How Strong was Your Voice When Being Involved as a Public Contributor in These Projects (Weak Voice or Strong Voice)?

The public contributors felt that they had a relatively strong voice in terms of raising critical questions and that their questions were well received by both the research team and health care professionals. However, they felt that, as they had not seen the final report, they were not sure how their voices had impacted the projects (reports were being peer-reviewed during the time of this evaluation). They noted that they could have received more regular updates, especially regarding whether their feedback had influenced project activities. They acknowledged the constraints of a project that was already planned and underway before they joined as funding was secured. The public contributors sometimes questioned where their voices could reasonably be integrated.

How Many Ways Did You Have an Opportunity to be Involved in These Projects?

Public contributors felt they could have been involved in more ways and would have liked more opportunities to get involved. There were relatively few ways to be involved, and these depended on activities organized or offered by the research team, thus being a top-down approach. They felt they could have contributed better if they had been involved earlier in the project, during its development, so they could have a stronger voice in its development and choice of methods. Public contributors expressed a willingness to take on a more active role in the projects and suggested that they could have contributed more if additional opportunities had been offered.

Was the Involvement Focused on the Organization or Public Concerns?

Public concerns were at the forefront of the projects. The focus was on issues that were important to public contributors. These included the well-being of those going through a cancer diagnosis, understanding the experiences of past and present patients, and wanting to provide more patient-centered and faster diagnosis to all those potentially going through the pathways.

XSL•FO
RenderX

There was recognition that certain issues were more relevant to the research team or clinical staff; however, it was felt that these did not take over the agenda of meetings attended by public contributors.

Has the Organization Changed or Resisted Change Based on Your Feedback?

Public contributors perceived that the research team had listened to them, and that their feedback was taken on board (or at least they did not hear back that it was not beneficial to the projects). However, as there was limited communication, the public contributors ranked the strength of their voice to implement change as fairly weak, but still, the research team and health care professionals implemented change. Public contributors suggested providing more regular feedback to keep them informed about the outcomes of their contributions.

Other limitations were around what things public contributors could comment on, as these were limited to mostly patients' data and experiences. Routine data and economic analysis became available toward the end of the project, and public contributors did not have the opportunity to discuss the findings with the research team or the implications of these findings on patients.

Public contributors felt that sometimes healthcare professionals' perspectives were heard more—they did not expect to have a strong voice, but it was the feeling that their voice carried louder. For example, the research team presented data when preliminary analysis took place, and data collection was still ongoing. This was seen as relevant to comment, but they also felt that it would not substantially change the projects. On the other hand, the research team met regularly with health care professionals (in some cases weekly) to discuss how the projects progressed. Meetings with public contributors were part of a 3-monthly management group meeting or as required when new findings were available.

Discussion

Principal Findings

This paper presents an evaluation of the experiences of 4 public contributors with lived experience of cancer in 2 cancer research projects. The creative methods allowed the capture of public contributors' experiences throughout the project; these were revisited during the evaluation meeting, thus offering a critical space for reflection and identifying what worked well and areas for improvement. The findings offer new insights into the process of involving public contributors in cancer research projects, but the findings could also benefit those working in public involvement in other fields.

Developing working and trusting relationships with public contributors requires time [21]. None of the public contributors involved in the projects or researchers have worked together previously. However, introductions and relationships were developed from the start (eg, through the WhatsApp support group). Remote involvement became commonplace during COVID-19 [32], but in-person meetings and attending conferences together built further connections among public contributors and with the research team.

Regular communications from researchers make public contributors feel a part of the team and foster productive relationships [33,34]. Feedback on how public contributors' comments were incorporated into the work could have been provided more regularly. Some attempts to incorporate a "you said, we did" approach were made at the start of the work. As this was time-consuming, the research team prioritized discussion of the projects rather than coming back to already discussed (and implemented input). These limited involvement opportunities were primarily affected by the restricted budget for reimbursement. Providing satisfactory feedback is not a new challenge in public involvement [34], and the expectations should have been agreed upon early in the projects and regularly revisited.

One of the functions of public involvement in research is to make it more democratic [35]. Cancer research is often embedded in complex health care settings, so training and support offered during the introductory stage of the involvement process increased the public contributors' ability to shape the projects. Through membership in the management group, public contributors had an opportunity to assess their influence over the research project in the same way as other stakeholders. However, early involvement of public contributors from as early as the prefunding stage can help to develop stronger relationships and facilitate a stronger public voice [33]. Recruiting public contributors after the projects were designed meant that there was limited scope for them to influence the overall design of the projects and research methods. Being a part of the process from the funding application stage could have made a difference, for example, by including public contributors in the preapplication study design and as the co-applicant on the funding application [36].

Similarly, the budget limited how much researchers could have involved public contributors at each stage of the projects. Thus, public contributors were willing to do more work, and they felt that they could commit to more and would prefer to receive documents in advance to read, not just during the meeting. This is not an unexpected finding given the nature of health services research, where the need for pragmatism often limits the depth of public involvement due to resource, time, and organizational constraints [37,38]. However, the level of public contributors' involvement, though contributing to some analysis and dissemination, seemed to be higher than most of the cancer research projects, as the scoping review by Colomer-Lahiguera and colleagues [7] found that it is rare for cancer researchers to involve public contributors outside design stages.

Public Contributors' and Researchers' Reflections

The following is a reflection from public contributor GD:

> *Having experienced prostate cancer diagnosis and treatment, it was a privilege to be given the opportunity to participate as a public contributor.*
>
> *I was keen to give something back to the health service but unsure how to do this without a medical background. This project showed me both how much*

XSL•FO
RenderX

work is ongoing to improve the patient experience as well as how public volunteers can contribute their own experience into projects. The project team were very accepting of our comment and feedback and we had several in-depth discussions around the project scope and then on the subsequent patient feedback.

Throughout the project, I gained confidence that I could contribute value to the project. I was so pleased that my life skills in another profession could be used in a medical research study. Being an amateur photographer I also enjoyed contributing to the Photovoice by choosing and photographing a subject that reflected on how I saw the project progressing. This was a new tool to me and one I enjoyed contributing to.

It was a pleasure to contribute to this project and I am now confidently looking forward to participating on future projects. [GD]

The following is a reflection from public contributor KG:

Having had my own breast cancer diagnosis alongside family members with both breast and prostate and as a mum of three naturally worry about their future health I became interested in ways of being able to find out more about screening diagnostics, treatments, trials that could be evolving therefore getting involved in a PPI group seemed the perfect way of gaining knowledge when I didn't have a medical background.

Both studies were very interesting for me as a patient contributor. I enjoyed engaging in the in person meetings with the research team and health professionals where I was able to gain in depth knowledge, contribute and felt listened too. In the beginning I wasn't sure what value I would be able to bring to the group but to see some of those suggestions that myself and the PPI put forward actually implemented into the study along the way really confirmed to me how valuable a part we played.

Over the 18 months it was encouraging to see each step progress within both studies and looked forward to hear feedback from medical professionals and patients at our meetings which was reassuring to see it was making a valuable difference to the patients but also see and hear the enthusiasm within the medical teams implementing this study.

I also enjoyed using the Photovoice tool throughout the project.

Having never delved deeper into photos other than it being a pretty picture to then be able to interpret it into a personal reflection of how I saw the study in its various stages and sharing all of our reflections within the group was really enjoyable and something I intend to keep doing with photographs, a new hobby perhaps.

This study has given me the confidence to seek out other projects I could become involved in and was my small way of giving something back to the NHS who were and still are invaluable to me.

I have met some really inspiring individuals within this project and I hope our paths will cross again. [KG]

The following is a reflection from public contributor ER:

I worked in the clinical sector for many years and had to retire due to ill health. I was very happy to be able to help with the study the team were working on as being a cancer patient I could see the very many advantages for the patients of the study and how it helped to reduce the stress of waiting for appointments. The fact that the patient could be immediately referred to the hospital breast or prostate cancer clinic rather than wait to see a GP was to me such a benefit.

I am well aware what the stress of waiting to see clinicians affects patients and this study was to me a breakthrough for the patients.

The team at Stirling University were so welcoming and friendly but at the same time professional in running the study with many updates and online meetings. I especially enjoyed the face to face meetings when the whole team including the clinical staff met together to discuss and hear updates and results of how the patients felt about the study. [ER]

The following is a reflection from public contributor LG:

I started work on this project 18 months ago. It was the first pathway project I had been involved with. I have been Co-Investigator in a number of studies—with involvement from design, pre-clinical to dissemination, but this was usually centred around clinical trials or occasionally funding and strategy.

I was keen to be involved with a pathway project—I believed that they could have a significant impact for patients, and early evidence for this study suggests that this may be the case.

For me, the process was very enjoyable—staff were extremely supportive and helpful—in PPI, you can find yourself being there to tick a box. This was not the case in this study—we were fully involved, and our thoughts and opinions were met with considered feedback. The PPI group worked well together and are hopeful we can work together again with future studies.

Our feedback and evaluation was captured using a variety of measures, which, for me, was a learning experience itself.

My conclusion on the study itself is that the importance of pathway studies is often underestimated. This is potentially a way to improve patient and staff experience in a way that should fit within NHS budgets.

A very positive and enjoyable experience. [LG]

The following is a reflection from researcher MM:

XSL•FO
RenderX

> *Engaging public contributors soon after project inception transformed our approach and deepened our understanding. In early meetings, GD, KG, ER, and LG questioned our assumptions about diagnostic pathways, pushing us beyond purely clinical and academic perspectives to focus on lived experience. Their use of Photovoice, selecting and discussing images that represented different stages and experiences of research involvement, revealed perceptual and practical challenges that we could have overlooked. In turn, we became more open about evolving data, acknowledged uncertainties, and truly listened. I came to appreciate that public contributors are essential partners whose insights enhance relevance, feasibility, and impact. This collaboration will fundamentally shape how I design, conduct, and disseminate all future research.* [MM]

The following is a reflection from researcher PT:

> *Public contributors' comments made me perceive the research projects differently. For example, when we shared initial interview data with them, public contributors noticed issues and had priorities different from some of the initial thoughts in the research team. Thus, their feedback shaped the analysis. I feel that themes became more patient-focused—something that would not have been possible without their genuine involvement.*
>
> *From the start, I wanted to ensure that public contributors feel a part of the team and have an enjoyable experience. Public involvement should not be about a one-off activity but rather a long-term process. Informal engagement was one of the ways to achieve it. First, the WhatsApp group became a good space for conversation. Second, I actively looked for opportunities for public contributors to attend conferences that were related to cancer research. This in-person networking helped to share ideas and get to know each other better, leading to more trust. That trust was an essential part of the evaluation process as public contributors felt comfortable telling us what went well and where the research team could have done better. For me, some of their feedback was expected, but other comments were surprising, for example, that they wanted to be involved in more ways than were offered. This is a meaningful learning that I aim to apply in future public involvement.*
>
> *I plan to stay in touch with all public contributors, and we hope to invite them to new involvement opportunities in the future.* [PT]

Strengths and Limitations

One of the strengths of this evaluation was the active involvement of public contributors from the design through analysis and reporting. There have been calls to evaluate public contributors' experiences of co-authoring publications and sharing the findings [39]. However, public involvement evaluation tools have been previously criticized for rarely being designed to report back findings to public contributors [40].

Photovoice allowed for a unique space to discuss the public contributors' experiences. This method was agreed at the start; however, 1 public contributor (who shared 1 photo) reflected later that they had difficulty interpreting images due to dorsal stream disruption and suggested that auditory descriptions or sound clips could be more accessible and helpful in representing their experiences. Another public contributor did not share any photos. Future projects using photovoice should embed introductory photography training to support people's confidence and increase the number of photos collected [41].

The perspective of this evaluation was only on public contributors' perspectives as they collected photos. However, during the evaluation meeting, public contributors felt that they would like to see some photos from researchers to understand other perspectives on how public involvement worked in these projects. The evaluation plan was designed at the start of the research projects, and it was agreed with the public contributors. The aim was to collect data around public contributors' experiences. As data collection was ongoing throughout the research projects, it was not possible for researchers to take photos retrospectively. Future evaluation should ensure data collection from all groups to capture the involvement process from researchers' and public contributors' perspectives [26].

Conclusion

This paper presents an evaluation of public involvement in 2 cancer research projects. The evaluation identified what worked well and areas for improvement, especially around building relationships and actively involving public contributors throughout the lifespan of the project. Public involvement in cancer research is still developing, and this evaluation has provided evidence of how to do it in a meaningful way for both the researchers and public contributors. Future cancer research projects should ensure public involvement as early as possible and provide a wide range of involvement opportunities for public contributors.

Acknowledgments

This work was supported by Cancer Research UK (PICATR-2022/100023 and PICATR-2022/100014).

Abstract

Background: Clinical trials are important for all stages of the cancer control continuum, including cancer survivorship.

Objective: The purpose of this study was to evaluate correlates of general clinical trial knowledge among US adult cancer survivors.

Methods: We conducted a cross-sectional analysis of the National Cancer Institute's 2021 Health Information National Trends Survey. Cancer survivors were recruited from 3 Surveillance, Epidemiology, and End Results registries: Iowa Cancer Registry, Greater Bay Area Cancer Registry, and New Mexico Tumor Registry. Data collection occurred from January 11 to August 20, 2021. Eligible participants had a cancer diagnosis prior to 2018. The primary outcome was self-reported knowledge of clinical trials, assessed by the question: "*How would you describe your level of knowledge about clinical trials?*" Responses were dichotomized as knowing "a lot" or "a little bit" versus "don't know anything." Independent variables included sociodemographic characteristics, patient-centered communication, health information seeking (including watching health-related videos on YouTube), and confidence in obtaining cancer-related information. We used survey-weighted logistic regression to examine univariable and multivariable associations with clinical trial knowledge. A total of 2 a priori hypotheses were specified: (1) cancer survivors with a higher perceived quality of patient-centered communication would have greater knowledge of clinical trials than those with a lower perceived quality of patient-centered communication and (2) cancer survivors who were "completely confident" in their ability to obtain cancer-related information would have greater knowledge of clinical trials than those less confident. Odds ratios (ORs), 95% CIs, and *P* values were estimated using SAS (version 9.4; SAS Institute Inc, Cary, NC, USA).

Results: Among cancer survivors (N=1207) included in the analysis, 269 (22.3%) reported that they did not know anything about clinical trials, while 938 (77.7%) reported knowing "a lot" or "a little." Neither of the 2 a priori hypotheses was supported. In the multivariable weighted logistic regression model, greater knowledge of clinical trials was significantly associated with non-Hispanic White race compared with all other races (OR 2.55, 95% CI 1.59, 4.08; *P*<.001), having a college degree compared with less than a college degree (OR 3.50, 95% CI 2.25, 5.46; *P*<.001), seeking cancer information from any source (OR 3.04, 95% CI 2.10 - 4.40; *P*<.001) compared with not, and ever watched health-related videos on YouTube (OR 2.71, 95% CI 1.49 - 4.94; *P*=.002) compared with never watched. In contrast, female sex assigned at birth was associated with lower odds of clinical trial knowledge compared with male sex assigned at birth (OR 0.57, 95% CI 0.41 - 0.80; *P*<.001).

Conclusions: Sociodemographic characteristics and health-seeking behaviors including watching health-related videos on YouTube were associated with clinical trial knowledge among cancer survivors. These findings highlight opportunities to leverage YouTube as a platform to promote clinical trial awareness and to strengthen survivors' cancer-specific information-seeking skills to improve access to clinical trial information.

Introduction

Background and Rationale

Clinical trials test new ways to identify, prevent, and treat cancer via diagnostic, behavioral, medical, surgical, and other types of interventions (eg, gene therapy) [1,2]. Over time, increased attention has been focused on improving clinical trial participation [3] and increasing age, sex, and racial or ethnic representation in clinical trials [4-6].

Factors Influencing Clinical Trial Participation

While many factors contribute to differences in general clinical trial participation, lack of knowledge and awareness about clinical trials is a significant barrier to recruitment [1,7-9]. That is, people cannot participate in a clinical trial if they do not know about the option of joining a clinical trial in the first place or do not have some level of health literacy to support informed decision-making about clinical trial participation. *Healthy People 2030* defines personal health literacy as "the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others" [10]. Prior research on cancer information seeking has demonstrated that patient-provider communication scores, self-efficacy in managing one's own health, difficulty understanding information, concern about the quality of information, and frustration during the search for information are associated with self-efficacy for obtaining cancer information [11,12].

Naturally, health literacy and cancer information-seeking skills can directly influence knowledge about clinical trials, especially because many clinical trial opportunities are posted online. Strategies to enhance general clinical trial knowledge about cancer and other medical conditions include media campaigns [13,14], clinical trial registries such as ResearchMatch [15], websites and online databases such as ClinicalTrials.gov [16], decision aids [17,18], tailored and targeted messages about research participation [19,20], direct-to-consumer and direct-to-patient invitations [21-23], patient education materials [24,25], and group-based information sessions [26,27].

Clinical Trial Knowledge and Awareness Among Cancer Survivors

Regarding cancer survivors' knowledge of clinical trials and willingness to participate in research, differences by race or ethnicity have been observed. Using cross-sectional data from 147 Black and White cancer survivors who took the "Minority Patient Participation in Cancer Clinical Trials" survey, Kumar et al [28] found that Black cancer survivors were less likely than White cancer survivors to be aware of cancer clinical trials, express willingness to participate in cancer clinical trials, and participate in cancer clinical trials. Using data from the 2020 Health Information National Trends Survey, Commaroto et al [1] described cancer survivors' (n=553) knowledge of clinical trials and prior invitations to participate in clinical trials. They found that cancer survivors with a high school diploma were less likely to have any knowledge of clinical trials than those with a baccalaureate degree or higher. However, no statistically significant differences were found in clinical trial knowledge or prior invitation to participate by sex, age, or race or ethnicity. Lastly, Cho et al [29] evaluated data from 958 cancer survivors from the 2021 Health Information National Trends Survey-Surveillance, Epidemiology, and End Results (SEER) Program and found that having 1 or more comorbidities was significantly associated with lower rates of clinical trial discussions but not clinical trial participation. While these studies provide useful information, it is also important to explore the correlates of clinical trial knowledge of cancer survivors that include but extend beyond sociodemographic factors.

Present Study

The purpose of this study was to evaluate the associations between knowledge of clinical trials among US cancer survivors and perceived quality of patient-centered communication, cancer information seeking, emotional support, and watching health-related videos on YouTube. A priori, we proposed 2 main hypotheses:

Hypothesis 1: Cancer survivors with a higher perceived quality of patient-centered communication would have greater knowledge of clinical trials than those with a lower perceived quality of patient-centered communication.

Hypothesis 2: Cancer survivors who were "completely confident" that they could get advice or information about cancer if they needed it would have a greater knowledge of clinical trials than those who are less than completely confident.

Greater insights into ways to enhance clinical trial awareness among cancer survivors can support ongoing efforts to improve equitable participation and inclusion in cancer clinical trials.

Methods

Overview of the Health Information National Trends Survey

The Health Information National Trends Survey (HINTS) regularly collects nationally representative data on the American public's knowledge of, attitudes toward, and use of cancer and health-related information [30]. The HINTS data collection program was created to monitor changes in the rapidly evolving field of health communication [31]. In 2021, the National Cancer Institute undertook a pilot project to oversample cancer survivors for the HINTS using 3 cancer registries from the SEER Program as a sampling frame for cancer survivors: Iowa Cancer Registry, Greater Bay Area Cancer Registry, and New Mexico Tumor Registry [32]. HINTS-SEER data can be accessed by submitting a data request through the HINTS website, where comprehensive methodology details are also available. All HINTS-SEER data are deidentified. HINTS-SEER data were collected from January 11, 2021, through August 20, 2021. Eligibility criteria were as follows: cancer diagnosis specified to invasive cancers, 18 years of age and older, last contact no earlier than January 1, 2016, and a diagnosis date prior to 2018 based on certified data. Survivors who were only diagnosed with nonmelanoma skin cancer were excluded. However, survivors diagnosed with nonmelanoma skin cancer, in addition to other cancers, were included.

XSL•FO
RenderX

The present study used HINTS SEER data to cross-sectionally explore the associations between knowledge of clinical trials and various sociodemographic factors. A total of 27 of the 1234 responses were removed from the data analysis because of a missing response on the dependent variable of interest (knowledge of clinical trials), leaving a final sample size for analysis of 1207.

Ethical Considerations

This study used publicly available, de-identified HINTS-SEER data to conduct a secondary analysis. The data contain no personal identifiers. Because the dataset is publicly available and deidentified, this research does not involve human subjects as defined by federal regulations (45 CFR 46.102) and is exempt from institutional ethics review. Accordingly, Institutional Review Board (IRB) review at the first author's institution was not required. It should be noted that a formal Micro-Data Dissemination Policy for the Health Information National Trends Survey: HINTS SEER data use agreement between the author's home institution and HINTS was signed on October 23, 2023. The parent HINTS-SEER pilot study underwent expedited review by the Westat IRB and was approved as an amendment to HINTS 5 on May 22, 2020 (Project Number 6048.14, Amendment ID #3212). The participating SEER registries obtained independent IRB approvals for their participation in the study. The full details of the selection of registries, the sampling and consenting procedures, and compensation can be found in the methodology report [33].

Measures

The following survey items were used to conduct the analysis for this study.

Knowledge of Clinical Trials (primary outcome). First, participants read the following prompt: "Clinical trials are research studies that involve people. They are designed to compare new kinds of health care with the standard healthcare people currently get. For example, a new drug or a new way for patients to track their diets." Next, participants were asked, "How would you describe your level of knowledge about clinical trials?" The response options were (1) I don't know anything about clinical trials, (2) I know a little bit about clinical trials, and (3) I know a lot about clinical trials. For the primary analysis, we compared "I don't know anything about clinical trials" with "know a lot" and "know a little bit" combined. As a secondary analysis, we compared survivors who reported that they know "a lot" with those who reported that they know "a little bit" about clinical trials.

Sociodemographic Factors

Age was evaluated continuously and by group (18 - 64 y, 65 - 74 y, and 75+ y). *Race or Ethnicity* was evaluated as non-Hispanic White versus all other racial or ethnic categories combined: Black or African American, Hispanic, Asian, and Other. *Sex Assigned at Birth* options were male and female. *Education* was evaluated as college graduate versus not college graduate.

Feelings about Household Income were assessed with the question, "Which one of these comes closest to your own feelings about your household's income?" The response options were (1) living comfortably on present income, (2) getting by on present income, (3) finding it difficult on present income, and (4) finding it very difficult on present income. We consolidated the difficulty-related answers such that 3 groups were evaluated in the analysis: "living comfortably" versus "getting by" versus "finding it difficult" or "finding it very difficult on present income."

Health Information Seeking, Trust, and Understanding

Cancer Information Seeking. Participants were asked if they had ever looked for information about cancer from any source. Response options were yes and no.

Confidence to Get Cancer Health Information was assessed with the item, "Overall, how confident are you that you could get advice or information about cancer if you needed it?" The response options were completely confident, very confident, somewhat confident, a little confident, and not confident at all. We compared "completely confident" responses with all other responses combined.

Health Information Seeking on Social Media. First, participants read the prompt, "Sometimes people use the Internet to connect with other people online through social networks like Facebook or Twitter." This is often called "social media." Next, they were asked, "In the last 12 months, have you used the Internet for any of the following reasons?" Response options were (1) to visit a social networking site, such as Facebook or LinkedIn; (2) to share health information on social networking sites, such as Facebook or Twitter; (3) to participate in an online forum or support group for people with similar health or medical issues; and (4) to watch a health-related video on YouTube. Given that YouTube is the most widely used social media platform [34] and a common way for people to get health information [35], we only evaluated responses to watching health-related videos on YouTube in this analysis.

Trust Information From Doctor. Participants were asked how much they would trust information about cancer from a doctor. The response options were a lot, some, a little, and not at all. We compared "a lot" responses to all the others combined.

Understanding Information in Online Medical Records. Participants were asked how easy or difficult it was to understand the health information in their online medical record. The response options were very easy, somewhat easy, somewhat difficult, and very difficult. We compared "very easy" with all other categories combined.

Communication with Health Professionals

Patient-Centered Communication Scale. The Patient-Centered Communication Scale variable was created using 7 items related to communication. Specifically, participants were asked how often doctors, nurses, or other health professionals they saw during the past 12 months were as follows: (1) give you the chance to ask all the health-related questions you had, (2) give the attention you needed to your feelings and emotions, (3) involve you in decisions about your health care as much as you wanted, (4) make sure you understood the things you needed to do to take care of your health, (5) explain things in a way

XSL•FO
RenderX

you could understand, (6) spend enough time with you, and (7) help you deal with feelings of uncertainty about your health or health care. The response options included always=1, usually=2, sometimes=3, and never=4. The values of these 7 variables were reverse-scored, such that never=1 and always=4. The mean of these 7 variables (if at least half of the variables had valid values) was generated. Finally, the mean value was transformed to a 0 - 100 scale.

Time Passed Since Final Treatment and Emotional Support

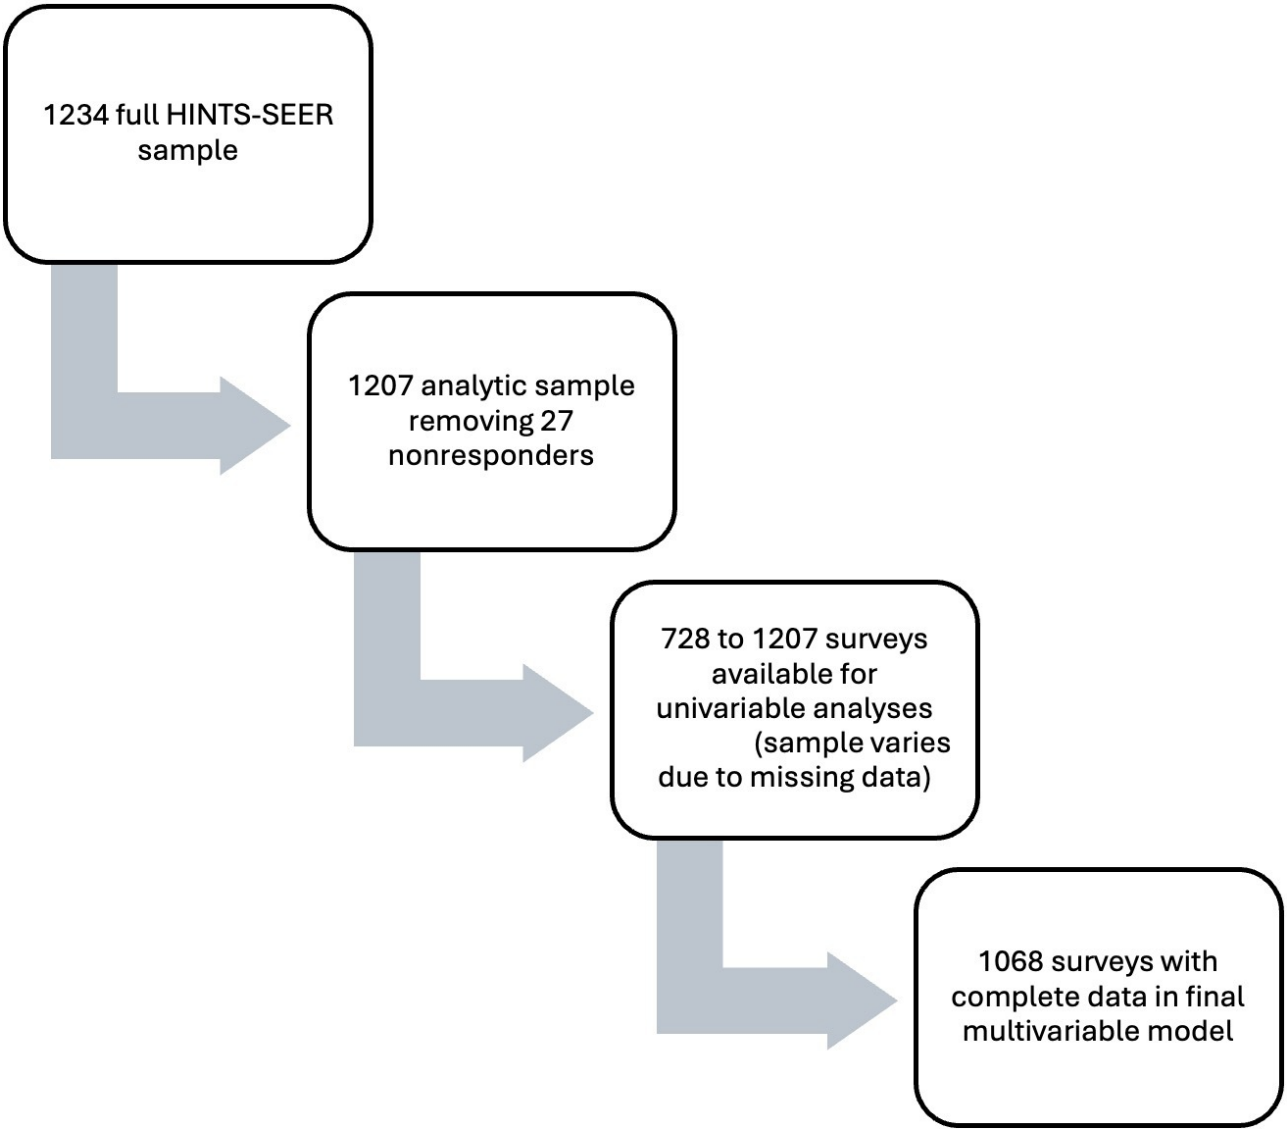
Time Since Last Cancer Treatment

Participants were asked, "About how long ago did you receive your last cancer treatment?" Response options were: still receiving treatment, less than 1 year ago, 1 year ago to less than 5 years ago, 5 years ago to less than 10 years ago, and 10 or more years ago. We evaluated the following 4 categories: still in treatment, <5 years ago, 5 - 10 years ago, and ≥10 years ago or more.

Emotional Support

This was assessed using the question, "Is there anyone you can count on to provide you with emotional support when you need it, such as talking over problems or helping you make difficult decisions?" The response options were yes or no.

Data Analysis



Odds ratios (ORs), 95% CIs, and *P* values were calculated using SAS (version 9.4; SAS Institute Inc, Cary, NC, USA) proc surveylogistic with jackknife weighting, including the overall weight and 50 replicate weights, and the Newton-Raphson algorithm. The results are presented as odds ratios [95% CIs] for the odds of having knowledge about clinical trials and *P* values. Due to the small sample size (<25), some response categories were combined. Factors that had a corresponding $P<.10$ in univariable models were attempted in the multivariable model. In univariable analyses, all available data were used for each factor. Surveys that were missing a response were simply excluded from consideration for that factor's univariable analysis. Using backward elimination, factors were removed one by one until all the remaining factors in the model were significant ($P<.05$). It should be noted that a higher percentage of the California registry respondents had knowledge of clinical trials than respondents from the New Mexico registry. Therefore, we adjusted for registry in the final models. When interpreting ORs, CIs that do not include the value 1 are considered significant. Data were analyzed using SAS (version 9.4) and SAS/STAT (version 14.1; SAS Institute Inc). Given that we first compared (primary analysis) "I don't know anything about clinical trials" with "know a lot or know a little bit" combined and secondarily compared "know a lot" versus "know a little bit," the sample sizes varied across analyses.

Results

Figure 1 shows the selection of the final sample size for the primary analysis. Table 1 provides counts and percentages (unweighted) for variables of interest. Overall, 486 (41.3%) of the sample were 75 years or older, 894 (80.0%) were non-Hispanic White, and 677 (57.3%) were college graduates.

Table . Demographic characteristics of the analytic sample (unweighted).

Characteristic		Clinical trials knowledge	
	All (n=1207)	Don't know anything, n=269; n (%)	Know a lot or a little bit, n=938; n (%)
Age (mean years), n=1176	71.3 (11.5)	73.85 (11.36)	70.58 (11.50)
Age (y), n=1176			
18 - 64	286 (24.3)	55 (19.23)	231 (80.77)
65 - 74	404 (34.4)	69 (17.08)	335 (82.92)
75+	486 (41.3)	136 (27.99)	350 (72.02)
Race or ethnicity, n=1118			
Non-Hispanic White	894 (80.0)	156 (17.45)	738 (82.55)
All other races	224 (20.0)	81 (36.16)	143 (63.84)
Birth sex, n=1182			
Male	548 (46.4)	112 (20.44)	436 (79.56)
Female	634 (53.6)	149 (23.50)	485 (76.50)
Education, n=1182			
College graduate	677 (57.3)	77 (11.4)	600 (88.63)
Not college grad	505 (42.7)	182 (36.04)	323 (63.96)
Income feelings, n=1167			
Living comfortably on present income	752 (64.4)	119 (15.82)	633 (84.18)
Getting by	318 (27.3)	99 (31.13)	219 (68.87)
Finding it difficult or very difficult	97 (8.3)	36 (37.11)	61 (62.89)
Registry			
California (Bay Area)	468 (38.8)	86 (18.4)	382 (81.6)
Iowa	401 (33.2)	91 (22.7)	310 (77.31)
New Mexico	338 (28.0)	92 (27.2)	246 (72.8)

In weighted univariable analyses (Table 2), the following factors were associated with higher odds of having knowledge of clinical trials: White respondents (compared to all other races combined), college graduates (compared to not college graduate), living comfortably on present income (compared to finding it difficult or very difficult), having looked for cancer information from any source, having someone to count on for emotional support, and used the internet to watch a health-related video.

[a]Row percentages are weighted. SE is the weighted standard error. Odds ratio is weighted, univariable (ie, not adjusting for any other variable). *P* value is weighted logistic regression *P* value. CI is a weighted 95% confidence interval for the odds ratio. Reference is the reference category of the independent variable. Some missing data for each factor.

[b]indicates reference category.

As shown in Table 3, the multivariable model adjusting for SEER-registry site revealed that White race, male sex, college graduate, looked for cancer information from any source, and having watched a health-related video on YouTube remained statistically significant and were associated with increased odds of having knowledge of clinical trials. Of the 1068 respondents in the table, 850 had knowledge of clinical trials and 218 did not. ORs and 95% CIs are weighted and are adjusted for all the other variables in the multivariable model. OR, CI, and *P* value are from weighted, multivariable logistic regression.

Discussion

Principal Findings

The objective of this study was to evaluate associations between knowledge of clinical trials among US adult cancer survivors and key correlates of interest. In the primary analysis comparing those who know "a lot" or a "little bit" combined versus those who did not know anything about clinical trials, we found that White race, a 4-year college education, and health information seeking including having watched a health-related video on YouTube were associated with increased odds of having knowledge of clinical trials, whereas female sex assigned at birth was associated with lower odds of having knowledge of clinical trials. Our first hypothesis that cancer survivors with a higher perceived quality of patient-centered communication would have greater knowledge of clinical trials than those with a lower perceived quality of patient-centered communication was not supported by the results. Moreover, our second hypothesis that cancer survivors who were "completely confident" that they could get advice or information about cancer if they needed it would have greater knowledge of clinical trials than those who are less than completely confident about finding cancer information if needed was also not supported by the results.

In the secondary analysis comparing those who know "a lot" versus "a little bit" about clinical trials, we found slightly

XSL•FO
RenderX

different trends. In summary, those who were college graduates, those who looked for cancer information from any source, and those who understood health information in their online medical records had higher odds of knowing "a lot" about clinical trials.

Health Information Seeking

A novel finding was that cancer survivors who watched health-related videos on YouTube had higher odds of clinical trial knowledge. Given YouTube's broad reach, including among older adults [34], video-based education may be a scalable avenue for improving awareness of clinical trial opportunities. Several mechanisms may explain why watching health-related videos on YouTube is associated with greater clinical trial knowledge. First, YouTube provides a dynamic, visually engaging format that can simplify complex topics such as trial design, consent, and risks or benefits, potentially improving comprehension and retention. Second, YouTube's algorithm can create an "information cascade," where viewing 1 cancer-related video leads to recommendations of related content including clinical trial education [36]. Third, YouTube allows for peer-to-peer storytelling. Accordingly, testimonials from survivors or clinical trial participants may build trust and normalize clinical trial participation, which could be particularly impactful compared to static text-based resources that are often used to describe clinical trials. Finally, unlike passive browsing, intentionally watching health-related videos likely reflects higher digital health literacy and proactive health engagement; these traits may predict greater awareness of clinical trial opportunities.

Our results related to watching health-related videos on YouTube complement Nutbeam's conceptualization of health literacy as not merely functional (basic reading and numeracy) but also interactive and critical [37,38]. Survivors who actively sought cancer information and who watched health-related videos on YouTube may be engaging in interactive or critical health literacy, leveraging digital platforms to deepen their understanding of research opportunities. Future interventions could therefore focus on improving survivors' critical health literacy, particularly among those with lower educational attainment, to reduce disparities in clinical trial knowledge [39]. Clinicians and cancer centers could incorporate curated video content into survivorship care, and policies that encourage evidence-based digital health communication may help ensure content quality. Future research should identify optimal video characteristics (eg, length, storytelling approaches) that most effectively promote informed decision-making.

Other health information-seeking findings were that cancer survivors who ever looked for information about cancer from any source had higher odds of clinical trial knowledge, further underscoring the importance of health information-seeking skills. Health systems and patient navigators could play a key role in training survivors to locate and evaluate credible information, while policies supporting digital health literacy initiatives may help reduce disparities. Research should examine which strategies best sustain long-term information-seeking engagement.

Sex Differences

Our finding that female sex assigned at birth was associated with lower clinical trial knowledge compared with male sex assigned at birth warrants further consideration. Although speculative, individuals assigned female at birth may engage more frequently with preventive and routine health care services yet experience different communication patterns during oncology visits, including shorter discussions about clinical research opportunities or lower referral rates to clinical trials. In addition, structural factors such as caregiving responsibilities and time constraints may limit opportunities to participate in research discussions or to seek supplemental information. Addressing these multifaceted factors through patient-centered communication strategies, tailored educational materials, and flexible clinical trial designs may help mitigate sex- and gender-related disparities in clinical trial knowledge and participation.

Race or Ethnicity Differences

We observed that non-Hispanic White survivors were more likely to have clinical trial knowledge. Knowledge of clinical trials is needed before a cancer survivor can make an informed decision about participation. While many studies have shown that *willingness* and *intent to participate* in clinical trials do not vary across racial or ethnic groups if a clinical trial is explicitly offered to a person [20,40-42], it is imperative that health care systems and health professionals ensure equitable opportunities for cancer patients to be aware and knowledgeable about the clinical trials for which they may be eligible [43]. For example, oncologists can routinely present clinical trial opportunities to cancer survivors during medical encounters. eHealth interventions may also play a role in enhancing clinical trial knowledge [44], while direct-to-patient invitations via patient portals may enhance awareness of clinical trial opportunities without relying on health professionals to be gatekeepers of information [23]. Additionally, policies could support funding for inclusive recruitment and education campaigns.

Education Differences

Our finding that survivors with a college degree were more likely to report higher clinical trial knowledge underscores the relationship between educational attainment and health literacy. General information seeking and health-specific information-seeking models posit that sociodemographic characteristics (eg, education) shape both the motivation to seek information and the skills required to evaluate and apply it [39,45-47]. Higher educational attainment is associated with stronger critical appraisal skills, greater self-efficacy for information seeking, and more frequent use of diverse information channels. These factors likely enhance survivors' ability to locate and interpret complex information about clinical trials, aligning with evidence that health literacy mediates the effect of education on knowledge and decision-making [43]. Higher educational attainment being linked to greater clinical trial knowledge may also reflect better access to academic medical centers that offer more clinical trial opportunities than community hospitals or federally qualified health centers. Additionally, cancer survivors with more education may proactively seek clinical trial options on health system websites,

XSL•FO
RenderX

the National Cancer Institute website, or ClinicalTrials.gov, which may enhance their general knowledge of clinical trials. Strengthening health literacy and providing simplified, accessible trial information across care settings may help mitigate this gap. Future work could evaluate interventions that promote trial awareness among survivors with less formal education.

Comparison to Prior Work

Our study complements the research by Gerdes et al, who explored clinical trial knowledge, discussions, and participation among cancer survivors using HINTS-SEER data [48]. In summary, they found that approximately 78% of cancer survivors reported having little or a lot of clinical trial knowledge and that those who discussed clinical trials with a health care provider had 8.71 higher odds of clinical trial knowledge than those who did not discuss clinical trials with a health care provider. Additionally, they found that clinical trial knowledge was lower for Hispanic versus non-Hispanic White participants. This study builds on the work of Gerdes et al by providing new insights into clinical trial knowledge among cancer survivors through our comprehensive evaluation of different correlates, including general patient-centered communication, emotional support, cancer information-seeking behaviors, and the use of YouTube to watch health-related videos. Additionally, while other studies have used HINTS data to evaluate associations between watching health-related videos on social media and correlates, including perceived patient-centered communication [49] and human papillomavirus awareness [35], to our knowledge, no studies have exclusively evaluated the relationship between watching health-related videos on YouTube and clinical trial knowledge among cancer survivors.

Strengths and Limitations

The strengths of this study include the large sample of cancer survivors recruited from 3 SEER registries and the breadth of the HINTS survey items, which allowed for a comprehensive analysis of variables that may be associated with knowledge of clinical trials. Despite these strengths, some limitations must be noted. First, although we assessed knowledge of clinical trials, we do not know whether cancer survivors who took the HINTS were knowledgeable about *specific* clinical trials (ie, those that were actively recruiting participants) versus general knowledge that clinical trials are possible options for cancer survivors. People who were knowledgeable about a specific clinical trial may have had more knowledge about clinical trials overall because they received information about what to consider when joining a clinical trial (eg, time demand, risks, benefits). Second, the question regarding clinical trial knowledge was broad and not limited to cancer-specific clinical trials. Third, it is unclear what knowing "a lot" about clinical trials meant to participants, and how that knowledge may have translated into actual enrollment in cancer clinical trials or other clinical trials beyond cancer (eg, mental health, diabetes, hypertension). Fourth, each of the 3 SEER registries had a different process for consenting cancer survivors to the HINTS-SEER survey, which may have affected those who were aware of the HINTS-SEER survey opportunity and ultimately participated. Lastly, this study represents survivors from only 3 SEER registries (Iowa, Greater Bay Area, and New Mexico), which may not be representative of all US cancer survivors.

Future Directions

Future work should explore specific domains of clinical trial knowledge among cancer survivors (eg, where to find them and different phases of clinical trials) and areas of greatest concern regarding clinical trial participation (eg, side effects and time commitment). Additionally, more research is needed regarding patient-provider communication regarding clinical trials and how the topic is typically introduced to cancer survivors. Finally, determining which attributes of health-related videos are most likely to appeal to cancer survivors warrants further research (eg, length, content, and types of people featured in videos).

Conclusions

In summary, sociodemographic factors and health information-seeking behaviors including engagement with online health videos were associated with clinical trial knowledge among US cancer survivors. These results suggest that enhancing digital health literacy, supporting evidence-based video education, and ensuring equitable clinician-patient discussions are promising strategies for increasing clinical trial awareness. Policies that fund digital outreach and promote equitable trial communication, along with research to identify the most effective educational approaches, will be critical to translating these findings into practice.

Abstract

Background: Relapse is a major event in patients with lymphoma. Therefore, early detection may have an impact on quality of life and overall survival. Patient-reported outcome measures have demonstrated clinical benefits for patients with lung cancer; however, evidence is lacking in patients with lymphoma. We evaluated the effect of a web-mediated follow-up application for patients with lymphoma at high risk of relapse.

Objective: This study aims to demonstrate that monitoring patients via a web application enables the detection of at least 30% more significant events occurring between 2 systematic follow-up consultations with the specialist using an electronic questionnaire.

Methods: We conducted a prospective, randomized phase 3 trial comparing the impact of web-based follow-up (experimental arm) with a standard follow-up (control arm). The trial was based on a 2-step triangular test and was designed to have a power of 90% to detect a 30% improvement in the detection of significant events. A significant event was defined as a relapse, progression, or a serious adverse event. The study covered the follow-up period after completion of first-line treatment or relapse (24 months). Eligible patients were aged 18 years and older and had lymphoma at a high risk of relapse. In the experimental arm, patients received a 16-symptom questionnaire by email every 2 weeks. An email alert was sent to the medical team based on a predefined algorithm. The primary objective was assessed after the inclusion of the 40th patient. The study was continued for the duration of the analysis.

Results: A total of 52 patients were included between July 12, 2017, and April 7, 2020, at 11 centers in France, with 27 in the experimental arm and 25 in the control arm. The median follow-up was 21.3 (range 1.3 - 25.6) months, and 121 events were reported during the study period. Most events occurred in the experimental arm (83/119, 69.7%) compared with 30.2% (36/119) in the control arm. A median number of 3.5 (range 1-8) events per patient occurred in the experimental arm, and 1.8 (range 1-6) occurred in the control arm (P=.01). Progression and infection were the most frequently reported events. Further, 19 patients relapsed during follow-up: 6 in the experimental arm and 13 in the control arm (P<.001), with a median follow-up of 7.7 (range 2.8 - 20.6) months and 6.7 (range 1.9 - 16.4) months (P=.94), respectively. Statistical analysis was conducted after including the 40th patient, which showed no superiority of the experimental arm over the control arm. The study was therefore stopped after the 52nd patient was enrolled.

Conclusions: The primary objective was not reached; however, patient-reported outcome measures remain essential for detecting adverse events in patients with cancer, and the electronic monitoring method needs to demonstrate its effectiveness and comply with international safety guidelines.

Trial Registration: ClinicalTrials.gov NCT03154710; https://clinicaltrials.gov/ct2/show/NCT03154710

(JMIR Cancer 2025;11:e65960) doi:10.2196/65960

KEYWORDS

patient-reported outcome measures; lymphoma; risk of relapse; relapse; randomized trial; web-based; quality of life; survival; detection; progression; T-cell lymphoma; Hodgkin lymphoma

Introduction

Relapse or progression is a major event in the management of lymphoma. Predictive factors for relapse include histological subtype, extranodal involvement, high metabolic volume, and elevated serum lactate dehydrogenase (LDH) levels [1]. Early detection of relapse correlates with survival. In most cases, relapse is detected by the appearance of symptoms, clinical signs, or biological abnormalities [2-4]. Repeated surveillance computed tomography (CT) detects asymptomatic recurrence in only 1.7% of patients and increases the risk of secondary cancers because of radiation overexposure [5-8]. Circulating tumor DNA monitoring may be used to detect early recurrence before the onset of symptoms; however, this method has not been validated [9]. Electronic patient-reported outcome measures (ePROMs) based on the Common Terminology Criteria for Adverse Events have emerged as a method of early detection. This has increased survival rates in some cases (locally advanced lung cancer) [10]. ePROMs affect early event detection and overall survival in patients with cancer [11-15]; however, such evidence is lacking for patients with lymphoma. In this study, we compare the effect of web-based follow-up with that of standard follow-up.

Methods

Overview

We conducted an open-label, longitudinal, prospective study between July 12, 2017, and April 7, 2020, at 14 centers in France.

Ethical Considerations

This study was conducted according to the 1975 Declaration of Helsinki, revised in 2008, and the guidelines of the International Conference on Harmonization of Good Clinical Practice in Biomedical Research. The Ouest II national ethics committee in Angers approved the study on November 8, 2016, and the Agence Nationale de Sécurité du Médicament approved it on November 22, 2016 (approval: 2021–A01670–41). All of the patients provided written informed consent, which included the points of analysis, the method of data collection, and the primary and potential secondary statistical analyses. All patient data were anonymized and no financial compensation was provided.

Study Population, Inclusion Criteria, and Exclusion Criteria

Patients with lymphoma who were aged 18 years or older and had a high risk of relapse were considered eligible for this trial. They could have T-cell lymphoma in the first partial or complete response, Hodgkin lymphoma in the second partial or complete response, or diffuse large B-cell lymphoma in the first partial or complete response with a revised high International Prognostic Index score (≥3) or in the second partial or complete response. Patients who had undergone autologous stem cell transplantation were not excluded. Eastern Cooperative Oncology Group performance status between 0 and 2, an internet connection, and affiliation to the French social security system were required. Patients were recruited during follow-up consultations by the referring physician at each center.

The exclusion criteria were an initial symptom score <7, progression within 3 months of the last treatment, brain or meningeal involvement, history of another cancer treated within 3 years—with the exception of skin cancer (except melanoma) and in situ cervical cancer—pregnancy, breastfeeding, and any psychiatric pathology that may prevent compliance with the protocol.

An initial symptom score was established in the previous Sentinel study. The e-request algorithm was more sensitive for patients who were not very symptomatic at inclusion and had an initial score of less than 7 (by summing scores from 0 to 3 for symptoms concerning cough, dyspnea, pain, anorexia, and asthenia: 0=no problem, 1=mild problem, 2=moderate problem, and 3=severe problem) [12].

Randomization

Randomization was planned through minimization once patients were enrolled in the study and programmed using ENNOV Clinical data management software. Patients were randomly assigned 1:1 to a routine follow-up (control arm) or web-mediated follow-up (experimental arm). Stratification was conducted at inclusion according to the center, performance status, autologous stem cell transplantation history, relapse, and lymphoma subtype.

Follow-Up

Patients were included no later than 3 months at the end of their last treatment. Follow-up was 24 months after enrollment. A medical consultation and a biological assessment were performed every 3 months. In the control arm, CT scans were performed every 6 months. In the experimental arm, scans were performed when medically necessary. Quality of life (QoL) was assessed by 2 questionnaires every 3 months (European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire of Cancer Patients [QLQ-C30] and Patient Health Questionnaire-9 [PHQ-9]) [16,17]. Patient satisfaction with the application was evaluated by an internal questionnaire for patients in the experimental group during the 6-month visit from inclusion.

Web Application

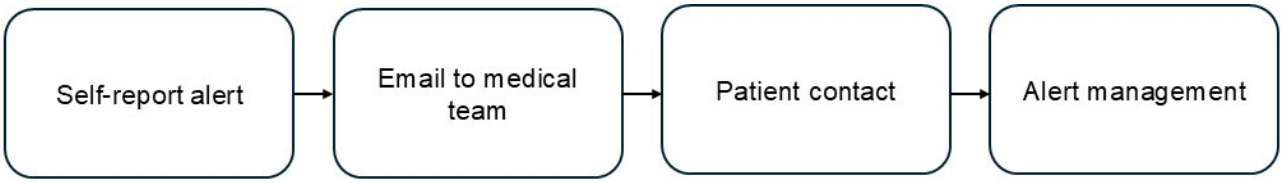
The Moovcare patient-reported outcome (PRO) system is a class 1 medical device registered by Sivan Innovation, Ltd.,

XSL•FO
RenderX

with Conformité Européenne marking obtained in July 2017. Versions 1.7 (from July 2017 to October 2019) and 1.8 (from November 2019 to April 2020) were used in this study. “The reimbursed indication of the MOOVCARE Lung device is the early detection of recurrences or complications for patients over the age of 16 with nonprogressive lung cancer after the last medical treatment, regardless of the histological type of the tumor”—an excerpt from the user guide [18]. The indication was validated by the data of the Sentinel Lung study (published in 2019), which demonstrated a survival benefit of 9 months for patients monitored by the application compared to standard monitoring (P=.005) [13].

A scientific committee adapted the questionnaire for patients who were being monitored for lymphoma, whereas the technical monitoring and the decision algorithm remained the same.

PRO data were collected using questionnaires sent by the application directly to the patient through a clickable link to their email address. Patients were asked to complete a 16-question self-assessment every 14 days for 24 months after being randomized to the experimental arm (smartphone or email). They were also able to report an event in the web application between the 2 questionnaires. The study coordinators provided them with a short training session on the application. If the patient failed to complete the questionnaire, a reminder was sent after 24 hours, and the health care team contacted the patient as necessary.



The questionnaire included 4 items, namely weight, LDH level (optional), hemoglobin level (optional), and a free comment (for other symptoms or remarks), and 12 following questions:

- Are you tired?
- Have you lost your appetite?
- Are you in pain?
- Are you short of breath?
- Do you feel depressed?
- Do you have a fever (temperature >38.1 °C, checked once at 1-hour intervals)?
- Do you have chills?
- Do you have pimples?
- Are you sweating profusely?
- Are you itching all over your body?
- Have you detected a lump under the skin or a lymph node?
- Have you noticed any abnormal swelling of the face or legs?

Patients were assigned a score based on their symptoms as follows: 0=no problem, 1=mild problem, 2=moderate problem, and 3=severe problem. An alert was triggered in the event of weight loss greater than 2 kg over 1 month, in the event of symptoms rated 3, the presence of fever or night sweats on 2 consecutive occasions, or elevation of serum LDH above 2-fold the normal level, or anemia indicated by hemoglobin levels of <10 g/dL.

In the event of an alert triggered by the application, an email was sent to the care team, with a reminder every 24 hours if there was no response (Figure 1). Patients could also report an event by writing a free text.

Figure 1. The decision algorithm used in this study.

Outcome Measures

The primary outcome was to demonstrate that follow-up via a web application could detect more significant events (including relapses) occurring between 2 routine follow-up consultations with the specialist in patients with lymphoma who were at high risk of relapse compared with standard follow-up. Secondary outcomes were overall and progression-free survival at 2 years, relapse rate at 2 years, QoL or patients in both arms, and compliance and satisfaction for the experimental arm.

Adverse and Significant Events

An adverse event was defined as any symptom reported by the patient either during the protocol consultation in the control arm or, through the application in the experimental arm. An event was considered significant if, the grade was greater (≥2) based on the Common Terminology Criteria for Adverse Events v4.02 or, if it prompted an imaging examination, treatment (of any kind), supportive care, unscheduled consultation, or emergency hospitalization.

QoL, Adherence, and Satisfaction

QoL was evaluated using the QLQ-C30 and PHQ-9 questionnaires at inclusion and, follow-up visits at 3, 6, 9, and 12 months. Patient adherence to the use of the web application was assessed according to the number of electronic questionnaires completed. A questionnaire had to be completed every 14 days. Patients completing less than 1 electronic questionnaire every 42 days (6 weeks) were considered noncompliant. Patient satisfaction with web monitoring and the use of the web application was assessed using a self-questionnaire at their 6-month follow-up visit.

Data Management and Statistical Analysis

Data Management

One electronic case report form (e-CRF; ENNOV Clinical) was created for each patient. The information required by the protocol was collated into the e-CRF, which included the data necessary to confirm compliance with the protocol and detect any major deviations, as well as the data necessary for statistical analysis. The information was collected without mentioning the

XSL•FO
RenderX

surname and first name in the e-CRF, with an identification number for the center and a patient number. Only the first letters of the patient's surname and first were visible. This code was the only patient identifier that appeared in the e-CRF, which made it possible to link e-CRFs to the corrresponding patients.

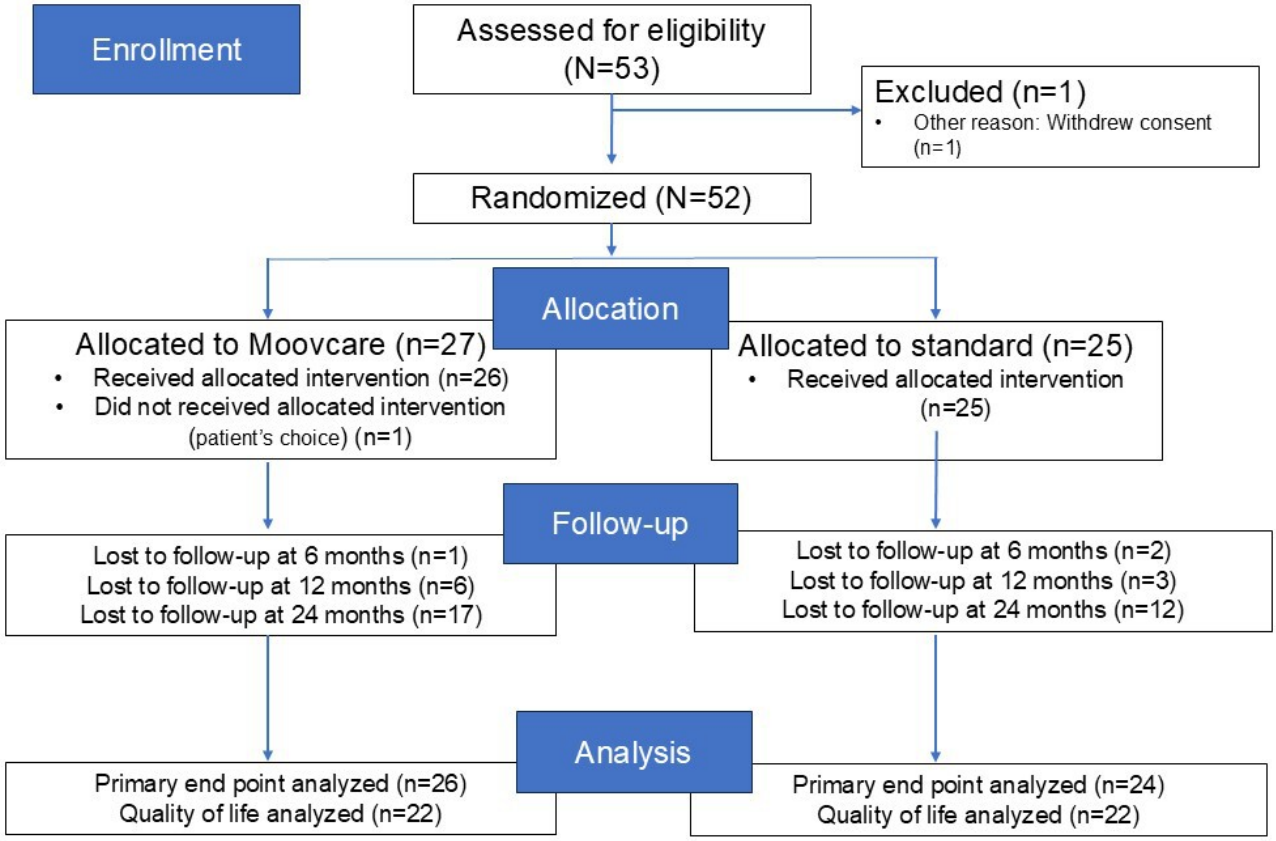
Statistical Analysis

Determination of the Size of the Study Population

The trial was based on a 2-step triangular test and was designed to have a power of 90% to detect a 30% improvement in the detection of significant events outside of routine consultations during the 6 months of follow-up with the web application. This is compared with a 60% rate of detection for significant events outside routine consultations among patients randomly assigned to conventional follow-up, with a significance of 5%. This sequential method made it possible to evaluate the application's effectiveness while controlling the power and type I error (the risk of falsely rejecting our null hypothesis) [19,20]. 40 evaluable patients were to be included per arm, and an interim analysis was to be performed when 20 evaluable patients per arm had 6 months of follow-up. Inclusion was not suspended before the 6-month follow-up.

Analysis of Variables, Progression-Free Survival, Overall Survival, and QoL Questionnaires

The analysis of the qualitative variables is presented in terms of numbers and percentages. The analysis of quantitative variables is presented as median or mean (SD) depending on the normality of the variable, whereas the minimum and maximum values are also indicated. The events are described in terms of frequency by etiological type (according to the Medical Dictionary for Egilatory Activities classification) and severity according to the NCI Common Terminology Criteria for Adverse Events version 4.02. For the analysis of censored data (overall survival and other event times), survival curves are plotted based on Kaplan-Meier estimates, and the median survival times and their 95% CIs are presented. For multivariate survival analyses, the Cox semiparametric model was used to calculate the odds ratios, which are presented with 95% CIs. The sensitivity of the application to detect a relapse and significant complications was calculated. The QoL scores were calculated according to the European Organisation for Research and Treatment of Cancer recommendations for the QLQ-C30 [16]. QoL is described for each measurement time, compared at inclusion, and then studied longitudinally using mixed analysis of variance models for repeated measures. PHQ-9 scores were calculated based on the recommendations described at each measurement time and compared at inclusion. Classes proposed in the literature (≤4; 5 - 14;>14) were used to describe the patients' state of depression [17]. Analyses were performed using SAS 9.3 software (SAS Institute, Inc).



Results

Study Design

A total of 53 patients were included between July 12, 2017, and April 7, 2020, from 14 centers in France: Le Mans (16/52, 31%), Besançon (9/52, 17%), Nantes (6/52, 11%), Bordeaux Bergonié (6/52,11%), Bordeaux Nord (6/52, 11%), Mont de Marson (4/52, 8%), Dijon (1/52, 2%), Grenoble (1/52, 2%), Paris (1/52, 2%), Strasbourg (1/52, 2%), and Vannes (1/52, 2%). One patient withdrew consent before randomization, and 27 patients were randomized to the experimental arm and 25 to the control arm. The median follow-up time was 21.3 (range 1.3 - 25.6) months. In total, 26 patients were evaluated at the primary end point in the experimental arm and 24 in the control arm (Figure 2). The Consolidated Standards of Reporting Trials (CONSORT) guideline (Checklist 1) was used to present the results.

XSL•FO
RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flowchart diagram.

Patient Characteristics

The median age of the entire population was 65.6 (range 20.3 - 87.8) years; the median age was 64.3 (range 20.3 - 87.8) years in the experimental arm and 69.2 (range 23.9 - 84.4) years in the control arm (P=.99). Further, 80% of patients (40/50) had large diffuse B-cell lymphoma, 10% (5/50) had T-cell lymphoma, and 10% (5/50) had Hodgkin lymphoma. The 2 arms were well balanced with respect to age and histological subtype (Table 1).

The median time from initial diagnosis to randomization in the study was 7.7 (range 5.0 - 170.2) months. The median was 7.5 (range 5.3 - 58.2) months for the experimental arm and 7.8 (range 5.0 - 170.2) months for the control arm (P=.43).

Rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone were the primary first-line chemotherapeutic regimens. In the experimental arm, 17/26 (65%) patients received a single line of chemotherapy, and 9/26 (35%) received 2 lines. In the control arm, 16/24 (67%) patients received a line of chemotherapy, and 8/24 (33%) received a second line.

Follow-Up

In the experimental arm, 25/26 patients (96.1%) were still included in the study at the 6-month follow-up, 20/26 (76.9%) at 12 months, and 9/26 (34.6%) at 24 months. In the control arm, 22/24 (91.6%) were still being followed at 6 months, 21/24 (87.5%) at 12 months, and 12/24 (50%) at 24 months (Figure 3).

XSL•FO
RenderX

Figure 3. Patient follow-up.

The primary reasons for the loss of follow-up were the planned end of the protocol for 20 patients and the premature termination of the study by the sponsor (19 patients; Table 2).

Table . Reasons for discontinuing the study.

	Total, n	Web application, n (%)	Control, n (%)
Death	4	3 (75)	1 (25)
Investigator decision	2	0 (0)	2 (100)
Patient decision	1	1 (100)	0 (0)
End of follow-up	20	8 (40)	12 (60)
Missing patient	2	1 (50)	1 (50)
Premature termination	19	11 (58)	8 (42)
Missing data	2	2 (100)	0 (0)

Events

During the study period, 119 events were reported (Table 3). Most occurred in the experimental arm (83/119, 69.7%) versus 36/119 (30.2%) in the control arm, with a median number of events per patient of 3.5 (range 1-8) in the experimental arm and 1.8 (range 1-6) in the control arm (P=.004). In the experimental arm, 47/83 (56.6%) events were reported directly by the medical team after a scheduled consultation, whereas 36/83 (43.3%) were reported through the web application.

In the control arm, 19/36 (52.7%) events were detected during a scheduled consultation, 2/36 (5.6%) during an unscheduled consultation, 9/36 (25%) during a consultation with another specialist, 3/36 (8.3%) during hospitalization, and 3/36 (8.3%) during a patient call.

Progression and infection were the most frequently reported events. 19 patients relapsed during follow-up, with a median follow-up time of 7 (range 1.9 - 20.6) months; 6 in the web experimental arm and 13 in the control arm (P<.001), with a median follow-up of 7.7 (range 2.8 - 20.6) months and 6.7 (range 1.9 - 16.4) months (P=.94), respectively. 13 patients were treated for relapse; 11 by chemotherapy and 2 by radiotherapy.

30 patients were infected (23 in the experimental arm and 7 in the control arm; P=.59): 5 patients had an influenza infection, and the infectious agent was not reported for the others. 14 patients received treatment; 13 with antibiotics, 1 with antivirals, and 1 with antibiotics and antivirals. The grade of adverse events was not available in 60 out of 119 (50.4%) cases, which limited data interpretation.

Event Management

Overview

Events led to 19 additional medical consultations with the referring hematologist in the experimental arm (alert management resulted in 8 additional medical consultations and 11 without an alert) versus 15 in the control arm (*P*=.99; Table 4). 30 consultations were conducted with other specialists (15 in the experimental arm and 15 in the control arm). For some events, several specialists or referring hematologists were required to manage the patient.

XSL•FO
RenderX

Table . Management of events.

	Total, n	Web application, n	Control, n	*P*-value[a]

Medical treatment	39	28	11	.94

[a]The *P* value was calculated using the chi-square test for qualitative variables, the Wilcoxon test for quantitative variables, and the Fisher test for the lower variables.

[b]N/A: not assessed.

Emergency hospitalization was required for 8 patients (4 for progression, 1 for myocardial infarction, 1 for respiratory distress, 1 for thoracic pain, and 1 for balance disorder), with no difference between the 2 arms (*P*=.78). 22 scans were performed in the web experimental arm versus 72 in the control arm (61 scanners scheduled for follow-up and 11 not scheduled for events*; P*<.001).

39 events required treatment, with a total of 24 patients receiving medical treatment (16 in the experimental arm and 8 in the control arm; *P*=.11; Table 5). 56 prescriptions were filled (37 in the web experimental arm and 19 in the control arm*; P*=.64).

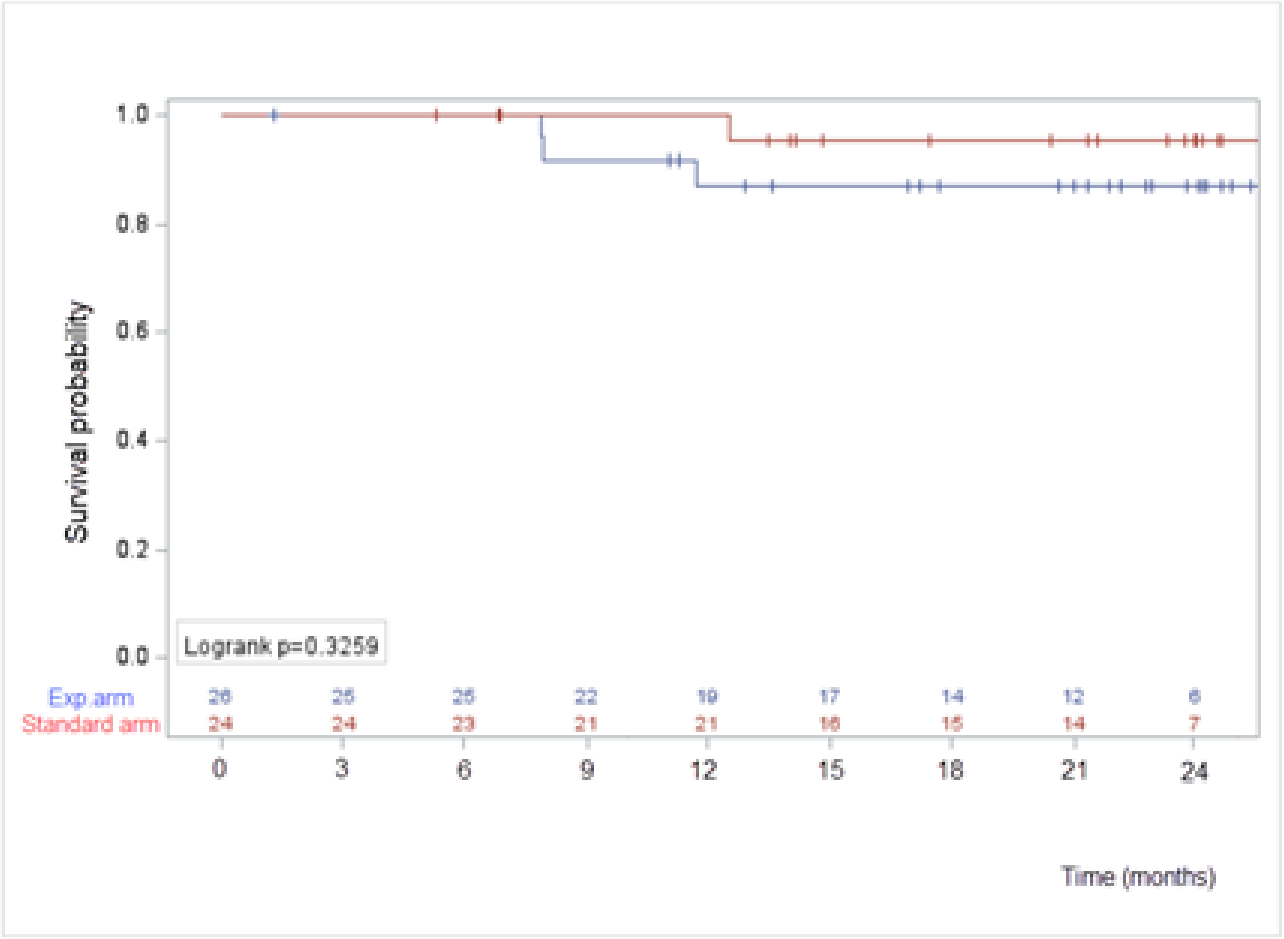
QoL and Depression

The patients were asked to complete the QLCQ-30 questionnaire every 3 months for 1 year. 44 patients completed at least 2 QoL questionnaires during the study; 22 patients per arm (ie, 22/26, 84.6% in the experimental arm and 22/24, 91.6% in the control arm). The higher the score, the poorer the QoL (maximum score: 114). The median scores did not differ between the 2 groups at 12 months with it being; 45 in the experimental arm (range 39-61) and 44 in the control arm (range 30-69*; P*=.94).

Regarding depression, 42 patients completed the questionnaire (21 per arm; ie, 21/26, 80.7% in the experimental arm and 21/24, 87.5% in the control arm]. The score was 1.0 (range 0 - 15) in the experimental arm versus 1.5 (range 0 - 13) in the control arm (*P*=.73).

Satisfaction (Experimental Arm)

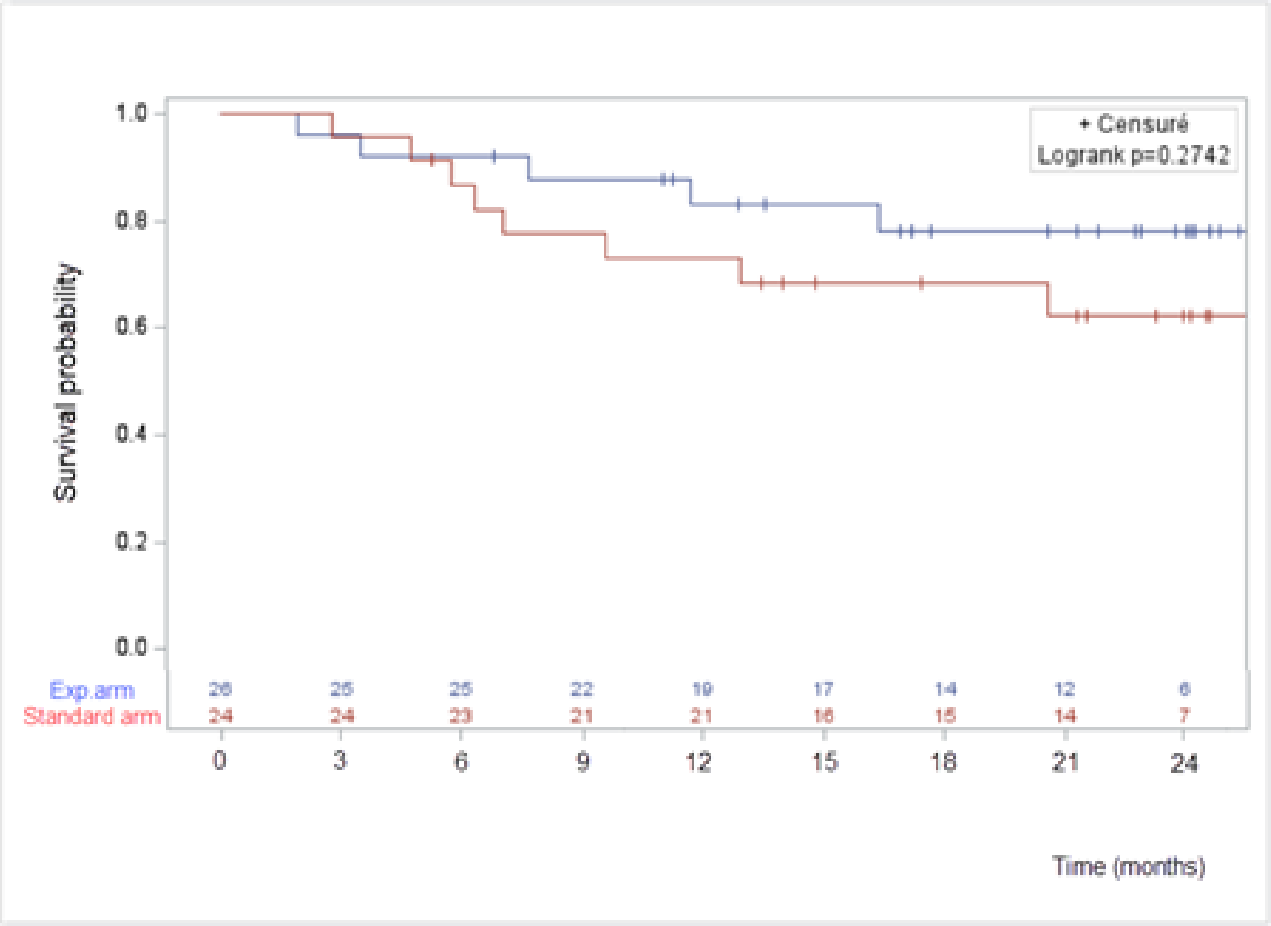
In total, 20 patients in the experimental arm completed the satisfaction questionnaire (20/25, 80%). Further, 95% (19/20) of patients who responded to the satisfaction questionnaire were



XSL•FO
RenderX

satisfied and reassured by the application, whereas 90% (18/20) felt better informed.

Survival



Four patients died during the trial; 3 in the experimental arm and 1 in the control arm (*P*=.34). Overall survival at 12 months was 87.1% in the experimental arm (95% CI 65%-95.7%) and 95.2% in the control arm (95% CI 70.7-99.3%; *P*=.32; Figure 4). Progression-free survival at 12 months was 83.2% in the experimental arm (95% CI 61%-93.3%) and 68.5% in the control arm (95% CI 44.9%-83.6%; *P*=.27; Figure 5).

Figure 4. Overall survival. Exp.: experimental.

XSL•FO
RenderX

Figure 5. Progression-free survival. Exp.: experimental.

Protocol Deviations and Technical Failures in the Experimental Arm

Three alerts were not handled by the care team within the required time frame and were subsequently classified as minor (grade 1).

The automatic sending of questionnaires was stopped for 9/26 (35%) patients. For 3 patients, the questionnaires were sent in paper form. For the other 6, no solution could be found despite repeated interventions by the electronic application's technical department. One of these patients suffered 2 major events: myocardial infarction and relapse. These 2 events were not reported in the electronic application. Because of these technical problems, compliance could not be assessed.

Outcomes

An interim analysis was performed based on the protocol when the first 40 patients reached 6 months of follow-up. The results of this analysis did not reject the null hypothesis, which stated that there was no difference in the diagnosis of events between the 2 arms. The Sentinel Lymphoma Study Committee met on March 11, 2021, to oversee the analysis of the primary outcome, which indicated no difference in the diagnosis of significant events. A decision was made at the end of the meeting to discontinue the trial early. Based on the protocol, the study was terminated on March 15, 2021, following the sponsor's decision.

Discussion

Principal Findings

In this study, there is no difference in the occurrence of significant events between the 2 arms (median number per patient of 3.5 in the experimental arm and 1.8 in the control arm; P=.004). Progression, infection, and pain were the most frequently reported events. Patient satisfaction was very high and the patients felt reassured to have electronic monitoring. The patients included in the experimental arm underwent fewer scans compared with those in the control arm, without impacting overall survival, despite a short follow-up (P<.001).

Strengths and Limitations

First, the primary outcome of a 30% superiority of reporting significant events in the experimental arm has been overly optimistic. Thus, reducing the end point would have led to a substantial increase in the number of included patients. The number of events was probably not the best criterion for evaluating the effectiveness of remote monitoring. An improvement in QoL or a reduction in the risk of relapse would likely have been more relevant [13,15].

Second, technical problems with the web application occurred (electronic questionnaires not received, with major biases in event reporting). The incidents were not expected because of the experience of the software developer (Moovcare, Sivan Innovation, Ltd); however, there was a change in the technical

XSL•FO
RenderX

team between this publication on lung cancer and the start of our study [11-13]. The blocking of automatic questionnaires required 42 direct interventions by clinical study investigators with calls to the patient (firewalls and spam). IT support did not correct these recurring anomalies, despite the changes to the application in November 2019 (5 patients were included in the experimental arm after this date). These operational problems resulted in 15 meetings without resolution of the problems, with an average response time of 4.6 months from technical support (frequent changes to contact persons). As a result, the events in the experimental arm were not reported correctly, leading to study bias. The final report has been sent to the Agence Nationale de Sécurité du Médicament on June 29, 2021.

Finally, only 43% of the events were declared by the application in the experimental arm, which would indicate a problem with patient training.

Comparison With Prior Work

PROs are underestimated in clinical practice and trials for patients with lymphoma and have most often consisted of paper-based QoL questionnaires [21]. The measurement of PROs via electronic questionnaires has subsequently been evaluated in randomized trials with a low representation of patients with lymphoid malignancies [22]. However, Maguire et al [23] demonstrated that real-time electronic monitoring of symptoms was feasible during an initial chemotherapy cycle in patients with solid tumors and lymphoma, with a reduction in the intensity of side effects and anxiety, compared with a control group.

Future Directions

Proposals for the future include improving the study design by limiting the patient population to a single type of lymphoma, defining the objective to demonstrate an improvement in morbidity and possibly reduce cost, and guaranteeing the reliability of the electronic application. PROMs require standardization of analysis for comparative purposes. Therefore, it is necessary to regulate the use of health care applications to avoid malfunction and abuse [24]. Denis and Krakowski [25] defined 20 criteria of effectiveness, safety, and functionality that should govern the development of ePROMs. Telemonitoring applications should strive to improve patient compliance and prevent patients from dropping out due to a lack of understanding or receiving excessive notifications [26]. Telemonitoring applications must evolve with therapeutic innovations and be regularly reevaluated to demonstrate their long-term benefits on a larger scale [27]. Finally, guidelines are recommended for the design of clinical trials to evaluate the effectiveness of electronic solutions [28-30].

Conclusions

Sentinel Lymphoma is the first randomized phase 3 trial to evaluate the effect of remote monitoring on the detection of significant events in patients with hematological malignancies. Progression, infection, and pain were the most frequently reported events. Despite a high number of events (83 in the experimental arm against 36 in the control arm), the difference was not significant. A more targeted population, a more precise objective, and better security for remote surveillance solutions are recommended for subsequent projects.

Acknowledgments

The authors would like to thank the patients and their families, as well as Antoine Giraud for his advice. The authors would like to thank Enago for the English language review. This study was funded by Takeda.

Data Availability

All data from the study are freely available upon request to the corresponding author.

Authors' Contributions

KLD, MB, and ALS designed the study. ALS collected, analyzed, and interpreted the data. KLD drafted the first version of the manuscript. All authors participated in the preparation and revisions of the manuscript and approved the final version of the manuscript for submission.

Conflicts of Interest

KLD has received consulting fees from AstraZeneca, Abbvie, Incyte Janssen-Cilag, and Gilead.

Abstract

Background: Cancer survivors face long-term health challenges posttreatment. Physical activity (PA) can help manage cancer-related side effects and offer additional health benefits, yet up to 80% of survivors do not meet PA guidelines. Effective and translatable PA interventions are needed.

Objective: This randomized trial assessed the feasibility, acceptability, and preliminary efficacy of a 12-week automated Internet program for increasing moderate-to-vigorous physical activity (MVPA) among cancer survivors. A secondary aim examined the effect of the intervention on physical and mental well-being.

Methods: Inactive (<60 min/wk of PA) cancer survivors who completed cancer-directed treatment in the past 3 - 12 months or those on a stable maintenance treatment regimen were randomized to the Energize! Exercise Program or Newsletter control condition. The Energize! Program was fully automated and involved weekly behaviorally-based video lessons, homework assignments, exercise planning and reporting, and progressive MVPA goals (75 to 200 min/wk). Algorithm-generated personalized feedback was provided based on PA goal attainment and homework completion. The newsletter group received bimonthly PA education newsletters (a total of 6). Assessments occurred at baseline, 3 months (postintervention), and 6 months (following a 3-month no-contact follow-up). Feasibility was assessed via enrollment and retention rates, acceptability was assessed via intervention engagement metrics and program satisfaction questionnaire, and MVPA was assessed via both self-report and accelerometer (min/wk of total and "bouted" MVPA [accumulated in bouts ≥10 min]). Health-related outcomes (eg, quality of life, fatigue, psychological distress, psychological symptoms, and fear of cancer recurrence) were assessed via electronic questionnaires.

Results: Forty-six adults aged 55.2 (SD 8.3) years, with BMI mean 33.0 (SD 7.6) kg/m^2; 42 (91.3%) female, and 37 (80.4%) non-Hispanic White enrolled in this trial. Feasibility metrics indicate that 69% (46/67) of those who screened eligible were randomized and 6-month retention among randomized participants was 94% (43/46). Acceptability was also high, as evidenced by the percentage of lessons viewed (mean 87.7%, SD 21.3%), exercise plans submitted (mean 82.6%, SD 25.8%), homework assignments completed (mean 77.2%, SD 25.2%), and weeks in which exercise minutes were logged (mean 85.9%, SD 22.1%). Program satisfaction ratings were higher in Energize (mean 5.8, SD 1.6; 1 - 7 scale) versus Newsletter (mean 3.2, SD 1.6; P<.001). Energize! increased self-reported (92.7 min/wk), bouted (35.4 min/wk), and total (46.3 min/wk) MVPA at 3 months (Cohen d=0.74 - 0.94), and these changes were partially maintained at 6 months. Increases in MVPA were smaller among Newsletter participants (d=0.28 - 0.47). Group differences in health-related outcomes were minimal and mixed, favoring Energize! over Newsletter for vitality (d=0.63) and somatization (d=0.76) at 3 months, and for depression (d=0.59) and anxiety (d=0.51) at 6 months.

Conclusions: The automated Energize! Program is feasible, acceptable, and associated with positive changes in MVPA, yet future studies are needed to improve MVPA long-term. Findings suggest that self-guided PA programs may be beneficial for increasing MVPA among cancer survivors.

KEYWORDS

eHealth; exercise; physical activity; survivorship; behavioral intervention

Introduction

Early detection and improved treatments have significantly reduced cancer mortality rates in recent years, resulting in greater numbers of cancer survivors [1]. Currently, there are over 18.1 million cancer survivors in the United States, and it is estimated that rates of cancer survivorship will increase by an additional 44% by 2040 [2]. While survivorship rates are encouraging, cancer survivors continue to face unique health challenges (eg, limitations in daily activities, anxiety, depression, fear of recurrence, and persistent fatigue [3-7]) which can persist well beyond the end of cancer treatment and reduce physical and mental health-related quality of life.

Physical activity (PA) is a modifiable lifestyle behavior that can help ameliorate these adverse health effects and is positively associated with numerous physiological and psychological health benefits. Findings from the American College of Sports Medicine's International Multidisciplinary Roundtable indicate that there is strong evidence that regular PA can improve common cancer-related side effects, which include anxiety, depression, fatigue, and reductions in health-related quality of life, physical functioning, and cardiorespiratory fitness [8,9]. PA is also associated with a lower risk of all-cause mortality, cancer recurrence, and the likelihood of other comorbid chronic diseases (eg, type 2 diabetes and cardiovascular disease) [10-12]. However, estimates suggest that only 17% to 58% of cancer survivors achieve the national PA guideline of ≥150 minutes/week of moderate-intensity PA [13-19]. Thus, translatable interventions for increasing PA among the growing number of cancer survivors are needed.

Automated, Internet-delivered PA programs, which are a type of eHealth intervention, allow for wide-scale dissemination at a relatively low cost. Pew Research data indicate that 95% of Americans use the Internet [20], making it an ideal medium for delivering behaviorally-based PA programs, as it can reduce provider costs and reach large numbers of individuals. Further, the cost of delivering an automated Internet program is low, and there is no added cost for enrolling additional participants. This is particularly important from a translation perspective, as this type of program does not need to be delivered by exercise physiologists, physical therapists, rehabilitation professionals, or physicians. Moreover, patients are not required to live near a treatment or rehabilitation center and can access the entire intervention on their own, without time constraints, travel barriers, or schedule limitations (eg, sessions only offered during certain hours at specific facilities).

Although eHealth interventions are widely used to promote PA and other lifestyle behaviors in "non-clinical" settings or within certain chronic disease populations (eg, cardiovascular disease and diabetes), application of these technologies to promote PA among cancer survivors has lagged behind [21]. Considerable progress has been made in the past several years; however, there remains a shortage of randomized controlled trials, with stringent investigative processes, evaluating the effects of behavioral eHealth interventions among cancer survivors [22-24]; additional research is clearly warranted.

This randomized trial examines the feasibility and acceptability of a 12-week, fully automated Internet program for increasing PA among cancer survivors and explores the effect of this program on PA relative to a newsletter control condition. Specifically, it uses rigorous methodology (eg, a randomized trial and PA assessment via accelerometers), incorporates essential behavior change techniques (eg, goal setting, action planning, self-monitoring, problem-solving, and affect regulation strategies), and examines whether intervention effects are sustained 3 months postintervention, thereby addressing important deficits in the current body of research. A secondary aim of this trial was to compare treatment groups on measures of physical and mental well-being over the entire study period.

Methods

Participants and Recruitment

To be eligible, individuals needed to have a confirmed cancer diagnosis (excluding nonbasal or squamous cell carcinoma) and have either completed all cancer-directed treatment in the past 3 - 12 months or be on a maintenance treatment regimen for which they have been stable for at least 3 months. Other eligibility criteria included being 18 - 70 years of age, a BMI of 18.5 to <45 kg/m^2, daily Internet access, English speaking, and inactive, defined as engaging in <60 minutes/week of self-reported moderate-intensity PA over the past 3 months. Exclusion criteria included current, recent, or planned pregnancy over the next 6 months, recent (< 2 y) hospitalization for a psychiatric condition, or the presence of a medical condition for which PA is contraindicated. These broad inclusion criteria were selected to enhance the generalizability of study findings and not limit enrollment to a particular cancer type.

Participants were recruited via advertisements at local oncology clinics in the greater Providence, Rhode Island area, and via national social media advertisements (eg, Facebook). Interested individuals could scan a QR code on physical flyers or click on a link within a social media advertisement to be directed to an electronic screener. This screener was designed to assess initial eligibility by confirming that age, BMI, ability to exercise, and PA criteria were met. Individuals deemed initially eligible based upon the electronic screener were then contacted by a member of the research team, and a more thorough eligibility screener was conducted via telephone. Those who continued to be eligible were invited to a one-on-one orientation session to learn more about the study, ask questions, and obtain informed consent. These sessions were conducted in-person or via videoconference (eg, Zoom).

Study Procedures and Randomization

Cancer survivors enrolled in this study and randomized to receive the 12-week Energize! Exercise Program or a Newsletter control condition. Randomization occurred at baseline using sealed, opaque envelopes containing pregenerated allocation assignments, stratified by maintenance therapy status (on vs off therapy) to ensure balance across conditions. Envelopes were prepared in advance, sequentially numbered, and opened in order of enrollment. Assessments, which consisted of electronic questionnaires and PA measurement, occurred at baseline, 3 months (immediately postintervention), and 6 months (following a 3-month, no-contact follow-up period). Descriptions of each assessment measure and treatment condition are provided in greater detail below.

Primary and Secondary Aims

The primary aims of this study were to assess the feasibility, acceptability, and preliminary efficacy of the Energize! Exercise Program for improving MVPA among cancer survivors, relative to a Newsletter control condition. Feasibility was evaluated via retention and enrollment rates. Of particular interest were the conversion rates of (1) those who completed the screening process who were deemed eligible, and (2) those who screened eligible but were eventually randomized. Acceptability was assessed via engagement with the intervention (eg, percentage of video lessons viewed, exercise plans submitted, homework assignments completed, and weeks in which exercise minutes were logged), and via the program satisfaction questionnaire. No predetermined thresholds for feasibility or acceptability were established before the study began. Changes in MVPA were assessed via both self-report and accelerometer (described in detail below). Secondary aims were to examine the effect of the intervention on health-related physical and mental well-being, which were assessed via a series of electronic questionnaires. This trial sought to enroll approximately 50 participants; however, no formal power calculations were conducted given the preliminary nature of this study.

Energize! Exercise Program

Participants randomized to the intervention group received the 12-week Energize! Exercise Program. This fully automated, behaviorally-based, Internet program was designed to increase moderate-intensity PA to a level consistent with national recommendations. The entire program was delivered via a study website, which could be accessed via any web browser on a computer, tablet, or smartphone. No human intervention contact was provided. Each week, participants were given a prescribed exercise goal and asked to submit an exercise plan, watch a multimedia lesson, complete a brief homework assignment, and report their exercise on the study website. Computer-generated, personalized feedback messages were also provided weekly. Each of the Energize! Program components is described in greater detail below.

Exercise Goals

Participants were given a weekly, moderate-intensity PA goal that started at 75 minutes/week and increased by 25 minutes/week every other week, until reaching 200 minutes by week 11. Given that this program was designed to increase "purposeful" moderate-intensity aerobic exercise (eg, brisk walking and cycling), participants were instructed not to count activities such as hatha yoga, strength training, household chores (eg, gardening or vacuuming), or occupational activities (eg, restaurant server and postal worker), toward their weekly aerobic PA minute goal. To promote a regular habit of PA, participants were encouraged to exercise 5 days/week.

Exercise Planning

Beginning at week 2, participants were encouraged to plan their exercise prior to the start of each week and submit that detailed exercise plan via the study website. Specifically, individuals were asked to consider their schedule for the upcoming week and record when they planned to exercise (ie, day of week and time of day), as well as the type and duration of exercise they planned to do.

Multimedia Lessons

Each week, participants were instructed to watch a 10‐ to 15-minute video lesson. These lessons were designed to teach behavioral principles for modifying PA behavior. During week 1, a general overview of the program was provided along with an exercise prescription. Other video lesson topics included exercise planning, managing negative thoughts, stimulus control, overcoming exercise barriers, affect and exercise enjoyment, a midpoint check-in, managing exercise slips, exercise motivation, turning sitting time into active time, future-oriented mindsets, and thinking like an exerciser.

Homework Assignments

Participants were asked to complete weekly homework assignments electronically to help apply the content from the video lessons to their personal lives. Each assignment was designed to correspond to the lesson of the week and take no longer than 10 minutes to complete. Example assignments included the creation of an exercise routine to promote habit formation, journaling about the value of exercise and positive feelings associated with exercise, problem-solving around exercise barriers, and personal self-reflection based upon one's progress in the program. No specific feedback was provided to the participant based on their responses to the homework assignments. However, as noted below, automated feedback, based solely upon whether the participant did or did not complete the homework assignment, was included as part of the weekly feedback message.

Self-Monitoring of Exercise

Similar to the exercise planning component of this program, participants were also asked to report all exercise performed on the study website daily. This included the time of day that the exercise was performed, the type of exercise, and the number of exercise minutes.

Automated Feedback Messages

Automated, yet personalized feedback was provided weekly based on the data input by the participant from the previous week. Twelve weeks of human-developed, tailored messages were embedded into the study website and took into consideration the following factors: (1) number of exercise minutes performed, (2) whether the homework assignment was

XSL•FO
RenderX

completed or not, and (3) whether any injury, illness, or vacation prevented the participant from achieving their weekly exercise goal. Table 1 provides the response options and example feedback message for each factor. Generally, feedback messages were designed to be encouraging and motivational, praising individuals for meeting goals and providing support, encouragement, and specific behavioral recommendations for when goals were not met.

XSL•FO
RenderX

Table . Response options used to generate weekly, algorithm-derived feedback messages and example messaging for a given week.

Response category and response options	Example feedback message
Amount of exercise reported	
Response option a: Did not report any exercise	It looks like you didn't report any exercise this week. We hope everything is OK. Perhaps something unexpected happened or you had a particularly busy week. Whatever the case, we hope you can get back on track! Consider the reasons you joined this program. Try to problem-solve around your current exercise barriers. Remember that when it comes to exercise, some exercise is always better than no exercise. You got this!
Response option b: Achieved exercise minute goal	You met the exercise goal for the week - great job! Hopefully, you're starting to get into the swing of things and that exercise is automatically becoming part of your daily routine. The exercise goal will be increasing to 125 minutes this week. Start thinking about how you will get those additional 25 minutes of exercise in so that you can meet your goal again next week.
Response option c: Some exercise but less than half of goal	Meeting the exercise goal is an important part of this program. We are glad to see that you were able to get at least a little bit of exercise this week. Challenge yourself next week to make exercise a priority. To help you achieve your exercise goal, you could consider adding a positive social cue. Ask a friend, coworker or family member to join you on a walk, hike or bike ride. This is a great strategy for adding additional accountability and for making exercise fun and social. Keep pushing yourself this week to reach the goal. We know that you can do it!
Response option d: Did not achieve goal, but exercised more than half of the total goal minutes	Meeting the exercise goal is an important part of this program. We are thrilled to see that you're putting in great effort to reach the goal. Although you fell a little short of the goal this week, keep pushing yourself this week. The goal will be increasing to 125 minutes. To help you achieve this goal, you could consider adding a positive social cue this week. Ask a friend, coworker or family member to join you on a walk, hike or bike ride. This is a great strategy for adding additional accountability and for making exercise fun and social.
Homework assignment completion	
Response option a: Assignment completed	It's awesome to see that you have completed the homework this week! Hopefully, this homework will help you in the future to identify inactivity cues in your daily life and determine which ones you can replace with cues for activity. As you go about the week, keep thinking about ways that you can add more active cues to your home or work environment.
Response option b: Assignment not completed	A big part of this program is the homework that we assign each week. We think that it's important to complete the assignment so that you can spend more time reflecting on what you learned in the lesson. You can still go back and complete the homework from last week. Take some time to do that now. Also, what got in the way of you completing the homework last week? If you simply forgot about it, try setting a reminder on your phone that prompts you at a certain time each week to complete your homework.
Atypical week	
Response option a: Injury	It looks like last week was a little atypical for you due to an injury. We hope that it isn't anything serious and that you start to feel better soon! Please reach out to us if this injury persists.
Response option b: Illness	It looks like last week was a little atypical for you due to an illness. We hope that you are feeling better! Once you feel back to normal, make it a priority to get back to your exercise routine. Please let us know if your illness continues for over 2 weeks.
Response option c: Vacation	It looks like last week was a little atypical for you due to vacation. We hope that you had a great time! While vacation can sometimes be challenging because we get out of our routines, many times we can still find ways to be active while away. If you are still going to be on vacation this week, try to think of creative ways to exercise so that you can reach your goal. If you are home from vacation, make it a priority to get back in an exercise routine this week.

Newsletter Condition

Participants randomized to the Newsletter condition, considered the usual care control condition, received newsletters twice per month for 3 months. Consistent with information available to individuals via the National Cancer Institute and traditional survivorship care plans, these newsletters focused on the general and cancer-specific health benefits of regular PA and reduced sedentary time and included recommended PA guidelines and general information for initiating aerobic PA, strength training, and flexibility programs. Other topics included were exercise safety, methods for gauging exercise intensity, an activity of the month (eg, Zumba, swimming, etc), and motivational, exercise-related stories from cancer survivors. Strategies for facilitating PA behavior change were not included in these newsletters.

Assessment of PA

Moderate-to-vigorous physical activity (MVPA) was assessed at baseline, 3, and 6 months via both accelerometer and self-report. The Actigraph GT9X Link accelerometer [25-27] was worn on the waist for 7 consecutive days, during all waking hours (exclusive of bathing or water activities), at each assessment period. Participants were required to have ≥4 "valid" days (ie, ≥8 hours of wear time [28]) to be included in the analyses. A previously published cutpoint (≥1952 activity counts/min) was used to define MVPA [26] and weekly MVPA performed in bouts ≥1 minute (total MVPA) and ≥10 minutes (bouted MVPA) were computed using ActiLife software (version 6.13.5; ActiGraph, LLC).

Self-reported PA was assessed via a modified version of the Paffenbarger Physical Activity Questionnaire [29]. At each assessment period, participants were queried by research staff regarding their PA over the previous 7 days. Specifically, participants were asked to report the number of days and minutes per day spent (1) walking briskly for the purpose of exercise or transportation (eg, outside, indoors, or on a treadmill) for at least 10 consecutive minutes, and (2) engaging in sports and recreational activities, excluding occupational and household activities (eg, cleaning, laundry, and yard work). Minutes per week spent brisk walking and engaging in sports and recreational activities were summed to compute total minutes per week of MVPA.

Questionnaire Measures

To address the secondary aim of comparing treatment groups on measures of physical and mental well-being, participants completed a series of questionnaires at each assessment period via REDCap (an online platform; Vanderbilt University). Health-related quality of life was assessed using the 36-Item Short Form Survey Instrument (SF-36) [30]. This previously validated and widely used questionnaire measures 8 domains of health status: physical functioning, physical role limitations, bodily pain, general health perceptions, vitality, social functioning, emotional role limitations, and mental health. Higher scores on each subscale indicate a more favorable quality of life. Fatigue was assessed using the Brief Fatigue Inventory, which has been previously validated in a cancer population [31]. This measure assesses the severity of fatigue and the impact of fatigue on daily functioning by querying individuals regarding fatigue over the past week, current fatigue, and usual and worst fatigue in the past 24 hours. An overall fatigue score was calculated, with higher scores indicating more severe fatigue. Psychological distress was assessed using the single-item Distress Thermometer developed by the National Comprehensive Cancer Network [32]. Individuals are asked to rate their distress on a scale of 0 - 10, with scores ≥4 typically suggesting clinically significant distress. The Brief Symptom Inventory-18 [33] is widely used to assess psychological symptoms in cancer survivors and has 3 subscales (somatization, depression, and anxiety) and a global score (Global Severity Index, which reflects the overall level of psychological distress). Higher scores on all subscales indicate greater psychological distress. The Fear of Recurrence Inventory – Short Form [34] assessed the intensity of fear related to the possibility of cancer returning. A total score was computed, with higher scores reflecting a greater severity of fear of cancer recurrence.

Statistical Analysis

The statistical analyses for this study were conducted using mixed-effects models to evaluate the impact of the program on various PA and psychological outcomes. The primary outcomes analyzed included self-reported MVPA, total MVPA, and bouted MVPA over time. Since this was a pilot study with a relatively small number of participants, we focus on effect sizes rather than *P* values.

For each outcome, mixed-effects models were used, incorporating random intercepts for participants to account for the repeated measures design of the study. These models included fixed effects for time points, treatment arms, and their interaction, as well as baseline values of each outcome to control for initial differences across groups. Additional covariates such as age, BMI, weight, sex, education, racial and ethnic minority status, maintenance therapy, days since treatment completion, and daily wear time (for accelerometer-based outcomes) were also included. All mixed-effects models were fitted using maximum likelihood estimation so that participants with incomplete data could be included with all available observations. This approach assumes that the data are missing at random, with missingness depending only on observed variables in the model (eg, baseline outcome, demographics, and clinical covariates). For accelerometer outcomes, analyses were restricted to assessments with ≥4 valid wear days, and daily wear time was included as a covariate. The primary interest was in the interaction between treatment arms and time points, which was used to evaluate whether changes in PA differed between the 2 groups (Energize! and Newsletter) at each time point (baseline, 3 months, and 6 months).

Post hoc pairwise comparisons of estimated marginal means were conducted to assess changes from baseline to 3 months and baseline to 6 months within each randomization group. Bonferroni corrections were applied to adjust for multiple comparisons. To further interpret the results, effect sizes were calculated using standardized mean differences (Cohen *d*), where 0.2 is considered a "small" effect, 0.5 is a "medium" effect, and 0.8 is a "large" effect.

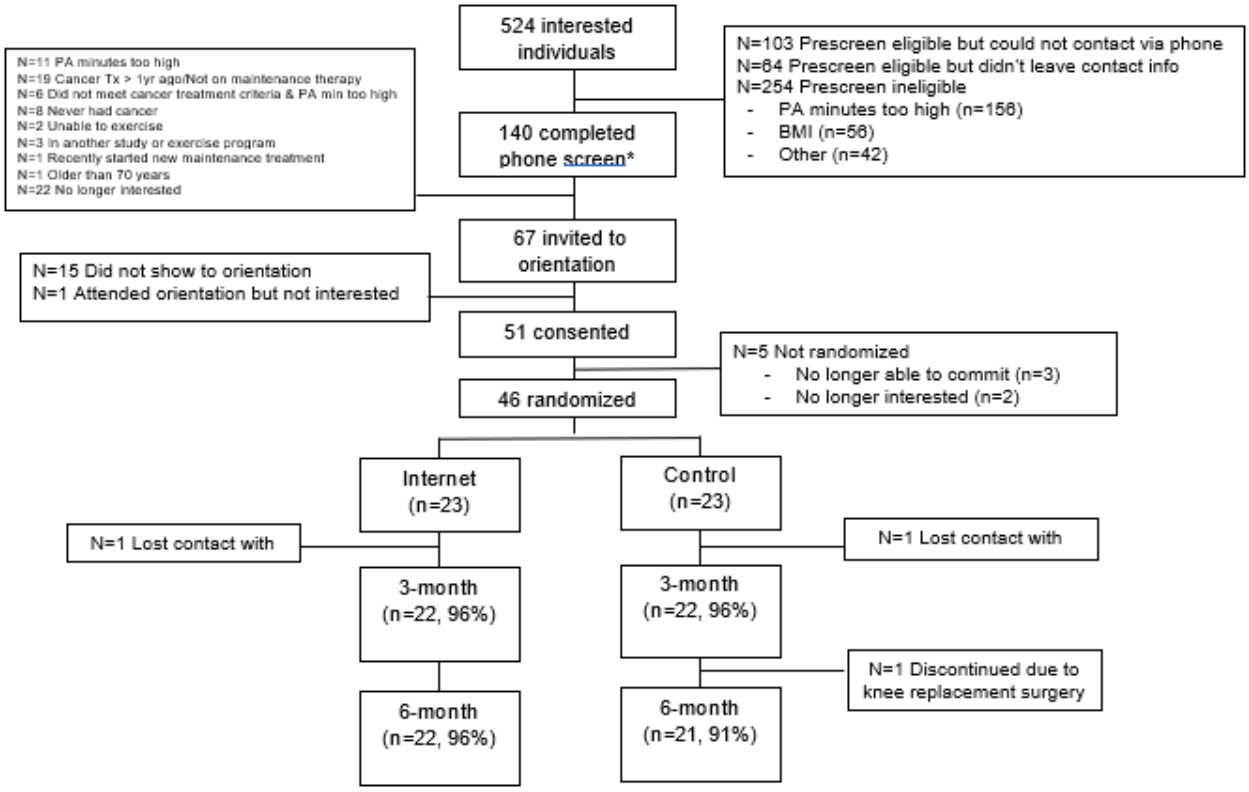
Ethical Considerations



Study procedures were approved by the Lifespan Institutional Review Board (Lifespan IRB 3, project # 1850077). Written or electronic informed consent was obtained by all participants prior to initiating any study procedures. All study data collected were deidentified and stored on a secure server. Participants were compensated US $25 in the form of cash or a gift card upon completion of assessment procedures at 3 and 6 months (for a total compensation of US $50). No compensation was provided for baseline assessments.

Results

Principal Results

Forty-six cancer survivors were randomized to the Energize! Program (n=23) or Newsletter condition (n=23; Figure 1). On average, participants were 55.2 (SD 8.3) years of age, had a BMI of 33.0 (SD 7.6) kg/m^2, 91.3% self-reported as female (42/46), and 80.4% were non-Hispanic White (37/46). Among the sample, 69.6% were breast cancer survivors (32/46; vs "other" cancer type), 65.2% were on a maintenance therapy regimen (30/46), and on average participants were 684.7 (SD 861.5) days posttreatment. From a health literacy perspective, only 1 participant indicated "sometimes" having someone help them read instructions, pamphlets, or other written material from their doctor or pharmacy [35]. Participants also rated the importance of exercise in their lives as moderately high, mean 5.0/7.0 (SD 1.5), which was significantly higher than prior to their cancer diagnosis, mean 3.9 (SD 1.3; P<.001). There were no differences between treatment groups on any baseline demographic characteristics (Table 2).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram depicting patient flow through the trial.

* N=140 completed the phone screen, but 37 of those didn't first complete the online prescreen (i.e., they contacted research staff directly); Retention numbers at follow-up assessments were calculated based upon whether physical activity portion of assessment was completed

Feasibility and Acceptability Metrics

Study enrollment (n=46) was consistent with the targeted goal of approximately 50 participants. Feasibility metrics indicate that 48% of those who completed the screening process were deemed eligible (67/140), and of those who were deemed eligible, 69% were randomized (46/67). Further, retention at 3 and 6 months was 96% (44/46) and 94% (43/46), respectively. Acceptability was assessed via intervention engagement and program satisfaction. On average, Energize! participants watched 87.7% (SD 21.3%) video lessons (10.5/12), submitted an exercise plan on 82.6% (SD 25.8%) of weeks (9.9/12), completed 77.2% (SD 25.2%) of all homework assignments (9.3/12), logged their exercise minutes on 85.9% (SD 22.1%) of all weeks (10.3/12), and achieved their prescribed exercise goal on 56.5% of all weeks (6.8/12; weeks 1 - 6: 70.3%, weeks 7 - 12: 42.8%). When asked to rate the usefulness of each of the intervention elements (via Likert scales 1 - 7), participants rated exercise planning (mean 5.0, SD 2.0) and exercise self-monitoring (mean 5.0, SD 2.0) as most useful, followed by video lessons (mean 4.7, SD 1.7), feedback messages (mean 4.3, SD 1.6), and homework assignments (mean 4.2, SD 1.8). Further, compared to the Newsletter condition, Energize! participants reported higher program satisfaction (mean 5.8, SD 1.6 vs mean 3.2, SD 1.6; *P*<.001), usefulness of the program (mean 5.6, SD 1.5 vs mean 4.2, SD 2.1; *P*<.001), and reported a higher likelihood of recommending the program to others (mean 5.9, SD 1.4 vs mean 4.8, SD 1.9; *P*=.001).

Physical Activity Outcomes

On average, participants had 6.4 (SD 1.1) “valid” days of accelerometer wear time, and the device was worn for mean 13.3 (SD 1.7) hours/day across all time points. Changes in MVPA over time by treatment arm are shown in Figure 2. Mixed-effects models revealed that the interaction between randomization group and time was not significant for any of the MVPA variables from either baseline to 3 months (*P*>.14, *d*=0.36-0.51) or baseline to 6 months (*P*>.41, *d*=–0.07 to 0.34). However, effect sizes for the change in PA from baseline to 3 months for Energize! participants were in the medium-to-large range, with mean changes as follows: +92.7 minutes/week for self-reported MVPA (*P*=.01; *d*=0.94), +46.3 minutes/week for total MVPA (*P*=.06; *d*=0.74), and +35.4 minutes/week for bouted MVPA (*P*=.04; *d*=0.81). Among the newsletter

XSL•FO
RenderX

conditions, no significant 3-month changes in MVPA were observed, and effect sizes were “small” for self-reported MVPA (+46.0 min/wk; *P*=.40; *d*=0.47), total MVPA (+17.2 min/wk; *P*≥.99; *d*=0.28), and bouted MVPA (+17.8 min/wk; *P*=.61; *d*=0.41). Changes from 3 to 6 months were not significant for either Energize! (*P*≥.99, *d*=0.19-0.26) or Newsletter (*P*>.95, *d*=0.02-0.32).

Questionnaire Measures

Table 3 reports the mean scores for all questionnaire measures over the 6-month study period and compares treatment groups at 3 and 6 months. Comparisons between Energize! and Newsletter with medium-to-large effect sizes (eg, ≥0.5) are highlighted below. At 3 months, the vitality subscale of the SF-36 (d=0.63) and the somatization subscale of the Brief Symptom Inventory (d=0.76) were more favorable in Energize! compared to the Newsletter. At 6 months, outcomes favored Energize! over Newsletter for the depression (d=0.59) and anxiety subscales (0.51) of the Brief Symptom Inventory. However, Newsletter improved more than Energize! on the bodily pain (d=–0.85) and general health (d=–1.26) subscales of the SF-36 and on the Brief Fatigue Inventory (d=0.61).

Global	9.69 (1.5)	10.71 (1.71)	9.7 (1.52)	11.19 (1.7)	8.07 (1.54)	10.07 (1.76)	.38	−0.33	.25	−0.44
Fear of cancer recurrence	13.55 (1)	14.23 (1.1)	11.94 (1.01)	13.04 (1.1)	12.17 (1.03)	12 (1.14)	.32	−0.38	.88	0.06

[a]For all health-related quality of life subscales, higher scores are indicative of a more favorable outcome; however, higher scores for fatigue, psychological distress, brief symptom inventory, and cancer recurrence are indicative of a less favorable outcome.

Discussion

Principal Findings

Results of this preliminary investigation support the feasibility and short-term efficacy of a 3-month, fully automated, web-based intervention (Energize!) for improving MVPA among cancer survivors. Participant retention (>94%), weekly engagement with intervention elements (73% - 86%), and program satisfaction ratings (average of 5.8 out of 7) were high. Additionally, the Energize! program resulted in significant increases in both self-reported and accelerometer-derived MVPA

XSL•FO
RenderX

from baseline to 3 months. Although there was no statistical difference between treatment groups, effect sizes for MVPA were in the small-to-medium range, favoring Energize! over the newsletter condition. At 6 months, there was little difference in MVPA between treatment groups.

Comparison With Prior Work

Although changes in PA between treatment groups were not statistically significant, within the Energize! group, participants significantly increased their MVPA from baseline to 3 months by 93 minutes/week for self-reported PA and 35 and 46 minutes/week for accelerometer-derived bouted and total MVPA, respectively. This magnitude of change is in line with prior reports of PA promotion interventions among cancer survivors [36-39], and has been suggested to be clinically meaningful for overall health and well-being [40]. Furthermore, self-reported increases in PA, as small as 35 minutes/week, have been shown to reduce cancer-specific and all-cause mortality, underscoring the relevance of the results from this investigation [41]. Finally, it should be noted that the improvements in PA observed within the Energize! group were partially maintained at 6 months, and full recidivism to baseline levels did not occur, despite the absence of any additional intervention during 3 to 6 months. While this recidivism is disappointing, these findings are consistent with the broader PA literature, which demonstrates the challenge of maintaining PA following an unsupervised exercise program [42,43]. Future investigations may want to consider extending the length of the active intervention period, adding additional behavior change strategies that specifically target habit formation or maintenance, or examining state and trait level differences between those who successfully maintain PA postintervention versus those who do not.

While effect size estimates indicate that changes in PA were larger with Energize! compared to the newsletter condition, the mean change in MVPA in the newsletter group ranged from 17 to 46 minutes/week (depending on the measurement method). This was somewhat surprising, as newsletter participants did not receive behaviorally-based PA promotion content. Further, we asked participants at 3 months whether they signed up for any formal exercise programs, and only 1 participant indicated joining a weight loss program. There may be several explanations for the higher-than-expected PA in the Newsletter condition. First, it is possible that being asked to wear a PA monitor and answer questions related to PA could have prompted greater PA, as participants may have gleaned the importance of this behavior for study outcomes [44]. Alternatively, there are some data to suggest that cancer survivors are often unaware of, confused by, or not informed of PA recommendations during cancer aftercare [45,46]; thus, providing even the most basic information regarding the benefits of PA may have been sufficient to stimulate some level of behavior change. Finally, it is also possible that motivation for increasing PA is already very high among cancer survivors who make the decision to sign up for a PA program. This is corroborated by past research in which participants were randomized to a wait-list control condition, yet improvements in PA were still observed [41]. Although we cannot pinpoint the exact reason for the increase in PA levels in the Newsletter condition, these findings highlight the need for further research on PA behavior change during cancer survivorship.

Another interesting, yet not surprising, finding was the discordance between self-reported and accelerometer-derived PA. The results from this study are consistent with prior research, in that accelerometer-derived bouted MVPA was lower than self-reported MVPA [47,48]. There may be several explanations for this incongruency. First, although the monitors used in this study were research grade, these waist-worn activity monitors do not capture all forms of activity (ie, cycling, swimming, water aerobics, etc) [41,49]. Our self-report data suggest that 7%, 16%, and 19% of participants engaged in these types of activities at baseline, 3, and 6 months, respectively. In addition, cutpoints used for classifying accelerometer-derived MVPA were established via validation studies in healthy individuals, yet cancer survivors often have lower fitness levels and deconditioning due to treatment or fatigue. While it could be possible that activities that were indeed “moderate” based upon a participant’s fitness level fell below the accelerometer threshold for MVPA, our data do not support this hypothesis. We conducted exploratory analyses which found that there were no differences in light intensity PA or total PA (which combines light, moderate, and vigorous PA) between Energize! and Newsletter participants from pre- to postintervention (data not presented). Future research should continue to obtain both self-report and device-measured assessments of activity to help garner a clearer understanding of PA behavior in this population [41,49].

Another aim of this study was to examine the effect of the Energize! Exercise program on common cancer-related mental and physical well-being outcomes. At 3 months, medium effect sizes, favoring Energize! over Newsletter, were observed for vitality (ie, energy and fatigue) and somatization (ie, the experience and expression of psychological distress through physical symptoms). At 6 months, mixed findings were observed, with some outcomes favoring Energize! (depression and anxiety) and others favoring Newsletter (bodily pain, general health, and fatigue). One potential explanation for these findings is that the magnitude of change in PA in Energize! (relative to Newsletter) was not sufficient to elicit changes in the majority of the health outcomes assessed. Another possibility is that baseline differences between treatment groups may have made it difficult for intervention effects to be observed (eg, the majority of health-related quality of life scores at baseline were significantly higher in Energize! than in Newsletter). Nonetheless, these mixed findings are similar to meta-analyses and systematic reviews of digital PA promotion interventions on health-related outcomes in cancer survivors, which have also reported mixed results [23,24,39]. Future studies are needed to better understand factors contributing to these discrepant findings and to determine which behavior change techniques are most effective within web-based interventions for modifying mental and physical well-being outcomes.

Limitations

This study has notable strengths, which include the use of both self-report and accelerometer-derived PA measurements, a no-contact intervention follow-up period to assess the lasting

XSL•FO
RenderX

effect of the intervention, and the inclusion of individuals with varying types of cancer, which enhances generalizability. However, it is not without limitations. First, this was a preliminary investigation examining the effect of the Energize! program on MVPA and cancer-related mental and physical well-being; thus, it was not powered to detect differences between treatment groups. While effect size estimates are initially favorable regarding the Energize! program, a fully powered trial is warranted. Further, the majority of the participants in this study were female and non-Hispanic White. This is common to both the broader eHealth literature and cancer-specific literature [43,50], and limits the generalizability of findings. Finally, while inclusion criteria required participants to report engaging in less than 60 minutes of PA over the past 3 months on the initial eligibility screener, some participants were above this threshold at baseline. This suggests that participants may have been highly motivated and begun to increase PA prior to the start of the intervention, which could also have attenuated the intervention effect. Finally, participants were in different stages of survivorship when enrolling in this study; therefore, it's possible that this could have affected rates of program engagement and changes in MVPA. Larger studies are needed to determine if individualized tailoring could improve outcomes.

Conclusions

This study supports the feasibility, acceptability, and preliminary efficacy of the Energize! Exercise Program, a 3-month remotely delivered PA promotion intervention for cancer survivors. Results of the investigation indicate participants were satisfied with the program, routinely engaged with all study elements, and the majority were retained for the entire study duration. PA significantly increased from baseline to 3 months among Energize! participants, and these increases were partially maintained at 6 months. Future studies should investigate whether additional components can be added to the Energize! program to enhance PA or health-related outcomes, and whether specific behavior change techniques could be used to promote the long-term maintenance of PA changes.

Acknowledgments

The authors would like to acknowledge Ariana Rafanelli, BS, for her time and effort in implementing study protocols. This study was funded by the Legorreta Cancer Center at Brown University.

Generative artificial intelligence was not used for any portion of the manuscript writing.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JLU, CD, DD, AF, and RRW were involved in the conceptualization of this study and obtaining grant funding. ZC analyzed the data and prepared tables and figures. JLU, SYT, KO, and ZC wrote the first draft of this manuscript, and all authors provided feedback on prior versions of the manuscript.

Conflicts of Interest

DD is a consultant for Puma and Immunogen. JLU is on the scientific advisory board of Medifast. The remaining authors have no relevant financial or nonfinancial interests to disclose.

Abstract

Background: Personalized nutritional management during cancer remains challenging in clinical practice. The development of an electronic patient-reported outcome platform (ePROM) provides novel opportunities.

Objective: This study aimed to evaluate the effectiveness and adherence of nutritional management using ePROM in patients with cancer.

Methods: This multicenter prospective longitudinal cohort study included 6124 patients diagnosed with cancer. Exposure was defined as adherence to the ePROM journal, measured by the longest consecutive month of weekly entries. Dietary intake was reported via food selection, voice input, or meal photos. The primary outcomes were adequate energy intake (EI, ≥25 kcal/kg/day) and protein intake (PI, ≥1 g/kg/day), defined according to European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines. Logistic regression analysis was conducted to identify the factors associated with EI and PI, reporting odds ratios (ORs) and 95% CIs. A restricted cubic spline plot was used to illustrate the association between the adjusted ORs and adherence duration. The semMediation approach was applied to assess the impact of multiple mediators on the outcomes.

Results: The study cohort comprised 3741/6124 (61.1%) men and 2383 (38.9%) women, with a median age of 60.85 (IQR 53.3-68.3) years. Overall, 1024/6124 (16.7%) and 2591/6124 (42.3%) patients achieved adequate EI and PI scores, respectively. At one month, 499/1024 patients (48.7%) in the adequate EI group and 1287/2591 (49.7%) in the adequate PI group continued journaling, compared with 1879/5100 (36.8%) and 1091/3533 (30.9%) in the corresponding inadequate groups (P<.001). This trend remained significant in the second, third, and sixth months. Logistic regression analysis demonstrated that longer adherence to ePROM journaling was independently associated with adequate EI (OR 1.05, 95% CI 1.01 - 1.08; P=.01) and PI (OR 1.22, 95% CI 1.16 - 1.28; P<.001) after adjusting for confounders. Mediation analysis revealed that most symptoms did not significantly mediate these effects, except for constipation, reflux, and delirium, which showed statistical significance but minimal indirect effects.

XSL•FO
RenderX

Conclusions: Nutritional management via ePROM is a feasible approach, with improved effectiveness as adherence duration increases. The observed benefits resulted primarily from direct effects rather than from symptom improvement.

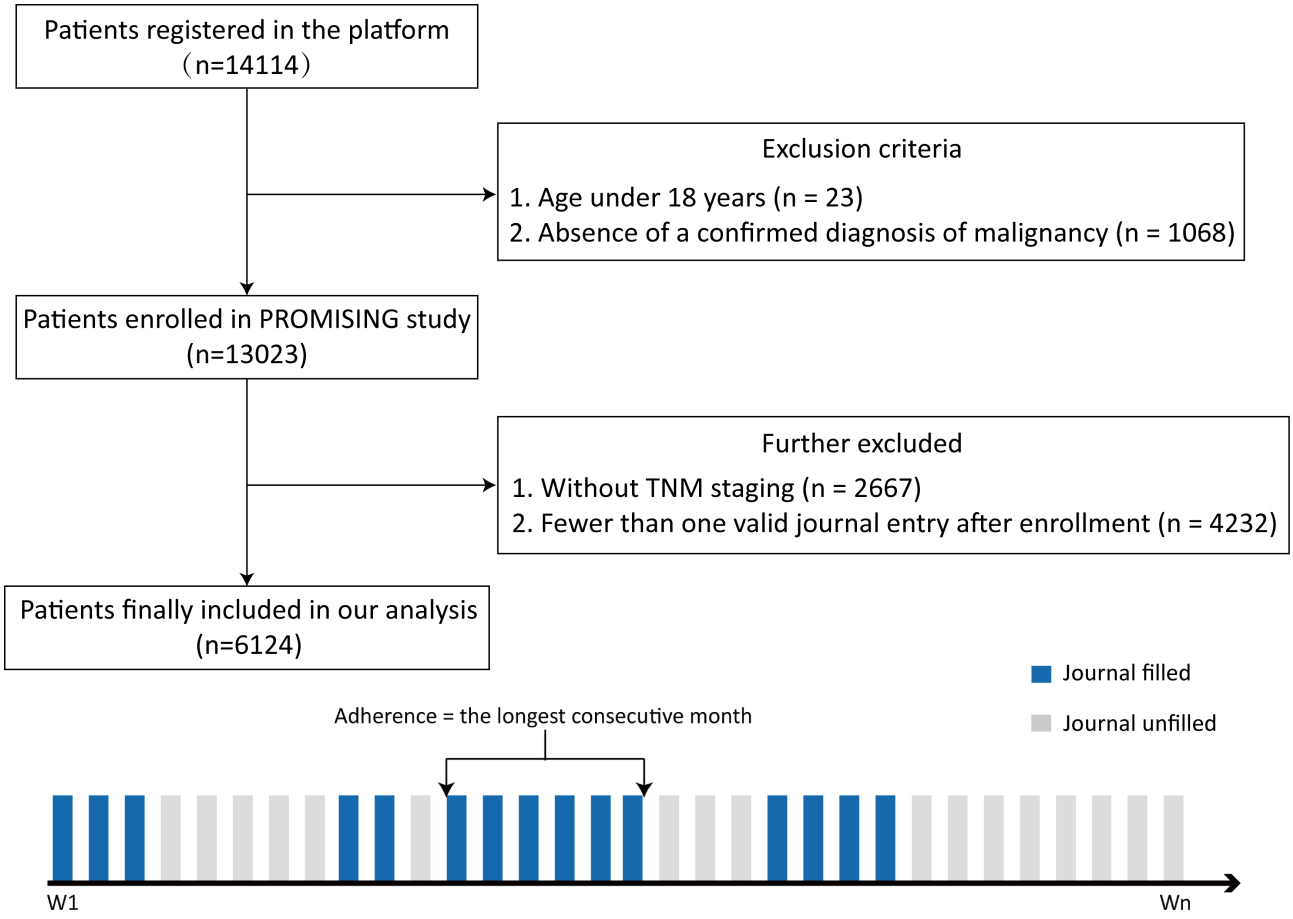
Introduction

Malnutrition is a common complication in patients with cancer that negatively affects clinical outcomes [1]. It is associated with increased treatment-related adverse effects, reduced therapeutic efficacy, impaired quality of life (QoL), and poor survival [2]. Given these detrimental effects, early recognition and timely intervention of malnutrition are key in cancer care. Evidence indicates that early nutritional therapy can enhance nutritional status, improve QoL, and augment responses to cancer treatment [3,4]. However, the effect of nutritional interventions on long-term outcomes such as survival remains inconclusive. One potential explanation for this is the relatively short duration of most nutritional interventions, which typically coincides with a single modality of anticancer treatment, lasting approximately 2 - 6 months [5]. However, patients with cancer often undergo prolonged and recurrent treatment regimens, including chemotherapy, radiotherapy, surgery, and recovery. Malnutrition often develops, persists, or worsens throughout this trajectory and is influenced by dynamic factors, such as demographic characteristics, comorbidities, tumor type and location, tumor, node, metastasis (TNM) staging, and the nature of anticancer therapies [6]. To improve long-term clinical outcomes, nutritional interventions, including regular screening, comprehensive assessments, timely interventions, and continuous monitoring, should be sustained through cancer treatment. However, applying such a continuous, adaptive nutritional strategy within the traditional framework is challenging because of the lack of tools for prescribing dynamic nutritional regimens and ensuring continuous monitoring, regardless of whether patients are hospitalized or at home.

Despite continuous nutritional management, patient compliance remains a significant challenge. Capra et al [7], proposed that nutritional intervention consists of 2 key components: prescription and implementation. Successful intervention requires active participation from both the medical team and patients. The medical team can merely prescribe, and the patients are expected to implement the recommendations with good compliance. However, traditional approaches are constrained by several factors, including irregular clinic visits, loss of contact during outpatient periods, and delayed responses to patients' dynamic nutritional needs [8]. A systematic review and meta-analysis revealed that compliance in randomized clinical trials involving dietary counseling with or without oral nutritional supplementation was generally poor, with often unmet energy and protein goals [9]. Moreover, poor patient compliance has been a major contributor to negative findings in several nutritional studies [10,11]. Therefore, nutritional interventions should provide timely and consistent access for patients to improve their outcomes.

At this time, telemedicine or remote monitoring is a means of overcoming these limitations and providing patient-centered continuous nutritional management. The electronic patient-reported outcome platform (ePROM) is a newly developed tool widely applied to monitor patient-reported symptoms in clinical cancer practice [12-16]. Accumulating evidence has confirmed its positive role in improving clinical outcomes by enabling better symptom reporting and communication through remote symptom self-reporting, promoting proactive management of symptoms through real-time clinician feedback, and facilitating clinician-patient interactions [17]. However, the evidence supporting the effectiveness of ePROM in nutritional management remains limited. Therefore, we conducted a prospective cohort study and developed an ePROM with three interconnected interfaces for patients, dieticians, and clinicians. The participants used the platform to report their nutritional status and symptoms while receiving timely feedback and adaptive nutritional regimens from dietitians and clinicians. This study aimed to evaluate the impact of ePROM-based nutritional management on achieving adequate energy and protein intake and reducing malnutrition risk in patients with cancer.

Methods



Study Participants and Design

Patient-Reported Outcome Management Including Surveillance and Intervention in Nutritional Group (PROMISING) is a multicenter prospective cohort study aimed at investigating the effect of patient-reported outcome (PRO)-based nutritional management across the disease continuum on clinical outcomes in patients with cancer (registration number: ChiCTR2100047535). Between March 2021 and April 2024, potentially eligible patients were consecutively recruited from oncology outpatient clinics and inpatient wards at 51 participating hospitals across China (Table S1 in Multimedia Appendix 1). During routine consultations, treating oncologists identified patients who met the preliminary eligibility criteria and referred them to the study platform. Trained research staff then screened patients against the full inclusion and exclusion criteria, explained the study procedures in detail, obtained written informed consent, and finally enrolled eligible patients in person, with enrollment simultaneously recorded in the ePROM system. Inclusion criteria were: (1) aged ≥18 years; (2) cytologically or histologically proven malignant tumors; and (3) an estimated life expectancy ≥3 months. Exclusion criteria included: (1) significant cardiovascular, renal, or hepatic

XSL•FO
RenderX

comorbidities; (2) pregnancy or lactation; (3) severe mental disorders with poor compliance; (4) abnormal glucose metabolism (glycated hemoglobin ≥7.0%); (5) allergic to the contents of oral nutritional supplements; (6) inability to feed by mouth due to dysphagia or recurrent laryngeal nerve injury; and (7) deemed unsuitable for inclusion by investigators. The present study included patients from the PROMISING study who completed at least one eligible journal entry after enrollment (Figure 1).

Figure 1. Flowchart of our study. PROMISING: patient-reported outcome management including surveillance and intervention in the nutritional group. TNM: tumor,node,metastasis;

Description of ePROM

The ePROM used in this study was the PRO tool, especially for patients with cancer undergoing treatment (SHCD-PROTEC), developed by Shanghai Chudong Intelligent Technology Co, Ltd embedded within WeChat (Tencent Holdings Ltd)—the most widely used social media platform in China—it provided multiend access for physicians, dietitians, patients, and caregivers. Physicians could review patient information, including medical history, treatment regimens, and efficacy evaluations. Dietitians used the platform for nutritional screening, assessment, and individualized care planning, while patients and caregivers accessed nutrition plans and reported rehabilitation data. To enhance management effectiveness, improve adherence, and ensure data quality, the platform included three core functions: (1) message board: a chat-style feature enabling real-time communication among patients, caregivers, and health care providers; (2) real-time alerts: automated notifications to clinicians when patient-reported data exceeded predefined thresholds or showed abnormal fluctuations, prompting timely intervention; and (3) task reminders: automated prompts for missed journal entries, with persistent noncompliance triggering follow-up by dietitians to reassess the patient's nutritional status.

Data Collection and Variables Definition

Baseline characteristics, including demographic information (age, sex, and residence), comorbidities, and tumor-related data were collected upon patient enrollment. The study enrolled patients with tumors in the following subsites: head and neck, lung, breast, upper gastrointestinal, hepatobiliary and pancreatic, colorectal, urogenital, hematological, and others. Pathological staging was performed according to the eighth edition of the American Joint Committee on Cancer TNM staging system [18]. Information regarding anticancer treatments, including surgery, chemotherapy, radiotherapy, immunotherapy, and targeted therapy, was recorded for all patients to assess their treatment regimens. Nutritional risk screening and malnutrition assessment were performed by trained dietitians recruited specifically for this study within 48 hours of enrollment and repeated every 21 - 28 days, using the electronic versions of the Nutritional Risk Screening 2002 (NRS-2002) and the Patient-Generated Subjective Global Assessment (PG-SGA) integrated into the ePROM system. All patients received standard nutrition support according to the European Society

XSL•FO
RenderX

for Clinical Nutrition and Metabolism (ESPEN) Clinical Nutrition in Cancer guideline. All participants were required to complete at least one journal per week via their personal account. Each entry included dietary intake, which could be reported by selecting foods from the system's database, using voice input, or uploading meal photographs. In addition, participants rated their symptoms on a 0‐10 scale. One adherent month was defined as four consecutive weeks during which all required weekly journals were completed. The adherence duration was calculated as the longest continuous number of such adherent months achieved by each participant. The ePROM management period was defined as the period from each participant's enrollment date to the date of their last completed ePROM journal entry or the study analysis cutoff date, whichever occurred first.

Outcomes

The primary outcomes were adequate energy intake (EI) and protein intake (PI) in patients with cancer. According to the ESPEN guidelines, the recommended thresholds for patients with cancer are an EI of at least 25.0 kcal/kg/day and a PI of at least 1.0 g/kg/day [2]. In our study, the EI and PI for each day were automatically calculated using the SHCD-PROTECT dietary analysis software based on the patients' meal consumption and nutrient supplementation. Patients whose average EI and PI values met or exceeded these thresholds during the ePROM management period were classified as having adequate EI or PI values. The secondary outcome was malnutrition risk assessed using the NRS 2002. For the current analysis, we used the most recent NRS 2002 scores from the patients' last recorded assessment to evaluate malnutrition risk.

Statistical Analysis

All analyses were performed using the R software (version 4.3.2; R Project for Statistical Computing). Missing weeks of journal data were not imputed because journal completion was voluntary and reflected real-world behavior. To reduce the potential influence of irregular reporting, EI and PI were calculated as the mean of all available valid entries within each participant's ePROM management period. Implausible total energy values (<50 kcal or >5000 kcal), together with their corresponding protein values, were excluded as outliers. Continuous variables are expressed as median (IQR) and compared using the Mann–Whitney *U* test, given that most variables did not meet normality assumptions. Categorical variables are expressed as absolute numbers or percentages and compared using the χ^2 test or Fisher exact test. Logistic regression analysis was performed to investigate risk factor-associated binary variables, reporting odds ratios (ORs) and 95% CIs. A restricted cubic spline plot was used to describe the potential nonlinear association between adjusted ORs and exposure. The impact of multiple mediators on the outcome was assessed using a semimediated approach, allowing for the estimation of direct, indirect, and total effects. To verify sample-size adequacy, a detectable-effect analysis for logistic regression was performed, assuming α=.05% and 80% power. Using the observed sample size (n=6124), event rates (EI=16.7% and PI=42.3%), and the SD of adherence (1.82), the minimum detectable OR was approximately 1.05 for EI and 1.04 for PI per 1-SD increase in adherence. Model stability was further confirmed using the events-per-variable criterion, with events-per-variable values of about 79 for EI and 199 for PI, both exceeding the conventional threshold of 10 events per variable. Statistical significance was defined as a 2-tailed *P* value of <.05.

Ethical Considerations

This study was reviewed and approved by the Ethics Committee of the National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China (approval number: 21/297‐2968), as well as the ethics committees of all participating institutions. All procedures involving human participants were conducted in accordance with the ethical standards of the institutional or national research committees and with the principles of the Declaration of Helsinki. Written informed consent was obtained from all participants prior to enrollment, covering both primary data collection and secondary analyses. All study data were stored in a secure, password-protected database. Identifiable patient information was removed and replaced with coded identifiers to protect privacy and confidentiality. Only authorized research personnel have access to the data. No financial or material compensation was provided to participants for their involvement in the study.

Results

Baseline Characteristics of Patients

A total of 14,114 patients were registered in the SHCD-PROTEC platform. After excluding 23 patients aged under 18 years and 1068 without a confirmed diagnosis of malignancy, 13,023 patients were enrolled in the PROMISING study. Among these, 2667 patients without TNM staging and 4232 with fewer than one valid journal entry after enrollment were further excluded. Consequently, 6124 patients were included in the final analysis, with a median age of 60.9 (53.3‐68.3) years. The cohort comprised 3741/6124 (61.1%) men and 2384/6124 (38.9%) women. The most common tumor sites were colorectal (1387/6124, 22.6%), lung (1346/6124, 22%), upper gastrointestinal (1311/6124, 21.4%), head and neck (615/6124, 10%), urogenital (595/6124, 9.7%), hepatobiliary and pancreatic (367/6124, 6%), and breast (293/6124, 4.8%) tumors. Approximately 80% (4882/6124) of the patients are diagnosed at an advanced stage. The median duration of the ePROM management period was 89 (32.8‐172) days. During the entire period, 1024/6124 (16.7%) patients achieved adequate EI, and 2591/6124 (42.3%) met the required PI. Patients who did not meet their goals tended to be older, male, in advanced stages of cancer, undergoing anticancer treatment, or with comorbidities (diabetes and hypertension). Detailed baseline information is provided in Table 1.

Association Between Adherence for ePROM Journal With Adequate EI and PI

As shown in Table 1 and Figure 2, patients with adequate EI and PI demonstrated significantly higher adherence to completing the ePROM journals. In the adequate EI group, 499/1024 patients (48.7%) continued to fill out the journals for one month, compared to 1879/5100 patients (36.8%) in the inadequate EI group (*P*<.001). Similarly, in the adequate PI group, 1287/2591 patients (49.7%) adhered for one month, compared to 1091/3533 patients (30.9%) in the inadequate PI group (*P*<.001). After 2 months, adherence remained higher in the adequate groups: 203/1024 patients (19.8%) versus 580/5100 (11.4%) in the EI groups, and 532/2591 (20.5%) versus 251/3533 (7.1%) in the PI groups (all *P*<.001). A similar significant trend was observed at 3 and 6 months. Logistic analysis revealed that long adherence duration for ePRO journals served as an independent protective factor associated with both EI (OR 1.05, 95% CI 1.01 - 1.08; *P*=.01) and PI (OR 1.22, 95% CI 1.16 - 1.28; *P*<.001), after adjusting for age, sex, residency, tumor site, TNM stage, anticancer treatments, diabetes, hypertension, and ePROM management period (Table 2). When we categorized the adherence duration into 1, 3, and 6 months, we observed that the adjusted OR increased as the adherence duration increased. The restricted cubic spline plot described an L-shape relationship between adherence duration for ePROM the journal with adjusted OR, with the cut-off value of 2.33 months for EI and 2.49 months for PI (Figure 3A-B).

Mediation Analysis of Symptoms

Across the study, appetite loss was the most prevalent symptom, reported in 5089/6124 patients (83.1%), followed by fatigue in 2259 (36.9%), dry mouth in 1388 (22.7%), pain in 1237 (20.2%), nausea in 822 (13.4%), constipation in 732 (12%), anxiety in 730 (11.9%), abdominal bloating in 654 (10.7%), cough in 624 (10.2%), diarrhea in 350 (5.7%), depression in 335 (5.5%), dyspnea in 218 (3.6%), delirium in 79 (1.3%), and reflux in 59 (1%) (Figure S1 in Multimedia Appendix 1). The median appetite score was 5.83 (IQR 3.50 - 7.00), while fatigue had a median score of 0.33 (IQR 0.00 - 1.67). More detailed symptom score data across patient groups are presented in Table S2 in Multimedia Appendix 1. Subgroup analysis revealed variations in the positive effects of long-term ePROM adherence across different symptom groups (Figure S1 in Multimedia Appendix 1). A significant interaction effect was observed for fatigue, appetite, abdominal bloating, diarrhea, and reflux, suggesting that ePROM adherence had different effects depending on the presence of symptoms. Furthermore, a mediation analysis was conducted to assess potential indirect effects (Table S3 in Multimedia Appendix 1). . The results indicated that no significant mediation effects were observed for most symptoms. Although constipation, reflux, and delirium were significant, the proportion of indirect effects was minimal.

Logistics Regression Analysis for Malnutrition Risk

Among the total cohort of 4978 participants, data from the most recent NRS 2002 scores recorded in the patients' most recent journals were available. Of these, 2135 patients with cancer were found to be at risk of malnutrition. Univariate logistic regression analysis revealed that several factors, including age, sex, tumor site, TNM stage, chemotherapy history, hypertension, the period of ePROM management, and adherence to ePROM journals, were significantly associated with malnutrition risk. Subsequent multivariate logistic regression analysis confirmed that a longer period of ePRO management was an independent and favorable factor that reduced the risk of malnutrition (Table 3).

Discussion

Principal Findings

Tailored and continuous nutritional management throughout the disease course is crucial for patients with cancer. However, traditional clinical care faces several barriers to implementing nutritional management, including time consumption, poor patient compliance, and high rates of follow-up loss [8,9]. The newly developed ePROM facilitates real-time PRO data collection, monitoring, and personalized feedback, thereby offering a promising solution for improving the effectiveness

XSL•FO
RenderX

of nutritional management [12,13,15,16]. Our research team has previously developed an ePROM specifically designed to provide nutritional management to patients with cancer. The use of our platform is flexible, free, and convenient to ensure the continuity and personalization of nutritional management, as well as to reduce the workload of health care teams. As with traditional nutritional interventions, the success of this approach depends largely on patient adherence. In this study, fewer than 40% of patients consistently completed ePROM journals beyond one month, with adherence declining significantly over time. This trend was observed in both the adequate and inadequate EI and PI groups; however, patients in the adequate EI and PI group demonstrated significantly higher proportions of sustained ePROM use at > 1, 2, 3, and 6 months. Multivariate logistic regression analysis adjusted for potential confounders confirmed that prolonged ePROM adherence was an independent protective factor associated with adequate EI and PI. However, in relation to malnutrition risk, patients with a longer ePROM management period showed a significantly lower risk of malnutrition at the final follow-up, rather than those with higher adherence. Further studies are required to clarify whether the duration of ePROM management or the level of adherence exerts a greater influence on nutritional outcomes. Subgroup analysis revealed variations in the effects of nutritional management across different symptom groups. Therefore, to explore the intrinsic role of nutritional management via ePROM further, we performed a mediation analysis. The results demonstrated that the achievement of EI and PI goals was directly influenced by nutritional interventions via ePROM rather than by the improvement of symptoms.

Comparison to Prior Work

The ePROM adherence rates in previous clinical trials range from 65% to > 90% [19,20]. Gebert et al [21] recently reported that the adherence to ePROM follow-up assessments in patients with invasive early breast cancer and ductal carcinoma in situ was moderate, ranging from 60% to 80%. In comparison, adherence in our prospective longitudinal study was relatively low, suggesting that many patients may still lack the capacity or motivation to actively engage in the self-management of their conditions. We suspect that this may be attributed to several potential reasons: (1) the importance of continuous nutritional monitoring and its benefit for health outcomes were not sufficiently addressed to patients, which may have contributed to low motivation to maintain long-term participation [22]. (2) Although our platform included a message-alert system to remind patients to record in their journals, it may not have been sufficient to ensure consistent engagement. Evidence suggests that patients prefer automatic telephone calls or video calls because these methods help them feel more closely connected with their caregivers [23]. (3) The process of regularly filling out journals using a digital platform may have been time-consuming or burdensome for some patients, especially the elderly and those with multiple advanced conditions. In contrast to the study by Gebert et al [21], most patients in our study were in advanced disease stages, which might have led to a lower adherence rate. (4) Unlike previous studies, nutritional management demands more frequent, prolonged, and detailed self-reporting, which may pose challenges for patients in consistently completing medical journals. Therefore, it is essential to explore the optimal balance between gathering sufficient information for prescribing nutritional regimens and minimizing the patient burden.

A study from Greece showed that meeting at least the minimum amounts of protein and energy recommended by ESPEN may prevent weight loss and improve nutritional status [24]. In our study, more than 15% and 40% of the patients ultimately achieved their goals for average EI and PI, respectively. The relatively high achievement rate of the PI may be attributed to the popular use of nutrient supplements, particularly protein supplements. This aligns with a previous randomized controlled parallel-group study, which confirmed that a high-protein oral nutritional supplement can enable the majority of patients with cancer to meet the PI recommendations [25]. Furthermore, our study showed that prolonged ePROM adherence was an independent protective factor associated with adequate EI and PI. During cancer, patients often experience a variety of moderate-to-severe symptom burdens that significantly impair their daily routine and QoL [26]. Recent research on ePROM has primarily focused on symptom monitoring, giving it the potential to effectively track symptom burden [15,27]. Nutritional treatment, especially counseling, is also aimed at symptom management [26]. In our study, the results demonstrated that the achievement of EI and PI goals was directly influenced by nutritional interventions via ePROM rather than by the improvement of symptoms, such as pain, fatigue, dyspnea, cough, loss of appetite, dry mouth, nausea, abdominal bloating, diarrhea, constipation, reflux, anxiety, depression, and delirium. This suggests a fundamental difference between our ePROM approach and those commonly used in clinical practice, which tend to focus on symptom management. However, further research is needed to determine whether a combined approach that addresses both nutritional and symptom management can lead to better clinical outcomes in patients with cancer.

Limitations

This study had some limitations. First, the overall adherence rate to ePROM was relatively low, and the duration of ePROM management varied among participants despite statistical adjustment, which may have hindered the comprehensive evaluation of long-term clinical outcomes. In addition, defining the ePROM management period based on the date of the last completed journal entry, although applied uniformly across all participants, may have introduced some arbitrariness. Second, our study did not specify a fixed day for journal entry, which may have introduced bias, as patients were more likely to report symptoms when they experienced discomfort or dietary difficulties. Moreover, voluntary journal completion led to inevitable missing entries; using mean values of available data and excluding implausible outliers may still have introduced minor bias. Underreporting, overreporting, and entry errors are also inherent to food diaries and were not validated by dietitians in our study due to the self-reported, real-world nature. Third, the absence of a control group that received standard nutritional management limited the ability to directly compare the effects of conventional care. Fourth, both the exposure and outcomes were derived from the journal of ePROM, which may have

XSL•FO
RenderX

introduced common source bias. Finally, the definition of adherence used in this study requires further validation, as no standardized criteria have yet been established in the digital health field. Large-scale randomized clinical trials with long-term follow-up are required to confirm the effectiveness of nutritional management using ePROM in patients with cancer.

Conclusions

In conclusion, our study demonstrated the potential and feasibility of using ePROM for nutritional management. However, adherence remains a challenge in real-world prospective studies and must be addressed. Longer duration of adherence to the ePROM journal significantly improves the likelihood of achieving adequate EI and PI goals, though its association with malnutrition risk was not statistically significant. Furthermore, the effectiveness of our ePROM approach is directly attributed to nutritional management rather than symptom monitoring, which is commonly used in clinical care.

Acknowledgments

We express our sincere gratitude to Shanghai Chudong Intelligent Technology Co., Ltd. for providing the data collection platform. We are also grateful to all the dietitians for their professional nutritional interventions, and we appreciate the support of the doctors in evaluating treatment efficacy.

Abstract

Background: Exercise can attenuate the deleterious combined effects of cancer treatment and aging among older adults with cancer, yet exercise participation is low. Telehealth exercise may improve exercise engagement by decreasing time and transportation barriers; however, the utility of telehealth exercise among older adults with cancer is not well established.

Objective: We aimed to evaluate the preliminary effectiveness of a one-on-one, supervised telehealth exercise program on physical function, muscular endurance, balance, and flexibility among older adults with cancer.

Methods: In this retrospective study, we analyzed electronic health record data collected from the Personal Optimism With Exercise Recovery clinical exercise program delivered via telehealth among older adults with cancer (≥65 y) who completed a virtual initial program telehealth assessment between March 2020 and December 2021. The virtual initial assessment included the following measures: 30-second chair stand test, 30-second maximum push-up test, 2-minute standing march, single leg stance, plank, chair sit and reach, shoulder range of motion, and the clock test. All baseline measures were repeated after 12-weeks of telehealth exercise. Change scores were calculated for all assessments and compared to minimal clinically important difference (MCID) values for assessments with published MCIDs. Paired samples *t* tests (2-tailed) were conducted to determine change in assessment outcomes.

Results: Older adults with cancer who chose to participate in the telehealth exercise program (N=68) were 71.8 (SD 5.3) years of age on average (range 65 - 92 y). The 3 most common cancer types in this sample were breast (n=13), prostate (n=13), and multiple myeloma (n=8). All cancer stages were represented in this sample with stage II (n=16, 23.5%) and III (n=18, 26.5%) being the most common. A follow-up telehealth assessment was completed by 29.4% (n=20) of older adults with cancer. Among those who completed a follow-up telehealth assessment, there were significant increases in the 30-second chair stand (n=19; mean change +2.00 repetitions, 95% CI 0.12 to 3.88) and 30-second maximum push-up scores (n=20; mean change +2.85 repetitions, 95% CI 1.60 to 4.11). There were no significant differences for the 2-minute standing march, plank, single leg stance, sit and reach, shoulder mobility, or clock test (P>.05). Nine (47.3%) older adults with cancer had a change in 30-second chair stand scores greater than the MCID of 2 repetitions.

Conclusions: Our findings suggest a one-on-one, supervised telehealth exercise program may positively influence measures of physical function, muscular endurance, balance, and flexibility among older adults with cancer, but more adequately powered trials are needed to confirm these findings.

Introduction

Adults aged 65 years and older currently account for 67% of cancer survivors (eg, individuals living with and beyond a cancer diagnosis) in the United States [1]. By 2040 it is projected that 73% of cancer survivors in the United States will be aged 65 years and older [2]. Cancer treatment compounds the normal effects of aging resulting in an accelerated aging effect [3]. A hallmark characteristic of accelerated aging is poor physical functioning [3]. Older adults with cancer experience worse physical function than their younger counterparts [4] and older adults without cancer [5,6]. Physical function plays a critical role in the health of older adults with cancer and poor function is associated with decreased cancer survival [7], increased all-cause mortality [8], and increased symptom severity [9].

Regular participation in exercise is one strategy to help mitigate declines in physical function among cancer survivors of all ages. Among older adults with cancer, individualized, in-person supervised exercise programming, including combined aerobic and resistance training, for at least 12-weeks significantly improves physical function [10,11], quality of life [12], muscular strength [10,11], aerobic endurance [10,11], and symptoms of anxiety and depression [11]. Despite the numerous benefits of exercise for older adults with cancer, participation in exercise in this population is low with only 12% of older cancer survivors meeting both the aerobic and strength training guidelines [13]. Reasons for low engagement among this population include: lack of available exercise programming in convenient locations [14], transportation concerns [14,15], lack of time [14,16], physical symptoms (eg, fatigue) [14,16,17], and comorbidities [14,17]. Strategies to reduce barriers to participating in exercise among older adults with cancer are needed to improve exercise engagement and physical function in this population.

Delivering exercise programs using telehealth is a useful strategy in attenuating these barriers. Telehealth delivery of exercise detaches the exercise program from a physical location, resulting in exercise engagement in a more convenient location, such as the home, eliminating the need for travel, and reducing overall time commitment [18]. Telehealth delivered exercise can also lower the cost of participation as participants do not need to pay for transportation or parking [18]. After transitioning two trials from in-person to telehealth exercise, due to the impact of the COVID-19 pandemic on in-person research, Winters-Stone et al [19] observed better adherence and retention for telehealth exercise compared to in-person exercise among adult cancer survivors of all ages. In addition to addressing these barriers, supervised, telehealth-delivered exercise programs among adult cancer survivors of all ages have demonstrated improvements in physical symptoms and comorbidities such as: physical function [20,21], aerobic endurance [20,22], muscular endurance [20,22], and fatigue [22]. Specific to older adults living with cancer, telehealth delivery of exercise programming is considered acceptable [23], feasible [24], and safe [25]. Moreover, older cancer survivors view telehealth delivery of exercise positively and report limited technology related barriers to telehealth exercise participation [26]. Barriers and facilitators to participating in telehealth exercise reported by older cancer survivors are similar to those reported by their younger counterparts [26]. To our knowledge, only two studies to date have evaluated effectiveness of supervised telehealth exercise programming (ie, delivered via telehealth in real time) exclusively in older adults with cancer [24,27]. Both trials delivered group resistance training programs and observed significant improvements in markers of physical function after participating in the program [24,27]. However, little is known regarding the effectiveness of one-on-one telehealth supervised exercise in older adults with cancer. Given the dearth of research, we sought to address the issue in this investigation.

The purpose of this investigation was to explore the preliminary effectiveness of a one-on-one, supervised telehealth clinical exercise oncology program among older adults with cancer on physical function, muscular endurance, balance, and flexibility. We hypothesized that participation in telehealth exercise would result in a statistically significant improvement in physical function, muscular endurance, aerobic endurance, balance, and flexibility among older adults with cancer.

Methods

Study Design and Sample

This was a retrospective analysis of electronic health record data collected between March 2020 and December 2021 from the Huntsman Cancer Institute (HCI) at the University of Utah's clinical exercise oncology program, the Personal Optimism With Exercise Recovery (POWER) program. This study was approved by the University of Utah Institutional Review Board (IRB_00072431). To be included in this analysis participants must have met the following inclusion criteria: (1) ≥65 years of age, (2) diagnosis of invasive cancer, and (3) completion of an initial POWER program assessment via telehealth. Demographic and clinical data including age, sex, race, ethnicity, cancer site, cancer stage, and cancer treatment history, were pulled from the medical record. Initial and follow-up assessment data were abstracted from the POWER program clinical database by a trained researcher (ERD) with support from certified exercise physiologists within our hospital-based exercise oncology program using a study specific spreadsheet developed in partnership with this study's team. Data were cleaned to ensure all measures were within a physiologically reasonable range and units were consistent within measures (eg, all plank assessments were reported in seconds). Cancer treatment history from manual data abstraction was verified with the electronic health record.

Exercise Program

The POWER program is a hospital-based exercise oncology program embedded into clinical practice at the HCI. Details of this clinical program have been previously published [28]; therefore, only pertinent details will be discussed here. While the program has traditionally been offered both in-person and via telehealth, the POWER program shifted to exclusive telehealth delivery due to the COVID-19 pandemic in March 2020 and continued to operate primarily via telehealth through December 2021. Anyone seeking care at the HCI is eligible to participate in the POWER program and patients can enroll in the program through self-referral or physician referral.

XSL•FO
RenderX

POWER provides personalized exercise prescriptions, including both aerobic and resistance training, to program participants based on an initial assessment conducted by a physiatrist and certified exercise physiologist with expertise in cancer via telehealth. The typical length of the program was 12-weeks, but varied based on participant preference. After about 12-weeks, participants were encouraged to complete a telehealth follow-up assessment to evaluate their progress (ie, reassess all baseline measures) and revise the exercise prescription to promote continued progress. Ultimately, the POWER program aims to help survivors become comfortable and capable of safely engaging in exercise independently.

The exercise prescription was individualized to each participant's needs and was informed by the initial telehealth assessment which included a review of medical and cancer treatment history, physical examination, review of current exercise behavior, and assessment of physical function, muscular endurance, and flexibility. Following the initial assessment each participant met with a certified exercise physiologist twice weekly, via telehealth, for the duration of their program, for a supervised, 60-minute resistance training session. Body weight training and resistance bands were the primary mode of resistance training delivery; however, the resistance training program may have also included resistance machines or free weights per participant access and preference. No equipment was provided to participants by the exercise program. Prescribed aerobic exercise was completed unsupervised by each participant. The goal of each participant's program was to work toward meeting the physical activity guidelines for cancer survivors [29].

Participants accessed the telehealth exercise visits directly through their online patient portal using any electronic device that was capable of video calls (eg, smartphone, tablet, laptop, etc). Telehealth visits were conducted directly through electronic health records (Epic Systems Corporation) which allow certified exercise physiologists easy access to the participants address, contact information, and emergency contacts. Participants' location for each telehealth exercise session and contact information, in case the telehealth session was disconnected, was verified by the certified exercise physiologist at the start of each session. While survivors had an out-of-pocket cost of approximately US $8 per telehealth exercise training visit, the baseline and follow-up assessments were covered by medical insurance reimbursement.

Measures

Overview

The following measures were included in the telehealth initial and follow-up assessments in the POWER program. When developing the telehealth assessment procedures, decisions about which measures to include were based on the feasibility of carrying out measures in a telehealth format and alignment with the in-person POWER program assessment [28]. When administering the telehealth assessments, the video camera angle was adjusted for each assessment so that the certified exercise physiologist could observe the full range of motion and ensure proper form was being used.

30-Second Chair Stand Test

Lower extremity function was evaluated with the 30-second chair stand test. Participants stood from a seated position, with arms crossed across their chest, and were instructed to stand up and sit down as many times as they could in 30-seconds [30]. The number of repetitions (ie, return to seated) completed in 30-seconds were recorded. Repetitions were counted using consistent methods across assessments and assessors to optimize the reliability of this assessment. The 30-second chair stand test has been shown to be a good predictor of lower extremity function in older adults [31] and safe to conduct using telehealth in adults with cancer [32]. Moreover, the 30-second chair stand test has good test-retest reliability in older adults with cancer (intraclass correlation [ICC]=0.89) [33,34]. A minimal clinically important difference (MCID) of 2.0 has been established for the 30-second chair stand test [35].

30-Second Maximum Push-Up Test

Muscular endurance was assessed using the 30-second push-up test. The starting position for push-ups was with the hands on the floor approximately shoulder width apart and arms straight. Participants were instructed to lower themselves down toward the floor until their chest was one fist width above the floor and then return to the starting position; this is one repetition. Participants were asked to complete as many push-ups as possible in 30-seconds. If the participant was unable to perform a standard push-up (on toes), they were able to modify by starting on their knees or performing wall push-ups depending on ability [36]. Any modifications made at baseline were replicated at follow-up.

2-Minute Standing March

Aerobic endurance was assessed using the 2-minute standing march test. Participants stepped in place with a step height no lower than the midpoint between the patella and iliac crest. The number of steps (right and left equals one) completed in 2-minutes were recorded. If necessary, participants could use one hand on a counter-top or a chair to assist with balance. The 2-minute standing march has been shown to be a good alternative to the 6-minute walk test [37,38] with strong test-retest reliability (ICC=0.99) when assessed among older adults via telehealth [39].

Single Leg Stance

Balance was assessed using a single leg stance. Participants were instructed to lift one foot off of the ground and balance on one leg without holding onto anything for support for as long as possible with their eyes open. The single leg stance was performed once on each leg. Time balancing without assistance (from hands or the other foot) was recorded for each leg. No maximum time cap was imposed for the single leg stance. The single leg stance test has demonstrated good reliability (ICC=0.86) among older adults [40].

Plank

Participants were asked to hold a forearm plank on either their toes or knees, self-selected based on their ability, for as long as they were able to assess torso muscular endurance. Each participant was instructed to keep their elbows directly under

XSL•FO
RenderX

their shoulders with forearms extended forward and a neutral spine and neck. The variation (ie, knees or toes) participants selected and total time participants were able to hold the plank were recorded. The plank assessment was not performed in cases where contraindications, such as cardiovascular concerns or upper extremity injuries, were present. Telehealth plank assessment has demonstrated good reliability (ICC=0.97) among adults [41].

Chair Sit and Reach

Hamstring flexibility was assessed using the chair sit and reach test. Participants sat on a chair near the front edge of the seat with one leg extended (ie, heel on the floor and foot dorsiflexed at approximately 90 degrees) and the other leg bent with the sole of the foot flat on the floor. Then they were asked to place one hand on top of the other with palms facing down. Participants were then instructed to slowly bend forward at the hips, keeping their back flat, as they reached down the extended leg as far as they could. A score was assigned based on how far participants were able to reach: a 2 for the toes, 1.5 for the ankle, 1.0 for the shin, 0 for anything above the shin. The chair sit and reach test has demonstrated good reliability (ICC=0.95) and validity among older adults [35,42].

Shoulder Range of Motion

Range of motion in the shoulder joint was assessed by measuring shoulder flexion, shoulder extension, and shoulder abduction. Range of motion for each movement was observed and visually estimated to the nearest 10 degrees during the telehealth initial assessment. Visual estimation of shoulder range of motion has demonstrated acceptable reliability (ICC=0.57 - 0.70) among adults [43].

Clock Test

The clock test is a modified back scratch test used to assess shoulder internal rotation. Participants were instructed to reach behind their back with their palm facing out with the goal of reaching their hand as far up their back as possible. The test was conducted on both the right and left sides. The test is scored by visually estimating the position of the arm in correspondence to a position on the face of a clock during the telehealth initial assessment. Scores range from six to eleven on the right and six to one on the left with eleven and one indicating the highest levels of shoulder flexibility, respectively.

Statistical Analysis

Descriptive statistics were reported as means and SDs or medians and IQRs for continuous variables and frequencies and percentages for categorical variables. Differences in age, BMI, and continuous initial assessment variables between older adults with cancer who did and did not complete a follow-up assessment were determined using independent samples *t* tests. Differences in categorical demographic, clinical, and initial assessment variables were assessed using chi-square tests. Among the older adults with cancer that completed a follow-up assessment, mean change variables were computed as the difference between the follow-up and baseline values. Missing assessment data were excluded case-wise to maximize the sample size for each variable. Change scores were compared to values considered to be the MCID. The 30-second chair stand test was the only assessment with a published MCID value [35]. Paired samples *t* tests were conducted to determine if there were significant differences in assessment outcomes following the exercise intervention. Cohen *d* effect sizes are reported as an indicator of effect size. A Cohen *d* of 0.2 was considered a small effect, 0.5 was considered medium, and 0.8 was considered large. For categorical outcomes mean change scores and 95% CIs were calculated to determine change across the intervention. All data were analyzed in SPSS (version 29.0; IBM Corp).

Ethical Considerations

The protocol and waiver of informed consent was approved by the University of Utah Institutional Review Board (IRB_00072431) in accordance with the Declaration of Helsinki. All data presented were deidentified using study identification numbers prior to analysis. Compensation was not included for this study.

Results

Participants

A total of 68 older adults with cancer completed an initial assessment via telehealth and participated in the POWER program between March 2020 and December 2021. Older adults with cancer who participated in POWER via telehealth were 71.8 (SD 5.3) years of age on average (range 65 - 92 y) and had a median BMI of 26.7 kg/m^2 (IQR 7.3; Table 1). Most older adults with cancer were female (n=45, 66.2%) and were not actively receiving treatment during their participation in POWER (n=40, 58.8%). The most common cancer types among older adults were breast (n=18, 26.5%), prostate (n=13, 19.1%), and multiple myeloma (n=8, 11.8%).

[a]Not able to detect differences between groups.

[b]Active treatment: receiving any curative treatment during participation in the Personal Optimism With Exercise Recovery program.

[c]Statistical significance (*P*<.05).

[d]Treatment history: receiving the treatment type at any point in their care.

[e]Unimodal: 1 treatment type.

[f]Bimodal: 2 treatment types.

[g]Multimodal: 3 or more treatment types.

Of the 68 older adults who completed an initial assessment and participated in POWER, 29.4% (n=20) completed a telehealth follow-up assessment. The median time elapsed between initial and follow-up assessments was 16.5 weeks (IQR 5.75). The majority of older adults with cancer who completed a follow-up were on active treatment (n=12, 60%). Statistically significant differences were not observed among the following clinical and demographic variables among older adults with cancer who did and did not complete a follow-up assessment: age, BMI, sex, race, ethnicity, cancer stage, history of hormone therapy, immunotherapy, surgery, and radiation, number of treatment types, or cancer type. A statistically significant difference was observed for the proportion of older adults with cancer who reported being on active treatment (*P*=.04) and having received chemotherapy (*P*=.04) between those who did and did not complete a follow-up assessment.

Change in Measured Outcomes

Values for each measured outcome from the initial telehealth assessment are reported in Table 2. There were no significant differences in initial assessment outcomes between the follow-up and no follow-up groups (*P*>.05).

Seated sit and reach							
Left	20	1.4 (0.6)	42	1.6 (0.4)	.16	62	1.6 (0.5)
Right	20	1.4 (0.6)	42	1.6 (0.5)	.40	62	1.5 (0.5)

Change in measured outcomes are reported in Table 3. Statistically significant changes were observed for the 30-second chair stand test (mean change +2.00 repetitions, 95% CI 0.12 to 3.88, Cohen *d*=0.51) and 30-second maximum push-up test (mean change +2.85 repetitions, 95% CI 1.60 to 4.11, Cohen *d*=1.06). Nine (47.3%) older adults with cancer had a change in 30-second chair stand scores that exceeded the MCID of 2.0 repetitions [35], and 14 (73.7%) older adults maintained their 30-second chair stand scores across the intervention. Although not statistically significant, positive changes were observed for the 2-minute standing march (mean change +12.79 repetitions, 95% CI −0.64 to 26.22, Cohen *d*=0.46), single leg stance on the left (mean change +4.80 s, 95% CI −0.67 to 10.27, Cohen *d*=0.44) and right (mean change +1.0 s, 95% CI −8.04 to 10.05, Cohen *d*=0.06), and shoulder abduction on the left (mean change +2.25 degrees, 95% CI −3.75 to 8.25, Cohen *d*=0.18) and right (mean change +0.25 degrees, 95% CI −4.34 to 4.84, Cohen *d*=0.03). The results from univariate analysis of covariance paralleled results from paired samples *t* tests.

Discussion

Principal Findings

This study aimed to evaluate the preliminary effectiveness of a hospital-based telehealth exercise oncology program on physical function, muscular endurance, balance, and flexibility among older adults with cancer. Our findings demonstrate that supervised, one-on-one telehealth exercise may positively influence physical function among older adults with cancer. Additionally, nearly half (n=9) of individuals who completed a follow-up assessment exceeded an MCID change in the 30-second chair-stand test, a marker of lower extremity function.

Comparison to Prior Work

The majority of research surrounding telehealth supervised exercise programs for older adults without [44,45] and with cancer [24,27] has focused on group exercise. Less is known about one-on-one telehealth exercise. Among older adults without cancer, participating in at least 12-weeks of supervised group telehealth exercise training prevents declines in physical function [44,45]. Among older adults with cancer, a feasibility study by Sattar et al [24] evaluated an 8-week group telehealth strength and balance training program and observed significant improvements in five time chair stand test scores. Additionally, Gell et al [27] carried out a pilot trial examining a 16-week group telehealth aerobic and resistance training program and observed significant improvements in 30-second chair stand test scores. Collectively, group telehealth exercise programming among older adults with and without cancer is effective at improving physical function.

Findings from this study contribute to the literature by addressing an important gap in our understanding regarding the effectiveness of one-on-one telehealth exercise among older cancer survivors. Among cancer survivors of all ages (range 14 - 83 y), effectiveness of one-on-one supervised telehealth exercise has been evaluated [22]. Following 12-weeks of one-on-one training with a cancer exercise trainer once per week, cancer survivors significantly improved cardiovascular endurance, muscular endurance, and flexibility [22]. Findings from our study support previous research suggesting one-on-one telehealth exercise programs may positively influence physical function among older adults with cancer. Without exercise

XSL•FO
RenderX

intervention, we would expect to see little to no change in physical function parameters over short durations in older adults living with cancer. Over 13-weeks Mikklesen et al [11] found a mean change of +0.4 repetitions in the 30-second chair stand test and −1.0 points in self-reported physical function among older cancer survivors receiving standard of care and no exercise intervention. Over longer durations (eg, ≥1 y) functional declines are greater and can persist for years following diagnosis [6]. Preventing declines in physical function is important in this population because physical function has been shown to have a protective effect against all-cause mortality in older adults with cancer [8].

In addition to examining the effect of one-on-one, supervised telehealth exercise on physical function in older adults with cancer, we also characterized older adults with cancer who chose to participate in a telehealth exercise program. This information adds to our body of knowledge by demonstrating that older adults with cancer can engage in one-on-one telehealth delivered exercise programs. Additionally, we observed that a significantly greater proportion of older adults with cancer who were on active treatment or had received chemotherapy completed a follow-up assessment. This finding suggests that older cancer survivors on active cancer treatment are willing to engage in telehealth exercise which is important as recent recommendations from the American Society of Clinical Oncology encourage cancer survivors on active treatment to participate in aerobic and resistance exercise [46]. Understanding who we are reaching with telehealth exercise programs, who may be missing, and who completes a telehealth follow-up assessment can inform the development of interventions to improve the engagement and reach of telehealth delivered exercise programming among cancer survivors of all ages.

Strengths and Limitations

To our knowledge, this is one of the first studies that has evaluated effectiveness of one-on-one telehealth exercise programming exclusively among older adults with cancer and characterized the older adults who used this programming. We consider this a strength of our work. Additionally, the use of an established hospital-based exercise oncology program with over 15 years of experience offering telehealth exercise ensured high-quality exercise programming in this study. However, our study is not without limitations. First, the low follow-up assessment completion rate resulted in a small sample size and an underpowered analysis to demonstrate statistically significant changes in all outcomes measured. Therefore, the findings from this study are preliminary and additional research with a larger sample is needed. Second, the retrospective design of this study may have resulted in selection bias of participants who were more motivated to exercise and follow-up. Highly motivated individuals may be more likely to complete a follow-up assessment in the program potentially confounding the effects of the telehealth exercise program. Third, baseline and follow-up assessments were scheduled based on the participants' availability which resulted in different staff conducting baseline and follow-up assessments for some participants. However, a small team of certified exercise physiologists administered all virtual assessments, adhering to standardized program procedures to minimize interrater variability. Fourth, the lack of a nonexercise control group limits the conclusions that can be made regarding the ability of telehealth exercise to prevent declines in physical function. Future work should consider a prospective study design and inclusion of potential confounding variables as covariates to determine the effectiveness of one-on-one telehealth exercise on markers of physical function.

Conclusions

In summary, older adults living with and beyond cancer are able to participate in an exercise oncology program delivered via telehealth. Our findings provide preliminary evidence that telehealth may be a beneficial tool to facilitate exercise program delivery among older adults following a cancer diagnosis. However, telehealth exercise should not be considered a one-size-fits-all all approach as in-person, telehealth, or a combination of the two may be a better fit for some older adults with cancer, based on their needs and preferences. Further research is needed to understand the magnitude of the effects of one-on-one, supervised telehealth exercise on physical function among older adults with cancer.

Abstract

Background: Exercise interventions are among the best-known interventions for cancer-related fatigue (CRF). Rural survivors of cancer, however, report specific barriers to engaging in exercise programs and lack overall access to effective programs.

Objective: The purpose of this investigation was to assess the feasibility of a novel telehealth exercise program designed specifically for rural survivors of cancer with CRF.

Methods: A single-arm clinical trial of the BfitBwell Telehealth Program was performed. Based on an established clinical program, this adapted 12-week program addressed barriers previously reported by rural survivors by providing synchronous videoconference exercise sessions (2 per program), asynchronous exercise sessions using a personal training smartphone or internet app (3-5 per week), and regular symptom (CRF) monitoring using automated emailed surveys (every 2 weeks). Personalized exercise prescriptions containing aerobic and resistance activities were implemented by cancer exercise specialists. Symptom-triggered synchronous sessions were initiated for participants failing to improve in CRF, as identified by a reference chart of CRF improvements observed during a supervised exercise program. Eligible participants were adult survivors of any cancer diagnosis who had completed treatment with curative intent in the past 12 months or had no planned changes in treatment for the duration of the study, lived in a rural area, and were currently experiencing CRF. Feasibility was assessed by objective measures of recruitment, data collection, intervention acceptability and suitability, and preliminary evaluations of participant responses. CRF was the primary clinical outcome (assessed using the Functional Assessment of Chronic Illness Therapy—Fatigue Scale [FACIT-Fatigue]) and was measured before, after, and 6 months after program completion.

Results: In total, 19 participants enrolled in the study, 16 initiated the exercise program, and 15 completed the program. A total of 14 participants were recruited through internet advertisements, and the total recruitment rate peaked at 5 participants per month. Participants completed 100% of initial and final assessments (30 assessments across all participants) and 93% (70/75 possible surveys across all participants) of emailed surveys and attended 97% (29/30 possible sessions across all participants) of synchronous exercise sessions. In total, 6 participants initiated symptom-triggered sessions, with 6 of 7 initiated sessions attended. The mean FACIT-Fatigue scores significantly improved (P=.001) by 11.2 (SD 6.8) points following the completion of the program. A total of 13 participants demonstrated at least a minimal clinically important difference in FACIT-Fatigue scores (≥ +3 points) at this time. FACIT-Fatigue scores did not significantly change from program completion to 6-month follow-up (n=13; mean change –1.1, SD 3.4 points; P=.29).

XSL•FO
RenderX

Conclusions: Results from this investigation support the feasibility of the BfitBwell Telehealth Program and a subsequent efficacy trial. Novel program components also provide potential models for improving exercise program efficacy and efficiency through asynchronous exercise prescription and symptom monitoring.

Introduction

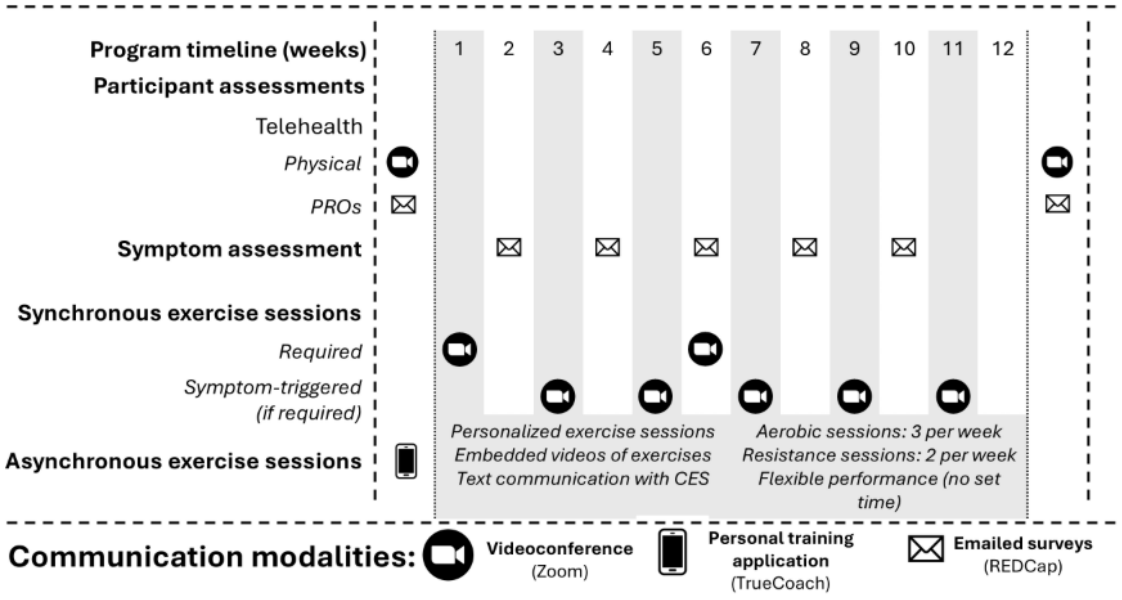
Cancer-related fatigue (CRF) is one of the most common and functionally limiting symptoms reported by survivors of cancer, with an estimated prevalence of 49% to 62% [1-4]. It is present in over a quarter of survivors up to 10 years after the completion of treatment [5], and survivors regularly report CRF as the symptom preventing them from living a "normal" life as well as the cause of major life events such as employment changes [6]. Participation in exercise interventions is an established intervention for the improvement of CRF in survivors of cancer [7,8], and a multidisciplinary roundtable pronouncement by the American College of Sports Medicine (ACSM) indicated that there is strong evidence that exercise can significantly reduce CRF. The current ACSM recommendation for an effective exercise prescription to remediate CRF is moderate-intensity aerobic training at least 3 times per week for at least 30 minutes and moderate-intensity resistance training at least 2 times per week [9].

Survivors of cancer living in rural locations [10], however, commonly lack access to many supportive services compared to nonrural survivors, including clinical exercise programs [11]. Rural survivors commonly report many specific barriers to engaging in exercise programs including lack of knowledge of available programs, distance and transportation to programs, lack of access to a knowledgeable exercise provider, and lack of flexibility in programming (in terms of time and location) [12,13]. An overall lack of accessible exercise programs for rural survivors has been identified in a recent review [14]. A survey of rural survivors reported that only 38% and 10% were currently meeting aerobic and resistance training guidelines for survivors, respectively [12], demonstrating a clear need to increase accessible exercise programs for this population.

While current initiatives are designed to increase the accessibility of exercise programs for rural survivors of cancer [15,16], additional opportunities exist in the development of novel rural-focused program designs. The Exercise for Cancer to Enhance Living Well study in Canada [15] provides an exemplary model of using and improving clinical networks to increase awareness of and access to exercise oncology programs for rural survivors. The intervention itself, however, mirrors the available supervised programs by replacing in-person services with telehealth services, similar to other telehealth adaptations in the United States [17], which may not address all barriers experienced by survivors in rural areas. Beyond these examples, most other currently accessible exercise programs for rural survivors are phone-based walking programs [14]. Given that supervised exercise programs consistently demonstrate greater improvements in CRF compared to unsupervised programs [8], the efficacy of these current programs may be limited by the lack of consistent supervision and the recommended resistance exercise. Continued innovation in program designs specifically for the rural population is required to truly reduce geographic disparities targeting both improved accessibility and efficacy.

The purpose of this single-arm feasibility study was to assess a novel telehealth exercise program designed specifically for rural survivors of cancer with CRF, with an emphasis on replicating the CRF improvements seen in clinically supervised exercise programs. The program addresses known participation barriers for rural survivors and uses a validated reference chart of CRF improvement in a supervised program combined with regular symptom monitoring and symptom-triggered intervention. Data collection and outcome selection were designed to assess recommended objectives for feasibility studies [18] including recruitment, data collection, intervention acceptability and suitability, and a preliminary evaluation of participant responses. It was hypothesized that the program would demonstrate overall feasibility based on these objectives, providing support for a larger efficacy study.

Methods



Study and Program Design

This was a single-arm clinical trial of the BfitBwell Telehealth Program (Figure 1), with assessments at baseline, program completion (12 weeks), and 6-month follow-up. Data collection occurred between November 2021 and September 2023. This 12-week telehealth exercise program was adapted from the clinically supervised BfitBwell Cancer Exercise Program [19,20]. Initial adaptations were made internally by program and research staff and designed to (1) address known barriers to exercise participation in rural survivors of cancer and (2) replicate the effects of a supervised clinical exercise program via telehealth. The specific barriers addressed were distance and transportation, lack of program flexibility (in regard to time and location), and lack of access to a knowledgeable exercise provider [12,13]. Participation in the BfitBwell Telehealth Program was decentralized, with centralized program oversight, to remove distance and transportation barriers. Three telehealth technologies were used: videoconferencing software (Zoom Video Communications, Inc), a personal training smartphone or internet app (TrueCoach Inc), and automated emails (REDCap [Research Electronic Data Capture]; Vanderbilt University

XSL•FO
RenderX

[21,22]). The majority of exercise sessions were delivered asynchronously (ie, without real-time interaction between the participant and cancer exercise specialist [CES]) via the personal training app to provide program flexibility. Participants received scheduled (eg, recommended day of performance) and personalized exercise sessions via the app, but the timing of performance was determined by participants (eg, participants could complete sessions at any time of day, and "missed" sessions could be performed on later days). The personal training app also allowed embedded text communication between the prescribing CES and the participant following each individual exercise or exercise session. This within-app communication facilitated direct access to a knowledgeable exercise provider, as did regular engagement via automated emails for symptom monitoring.

Figure 1. The design of the BfitBwell Telehealth Program with the timing of program components delivery. CES: cancer exercise specialist; PRO: patient-reported outcome; REDCap: Research Electronic Data Capture.

Symptom monitoring was accomplished by plotting individual participant CRF scores on a validated reference chart of CRF improvements during a supervised exercise program [23]. The reference chart displays the typical course of CRF improvement for individuals in the supervised BfitBwell Cancer Exercise Program, against which the progress of individual participants can be easily monitored. The supervised BfitBwell Cancer Exercise Program has demonstrated effectiveness for improving CRF [19,20]. This type of reference chart has previously been proposed to inform personalized rehabilitation in other clinical populations [24,25]. In the BfitBwell Telehealth Program, CRF was monitored every 2 weeks and used to initiate symptom-triggered exercise sessions for participants failing to improve as predicted by the reference chart (see Symptom Tracking and Symptom-Triggered Sessions section). This served as the primary means of replicating the effects of a supervised program in a rural setting, as the reference chart allows individual participant progress to be compared to that of similar participants from a supervised program.

Finally, to promote participant safety in this remote telehealth context, a detailed safety and emergency response plan was developed. This plan included regular verification of the physical location of all videoconference sessions and the identification of a nearby "local support individual" (though this individual did not need to be present for assessments or sessions). Detailed plans of action were developed for emergent and nonemergent adverse events.

Participants

Eligibility criteria for participation were adults ≥18 and ≤80 years of age, a diagnosis of any cancer type and any stage, completion of medical cancer treatment with curative intent within the past 12 months, or currently receiving treatment with no planned changes for the next 4 months. These criteria are similar to the patient population in the supervised BfitBwell Cancer Exercise Program and the associated CRF reference chart. Additional eligibility criteria included current moderate to severe CRF (>3 on a 10-point scale per National Comprehensive Cancer Network definition [26]), high-speed home internet and videoconference capable device (smartphone or laptop with camera), and residence in a rural area (defined here as >1-hour commute to a major city in Colorado or surrounding states with a known exercise oncology program, based upon review of a national program directory) [27]. Exclusion criteria included medical conditions that would impact the safety of, or participation in, a telehealth exercise program (eg, significant pulmonary or cardiovascular conditions and

XSL•FO
RenderX

mobility-limiting orthopedic conditions). These conditions were self-reported on screening forms and individually reviewed by a licensed physical therapist (RJM) to determine eligibility. Safety was again assessed by the same therapist during the initial assessment (see Assessments section)).

A power analysis was not performed a priori, but a goal of 20 enrolled participants (with 15 completing the program) was set at study initiation. This recruitment goal was based primarily on the capacity of the supporting clinical exercise program combined with historical attrition rates of 25%.

Recruitment and Enrollment

Initial recruitment efforts were made through clinical staff at a large urban cancer center that serves rural Colorado and surrounding states. Incoming and recent participants in the supervised BfitBwell Cancer Exercise Program were screened for eligibility. Recruitment efforts were later adapted to include targeted internet and social media advertisements (BuildClinical, LLC). Participants recruited through these efforts completed screening evaluations via emailed surveys or phone calls with study personnel. Eligible and interested participants were then invited to live videoconference sessions to further discuss the study and provide written informed consent. Enrolled participants were mailed all necessary equipment including a resistance exercise band set, a commercial fitness tracker (Withings Move, Withings Health), a smartphone tripod, an aerobic step (adjustable height 2-8 inches), and other necessary assessment equipment (eg, a measured length of rope, tape measure, and a pulse oximeter). Participants were incentivized to enroll by being allowed to keep all mailed study equipment, and gift cards were distributed to facilitate program and within-program survey completion.

Primary Clinical Outcome

CRF was the primary clinical outcome and was assessed using the Functional Assessment of Chronic Illness Therapy—Fatigue Scale (FACIT-Fatigue) [28]. The FACIT-Fatigue is one of the most common measures of CRF with demonstrated reliability and validity in survivors of cancer [8,29]. It is a 13-item scale with scores ranging from 0 to 52, with higher scores indicating less CRF, asking participants to consider how they have felt during the past week. The minimal clinically important difference (MCID) of the FACIT-Fatigue scale has been identified as 3 points [30].

Assessments

Initial and final assessments were performed via videoconference by a licensed physical therapist (RJM, separate from program CESs). In addition to collecting study outcomes, the initial assessment served as a final assessment of participant safety (based on the physical therapist's clinical observations and judgment) and provided information used by the CES to personalize the exercise prescription. Demographic and cancer-related information were collected, and basic measures of physical fitness and function were performed similar to prior studies of telehealth assessments in survivors of cancer (adapted to be performed safely if the participant was alone) [31]. Physical assessment outcomes included single limb stance [32], gait speed [33], timed up and go [33], 30-second sit-to-stand [34], and a 3-minute step test (following the Tecumseh protocol [35]). Participants were interviewed about previous exercise experience, exercise preferences and goals, and available exercise resources (eg, home equipment and local gymnasiums). Patient-reported outcomes were then collected via emailed surveys. These included the FACIT-Fatigue [28], Functional Assessment of Cancer Treatment—General [36], Hospital Anxiety and Depression Scale [37], and the Godin Leisure-Time Exercise Questionnaire (GLTEQ, modified to estimate weekly moderate to vigorous physical activity and resistance exercise) [38]. Assessments occurred within the 2 weeks prior to intervention initiation and after completion. Patient-reported outcomes were again emailed to participants 6 months following program completion (follow-up assessment).

Exercise Intervention

Exercise prescription followed current recommendations for survivors of cancer from the ACSM, specifically targeting 2 resistance exercise sessions and three 30-minute aerobic exercise sessions per week [9]. The prescribed exercise plan was delivered by 2 CESs employed by the supervised BfitBwell Cancer Exercise Program and resembled typical sessions for this program, previously described [19,20]. Both CESs (IAM and JJS) had an undergraduate degree in exercise science (or a related field), an exercise training certification (ACSM Certified Exercise Physiologist or equivalent), and at least 4 years of experience working exclusively with survivors in the supervised BfitBwell Cancer Exercise Program, and the primary CES (IAM) had an ACSM-CES certification. Resistance exercises targeted large upper and lower extremity muscle groups (using resistance bands, participant equipment, household objects, and body weight), and aerobic exercise was based on participant preference and available equipment (typically outdoor walking, treadmill walking, or stationary cycling). All exercise plans were personalized based on participant abilities, preferences, and available resources (established during the initial assessment).

Exercise Sessions

One-hour, synchronous videoconference telehealth exercise sessions were scheduled with all participants in weeks 1 and 6. These sessions were performed in real time with the CES and participants interacting via live videoconference, mirroring an in-person supervised exercise session. Session content focused on providing education on exercise, demonstration and practice of proper exercise form, and supervised performance of exercises prescribed in the subsequent 6 weeks. All other exercise sessions (except the symptom-triggered sessions described in the next section) were delivered asynchronously via the personal training smartphone or internet app and included detailed individualized exercise content with embedded videos of a program CES performing the prescribed exercises. Participants had to indicate each exercise as completed within each session, creating a self-report measurement of asynchronous session completion. The embedded text communication between the prescribing CES and participant was regularly reviewed by the CES, who would then respond and adapt subsequent asynchronous exercise sessions, as

XSL•FO
RenderX

necessary. The app was available via both smartphone app and internet browser.

Symptom Tracking and Symptom-Triggered Sessions

Participants were emailed the FACIT-Fatigue 2 days prior to initiating the exercise program and every 2 weeks during the program, with daily reminders sent for up to 3 days. FACIT-Fatigue scores were monitored using the CRF reference chart to detect whether an individual's progress matched the typical progress of similar individuals in a supervised exercise program, based on percentile rank established by initial scores. A symptom-triggered, synchronous videoconference exercise session was scheduled in the week following a FACIT-Fatigue score ≥3 points lower than the projected percentile at a given measurement time. The threshold was based on the MCID of the FACIT-Fatigue [30] in an attempt to ensure that symptom-triggered sessions were initiated due to a true lack of progress rather than normal variation or measurement error. Symptom-triggered session length ranged from 15 to 60 minutes, and a CES discussed program progress and challenges with the participant, with adaptations made to improve program response. These sessions were designed to mirror what would occur in a supervised program for participants who expressed a poor exercise response (eg, stated they continued to have fatigue) or in whom the CES identified a poor response (eg, performance plateau or decline). Common adaptations included changes in various exercise prescription components (Frequency, Intensity, Timing, and Type, via the ACSM guidelines [39]) and were made based on CES judgment in each occurrence. Emailed surveys also included a simple form for participants to ask exercise-related questions and request an additional videoconference exercise session the following week, even if not triggered by FACIT-Fatigue scores.

Outcomes

Rationale

All outcomes were designed based on the recommended objectives, with guiding questions, for feasibility studies, as described by Orsmond and Cohn [18]. The current investigation focused on the use of collected objective data. While the ability of the research team to conduct the study and provide the intervention was not directly assessed, evaluation of other objectives allowed an indirect assessment (eg, successful data collection and attendance rates support the ability of the research team to perform these tasks). "Success" thresholds for feasibility outcomes were not set a priori, but rather outcomes were assessed holistically following the study as a means of assessing overall feasibility, providing the context of experience acquired while delivering the pilot program.

Recruitment

The number of participants screened, determined eligible, and ultimately enrolled were tracked, as was the recruitment rate (participants enrolled per month). The medium by which enrolled participants were recruited was recorded (eg, clinical referral or targeted internet and social media advertisements). The demographics of enrolled participants were summarized and separated by those who did and did not complete the program.

Data Collection

Completion rates of all clinical program outcomes from the initial, final, and follow-up assessments were calculated. Completion rates of the within-program emailed surveys (of 5 total) were calculated.

Intervention Acceptability and Suitability

Attendance rates were calculated for videoconference assessments and synchronous exercise sessions (including both the standard [2 sessions] and symptom-triggered sessions [up to 5 sessions]). Completion rates were calculated for asynchronous exercise sessions (based on downloaded session logs including previously described self-reported completion). Program safety was assessed by recording the number and nature of adverse events.

Preliminary Evaluation of Participant Responses

Participant responses to the intervention were evaluated by calculating changes in patient-reported and physical outcomes from initial to final assessments. Maintenance of participant responses following the intervention was investigated by calculating changes in patient-reported outcomes from final to follow-up assessments. FACIT-Fatigue change was also assessed on an individual participant level, with the number of participants achieving an MCID following the program determined. Within-program individual changes were visually investigated by plotting FACIT-Fatigue scores on the CRF reference chart, along with the occurrence of symptom-triggered sessions.

Statistical Analysis

As a feasibility study with a small sample size, the majority of outcomes were summarized with descriptive statistics (counts, percentages, means, and SDs) and separately quantified for each assessment time point (initial, final, and follow-up) when appropriate. Following recommendations [18], the preliminary evaluation of participant responses was assessed using multiple approaches. In addition to the descriptive statistics provided for clinical outcomes and their change scores, the significance of change scores was assessed by statistically comparing these scores to 0 (ie, representing no change) using the nonparametric Wilcoxon signed rank test, as recommended for smaller studies as it does not assume a normal data distribution [40]. Significance was set at $\alpha<.05$, established a priori, without correction for multiple tests, but with the presentation of individual *P* values facilitating further scrutiny. The clinical meaningfulness of changes in FACIT-Fatigue scores, the primary clinical outcome, was assessed by summarizing the participant-level outcomes and visual investigations (see Preliminary Evaluation of Participant Responses section). Only participants with available data were included in each analysis, with sample sizes reported for each analysis. All statistical analyses were performed using R statistical software (R Foundation for Statistical Computing).

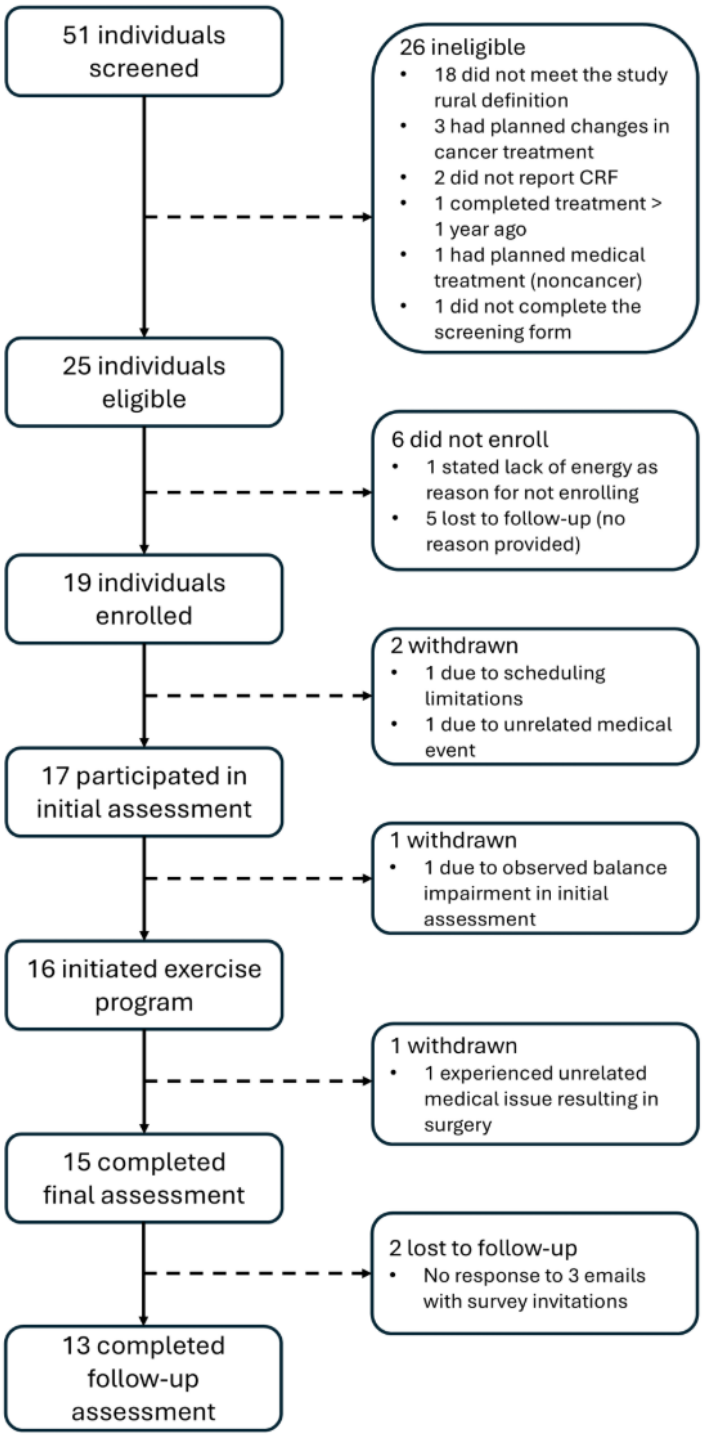
Ethical Considerations

This study was reviewed and approved by the Colorado Multiple Institutional Review Board (COMIRB # 20-2015) and registered on ClinicalTrials.gov (NCT04533165). All participants provided

XSL•FO
RenderX

written informed consent prior to enrollment. Participants were incentivized to enroll by being allowed to keep all distributed assessment and exercise equipment (approximate US $200 value). Within-program survey completion was incentivized by providing a US $50 gift card if at least 3 were completed. Participation in the final assessment was incentivized with a US $50 gift card upon completion. Study data were stored securely in REDCap, and analyses used deidentified data.

Results



Recruitment

Figure 2 displays the flow of participants from screening to program completion, with attrition at each stage. Ultimately, 51 survivors of cancer were screened, 19 enrolled in the program, and 15 completed the program. All enrolled participants reported a “White” racial background. No participants reported Hispanic or Latino ethnicity. Of the enrolled participants, 14 (74%) were recruited through internet and social media advertisements, 4 (21%) were recruited from a registry of past participants in the supervised BfitBwell Cancer Exercise Program, and 1 person was recruited through clinical connections at a large urban cancer center. When all recruitment efforts were active, the maximum recruitment rate was 5 enrolled participants per month. Demographics and cancer-related data for enrolled participants, separated by those who did and did not complete the program, are shown in Table 1, and reasons for study withdrawal are shown in Figure 2 (note that most withdrawal reasons are unrelated to demographic and cancer-related data). All subsequent results include only participants who completed the program (and follow-up assessment when relevant).

One participant was withdrawn from the study due to the clinical determination that participation in a telehealth exercise program would not be safe due to previously unreported balance impairments, making the participant ineligible for the investigation. This safety determination was based primarily upon movement observation and objectively supported by poor performance on physical measures (single limb stance=3.5 seconds, gait speed=0.92 m/s, and inability to perform step test despite adaptation). Upon informing the participant of this decision, the study team facilitated a connection to a nearby facility providing supervised and skilled rehabilitation.

Data Collection

All physical assessment outcomes were successfully completed during the initial and final assessments except the 3-minute step test. In total, 3 participants were unable to maintain the required step rate for the duration of the test, 1 participant did not perform the test due to concerns of exceeding a safe heart rate (85% age-predicted maximum), and 2 participants experienced technical difficulties in measuring heart rate following completion of the test. All patient-reported outcomes were successfully completed at the initial assessment, and only 1 participant failed to complete both the Hospital Anxiety and Depression Scale and GLTEQ (presented last in emailed surveys) at the final assessment. In total, 13 (87% of those completing the program) participants completed all patient-reported outcomes at the follow-up assessment. The average completion rate of the within-program emailed surveys was 93% (70/75 surveys across all participants), with 12 (80% of those completing the program) completing 100%.

Intervention Acceptability and Suitability

Attendance at initial and final videoconference assessments was 100% (30/30 possible assessments attended across all participants). Attendance at videoconference exercise sessions (weeks 1 and 6) was 97% (29/30 possible sessions attended), with only 1 participant missing 1 session. In total, 7 symptom-triggered sessions were initiated in 6 participants, with 6 (86%) of these sessions attended. A total of 3 participants requested 1 additional session, and 1 participant requested 2 additional sessions (non–CRF related). A total of 5 participants did not trigger or request any additional sessions. Participants received an average of 58 (SD 7) asynchronous sessions each, with an average of 49 (SD 11) indicated as complete (49/58, 84%, individual range 38%-100% [23/60 and 60/60 possible sessions completed, respectively]).

In total, 7 adverse events were reported in 6 participants. Of them, 2 were minor musculoskeletal issues (muscle strains) likely related to the exercise intervention. The remaining events were unrelated to the exercise intervention (minor musculoskeletal issues and illness).

Preliminary Evaluation of Participant Responses

Table 2 displays the averages and changes in all outcomes at initial, final, and follow-up assessments. Group changes in all patient-reported outcomes from initial to final assessments were significantly different from 0 (in directions demonstrating improvement; all P values <.05, see Table 2 for individual values). Change in 30-second sit-to-stand was significantly greater than 0 (P=.005), and change in timed up and go trended toward being less than 0 (P=.09). At the follow-up assessment,

XSL•FO
RenderX

only self-reported resistance exercise (GLTEQ-Resistance) significantly decreased from the final assessment (*P*=.01).

Discussion

Principal Findings

This investigation assessed the feasibility of the novel BfitBwell Telehealth Program for rural survivors of cancer with CRF. Initial recruitment barriers were overcome through the adoption of alternative strategies (targeted internet advertisements). Outcome completion rates and intervention adherence rates were high, demonstrating the feasibility of data collection and intervention acceptability and suitability. Significant and meaningful improvements in CRF were observed at both the group and individual levels in the preliminary evaluation of participant responses. Based on these assessments of the recommended objectives [18], the BfitBwell Telehealth Program appears to be highly feasible, supporting the progression to a large efficacy trial.

Comparisons to Prior Work

One of the main goals of this feasibility study was to adjudicate avenues for recruitment of eligible rural-living individuals. Given the barriers in accessing this population, it is not surprising that little work has been done specifically investigating the recruitment of rural-living people with cancer into exercise programs. A recent review of recruitment rates and strategies in exercise trials for survivors of cancer (not rural specific) revealed a low overall recruitment rate of 38%, with only 11% of included trials using web-based advertisements [41]. Additionally, “passive” strategies (including web-based advertisement) resulted in lower rates than “active” strategies (including clinic-based recruitment). Another larger exercise trial in rural survivors also demonstrated the success of active strategies such as community and clinical engagement [16]. Our findings contrast with these previous studies, in that only 5% of participants were enrolled as a result of active recruitment strategies (ie, clinical connections) at a large urban cancer center. A much more productive approach involved the use of targeted internet and social media advertisements. These approaches may indeed be considered more “active” than previous web-based approaches, as advertisements are routed to individuals based on their past internet activity. The reach of these advertisements to rural communities is undoubtedly broader than what can be achieved through clinic-based recruitment approaches. In our case, web-based recruitment might also provide a good match for individuals seeking a web- or telehealth-based program. More investigation is required into how to best engage and recruit rural survivors in exercise programming and associated clinical trials.

A unique aspect of our particular program was the reference chart–based monitoring of participant response to exercise along with the standardized addition of symptom-triggered sessions when participant progress deviated from the expected response. Lower than expected CRF improvements triggered additional sessions in 6 (40%) participants, and subsequent CRF scores appeared to improve following these symptom-triggered sessions (Figure 5). The purpose of these sessions was to mirror within-program exercise adaptations that are common in supervised clinical exercise programs in response to provider observations. While this facet of personalized exercise prescription is a relatively emergent feature in contemporary clinical research, the approach adheres to recommended best practices published by the National Comprehensive Cancer Network [42]. The current combination of symptom monitoring and symptom-triggered intervention is similar to a previous study of “chemotherapy-periodized” exercise, which demonstrated improved attendance when exercise prescription was adapted in anticipation of changing chemotherapy-associated symptoms during consecutive chemotherapy cycles [43]. Adaptations in the current program were made in accordance with the ACSM Frequency, Intensity, Time, and Type criteria of exercise prescription [39] and were

XSL•FO
RenderX

based on CES expertise and information gathered during participant discussions.

Exercise attendance and program completion rates in our study were high. In total, 15 of 16 (94%) participants completed the program, and attendance and completion of all exercise sessions ranged from 84% (49/58 asynchronous sessions completed, on average) to 97% (29/30 videoconference sessions attended, across all participants). Additionally, within-program CRF monitoring was objectively successful, with an overall survey completion rate of 93% (70/75 surveys completed, across all participants). In total, 9 participants did not require symptom-triggered exercise sessions, completing the program largely autonomously and asynchronously. The lack of symptom-triggered sessions indicates similar CRF improvement compared to participants in a supervised exercise program, despite a reduced number of real-time (or synchronous) exercise sessions compared to many of these programs [19]. The asynchronous method of providing exercise programming and supervision used in this investigation may hold promise for improving both exercise efficacy and program efficiency in telehealth exercise programs.

The mechanisms underlying the observed CRF improvements remain uncertain, given the current investigation is a feasibility trial. Nonetheless, several strategies are likely to have contributed to engagement with the exercise prescription, facilitating exercise-associated CRF improvements in this cohort. The programmatic design specifically addressed three known barriers to exercise engagement in rural survivors of cancer, which are not frequently or consistently addressed in other programs (beyond reducing travel burden) [12,13]: (1) the need to travel was completely removed, (2) asynchronous programming provided flexibility for where and when exercise was performed, and (3) several methods of communication provided direct access to a knowledgeable exercise provider. For the involved CES, an unanticipated benefit of asynchronous programming was that the time commitment required may be lower than for a supervised program. While perhaps obvious, pragmatic and cost-effective strategies for improved exercise engagement may prove critical to overall program effectiveness, where personnel costs and reimbursement funds limit more intensive strategies. To this end, additional investigation of objective measures of program efficiency using asynchronous exercise programming is required.

Strengths and Limitations

The primary limitation of this investigation is the lack of a control group and small sample size. Particularly in evaluating preliminary participant responses, the observed improvements during the program or in response to symptom-triggered sessions cannot be solely attributed to the intervention. However, several outcomes support the plausibility of the program influencing a meaningful improvement in CRF. First, the observed within-program improvements in CRF were similar to those documented in the supervised exercise program used to develop the CRF reference chart [23]. Second, significant improvements in CRF were observed immediately following the program, but no significant changes were observed in the 6 months following the program, indicating a lack of change due to time as well as the potential maintenance of program effects. Statistical analyses of pilot and feasibility trials, however, should be interpreted with caution [18]. Finally, on the participant level, the majority of participants (13/15, 87%) experienced a clinically meaningful improvement in CRF.

The sample in the current investigation is also likely biased in several ways. Given that participants responded to advertisements for an exercise intervention, the current sample is likely to reflect individuals who are able and willing to exercise. Additionally, the current sample is not large enough to adequately assess the contribution of various demographic and clinical variables on program adherence and response. The use of web-based recruitment methods and telehealth technology may discourage the participation of survivors without or not comfortable with technology. While the incorporation of this self-selecting sample population may contribute to a current "digital divide," parallel efforts are actively reducing technological barriers through efforts to increase the availability and acceptance of adequate technology and internet connections. For example, the Broadband Equity, Access, and Deployment Program [44] seeks to expand high-speed internet access throughout the United States, facilitating a societal migration to technology-based health care interventions (including exercise). Given that the current investigation was performed during the COVID-19 pandemic, participants' perspectives of and adherence to telehealth exercise may have been positively influenced in a manner unrepresentative of their more general context.

The used definition of rurality was developed independently by the research team, designed to target a population in need of services in the local region (Colorado and surrounding states). While this emphasis on local context is appropriate for this small feasibility study, future studies targeting larger populations in larger regions should use standardized rurality definitions to facilitate broader generalizations [10]. The telehealth tools used to facilitate access to this rural population may also contribute to a decrease in the fidelity of the prescribed exercise prescription. Specifically, only self-report completion data were available for asynchronous exercise sessions, limiting the knowledge of actual completion and performance. Future work could integrate additional technology (eg, improved activity trackers) to objectively assess the performance of these sessions.

Finally, while this investigation supports the feasibility of the BfitBwell Telehealth Program, it does not represent a comprehensive assessment of feasibility. While one set of recommended assessments was followed, multiple alternative definitions of feasibility and associated measures exist. Specifically, the assessment of intervention acceptability can be complex, including both quantitative and qualitative evaluations [45]. Nonetheless, the presented feasibility assessments provide strong support for further investigation of this program and its methods.

Conclusions

The BfitBwell Telehealth Program used several telehealth modalities combined with regular within-program symptom monitoring and symptom-triggered intervention to deliver an exercise program to rural survivors of cancer with CRF. This

XSL•FO
RenderX

investigation demonstrated high program feasibility, supported by positive assessments of recruitment, data collection, intervention acceptability and suitability, and preliminary evaluation of participant responses. Novel methods used by the program also provide a potential model for improving exercise program efficiency by using asynchronous exercise prescription. Future work should pursue large-scale efficacy testing, objective assessments of program efficiency, and systematic investigations of the effects of within-program exercise adaptations.

Abstract

Background: Although physical activity (PA) is recommended for patients with cancer, changes in PA across cancer diagnosis and treatment have not been objectively evaluated.

Objective: This study aimed to assess the impact of cancer diagnosis and treatment on PA levels.

Methods: This was a retrospective cohort study using a Japanese claims database provided by DeSC Healthcare Inc, in which daily step count data, derived from smartphone pedometers, are linked to the claims data. In this study, we included patients newly diagnosed with cancer, along with those newly diagnosed with diabetes mellitus for reference. We collected data between April 2014 and September 2021 and analyzed them. The observation period spanned from 6 months before diagnosis to 12 months after diagnosis. We applied a generalized additive mixed model with a cubic spline to describe changes in step counts before and after diagnosis.

Results: We analyzed the step count data of 326 patients with malignant solid tumors and 1388 patients with diabetes. Patients with cancer exhibited a 9.6% (95% CI 7.1%-12.1%; *P*<.001) reduction in step counts from baseline at the start of the diagnosis month, which further deepened to 12.4% (95% CI 9.5%-15.2%; *P*<.001) at 3 months and persisted at 7.1% (95% CI 4.2%-10.0%; *P*<.001) at 12 months, all relative to baseline. Conversely, in patients with diabetes, step counts remained relatively stable after diagnosis, with a slight upward trend, resulting in a change of +0.6% (95% CI –0.6% to 1.9%; *P*=.31) from baseline at 3 months after diagnosis. At 12 months after diagnosis, step counts remained decreased in the nonendoscopic subdiaphragmatic surgery group, with an 18.0% (95% CI 9.1%-26.2%; *P*<.001) reduction, whereas step counts returned to baseline in the laparoscopic surgery group (+0.3%, 95% CI –6.3% to 7.5%; *P*=.93).

Conclusions: The analysis of objective pre- and postdiagnostic step count data provided fundamental information crucial for understanding changes in PA among patients with cancer. While cancer diagnosis and treatment reduced PA, the decline may have already started before diagnosis. The study findings may help tailor exercise recommendations based on lifelog data for patients with cancer in the future.

Introduction

With the increasing number of cancer survivors, attention has been paid to not only cancer remission but also quality of life, which strongly correlates with physical activity (PA) in patients with cancer [1,2]. PA has been reported to be associated with a favorable prognosis in cancer survivors, with associations demonstrated in various cancer types, such as breast and colorectal cancers [1,3].

Although PA is a pivotal factor in patients with cancer, objective evidence on how it declines after cancer diagnosis and treatment is still lacking. Objective evaluation of prediagnostic PA is challenging. Previous studies that compared PA before and after cancer diagnosis relied on retrospective recall [4,5], which may introduce recall bias [6]. Therefore, research using objective precancer onset data is necessary to avoid this bias. However, this is challenging in studies that recruit participants after hospital visits.

Recently, many studies have leveraged real-world data collected during daily clinical practice and patients' daily lives [7]. With advancements in digital devices, access to patients' daily life data has improved [8]. Furthermore, the prevalent use of smartphone apps has facilitated the routine tracking of step counts, which strongly correlate with PA levels [9,10]. A daily step count of at least 10,000 steps is recommended for adults by the World Health Organization, while Japan's Ministry of Health, Labour and Welfare sets a more realistic target of 8000 steps per day for adults [11,12]. Integrating step count data obtained using smartphones with medical information allows for objective evaluation of changes in PA from the prediagnosis period. Thus, this study aimed to assess the effect of cancer diagnosis and treatment on PA levels by analyzing real-world step count data.

Methods

Data Source

This was a retrospective cohort study analyzing a database provided by DeSC Healthcare Inc, in which daily step count data are linked to a Japanese claims database [13,14]. Briefly, members of affiliated health insurance associations can access the Kencom smartphone app, developed by DeSC Healthcare Inc, free of charge. Daily step counts were measured using the Kencom app, synchronized with smartphone pedometers [13,14]. The Kencom database was integrated and anonymized with the Japanese claims database in affiliated health insurance associations under the opt-out agreement. Subsequently, DeSC Healthcare Inc merged data from various insurance associations, creating a large, longitudinal database for research use [13,14]. Diseases were classified according to *International Classification of Diseases, 10th edition* (*ICD-10*) codes. This database, which integrates step count information with medical information, mainly includes employees of large businesses and their dependents [13,14]. In this study, step count data were used to quantify PA levels.

Study Population

This study included patients newly diagnosed with malignant tumors (*ICD-10* code: C). In addition, patients newly diagnosed with diabetes mellitus (*ICD-10* code: E11-E14), a representative chronic disease in which the importance of PA is widely recognized [15], were included as a positive control, given the expectation that step counts would increase after diagnosis [16]. The inclusion of newly diagnosed patients also simplified the identification of index time [17]. Data between April 2014 and September 2021 were analyzed. The observation period spanned from 6 months before diagnosis to 12 months after diagnosis. The detailed eligibility criteria are described in Table S1 in Multimedia Appendix 1. Patients who did not receive treatment were excluded, and the Japanese Claims database has been validated as having over 98% specificity for identifying patients using this method [18].

Statistical Analysis

We applied a generalized additive mixed model with a cubic spline to describe changes in step counts. Individual-specific random effects, age at diagnosis, seasonal effects, day of the week (weekday, weekend, or holiday), and sex were included as covariates. Days with missing step count records were excluded from the analysis. A negative binomial distribution was assumed for step counts because of the considerable variability.

Subgroup analysis was performed on changes in step counts stratified by treatment method and cancer type. The definitions of treatment methods and cancer types are described in Tables S2 and S3 in Multimedia Appendix 1, respectively. Statistical analyses including data cleaning were conducted using R version 4.3.1 (R Foundation) with packages *mgcv* (version 1.8-42) and *ggplot2* (version 3.4.2).

Ethical Considerations

The Kyoto University Graduate School and Faculty of Medicine Ethics Committee approved this study (reference R3514). The need to obtain written informed consent from patients was waived because the data were anonymized.

Results

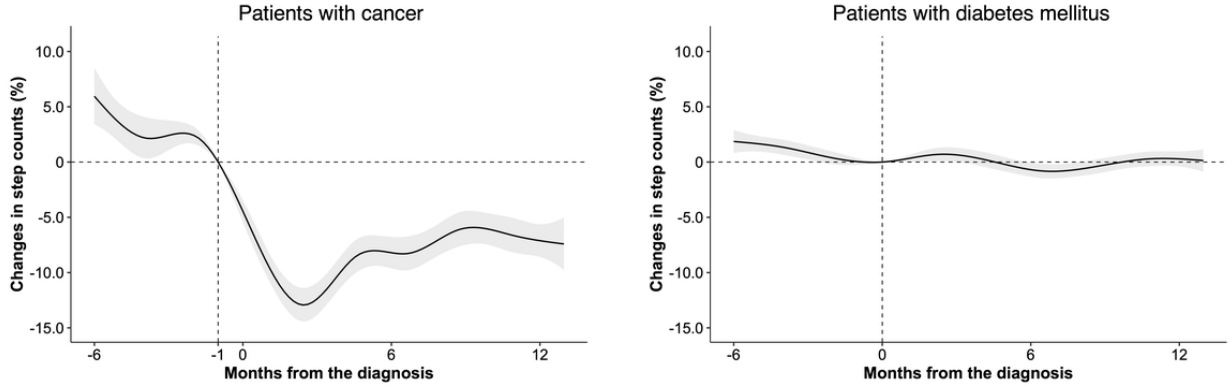
Study Population

A final cohort of 326 patients with malignant solid tumors and 1388 patients with diabetes met the eligibility criteria and were included in the analysis (Figure S1 in Multimedia Appendix 1). Table 1 shows patient characteristics and their respective cancer treatments. The median age of patients with cancer was 51 (IQR 45-56) years, and that of patients with diabetes was 50 (IQR

XSL•FO
RenderX

44-55) years. The median proportion of missing step count days during the observation period was 0.5% (IQR 0.0%-2.1%) among patients with cancer and 0.2% (IQR 0.0%-1.9%) in patients with diabetes. Further data on specific cancer diagnoses and the corresponding treatment for patients with cancer are described in Table S4 in Multimedia Appendix 1.

Table 1. Patient characteristics.



Characteristic	Patients with cancer (n=326)	Patients with diabetes mellitus (n=1388)	*P* values
Age (years), median (IQR)	51 (45-56)	50 (44-55)	.38
Male sex, n (%)	194 (59.5)	1144 (82.4)	<.001
Surgeries, n (%)	207 (63.5)	—[a]	—
Small interventions[b], n (%)	114 (35)	—	—
Radiation, n (%)	67 (20.6)	—	—
Conventional cytotoxic chemotherapies, n (%)	67 (20.6)	—	—
Molecular targeted therapy, n (%)	16 (4.9)	—	—
Immunotherapies, n (%)	3 (0.9)	—	—
Daily step counts for the reference month[c], median (IQR)	5754.9 (4219.2-7283.5)	6210.6 (4339.4-8015.8)	.01
Year of diagnosis, n (%)			
2015	6 (1.8)	49 (3.5)	—

2018	81 (24.8)	324 (23.3)	—
2019	102 (31.3)	414 (29.8)	—
2020	61 (18.7)	260 (18.7)	—

[a]Not applicable

[b]The following procedures were classified as small interventions: cervical conization, diagnostic laparoscopy and thoracoscopy, endometrial curettage, excision of skin tumors, orchiectomy, transurethral resection of bladder tumors, and upper and lower gastrointestinal endoscopic surgeries (mucosal resection, polypectomy, and submucosal dissection).

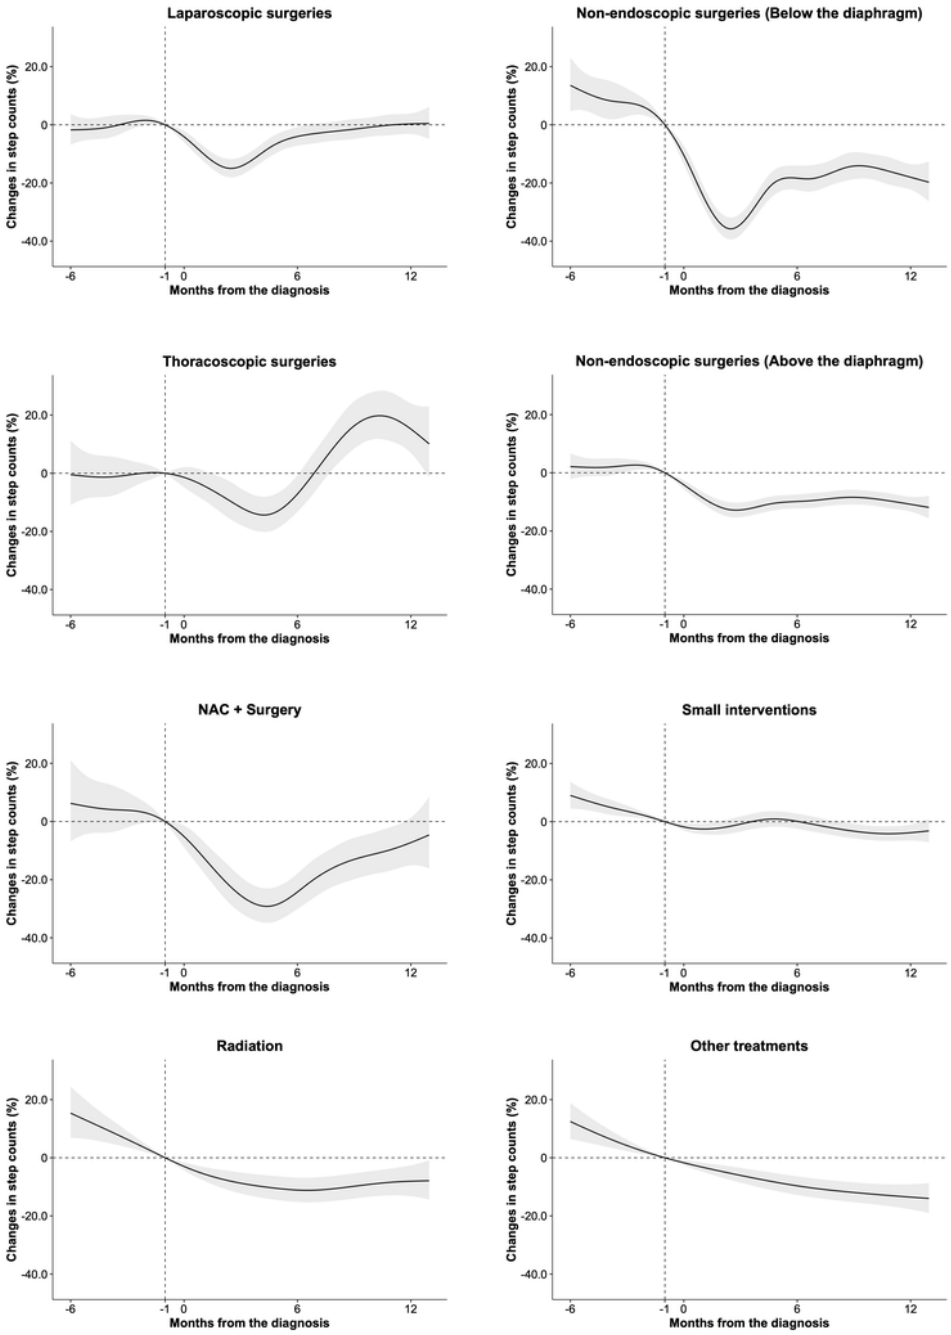
[c]Reference month is month −1 for patients with cancer and month 0 for patients with diabetes mellitus (Figure 1).

Figure 1. Estimated daily step count changes before and after diagnosis. Daily step count changes in (left) patients diagnosed with cancer and (right) patients diagnosed with diabetes mellitus are described. Shading indicates the SE. Month 0 signifies the month of diagnosis. For patients with cancer, the baseline for step count change was defined as the first day of month −1, accounting for the time needed for pathology after biopsy or diagnostic surgery to confirm diagnosis.

Changes in Step Counts

The results of the descriptive analysis of step count data are presented in Figure S2 in Multimedia Appendix 1. Step counts showed no significant difference between patients with cancer and those with diabetes 2 months before diagnosis (*P*=.17) but declined significantly in the former during the diagnosis month (*P*<.001). In subsequent analyses, the baseline for step counts in patients with cancer was therefore set at the beginning of the month before diagnosis. Figure 1 shows the percent change in step counts over time in relation to the time of diagnosis. Patients with cancer showed a 9.6% (95% CI 7.1%-12.1%; *P*<.001) reduction in step counts from baseline in the month of diagnosis, which deepened to 12.4% (95% CI 9.5%-15.2%;

XSL•FO
RenderX



P<.001) at 3 months and persisted at 7.1% (95% CI 4.2%-10.0%; *P*<.001) at 12 months, all relative to baseline. Conversely, in patients with diabetes, step counts remained relatively stable after diagnosis, with a slight upward trend, resulting in a change of +0.6% (95% CI –0.6% to 1.9%; *P*=.31) from baseline at 3 months after diagnosis. The change from baseline at 12 months after diagnosis was not significant (+0.3%, 95% CI –1% to 1.6%; *P*=.68).

Changes in Step Counts According to Treatment Modalities

Figure 2 shows the results of the subgroup analysis stratified by treatment modalities. Patients who received systemic chemotherapy without surgery were classified as the other treatment group because of the limited number of patients. There were no significant changes in the distribution of patient numbers by treatment group across the years (*P*=.69; Table S5 in Multimedia Appendix 1). At 3 months after diagnosis, the reduction in step counts from baseline was 14.3% (95% CI 8.0%-20.1%; *P*<.001) in the laparoscopic surgery group and 34.2% (95% CI 26.6%-41.1%; *P*<.001) in the nonendoscopic subdiaphragmatic surgery group. At 12 months after diagnosis, step counts remained decreased in the nonendoscopic subdiaphragmatic surgery group, with an 18.0% (95% CI 9.1%-26.2%; *P*<.001) reduction, whereas step counts returned to baseline in the laparoscopic surgery group (+0.3%, 95% CI –6.3% to 7.5%; *P*=.93). At 12 months after diagnosis, the nonendoscopic supradiaphragmatic surgery group showed a 10.9% (95% CI 5.7%-15.7%; *P*<.001) step count reduction, whereas this reduction was not seen in the thoracoscopic surgery group, and the step count change was not significant (+15.2%, 95% CI –0.4% to 33.1%; *P*=.06).

XSL•FO
RenderX

Figure 2. Estimated daily step count changes before and after diagnosis by treatment methods: Other treatments include conventional cytotoxic chemotherapy, immunotherapy, molecular targeted therapy, small interventions with chemotherapy or immunotherapy, and chemoradiotherapy. Shading indicates the SE. NAC: neoadjuvant chemotherapy.

Changes in Step Counts According to Cancer Type

Figure S3 and Table S6 in Multimedia Appendix 1 show the results of the subgroup analysis stratified by cancer type. A significant postoperative reduction in step counts was observed in patients with gynecologic cancers, and the majority of them underwent nonendoscopic surgeries (endometrial cancer: 4/5, 80%; cervical cancer: 3/6, 50%; and ovarian cancer: 3/4, 75%). Conversely, in gastrointestinal and urologic cancers, where abdominal surgeries were also performed, the proportion of patients who underwent small interventions or laparoscopic surgeries was high, and the postoperative reduction in step counts was not as pronounced.

Discussion

Principal Findings

The analysis of objective pre- and postdiagnostic lifelog data showed that step counts in patients with cancer decreased with cancer diagnosis and treatment, with step counts already below baseline at the beginning of the diagnosis month and failing to return to baseline 12 months later. Conversely, the change from baseline in those newly diagnosed with diabetes was not significant. The decline in step count varies with treatment and cancer type.

XSL•FO
RenderX

Comparison With Previous Work

To the best of our knowledge, this is the first study to objectively describe the decline in PA levels from precancer diagnosis using lifelog data on step counts. Previous studies that relied on retrospective recall have reported a decline in PA by 59% after treatment of breast cancer [4]. In colorectal cancer, the reduced PA during treatment improved after treatment completion [5]. Our analysis using objective real-world data provides a closer representation of real-life events. In patients with diabetes, while the increase in step counts was not significant, an upward trend was observed after diagnosis, consistent with previous reports [16].

This study showed possible variations in PA measured as step count based on the specific treatment modality used. Treatments for specific cancer types are typically standardized. However, by analyzing patients with varying cancer types, this study explored the impacts of different treatments on step counts. Interestingly, a prominent decrease in step counts was observed in patients who underwent nonendoscopic surgery, suggesting that opting for less invasive surgical approaches may help mitigate the decrease in step counts. However, this result should be carefully interpreted because patients requiring open surgery may have had more advanced stages with worse prognoses or require more intensive treatment. Further examination is needed to assess the long-term impact of surgical approaches on PA.

Measuring PA has become increasingly accessible through the use of smartphones and other wearable devices [8]. Previous studies have been conducted to categorize PA in patients with cancer using these devices. However, no established threshold has been identified [19]. This study adds new insights by focusing on changes in PA, which are recorded as step counts. Step counts serve as a valid and useful surrogate marker of PA, and a decrease in step counts is strongly associated with an increase in all-cause mortality [20,21]. Therefore, conducting close follow-ups on posttreatment PA levels using step counts has the potential to contribute to patient-centered care and personalized recommendations for PA, which remain insufficient [2]. Further studies are needed to address tailoring recommendations for PA during cancer treatment according to cancer type, treatment approach, and comorbidities.

Limitations

This study has some limitations. First, influences beyond cancer diagnosis and treatment, such as aging, societal changes, and changes in smartphone pedometer specifications due to device upgrades or replacements by users, may be involved. However, minimal changes in step counts in the diabetes group indicated a limited impact of these factors. Second, the proportion of patients managed with small interventions was high, indicating that a considerable number of patients were detected at an early stage. This might be because this study included relatively young patients with a median age of 51 (IQR 45-56) years, primarily employees of large businesses and their dependents, who were exclusively Kencom app users, indicative of a potential high health awareness demographic. Therefore, this population may not represent the general Japanese population. However, the decline in step count levels would be more pronounced in patients with a higher prevalence of advanced-stage cancer, who are likely to undergo more invasive treatments [22]. Third, the cancer stage was not determined in this study. However, because treatments are generally determined by cancer stage, results stratified by treatment may have higher generalizability to populations with different cancer stages. Fourth, the follow-up period in this study was 1 year, which did not allow for the analysis of step count data in relation to patient prognosis. PA may improve prognosis in cancer survivors [1,3]. Therefore, further studies are needed to assess its effect on patient prognosis. Finally, step count data may not fully reflect actual PA levels, as its accuracy can be affected by factors, including the possibility that individuals are not always carrying their smartphones.

Conclusions

This study used objective pre- and postdiagnostic step count data and showed that while PA decreased with cancer diagnosis and treatment, the decline may have already started before diagnosis. The decline varies with treatment and cancer type, with a notable decrease in patients who underwent nonlaparoscopic abdominal surgeries. Assessing PA using step count data has the potential to contribute to patient-centered care. This finding may help tailor exercise recommendations based on lifelog data for patients with cancer.

Acknowledgments

This study was conducted as part of a research project selected through an open call by DeSC Healthcare Inc. We would like to thank Enago for the English language review. This research did not receive any funding. The first draft was prepared in Japanese without the use of generative artificial intelligence and was translated into English with the assistance of ChatGPT-4o by OpenAI [23]. Abstract

Background: The APPROACH pilot study explored the feasibility and acceptability of an app (NHS Active 10) with brief, habit-based, behavioral support calls and print materials intended to increase brisk walking in people diagnosed with cancer.

Objective: Following UK Medical Research Council guidelines, this study assessed the implementation of the intervention, examined the mechanisms of impact, and identified contextual factors influencing engagement.

Methods: Adults (aged ≥18 y) with breast, prostate, or colorectal cancer who reported not meeting the UK guidelines for moderate-to-vigorous physical activity (≥150 min/wk) were recruited from a single hospital site in Yorkshire, United Kingdom. They were randomly assigned to the intervention or control (usual care) arm and assessed via quantitative surveys at baseline (time point 0 [T0]) and 3-month follow-up (time point 1 [T1]) and qualitative exit interviews (36/44, 82%) at T1. The process evaluation included intervention participants only (n=44). Implementation was assessed using data from the T1 questionnaire exploring the use of the intervention components. The perceived usefulness of the app, leaflet, and behavioral support call was rated from 0 to 5. Behavioral support calls were recorded, and the fidelity of delivery of 25 planned behavior change techniques was rated from 0 to 5 using an adapted Dreyfus scale. Mechanisms of impact were identified by examining T0 and T1 scores on the Self-Reported Behavioural Automaticity Index and feedback on the leaflet, app, call, and planner in the T1 questionnaire and qualitative interviews. Contextual factors influencing engagement were identified through qualitative interviews.

Results: The implementation of the intervention was successful: 98% (43/44) of the participants received a behavioral support call, 78% (32/41) reported reading the leaflet, 95% (39/41) reported downloading the app, and 83% (34/41) reported using the planners. The mean perceived usefulness of the app was 4.3 (SD 0.8) in participants still using the app at T1 (n=33). Participants rated the leaflet (mean 3.9, SD 0.6) and the behavioral support call (mean 4.1, SD 1) as useful. The intended behavior change techniques in the behavioral support calls were proficiently delivered (overall mean 4.2, SD 1.2). Mechanisms of impact included habit formation, behavioral monitoring, and support and reassurance from the intervention facilitator. Contextual factors impacting engagement included barriers, such as the impact of cancer and its treatment, and facilitators, such as social support.

Conclusions: The APPROACH intervention was successfully implemented and shows promise for increasing brisk walking, potentially through promoting habit formation and enabling self-monitoring. Contextual factors will be important to consider when interpreting outcomes in the larger APPROACH randomized controlled trial.

Introduction

Background

The number of people being diagnosed with cancer is continuing to increase in the United Kingdom, with an estimated 4 million adults living with and beyond cancer (LWBC) by 2030 [1]. Many people LWBC experience challenges related to cancer and its treatment, including increased fatigue, pain, psychological distress, and reduced physical capacity [2-5]. These challenges can significantly impact their quality of life and well-being [6]. Therefore, the importance of improving outcomes for those LWBC is vital [7]. A large body of trial data demonstrates that physical activity (PA) improves many outcomes after a cancer diagnosis, including reduced fatigue, pain, anxiety, depression, and sleep problems and an overall improvement in quality of life [8-11]. Observational data suggest that PA is also associated with improvements in survival [12-14]. In light of this ever-growing evidence base, the World Cancer Research Fund recommends that people LWBC follow the guidelines for healthy populations in achieving at least 150 minutes of moderate-to-vigorous PA (MVPA) per week and recommend limiting the amount of time spent sedentary [15]. Despite this, many people LWBC are physically inactive, with Macmillan Cancer Support (United Kingdom) estimating this to be as high as 80% of those LWBC not meeting recommended PA levels [16]. This is supported by the systematic review of 41 studies conducted by Wong et al [17] that indicated that only around a third of people LWBC were meeting PA guidelines, although this ranged from 16% to 88% across studies. Brisk walking is a form of MVPA that may be more appropriate for people LWBC due to its accessibility and achievability. In a systematic scoping review of 98 studies in people LWBC, walking was cited as the preferred type of PA across all cancer types and treatment stages [18].

The APPROACH Intervention

APPROACH is an app-based, multicomponent intervention informed by extensive development work with individuals with breast, prostate, or colorectal cancer and cancer nurse specialists [19,20]. It focuses on promoting and monitoring brisk walking using a publicly available mobile phone app, alongside brief behavioral support in the form of a specially designed leaflet, walking planner cards, and 2 phone or video calls with a trained researcher (CB) [21]. In line with the Medical Research Council framework for intervention development and evaluation, the pilot trial explored the feasibility and acceptability of conducting a complex PA intervention trial with people LWBC. A total of 90 people diagnosed with breast, prostate, or colorectal cancer were recruited for the pilot randomized controlled trial (RCT), with 49% (n=44) randomly assigned to the intervention group and 51% (n=46) to the control group. APPROACH pilot results demonstrated a high retention rate (97%) and high assessment completion rates (>86%), indicating that the trial procedures were feasible and acceptable to be carried out as intended in a confirmatory, phase-3, larger trial [22]. In addition, results showed that the intervention was delivered successfully with 98% receiving at least 1 behavioral support call and 95% of participants downloading the app [22].

Conducting a Process Evaluation

The importance of conducting process evaluations within RCTs has been emphasized to explore the way in which any complex intervention is implemented [23,24]. This can help uncover why interventions are successful or unsuccessful, determine why they may have unexpected consequences, as well as explore how an intervention that is effective can be optimized [23]. Moore et al [25] provided specific guidance for carrying out process evaluations, which highlighted the importance of exploring the implementation (eg, the fidelity of intervention calls), the mechanisms of impact (eg, views on the different components of the intervention), and the contextual factors influencing use and outcomes (eg, barriers or facilitators to engagement) [25].

Therefore, this paper extends the published APPROACH feasibility results [22] with the following aims: (1) to evaluate the implementation of the APPROACH intervention and the fidelity of the delivery of intended behavior change techniques (BCTs), (2) to identify the potential mechanisms of impact that underlie behavior changes attributed to the APPROACH intervention, and (3) to better understand how contextual factors influence engagement with the APPROACH intervention.

Methods

Design

This was an embedded design, mixed methods study where qualitative and quantitative data were collected simultaneously with equal priority [26]. Data were collected as part of the APPROACH pilot RCT [21,22]. The pilot RCT compared an app-based, brisk walking intervention delivered alongside usual care with a control arm (usual care alone) in people diagnosed with breast, prostate, or colorectal cancer at a single hospital site. The trial was registered on the International Standard Randomized Controlled Trial Number registry on April 16, 2021 (ISRCTN 18063498). The primary outcome for the pilot and future RCT is weekly minutes spent brisk walking (a cadence of 100 steps per min or more [27) measured by an activPAL accelerometer (PAL Technologies Ltd). Following baseline assessments, participants were individually randomly assigned (1:1 allocation) using minimization to either the control or intervention arm, stratified by cancer type (breast, prostate, or colorectal) and disease status (metastatic vs not).

XSL•FO
RenderX

Participants

The pilot RCT included 90 participants: 49% (n=44) in the intervention arm and 51% (n=46) in the control arm. All participants had a confirmed diagnosis of breast, prostate, or colorectal cancer (localized or metastatic). At the point of screening, localized participants had to be within 6 months of completion of radical treatment. This criterion was not applied to participants with metastatic disease. All participants required a clinician's sign-off that their life expectancy was >6 months. All participants self-reported achieving <150 minutes of MVPA weekly. Full inclusion and exclusion criteria have been published previously [21].

Procedure and Description of Intervention

The recruitment procedure and trial data collection have previously been described [21,22]. Participants completed assessments at baseline (time point 0 [T0]) and 3 months (time point 1 [T1]; operationalized as 12-16 wk after randomization). The intervention included an endorsement letter from a member of the participant's clinical team, alongside the provision of a leaflet with information about the importance of PA after cancer and a recommendation and instructions on how to download the freely available NHS Active 10 app. The NHS Active 10 app promotes brisk walking in bouts of 10 minutes, called "Active 10s." This was augmented with 2 behavioral support phone or video calls with the intervention facilitator (CB). The app was chosen after previous qualitative work with people LWBC, and clinicians identified key features that were important to be offered within the app and highlighted the importance of the app being supported by a professional organization, such as the NHS [19,20]. These behavioral support calls were underpinned by habit theory [28] and BCTs shown to be effective in promoting PA [29-31] and involved supporting participants in downloading and using the app and discussions around setting PA goals. The intervention facilitator was trained in the principles of behavior change theories and in the application of BCTs [32], with a thorough understanding of habit theory [33]. This training, alongside previous experience in delivering health behavior change interventions, allowed them to conduct conversations with patients closely mirroring those a health care professional might have with a patient in a routine care situation. The intervention calls took place via Zoom (Zoom Video Communications) [34] or telephone and were recorded by the intervention facilitator with the participants' permission. The first call took place approximately 1 week after randomization, and the second call took place approximately 4 weeks after the first call to check in with the participant about their goals and recap any information required. Participants were asked during the first intervention call if they had downloaded the NHS Active 10 app, and the intervention facilitator noted this in their records. Participants were also given 12 copies of a walking planner card that was designed to enable them to plan how many "Active 10s" they were aiming for and how they were going to achieve these, including where and when they would complete them.

Implementation of the APPROACH Intervention

Delivery of the Intervention

The implementation of the intervention was explored by looking at whether each component was delivered as intended and the participants' use of each intervention component. Between 12 and 16 weeks after randomization participants completed the T1 questionnaire. Participants were asked about the intervention, including the following: whether they downloaded the app (yes or no), their self-reported app use if still using the app (less than monthly, monthly, fortnightly, weekly, 3-4 times a week, almost every day, or every day), how long they used the app for if they had stopped using it (never, once, less than monthly, fortnightly, weekly, 3-4 times per week, almost every day, or every day), perceived accuracy of the app in recording their time spent walking (5-point scale from not accurate to very accurate), whether they read the leaflet (all, some, or did not read), used the walking planner cards (yes or no), and received either behavioral support call (yes or no).

The Usefulness of Intervention Components

Participants rated the usefulness of the call for going through the leaflet information, downloading the app, and thinking about ways to use the app to increase their brisk walking (5-point scale from not at all useful to extremely useful). Using the same scale, they rated the usefulness of the app and sections of the leaflet for supporting their walking.

Delivery Fidelity of Behavioral Support Calls

The recorded intervention calls were coded by 1 researcher (SW) to assess delivery fidelity. All calls were listened to and coded according to a 25-item checklist of BCTs [31] as presented in the study's protocol paper [21]. Each item represented a BCT paired with the intended delivery technique (Multimedia Appendix 1). If a participant received 2 calls, these were combined when coding delivery of the BCT. A 5-point rating scale was applied to the fidelity checklist using an adaptation of the Dreyfus scale [35,36] ranging from low fidelity (0), indicating that the facilitator did not mention the intended BCT at all, to expert (5), indicating that the facilitator delivered the BCT to an exceptional standard (Multimedia Appendix 2). A value of ≥3 represented competent delivery of an individual BCT, thus presenting successful delivery. A second researcher (SS) coded a subset of interviews (n=5). It was agreed that if there was a discrepancy of over 20% in the coding, then the transcript would be discussed among the researchers. This occurred for 1 transcript that was double coded. This iterative process enabled SW to incorporate any learnings from the discussion into the coding of all transcripts and allowed a more consistent coding of the data.

Mechanisms of Impact and Contextual Factors Influencing Engagement

T0 and T1 Questionnaires

Habit strength for walking ("going for a walk" and "walking briskly") was assessed using the Self-Report Behavioural Automaticity Index (SRBAI) [37] in the T0 and T1 questionnaires. Participants responded on a 7-point scale ranging from disagree to agree for 4 statements on their perceived

XSL•FO
RenderX

automaticity of performing the behavior. An average score across items was calculated, representing the level of automaticity for the behavior being measured. Higher average scores indicate stronger habit or greater automaticity [37]. The SRBAI is presented in Multimedia Appendix 3. Mechanisms of impact and contextual factors impacting engagement were also identified by examining responses to the T1 questionnaire about the delivery of intervention components and their perceived usefulness.

Qualitative Interviews

Participants were asked in the initial study consent form if they agreed to be invited to participate in a semistructured interview at the end of the study. After the completion of all other data collection at T1, all participants who agreed were invited to be interviewed. Two members of the research team (SS and FK) carried out the interviews. SS and FK were involved in organizing assessments with participants throughout the pilot RCT. The interviews followed a topic guide exploring trial procedures, and participants were asked to give feedback on the intervention components (Multimedia Appendix 4). Interviews took place over the phone and, with the participants' permission, were audio recorded and transcribed verbatim. Contextual factors were explored in the interviews and were described in terms of barriers and facilitators of engaging with the intervention.

Data Analysis

Implementation of the APPROACH Intervention

The T1 questionnaire responses on intervention components were explored descriptively by calculating percentage frequencies and, where relevant, measures of central tendency. Mean scores were calculated for the delivery of each BCT in the intervention calls as well as an overall mean fidelity score for each call.

Mechanisms of Impact and Contextual Factors Influencing Engagement

The data from the questionnaires and interviews were pooled during interpretation to investigate the mechanisms of impact and contextual factors of intervention engagement. Qualitative and quantitative data were analyzed separately. The SRBAI results from the T0 and T1 questionnaires were explored descriptively using medians and IQRs due to the skewness of the data. The T1 questionnaire responses on intervention components were also used to identify mechanisms of impact.

Three authors (SW, FK, and SS) analyzed the data from the qualitative interviews using reflexive thematic analysis [38,39]. Inductive coding was undertaken, with these codes then used to develop themes, and early and final themes were discussed throughout the coding process among multiple authors (FK, SS, and PL). While initial coding was inductive and focused on identifying commonalities across the transcripts, final theme development was also organized by focusing on the outlined process evaluation aims on exploring the delivery of the intervention, the mediating processes (mechanisms of impact), and the barriers and facilitators to engagement (contextual factors). All interview transcripts were managed in NVivo (version 12; Lumivero) to facilitate analysis and data management.

Data were integrated using a complementarity approach where the interpretation of quantitative and qualitative results together allowed a more holistic interpretation of the findings [40].

Ethical Considerations

This pilot study was approved by the Yorkshire & The Humber-South Yorkshire Research Ethics Committee (21/YH/0029, Health Research Authority and the local hospital. All participants gave informed consent and the data reported are anonymized.

Results

Overview

Table 1 presents the sample characteristics of the 44 participants in the intervention arm. Most (42/44, 95%) of the participants were of White ethnicity, comprising an equal number of male participants (22/44, 50%) and female participants (22/44, 50%), with a mean age of 63 (SD 11; range 40-85) years. Participants had received a diagnosis of breast cancer (18/44, 41%), prostate cancer (18/44, 41%), or colorectal (8/44, 18%) cancer. The CONSORT (Consolidated Standards of Reporting Trials) diagram and the flow of participants through the study have previously been reported [22]. After eligibility screening and assessment of interest in taking part, the study information sheet was sent to 148 patients, and 63% (n=93) consented to participate, with 61% (n=90) being randomized.

Implementation of the APPROACH Intervention

Overview

In total, 2 (5%) of the 44 participants withdrew from the intervention group for reasons unrelated to the intervention (frustration with the accelerometer and increased caring responsibilities). Most (41/42, 98%) participants who remained in the study answered the section of the T1 questionnaire on intervention feedback. Moreover, 1 (2%) of the 42 participants did not complete this section on intervention feedback.

Delivery of the Intervention

Leaflet

In the T1 questionnaire, 78% (32/41) of the intervention participants reported reading the entire intervention leaflet, while 10% (4/41) reported reading some of it, and 12% (5/41) reported not reading it at all. Of those who did not read it at all, 80% (4/5) stated that they did not remember receiving the leaflet, and 20% (1/5) stated that it was not relevant to them.

NHS Active 10 App

At the time of the first behavioral support phone call, the intervention facilitator recorded that 95% (42/44) participants had downloaded the NHS Active 10 app, with 93% (39/42) independently downloading it before the first intervention call and 7% (3/42) downloading it during the call. However, 2% (1/43) of the participants left call 1 not having downloaded it. In the T1 questionnaire, 95% (39/41) of the intervention participants self-reported successfully downloading the app. In total, 5% (2/41) of the participants were not asked about their use of the app as they reported not downloading the app earlier in the questionnaire. Most (33/39, 85%) participants reported still using the app. Of these, 82% (27/33) reported using it "almost every day or every day," and 18% (6/33) reported that they used it "3-4 times per week." A few (5/41, 12%) participants reported using the app during the study but were no longer using it. When asked how long they had used the app, the participants reported using it for "1 week," "2 weeks," "1 month," "2 months," and "3 months." In addition, 2% (1/41) of the participants reported not using the app at all despite downloading it.

Planner Cards

In the T1 questionnaire, 83% (34/41) of the participants reported using the walking planner cards, whereas 17% (7/41) did not, including 1 participant who said they did not receive any cards. Other nonuse was mainly explained in terms of not finding it helpful/not needing to plan (5/41, 12%) or having a more physical job (1/41, 2%). Of those who used the planners, 65% (22/34) reported using the planners for the full 3 months, whereas others reported using them for 2 weeks (4/34, 12%), 1 month (4/34, 12%), or 2 months (4/34, 12%).

The Usefulness of Intervention Components

Overview

The perceived usefulness of the intervention components is presented in Table 2.

XSL•FO
RenderX

Table 2. Perceived usefulness of the APPROACH intervention components (n=41).

Intervention components[a]	Values, mean (SD)	Respondents, n (%)
Behavioral support call	4.1 (1.0)[b]	40[c] (98)
Leaflet sections		
Physical activity and cancer	3.8 (0.9)[b]	36[d] (88)
Walking	4.0 (0.8)[b]	36[d] (88)
Information about Active 10	3.9 (0.8)[b]	36[d] (88)
Instructions on how to download Active 10	4.0 (0.8)[b]	36[d] (88)
Walking habits	4.1 (0.7)[b]	36[d] (88)
Walking websites	3.8 (1.5)[b]	36[d] (88)
Mean usefulness of leaflet sections	3.9 (0.6)[b]	36[d] (88)
App usefulness in participants still using the app	4.3 (0.8)[b]	33[e] (80)
App usefulness in participants who had stopped using the app	2.6 (0.9)[b]	5[e] (12)
App accuracy in participants still using the app	3.9 (1.2)[f]	33[e] (80)
App accuracy in participants who had stopped using the app	2.2 (0.8)[f]	5[e] (12)

[a]The perceived usefulness of the walking planner card was not explored in the time point 1 questionnaire (n=41).

[b]A 5-point scale from not at all useful to extremely useful.

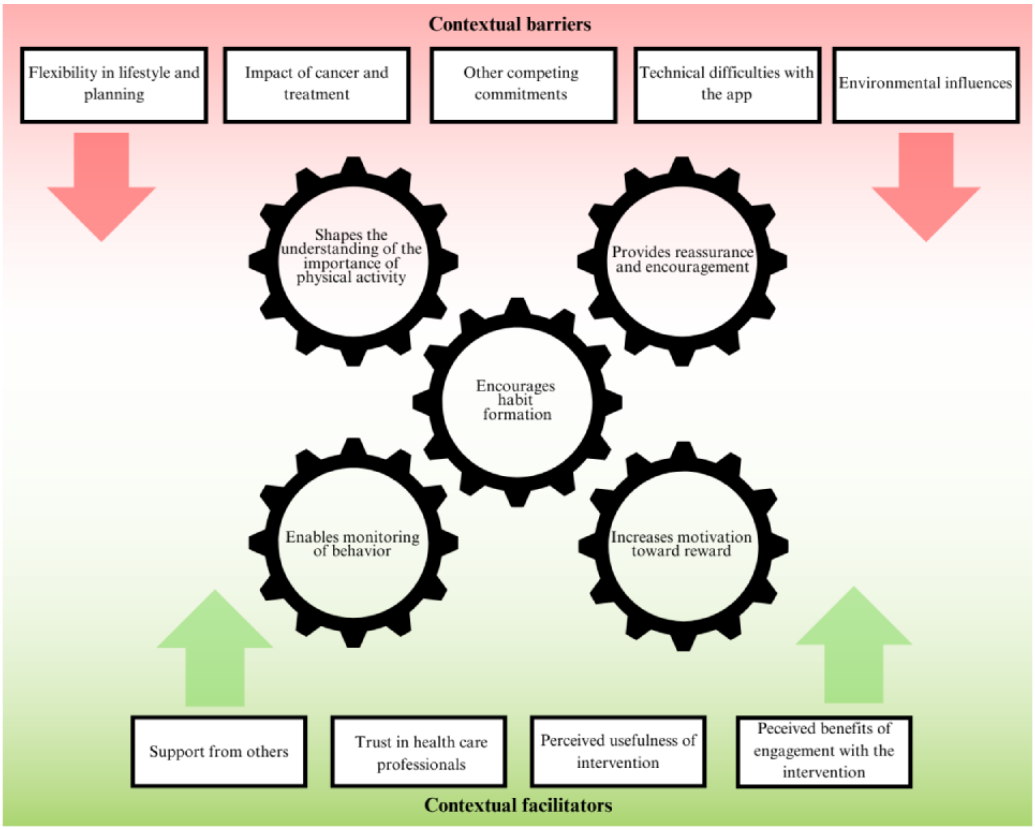
[c]One person reported not receiving a behavioral support call and was not shown this question.

[d]Five people reported that they had not read the leaflet and were not shown these questions.

[e]One participant reported downloading but never using the app to track their walking. Two participants self-reported not downloading the app earlier in the questionnaire. These participants were not shown this question.

[f]A 5-point scale from not accurate to very accurate.

Delivery Fidelity of Behavioral Support Calls



Most (43/44, 98%) of the participants received the first behavioral support call. The mean time from randomization to the first intervention call was 11.6 (SD 9.8; range 5-57) days, and the mean time from randomization to the second intervention call was 39.2 (SD 9.0; range 33-78) days. In total, 31 (72%) of the 43 calls were conducted on Zoom and 12 (28%) via telephone. Most (40/41, 91%) of the participants received the second call. Some (22/40, 55%) of these calls were conducted on Zoom and 45% (18/40) via telephone. In total, 81 intervention calls from 42 participants were included in the analysis (n=42, 52% first calls and n=39, 48% second calls). One intervention participant did not receive any calls, and another participant was removed from the analysis due to a recording issue with the first call, so neither of their calls was included in the fidelity results. The overall mean delivery fidelity score across all BCTs and all participants was 4.2 (SD 1.2), which demonstrates overall proficient delivery. Some (18/25, 72%) of the BCTs had a rating of >4, 16% (4/25) had a rating of 3 to 4, and 12% (3/25) had a rating <3. The BCT called provide information on health consequences had the highest fidelity (4.98). This was followed by action planning (4.90) and habit formation (4.88). The BCT called framing/reframing had the lowest fidelity (1.31). Nonspecific reward (2.71) and nonspecific incentive also displayed low fidelity. The delivery fidelity of each BCT that was intended to be delivered during the calls is presented in Multimedia Appendix 1.

Mechanisms of Impact and Contextual Factors Influencing Engagement

Figure 1 presents the theme diagram showing the identified mechanisms of impact and the contextual barriers and facilitators that affect these mechanisms and intervention engagement.

XSL•FO
RenderX

Figure 1. Theme diagram presenting the identified mechanisms of impact and the contextual barriers and facilitators that affect these mechanisms.

T0 and T1 Questionnaires

All (44/44, 100%) intervention participants completed the SRBAI at baseline. All (42/42, 100%) participants who remained in the study completed the SRBAI at T1. As mentioned earlier, most (41/42, 98%) of the participants who remained in the study answered the section of the T1 questionnaire on intervention feedback.

Qualitative Interviews

Of the 42 participants who remained in the study, 86% (n=36) took part in the qualitative interviews. A few (n=3, 7%) participants did not give a reason for declining to participate, and 2 (5%) participants consented to the interview but then did not respond to the interview invitation. Moreover, 1 (2%) participant did not feel up to taking part in the interview due to illness-related side effects.

Mechanisms of Impact

Identified mechanisms of impact are outlined in the subsequent sections with exemplar quotes indicating the participants' self-identified sex (male or female) and age.

Shapes Understanding of PA and Its Importance

Many participants reported gaining information about brisk walking and its benefits as well as information on how to use the app through the intervention call and the leaflet:

> *...the lady basically went through everything. That was probably the most helpful thing. How to use things and everything.* [Female participant; aged 42 y]

The delivery of comprehensive and meaningful information enhanced participants' understanding of the target behavior and provided them with a clear purpose for implementing it:

> *She went thoroughly through the app with me...Then when she started to explain it, I thought yes, that makes sense.* [Male participant; aged 60 y]

Enables Monitoring of Behavior

Participants reported that having 2 intervention calls was motivating as it helped them to reflect on their progress between the calls:

> *...the follow up call halfway through was touching base and seeing how I was getting on which obviously encouraged me to do it.* [Male participant; aged 73 y]

The feedback on behavior received via the app showing daily, weekly, and monthly minutes of brisk walking was considered effective. Participants reported that they found the tracking feature motivated them to continue their walking efforts:

> *And actually, when I realised I wasn't doing enough, when I felt able to, I extend my walk to get the thirty minutes.* [Female participant; aged 60 y]

Several participants reported using the planner cards to record their walks afterward rather than planning with them upfront. However, this sense of accountability through recording their activity engaged them to keep walking:

> *I wrote down what was on my app, every day, how many minutes walking I did everyday.* [Female participant; aged 62 y]

XSL•FO
RenderX

Increases Motivation Toward Rewards

Many participants reported that the app was the primary intervention component that kept them most motivated and engaged, particularly through the trophies or cups awarded (for every 10 min of brisk walking):

> *I did enjoy getting them cups every day, I thought that were great.* [Female participant; aged 61 y]

Participants often reported walking a few more minutes to achieve the next reward or cup on the app, some even referring to being obsessed or addicted to achieving their goals:

> *...if I get to say 28 minutes, I'll just do the extra two to make it thirty.* [Female participant; aged 49 y]
>
> *30 has been the minimum goal I've gone for. So even if it's not been a nice day or if I'm tired...I still go out...it's addictive.* [Male participant; aged 75 y]

The achievability of these rewards influenced engagement, with several participants reporting exceeding their targets and wishing that more rewards were available:

> *That's another downside, you can't set your goal to any more than three.* [Female participant; aged 61 y]

Participants also reported a sense of satisfaction when being able to tick off completing their walks in their planners:

> *...you can see something, you're achieving something.* [Female participant; aged 47 y]

Encourages Habit Formation

Many participants reported feeling that they had formed habits throughout the intervention period, and this enabled them to establish and maintain their walking and brisk walking habits:

> *It's part of it now, it's part of your day, it's part of your walk so its not I'm going I've got to do this, I've got to do that...It's just a normal day for us going for a walk. And you get back and you think, mmm, I didn't realise I was doing that quick.* [Female participant; aged 65 y]

This is also supported by the SRBAI results for "walking," where total SRBAI scores in the intervention group increased from baseline (mean 4.1, SD 1.6) to T1 (mean 4.7, SD 1.9). Similarly, total SRBAI scores for "brisk walking" in the intervention group increased from baseline (mean 4.0, SD 1.7) to T1 (mean 5.1, SD 1.8).

Providing Reassurance and Encouragement

Many participants recalled how helpful and friendly the facilitator was in the intervention calls:

> *...they were lovely, caring and friendly.* [Female participant; aged 61 y]

This positive rapport helped participants adhere to their brisk walking, and they recalled feeling encouraged and supported throughout the intervention period:

> *...it's useful because it makes you feel as if you're not forgotten.* [Male participant; aged 73 y]

Contextual Factors

The contextual factors influencing engagement are summarized according to barriers and facilitators with exemplar quotes indicating the participants' self-identified sex (male or female) and age.

Barriers

Flexibility in Lifestyle and Planning

Data from the qualitative interviews and the T1 questionnaire indicated that participants felt the planners, in their intended use (to plan walks each week), were not flexible enough and did not fit their lifestyles:

> *...it didn't work for me at all because every day is different.* [Female participant; aged 42 y]

Related to this, some participants suggested making the planners daily, rather than weekly, which would allow more nuanced plans to be made:

> *...it wasn't going to be at the same time every day so it just needed breaking down into a daily thing.* [Female participant; aged 57 y]

The Impact of Cancer and Its Treatment

Several participants reported in the interviews and the T1 questionnaire that their cancer diagnosis and treatment sometimes made it difficult to engage with the intervention:

> *...this was just after my treatment and I was tired a bit.* [Female participant; aged 67 y]
>
> *I couldn't plan, because I was in and out of different appointment times.* [Female participant; aged 57 y]

This was also seen when participants were asked about the appropriateness of the app for people LWBC, with several participants reflecting on how differing experiences may help or hinder engagement:

> *I had some days where I felt like I didn't want to see daylight, not talk to anybody...I think on those bad days I wouldn't have wanted to be bothered with it.* [Female participant; aged 67 y]

Many participants discussed that the appropriateness of the timing of the intervention would be dependent on where the patient was in their cancer care. Although many participants noted that taking part in the intervention during treatment would have been too difficult for them due to the side effects, several also suggested that using the intervention during treatment was suitable as it gave them something else to focus on:

> *No I wouldn't have been able to do it when I was having chemo, I could barely even walk round the garden.* [Female participant; aged 58 y]
>
> *This gave me something else to think about you know something on a daily basis which took me mind off you know that three-week cycle as much as it could.* [Male participant; aged 65 y]

XSL•FO
RenderX

Other Competing Commitments

Several participants reported not having time to walk due to factors, such as having caring responsibilities, working hours, and appointments:

> *...well the kids can't walk with me they have only got little legs, who is going to watch them?* [Female participant; aged 41 y]

Technical Difficulties With the App

In the interviews, several participants reported experiencing difficulties with the recording of walks on the app if there was a lack of signal or due to the phone's positioning. For example, sometimes participants found the recording differed depending on what pocket their phone was in:

> *...if I had it in my trouser pocket by my leg it worked all fine, ok, no problem at all, if I had it in my shirt pocket it didn't register anything.* [Male participant; aged 73 y]

This is supported by the T1 questionnaire results indicating that perceived app accuracy was an issue that likely influenced use and engagement with the app over time:

> *Didn't find the app as accurate as it could be and doubted its recordings on occasions.* [Female participant; aged 41 y]

Environmental Influences

Participants described how the weather played an influential role in their ability and motivation to go on their walks:

> *What it's going to be like when it starts raining and it's really awful weather I don't know.* [Female participant; aged 40 y]

As well as hindering their ability to go out on a walk, some participants also described feeling guilty if they did not go out and walk due to the weather:

> *There were some days where it was absolutely throwing it down outside…and I thought oh no and I really felt guilty that I'd not actually done it.* [Female participant; aged 61 y]

Facilitators

Support From Others

Many participants talked about telling people of their involvement in the trial and their efforts to increase their walking, describing a sense of accountability from sharing the experience with others:

> *...so now it's a case of, "Have you got your minutes in yet dad?" and it, everyone's sort of like joining in with it.* [Male participant; aged 75 y]

In addition, having someone to go on a walk with and even having family members and friends also use the app was described as encouraging and gave participants a sense of comradery in changing their behavior:

> *It made us all as a family go for a walk. It not just helped me with that. It helped all of us.* [Female participant; aged 42 y]

Personal contact from the study team also facilitated engagement, with several participants reporting that they felt supported and that they had the opportunity to get in touch if needed:

> *...it were good to know that somebody you know, I'd phone and they'd take an interest.* [Female participant; aged 61 y]

Trust in Health Care Professionals

Several participants noted that endorsement from their health care professional facilitated their engagement with the intervention and willingness to change their behavior, as their medical team is seen as a credible source of information:

> *So the fact it had come from the doctor made me want to do it even more.* [Female participant; aged 42 y]

Perceived Usefulness of the Intervention

The perceived usefulness of the intervention components appeared to influence engagement in the target behavior, with participants reporting that some components (eg, app) were more helpful than others (eg, planners).

Overall, the behavioral support call was rated as useful (mean 4.1, SD 1; Table 2). In the qualitative interviews, the participants reported finding the calls useful as a source of information and motivation as well as helping them to regain their focus:

> *You know, if you've got an issue you can talk to somebody about it. But also it keeps you motivated.* [Female participant; aged 56 y]

The leaflet was generally rated as useful (mean 3.9, SD 0.6), particularly the sections on "walking," "downloading the app," and "walking habits" (Table 2). The qualitative data suggested that although this was useful for reading initial information about the benefits of brisk walking and particularly for downloading the app, some participants reported limited recollection of the leaflet at the follow-up point:

> *I did have a quick flick through it. And obviously the bit about finding the app.* [Female participant; aged 49 y]

T1 questionnaire results indicated a mean usefulness of 4.1 (SD 1) for the app, but with higher ratings among the 33 participants still using it compared to the 5 who had ceased. Most (28/38, 74%) of the users found it extremely useful or very useful. Participants who reported still using the app reported higher perceived accuracy of the app in recording their time spent walking compared to those not using the app anymore (Table 2). This is supported by the qualitative findings, with participants reporting still using the app and finding it enjoyable to monitor their progress on it:

> *I use it all the time now...I still want to make sure I have got at least two cups.* [Male participant; aged 74 y]

The usefulness of the planner explored in the qualitative interviews highlighted that although the planners were useful to get started and to form habits, their use ceased over time due to factors such as not finding planning as helpful long-term,

XSL•FO
RenderX

finding the app sufficient to motivate them, and just forgetting to use them:

> *I think you need the planner thing for the first week or so but after that I don't think you do.* [Female participant; aged 56 y]

Perceived Benefits of Engagement With the Intervention

Where participants felt they were benefiting from taking part, they reported feeling motivated to continue their brisk walking, reporting feelings of enjoyment, better mood and well-being, and improvements in physical health and fitness:

> *I definitely felt better in myself, there's no question about that. I felt fitter as well.* [Male participant; aged 60 y]

As well as the direct impact of the intervention, many participants also reported feeling more able to engage in activities of daily living, such as going shopping, socializing, and doing housework because of their improved fitness and well-being:

> *I have started going out with more friends...getting out a bit more and feel better and everything.* [Female participant; aged 67 y]

Discussion

Summary of Findings

This study combined data collected as part of the APPROACH pilot RCT to assess the implementation of a multicomponent, app-based behavioral intervention to promote brisk walking in people LWBC. The findings of this process evaluation demonstrated proficient implementation of the intervention and suggest that there are several mechanisms of impact underlying the efficacy of the intervention as well as contextual factors that can be barriers or facilitators to engagement.

Successful Implementation of the APPROACH Intervention

The successful delivery of intervention components and intended BCTs is essential for attributing any changes in behavior to the intervention in question [41]. This study demonstrated proficient implementation, with most participants reporting engagement with the intervention components, including downloading the app, reading the leaflet, receiving the behavioral support call, and using the planners. In addition, fidelity is rarely reported in evaluations of PA interventions [29]. In a systematic review of 21 studies assessing the quality of measuring delivery fidelity in PA interventions, Lambert et al [42] reported considerable heterogeneity in evaluating delivery fidelity. This study reports high delivery fidelity of the intended BCTs in the behavioral support calls [21]. While interventions with only a single intervention facilitator often exhibit higher fidelity, investigating how various intervention facilitators across different contextual settings deliver BCTs is essential for understanding the real-world application and scalability of interventions [43]. Particularly where multiple intervention facilitators are involved in the delivery, future research should consider factors such as personal characteristics and individual context when evaluating intervention delivery [44,45].

The BCTs called information on health consequences, action planning, and habit formation showed the highest fidelity, and these BCTs appear to influence key mechanisms of impact highlighted by participants in the qualitative interviews. Empowering participants with information on why they should go walking and providing them with information about its benefits appeared to enhance their engagement and adherence to their planned walks. The delivery of and engagement with the action planning BCT is promising, as this BCT was shown to be associated with larger effect sizes in a systematic review of 26 studies evaluating BCT effectiveness in PA interventions in adults who are healthy and inactive [29]. This study extends this finding and suggests that this BCT is suitable and appropriate for people LWBC and should be included in future intervention designs with this population. The BCTs that were not successfully delivered included those called nonspecific reward, nonspecific incentive, and framing or reframing. Despite the BCT called nonspecific reward receiving a low fidelity rating in the recorded behavioral support calls, the qualitative interviews suggested that this BCT was effectively covered in other aspects of the intervention, with participants reporting enjoying working toward the rewards and trophies in the NHS Active 10 app. The low delivery fidelity of the BCT called framing/reframing could be attributed to participants' voluntary enrollment in a PA trial. It is likely that they already recognized the importance of PA even without fully recognizing its role in life beyond a cancer diagnosis [46,47].

BCTs Underlying Change

The mechanisms of impact identified by participants in the qualitative interviews and follow-up questionnaire were in line with previous research. For instance, self-monitoring of behavior is one of the most frequently used components in complex PA interventions [48], and multiple systematic reviews have demonstrated its effectiveness in increasing PA that is maintained long-term [49-51]. In this intervention, the NHS Active 10 app allowed participants to track their brisk walking and total walking, and participants reported that being able to see their improvement over time motivated them to continue their behaviors. In a similar pilot RCT using a self-monitoring app alone, Ormel et al [52] reported that participants in the intervention group increased their activity more from baseline to 6 weeks, but this difference was not maintained at 12 weeks. The authors attributed this to a potential loss of novelty and interest in the app. Although not powered to detect differences in PA, the findings of this study suggest that the second behavioral support call was important in continuing encouragement of monitoring of behavior and reviewing of goals, with participants describing a sense of accountability with the later call. This feedback indicates that a light-touch intervention call to check in with participants can be beneficial in consolidating commitment to PA goals in people LWBC. While technology can help reduce resource demands, future research should consider the benefits of a low-burden behavioral support call to augment an app as an already powerful and scalable intervention component.

Participants extensively discussed the app as the driving component of the intervention, supporting our previous reports of high engagement with the NHS Active 10 app [22]. The

XSL•FO
RenderX

discussions revealed that another mechanism underlying behavior change in this context was the ability of the app to increase motivation toward reward using gamification techniques [53]. The performance of the desired behavior (brisk walking) was reinforced by the positive feelings of encouragement and dedication resulting from these cups and trophies in the app.

Encouraging Habit Formation

The APPROACH intervention was informed by habit theory [21], and the identification of habit formation as a mechanism of impact in both the qualitative interviews and questionnaire data demonstrates that this BCT was delivered effectively in the intervention. Participants reported that the leaflet, app, behavioral support call, and planners helped to establish sustainable walking habits. Gardner et al [54] define habit formation as "learning cue–behaviour associations, that when cued, automatically generate action impulses." This sense of automaticity was described by participants in the qualitative interviews, whereby consistent repetition of their walking daily led to the enactment of brisk walking. This meant that they engaged in brisk walking even during activities that previously would not have involved this exercise intensity. These findings are also supported by the increased SRBAI results from baseline to follow-up, which showed an increase in the initiation of walks as well as the way walking was executed (ie, briskly) [55]. The importance of encouraging long-term engagement in PA after the intervention period is highlighted in systematic reviews of PA maintenance in cancer populations that report only modest improvements at longer follow-up time points [30,56]. The results of this study endorse the integration of habit theory into future interventions aimed at increasing PA to overcome the challenge of sustaining behavioral changes over time [56].

To reinforce the idea of habit, the walking planner cards were designed to promote habit formation, facilitate planning, and prompt participants to engage in PA [21,54]. However, both questionnaire data and interview data showed that the structured design of the planner cards was not compatible with the day-to-day changing schedules and lifestyles of some participants, highlighting the importance of conducting this process evaluation to account for and reconsider this contextual aspect of the intervention and future similar interventions. The need for flexibility in lifestyle and planning was reported as a barrier by participants and further confirmed by the reflections of the intervention facilitator (CB) after discussing their use with participants.

Barriers to Engagement: Cancer Impact and Competing Commitments

Other contextual barriers included the impact of cancer and its treatment, having other competing commitments, technical difficulties with the app, and environmental influences. The side effects of cancer and its treatment have previously been identified as a key barrier to PA participation in systematic reviews [18] as well as in our own preparatory work for this pilot RCT [19]. Participants in this study reported that the impact of cancer and its treatment inhibited their ability to engage in some elements of the intervention due to different physiological, structural, and psychological factors. Cancer-related fatigue is the most reported symptom in people LWBC who have undergone treatment with prevalence estimates of up to 90% of those treated with radiotherapy and 80% of those treated with chemotherapy [57,58]. In this study, participants discussed fatigue symptoms and felt that engaging with the intervention during treatment would have been difficult. Beyond this physiological barrier, the structural barrier of having any appointments for their cancer care also reduced their ability to engage with some components, including the planner card, as there were many hospital appointments that they had to attend and plan around. We have previously reported on the perceived suitability of the timing of the APPROACH intervention, with most participants feeling that it was reasonable [22]. While some participants felt that engaging during treatment would be difficult, others felt that it was useful to have something else to focus on and have control over [22]. Previous reviews in this area have also reported discrepancies in the preferred timing of PA intervention delivery within the cancer care pathway [18,59]. Involvement in PA at an earlier stage has been associated with improved treatment response, tolerance, and quality of life [13,60,61]. Considering, the delivery of the APPROACH intervention during and after the treatment for cancer is still endorsed while recognizing the contextual barriers, such as this, when interpreting APPROACH intervention outcomes. These findings highlight the importance of involving patient perspectives in future intervention design with this population, with the acknowledgment that different stages of the treatment pathway can facilitate or inhibit PA participation and should be accounted for when assessing intervention delivery and engagement.

Driving Engagement: Support, Trust, and Perceived Benefits

Facilitators to engagement included having support from others, trust in health care professionals, the perceived usefulness of the intervention, and the perceived benefits of engagement with the intervention. The BCTs called social support (practical) and social support (emotional) were competently delivered in line with the protocol [21,31]. Accordingly, participants recognized how having support from others, such as family members and partners, enhanced their engagement with the intervention and how they felt supported by the intervention facilitator. Social support has previously been identified as highly important in PA engagement [62], with reasons, such as accountability, being cited as helping to facilitate and promote engagement [63]. In our preparatory work for this RCT, trust in health care professionals emerged as a crucial factor influencing engagement [19], and this was highlighted again in this study, where incorporating an endorsement letter from the clinical care team enhanced app credibility.

Limitations

Limitations of this study include that only 1 intervention facilitator delivered all behavioral support calls, which may explain the high-fidelity ratings. It is crucial to consider the transferability of the intervention across individuals, particularly when envisioning integration into routine NHS care [20,22]. In addition, there may be some recall bias influencing results, as most of the questionnaire data were collected at the 3-month

XSL•FO
RenderX

follow-up [64]. Participants may have had difficulty in answering questions on earlier components (eg, leaflet information) compared to components they were still using (eg, app). Due to the pilot nature of this study, where feasibility and acceptability were the main outcomes of interest, we were unable to examine how engagement with each intervention component influenced the primary outcome of brisk walking. For future research, the application of the Multiphase Optimization Strategy with a factorial design could offer more insights into how differing engagement with each component can impact the main outcomes and help inform intervention optimization for larger efficacy RCTs [65,66]. Finally, despite its recognition as a potential mechanism, it is difficult to assess how the intervention helps to establish longer-term habits, which are key for PA maintenance [67], as this pilot RCT only examined outcomes at 3 months.

Conclusions

This study extends our previously published findings on the APPROACH pilot RCT [22] by demonstrating that the intervention was delivered as intended with high levels of engagement from participants. In addition, this paper highlighted the potential mechanisms through which change occurs, such as habit formation and behavioral monitoring, which are in line with the intended BCTs used in this intervention. The process evaluation also highlighted important contextual factors to consider when progressing to the APPROACH main trial, including facilitators, such as social support, which played a significant role in promoting adherence to the intervention. The protocol for the definitive RCT will report on adaptations made to APPROACH based on the feedback gathered in this study. This process evaluation provides strong support for the progression to the stage-3, definitive RCT to evaluate the effectiveness of the APPROACH intervention (began in November 2023) and enables a more nuanced understanding of how the APPROACH intervention works and the contextual factors to consider with implementation.

Acknowledgments

The authors would like to thank Yorkshire Cancer Research for funding this pilot study and the participants for dedicating the time to participate and complete the assessments. They also thank the extended APPROACH team members Rithu Anand and Gaby Heuchan for their help with carrying out trial tasks.

Abstract

Background: Outpatient treatments, including targeted therapies, in oncology are on the rise. The implementation of remote patient monitoring (RPM) between therapy sessions has the potential to enhance patient care and therapy outcomes in the future.

Objective: This pilot study assessed the feasibility of a new, app-based RPM system (bwHealthApp) by capturing patient-reported outcomes (PROs) and vital parameters using a wrist- or in-ear wearable. The study examined adherence, acceptance, and satisfaction, as well as the differences between the two types of wearables.

Methods: Outpatients with gastrointestinal cancer receiving systemic therapies were invited to use and evaluate the bwHealthApp system for 1 month. The system was set up as an Android smartphone app to assess electronic PROs (ePROs) and connect to wearables for continuous vital sign measurements. A wrist wearable (Beurer AS99) that measured activity and heart rate or an in-ear wearable (Cosinuss Two) that measured heart rate, oxygen saturation, and temperature was used. The data were synchronized remotely to a web client. Outpatients were randomly assigned to the wrist wearable (n=17) or in-ear wearable (n=14) group. At the beginning, middle, and end of the study, patients (N=31) completed questionnaires on various feasibility aspects. Adherence to ePRO completion; wearable use, acceptance, and satisfaction; wearable data quantity and quality; and differences between the wearables were evaluated.

Results: The mean adherence to bwHealthApp including dropouts was 46% (449/971 days) for ePRO completion and 61% (593/971 days) for wearable use. The system was most frequently used during everyday activities. More than half of the participants were satisfied with bwHealthApp (18/30, 60%) and could imagine continued use (21/30, 70%). Notably, 70% (21/30) rated the system as easy to use. Participants recorded more than 20 million wearable measures; however, 29% (SD 22%, range 3%-76%) of temperature values and 33% (SD 25%, range 10%-92%) of oxygen saturation values were outside the physiological range. For heart rate, the mean proportion of excluded values was 10% (SD 11%, range 4%-48%; in-ear) and 11% (SD 8%, range 4%-33%; wrist). The frequency of use of the two wearables did not differ significantly (t_{29}=1.81; P=.08). The wrist wearable scored significantly better than the in-ear wearable regarding wearing comfort (t_{28}=−11.17; P=.03).

Conclusions: This bwHealthApp pilot study demonstrates the feasibility of RPM via a mobile app and wearable devices during outpatient systemic cancer therapy, including targeted therapies. The adherence level was moderate, and patients were generally satisfied with the system, although the wrist wearable received a higher rating. The system's functionality may be enhanced through the integration of additional wearables. This pilot study serves as a foundational framework for long-term assessments examining RPM and clinical data to improve cancer treatments.

Introduction

Systemic cancer therapies are frequently used in the outpatient setting. Personalized biomarker-based treatment strategies lead to increasingly individualized therapy regimens, which pose new challenges for patient monitoring, especially if therapy sessions are several weeks apart.

Missing monitoring may lead to late detection of treatment failure, adverse drug effects, and worsening of an outpatient's condition. In addition, recall bias may result in incorrect patient information. Therefore, subjective assessments should be supplemented by objective measures of vital parameters that show associations with the treatment.

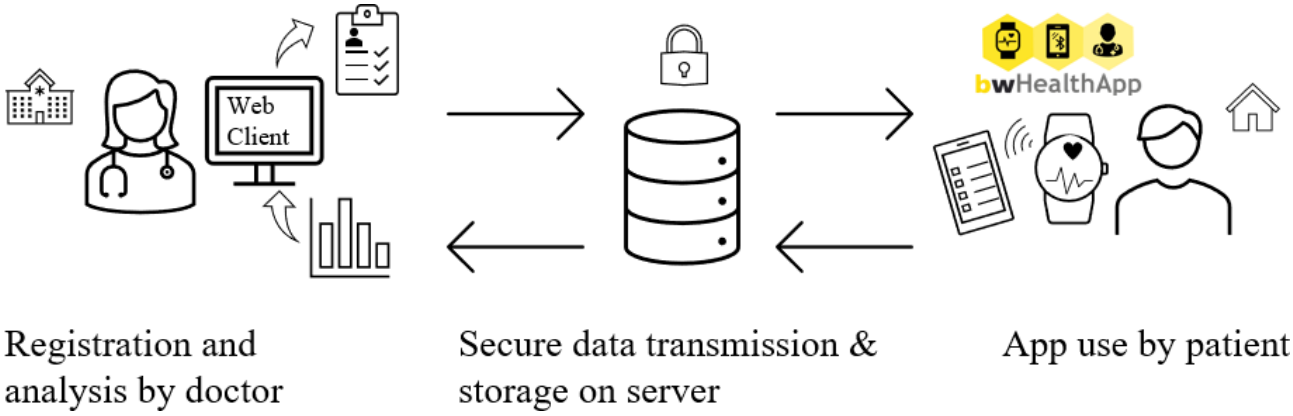
The resulting monitoring gap and bias can be addressed by remote patient monitoring (RPM), in which patient assessments are transmitted electronically, for example, via mobile apps. Objective sensor measurements complement the subjective data and provide important real-world data (RWD). RWD are derived from various sources, such as electronic patient-reported outcomes (ePROs) and sensor measurements [1], and are associated with outcomes in heterogeneous outpatient populations in real-world settings. In precision oncology cohorts, RWD play a pivotal role and represent a data repository for future improvement of patient care and therapy by detecting serious side effects as well as potential therapy failure at an early stage [2].

Precision medicine has an important impact on outpatient treatment regimens for prevalent disease entities such as gastrointestinal cancers [3]. For example, adenocarcinomas of the stomach and esophagogastric junction are treated with the checkpoint inhibitor nivolumab [4]. Unlike conventional chemotherapeutic agents, precision medicine drugs target the molecular structure of the tumor. Immunotherapy may lead to immune-related adverse events, such as autoimmune pneumonitis, which can be detected by monitoring oxygen saturation and ePROs (such as dyspnea) [5]. Other parameters are also important for monitoring purposes; for example, body temperature can be used to detect chemotherapy-induced neutropenia.

Monitoring requires technology. Although both smartphones and fitness trackers are well established in society, it remains uncertain whether their use in the medical field will be accepted. Currently, there are no guidelines on RPM in the context of personalized cancer therapy. Previous studies show that physical activity is the most frequently examined factor. Physical activity can be increased by wearing fitness trackers and is associated with improved quality of life and lower mortality [6,7]. Physically inactive patients are more likely to be hospitalized [8]. Thus, measuring physical activity is important for disease and treatment monitoring. Physical activity is typically measured with wearable wristbands, which have been the focus in previous RPM studies on patients with cancer [9,10]. Other types of wearables such as in-ear sensors have not been assessed in this context. These offer the advantage that the body temperature and oxygen saturation are continuously recorded. However, potential differences in the use and acceptance of the two wearable systems (wrist and in-ear), especially in critically ill patients, have not yet been examined.

Numerous nonmedical wearable devices are available on the market. It has not been established whether they can be used to obtain clinically usable data that are correlated with cancer progression indicators such as laboratory results or staging. In future, these could be used to detect, for example, early signs of a condition worsening, which could be validated in the clinic. The vision is that patients will connect personal wearables to a monitoring system and provide low-threshold data for monitoring. This approach is expected to improve adherence and economic outcomes in the future and enable rapid adaptation to technical innovations in wearables.

For this purpose, a new RPM system—bwHealthApp—was created with ePROs and connected commercial wrist and in-ear wearables. Prior to analyzing correlations with clinical progression indicators, a pilot feasibility study was conducted. This pilot study aimed to test bwHealthApp for feasibility in patients with late-stage cancer. Feasibility in this context focuses on acceptability, adherence, use rates, and satisfaction. Moreover, the study aimed to analyze the differences in use and satisfaction between a wrist wearable and an in-ear wearable.



Methods

Design

This study was a prospective feasibility pilot study using bwHealthApp to record information on health status (via ePROs), vital and activity parameters via wearables worn on the wrist or in the ear (Figure 1). The study period involved 3-5 systemic therapy cycles, leading to a duration of 3-8 weeks, depending on the therapy regimen. Surveys on bwHealthApp were conducted over 3 visits at the hospital. The outcomes were descriptive adherence to ePRO completion and wearable use as well as self-reported (technology) acceptance of and satisfaction with the bwHealthApp system. Participants were randomly assigned to the wrist or in-ear wearable. The outcomes were the descriptive quality of sensor measurements and significance of the difference in use variables and satisfaction.

XSL•FO
RenderX

Figure 1. Study procedure for using the bwHealthApp software platform with the web client.

Participants

Thirty-two outpatients of a gastrointestinal-oncological unit at the University Hospital Tübingen were recruited in consultation with their oncologist between July and October 2022. The sample size was calculated for the feasibility analysis. Due to the variation in wearable type and the first-time use of the system, it was expected that the differences between the self-perceived use rates at the beginning and end of the study between the two types of wearables would be medium (partial $\eta^2 \geq 0.06$; n=34) to strong (partial $\eta^2 \geq 0.14$; n=16) using repeated measures ANOVA (power 0.8; $\alpha = .05$; calculated using G*Power [11]). A sample size of 34 was considered sufficient. During the planned recruitment period, 32 patients were willing to participate. Women and men older than 18 years with a histologically confirmed gastrointestinal malignancy and receiving systemic therapy were included in the study. The exclusion criteria were preexisting diseases associated with restricted mobility and preexisting conditions that make it unfeasible to operate a smartphone app. First, 100 eligible patients were informed about the study by an MD student. Patients interested in participating received an information flyer. At the next treatment session, the patients stated whether they agreed to participate. After informed consent was obtained, participants were randomly assigned to two groups by drawing a paper lot marked with a group code: the wrist wearable group (Beurer AS99; n=18) or in-ear wearable group (Cosinuss Two; n=14). In total, 20 participants used the app on their own Android smartphone, and 12 were provided with a smartphone (Samsung A70) due to the absence of an iOS version of the app at the time.

Procedure

Outpatients were asked to use the bwHealthApp system as much as possible to evaluate the use in everyday life between therapy sessions. The app could be accessed with anonymized login credentials, starting at the dashboard (Figure 2). The app sent push notifications as reminders to complete the ePROs and use the wearables. Through bwHealthApp, health status was assessed daily using 10 items, whereas quality of life was assessed weekly using 30 items. At the same time, commercial wearables for the continuous measurement of activity and vital signs could be connected to bwHealthApp via Bluetooth Low Energy. bwHealthApp saved the values on the smartphone and sent them to a server when connected to the internet, as previously described [12]. The data could be viewed almost in real time, with a delay of only a few minutes.

User-friendliness, satisfaction, and acceptance of bwHealthApp were assessed using a paper-and-pencil survey at the beginning and end of the study. In the intervening period, a short interview was conducted. These sessions were scheduled at the same time as the patients' respective treatment sessions at the clinic, resulting in different schedules due to various therapy regimens. The midpoint interview was conducted 2-4 weeks after the initial survey, and the final survey was conducted 4-8 weeks after the initial survey. Moreover, digital competence was assessed at the beginning of the study. The Technology Usage Inventory (TUI) [13] was completed before and after using bwHealthApp.

XSL•FO
RenderX

Figure 2. User interface of the bwHealthApp dashboard when using the in-ear wearable during the pilot study.

Outcomes

Adherence

Prior to using the bwHealthApp system, the expected self-perceived use rate was evaluated on a 6-point scale (1="not weekly" to 6="continuously daily"), as well as use scenarios (sleep, everyday activities, physical activities, illness, others; multiple answers possible). At the end of the study, the same scales were used to assess the use rate. Objectively, adherence was assessed on the basis of the actual use of the wearables or ePROs sent. The use rate was calculated as the proportion of days of bwHealthApp use during the study period. Adherence to digital systems depends on whether users can understand and operate them. Digital skills and previous experience, which play a key role in adherence, were assessed to characterize the sample. At the beginning of the study, knowledge of and previous experience with wearables was examined. Digital competence was assessed on the basis of the Digital Competence (DigiKom) questionnaire [14] using the domains of knowledge and skills [15]. Participants were asked whether they had access to smartphones, computers, and tablets; how often the devices were used; and how they rated the handling of the devices. To assess the use of digital devices, the participants were asked to rate 8 statements on a 5-point Likert scale (1="I do not agree at all" to 5="I fully agree").

Acceptance and Satisfaction

At the beginning and end of the study, satisfaction, convenience of use, and wearing comfort were assessed on a 5-point Likert scale (1="I do not agree at all" to 5="I fully agree"). Technology-specific and psychological factors—important for the acceptance of new technologies—were examined using the TUI [13], which assesses curiosity, anxiety, interest, user-friendliness, usability, and skepticism on a 7-point scale. The TUI also measures the intention to use.

Wearable Data

Each participant was equipped with a commercially released wearable: the Beurer AS 99 Pulse wristband or the Cosinuss Two in-ear wearable. The selection of wearables was based on the price range and the location of the manufacturers in Germany, which simplified communication with the manufacturers for wearable–app integration. Furthermore, both wearables operate according to open Bluetooth standards, which allow data to be accessible without the data being sent to a manufacturer's server. The wrist wearable was worn on the nondominant hand and measured heart rate; sleep duration (manually derived); and activity parameters such as daily step count, distance, activity time, and calories burned. The in-ear sensor measured heart rate, body temperature, and oxygen saturation.

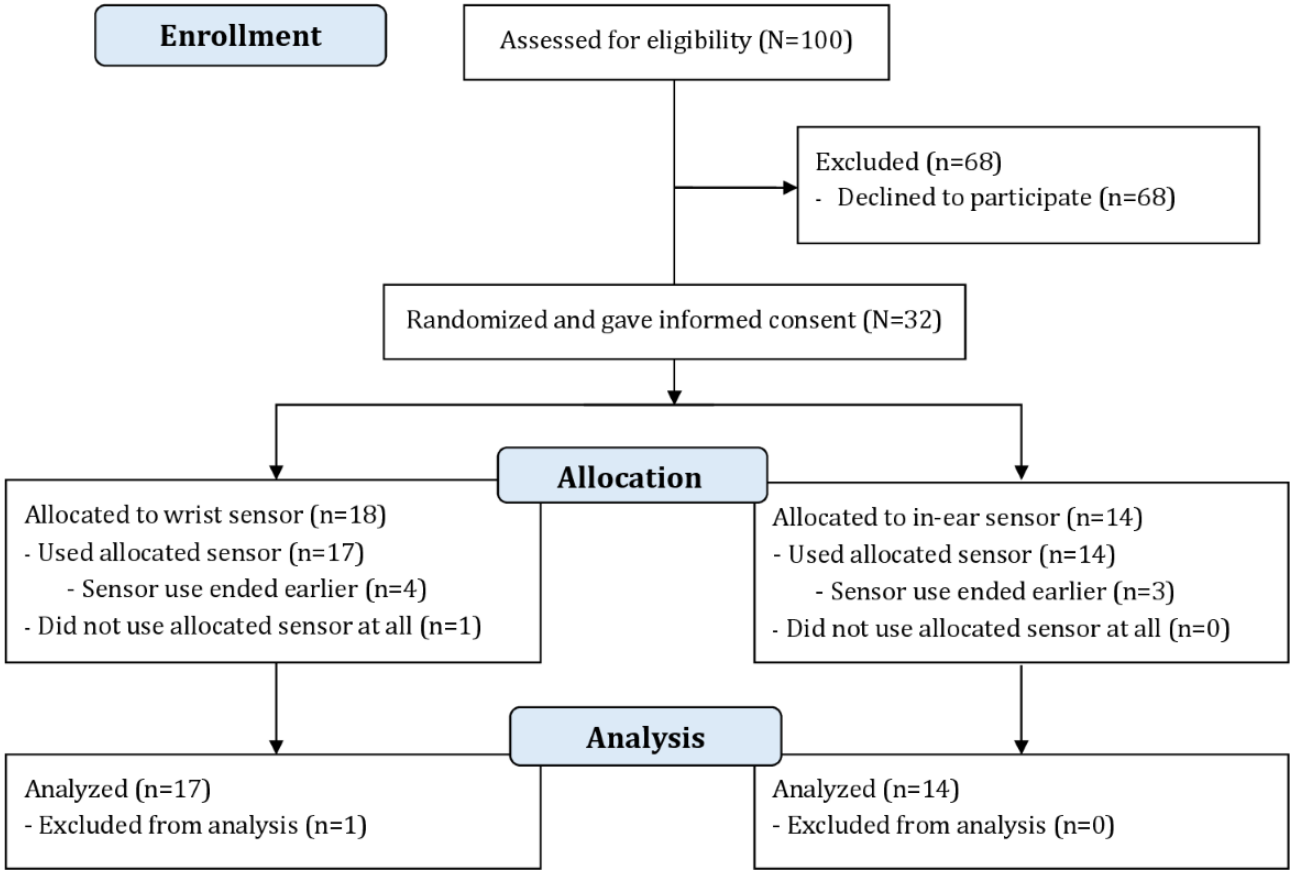
Data Processing and Analyses

The data collected via bwHealthApp could be visualized and exported via a web client. These data were used to calculate the number of days on which wearables and ePROs were used. Vital measures outside the physiologically feasible range were excluded from the analysis. The proportion of excluded data was used as a data quality measure. The included values were as follows: heart rate 35-250 beats per minute, temperature 34-42 °C, and oxygen saturation above 84%. The file showed

XSL•FO
RenderX

the remaining raw data and daily average values of the vital parameters as well as daily sum values of the activity parameters. Paper-and-pencil surveys were digitized and analyzed in SPSS (version 28; IBM Corp). Missing values were excluded from analysis. Most of the presented statistics are descriptive and were used to assess general feasibility. After ensuring that the statistical assumptions were met, between-group *t* tests (2-tailed) were performed for independent groups (wrist and in-ear wearables).

Ethical Considerations



Ethical approval for the pilot study was obtained from the University of Tübingen Ethics Committee (046/2022BO1). All participants provided informed consent. The data reported are anonymized. The participants were not compensated for their participation.

Results

Study Sample

As Figure 3 shows, 32 outpatients participated in the study between July and November 2022 (17/31, 55% male; mean age 59.3 y, range 39 - 74 y). One patient did not record data and was excluded from analysis. Of the remaining 31 outpatients, 6 ended data collection earlier due to handling issues with the provided phone (n=4) or disease progression (n=2). Additionally, 1 outpatient did not complete the final paper-based questionnaire. In total, 17 patients received the wrist wearable, whereas 14 used the in-ear wearable (Table 1). Of the 31 patients, 10 (32%) were being treated for esophageal or gastric cancer, 9 (29%) for colorectal cancer, 6 (19%) for biliary cancer, 4 (13%) for pancreatic cancer, and 2 (7%) for liver cancer. In 29 of 31 patients, the primary tumor had already metastasized. In total, 17 types of treatment strategies were used: of the 31 participants, 23 (74%) were being treated with systemic chemotherapeutic agents as monotherapy or combination therapy, 11 (35%) with targeted therapy, and 12 (39%) with immunotherapy.

Immunotherapy	7 (41.2)	5 (35.7)

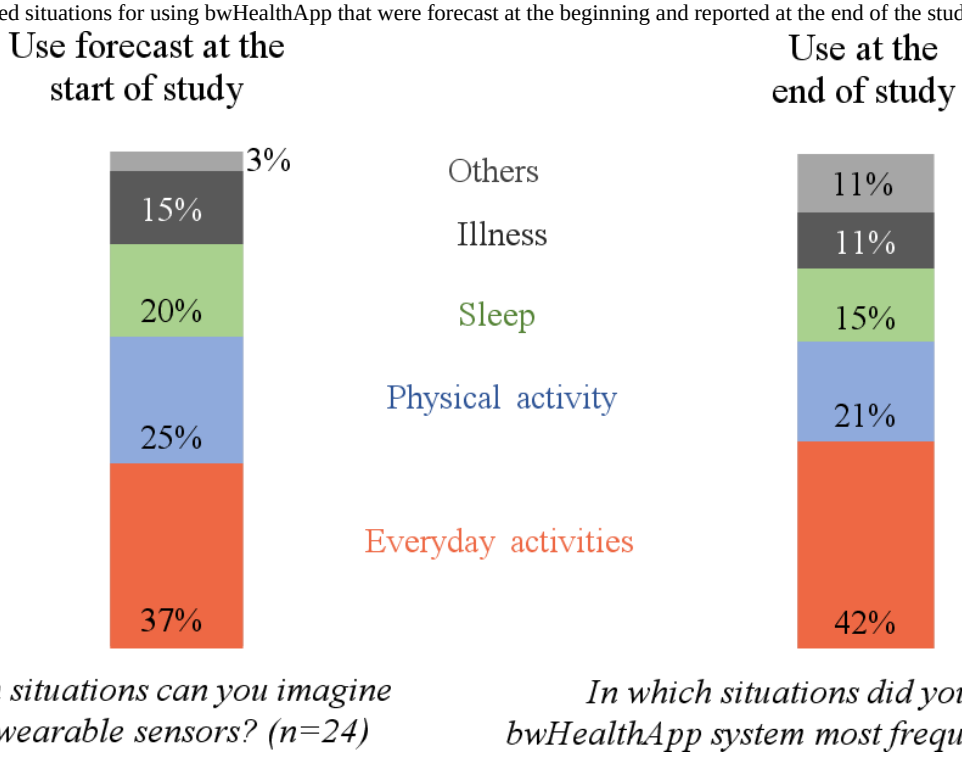
[a]As either monotherapy or combination therapy.

Adherence

Study participation averaged 31 (SD 10.4) days. ePROs were sent on 46% (449/971) of the days, and the wearable was connected on 61% (593/971) of the days [16]. Participants reported a total of 571 ePROs in bwHealthApp, with an average of 18 (SD 14) ePROs per participant.

At the beginning of the study, 73% (23/31) of the participants stated that they intended to use bwHealthApp daily. At the end of the study, 54% (16/30) reported daily use of bwHealthApp. In fact, 17% (5/31) of the participants used the bwHealthApp system every day.

During the analysis, an explorative finding indicated that on the basis of use behavior, the participants could be divided into heavy (n=18) and light users (n=13)—participants who used the app for more and less than 50% of the study duration, respectively. Notably, 77% (10/13) of light users used a study smartphone, whereas for heavy users, this percentage was 11% (2/18).



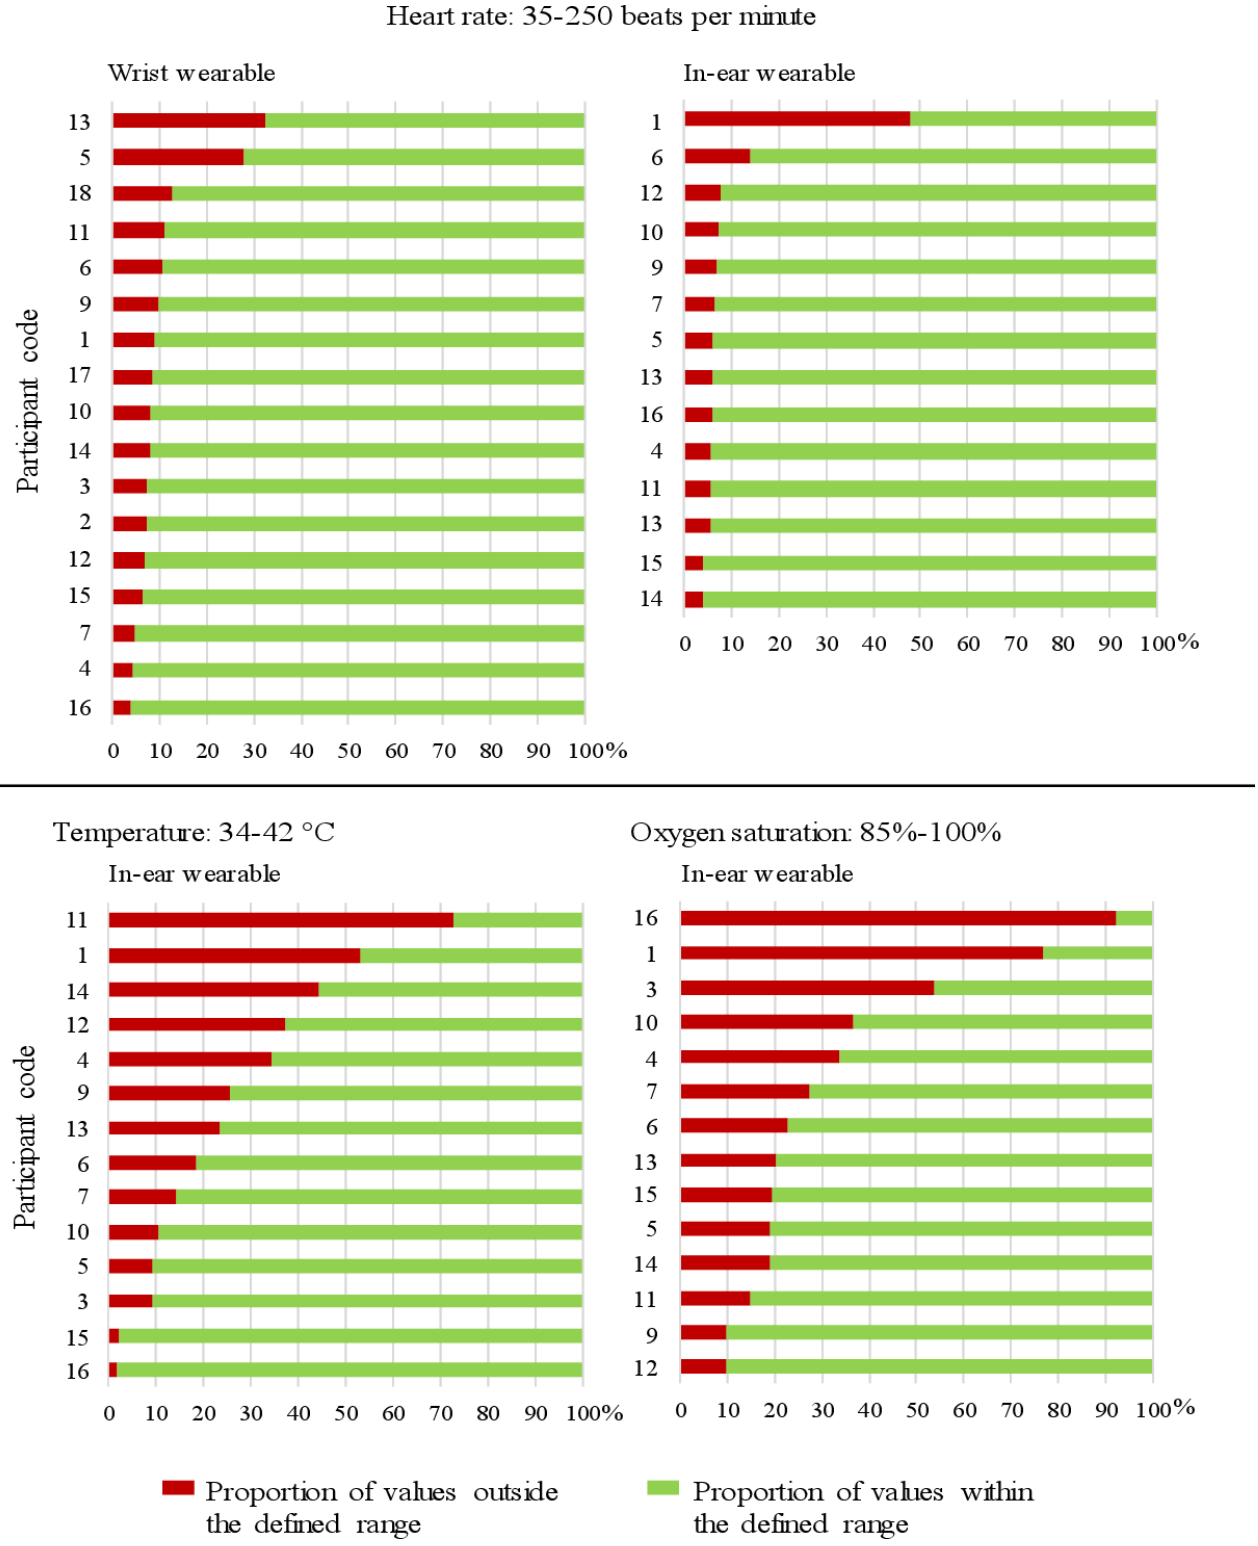
The participants' average digital competence score based on their self-reported skills was 30.78 (SD 11.19) points, where the maximum achievable score was 40. Notably, 20 participants were already familiar with wearables, mostly from their own environment (13/20, 65%). Eleven patients already used a wearable in their daily lives. The main reason given for not having used wearables previously was the lack of need. In terms of technology acceptance, the bwHealthApp system was rated highest on the scales of usefulness (mean 7.78, SD 1.59) and curiosity (mean 6.30, SD 1.93). Skepticism toward the new technology was low (mean 3.77, SD 1.94).

Acceptance and Satisfaction

At the end of the study, 60% (18/30) of the participants were satisfied with bwHealthApp. Moreover, 70% (21/30) reported that they were willing to continue using the app. No participant rated the use of wearables for medical purposes as unsuitable, and 70% (21/30) rated the system as easy to use. bwHealthApp was most frequently used during everyday and physical activities (Figure 4).

XSL•FO
RenderX

Figure 4. Preferred situations for using bwHealthApp that were forecast at the beginning and reported at the end of the study.



Wearable Data

Data Quantity and Quality

Of 20,067,891 wearable measure points, an average of 543,528 (SD 462,028) heart rate data points and 1725 (SD 1109) activity parameter data points were collected per participant. For the in-ear sensor, the average number of data points collected for heart rate, temperature, and oxygen saturation was 327,559 (SD 450,404), 355,764 (SD 476,509), and 88,005 (SD 13,631), respectively. On average, 11% (SD 8%, range 4%-33%, wrist) and 10% (SD 11%, range 4%-48%, in-ear) of the heart rate values were outside the physiological range and were considered nonsense data (Figure 5). Notably, 29% (SD 22%, range 3%-76%) and 33% (SD 25%, range 10%-92%) of the data points for temperature and oxygen saturation, respectively, were excluded. According to bwHealthApp data, the nightly sleep duration ranged from 1 to 755 minutes; the median (IQR) was 255 (36-399) minutes, corresponding to 4 hours of sleep. The sleep function was activated on 139 of the total 380 days on which the wrist wearable was used by all participants.

XSL•FO
RenderX

Figure 5. Visualization of the proportion of excluded values of heart rate (wrist-, in-ear wearable) as well as temperature and oxygen saturation (in-ear wearable) per participant. Heart rate measurement from wrist wearable and in-ear wearable; temperature and oxygen saturation measurements from in-ear wearable only.

Wearable Differences

Table 2 and Table 3 show the results of the analysis of differences between the two wearable groups. The expected use rates reported at the beginning of the study differed significantly from the postuse self-assessment depending on wearable type (Table 2). Wrist wearable users (preuse: mean 5.43, SD 0.85; postuse: mean 4.86, SD 1.35) reported more frequent use than in-ear wearable users (preuse: mean 3.54, SD 1.71; postuse: mean 3.23, SD 1.79). Objectively, bwHealthApp use (in days), in terms of wearable use and ePRO completion did not differ significantly between the two groups (Table 3). Descriptively, the use of the wristband was higher. The wrist and in-ear wearables differed significantly in wearing comfort, with a higher rating for the wristband. Overall satisfaction showed no significant difference between the two wearable groups.

XSL•FO
RenderX

Table . Results of the repeated measures ANOVA with within-subjects factors to test for differences between the wrist and in-ear wearable groups for self-perceived use rates at the beginning and end of the study. Self-perceived use rates were based on a scale of 1 (lowest) to 6 (highest) at various measurement time points (beginning and end of the study) for each wearable group (wrist or in-ear wearable).

Discussion

Principal Findings

This pilot study examined the feasibility of an RPM system (bwHealthApp) incorporating ePROs and two types of wearables (wrist and in-ear) for outpatients with gastrointestinal cancer undergoing systemic therapy. A heterogeneous sample of patients, including dropouts, showed an adherence rate of 61%. Descriptively, perceived use was higher than the actual use. The system was primarily used during everyday activities. One possible influencing factor on the frequency of use of the app could be the use of one's own smartphone or an additional one. Despite the overall high digital competence, the dropout rate was descriptively higher among participants using a study smartphone. Nevertheless, most participants were satisfied with bwHealthApp and were willing to continue using this RPM system. Participants exhibited low skepticism about this new technology. The use of bwHealthApp by the participants enabled the collection of hundreds of ePROs and millions of wearable data points.

The two wearables showed differences. On average, one-third of the in-ear temperature and oxygen saturation values were outside the physiological range. In contrast, this proportion was approximately 10% for heart rate. The sleep function of the wrist wearable was activated on fewer than half of the days it was used. Overall, the wristband performed better than the in-ear wearable. The results showed subjectively and descriptively better adherence and a significantly higher wearing comfort.

Comparison to Prior Work

The findings of this study contribute to the growing field of RPM. It emphasizes the significance of technical solutions and their assessment in feasibility studies, with the vision of enhancing outpatient cancer therapy.

Patients with advanced cancer and a mean age of 59 years demonstrated a high level of digital competence and acceptance of technology. This finding lends further credence to the prevailing assumption that individuals older than 55 years seldom encounter challenges in using wearable technology [17]. The participants used bwHealthApp on average on 60% of the study days [16]. This level of adherence is comparable with previous RPM studies [18-20]. However, given that as many as 50% of participants were excluded from previous studies, adherence to bwHealthApp may be higher [10,21]. The observed use rate was lower than that estimated by the participants at the beginning of the study. One potential explanation for this phenomenon is that users overestimated themselves, as has been reported for physical activity [22]. The app was assessed as a beneficial tool, a conclusion that is corroborated by previous findings in related oncology disciplines [23,24]. The accuracy of the health data was not assured, especially for the in-ear sensor. A considerable percentage of body temperature and oxygen saturation values was found to be outside the physiological range. This suggests that, in contrast to previous studies, a field survey of biosignals in the ear canal may not be feasible [25]. It is not clear if medical devices would be a more reliable source of data in this case. It is generally assumed that an accurate measurement, particularly of heart rate and step

XSL•FO
RenderX

count, is feasible with other forms of wearable technology [26-29]. Despite the necessity of filtering the heart rate values, the proportion of excluded data points was consistent with the range observed with other wearables that have been reported to achieve acceptable measurement accuracy [30]. The better performance of the wrist wearable may provide a rationale for the widespread use of such devices within RPM systems [31,32].

Strengths and Limitations

The study protocol was executed in accordance with existing treatment regimens. However, the integration of the study into the the participants' treatment plans resulted in varying study periods and clinical measurement intervals. This may have influenced the evaluation of the bwHealthApp system. However, these issues also arise when bwHealthApp is used routinely, as data cannot be collected from all patients at the same time. In addition, the study period was limited to a few therapy cycles. However, treatments often last for years. Future research should evaluate the use of the app over a longer period.

The heterogeneous sample of patients with advanced cancer met the study's objective of obtaining feedback on the system from a wide array of users. However, it is important to note that influencing factors cannot be kept constant in this approach, and the generalizability of the findings is limited. A potential limitation to consider is the possibility that the study participants were predominantly technophiles, potentially skewing the results toward individuals with higher digital competence. In future studies, a sample with a similar treatment regimen should be investigated, if possible with a higher degree of personalized therapy. Furthermore, an analysis of correlations between the bwHealthApp data and clinical data may provide insights for improving treatment benefit.

During the study, participants who were non-Android users were provided with Android smartphones, which may have affected the frequency of use and the evaluation of user-friendliness and acceptance of bwHealthApp. The development of an iOS version of bwHealthApp is planned. Furthermore, adherence may have been underreported in the Results section. Despite wearable use, functionality errors in bwHealthApp may result in the absence of data recording, which may be attributed to factors such as Bluetooth deactivation. In the future, it will be necessary to determine whether other wearables offer superior functionality. Further analysis of factors influencing wearable use is necessary, as the high standard deviation suggests interindividual differences.

In certain instances, validated questionnaires were not used due to their extensive number of items. The implementation of daily questionnaires and in-clinic surveys presented a potential challenge, as it could potentially overwhelm patients, leading to a decline in response rate or changes in response behavior. Nevertheless, the data collected in this pilot study provide validation and a baseline for the scales in future studies.

The technology used in this study is not considered a form of medical device. To interpret the reported values, the patients need to be examined by medical staff. As these values are displayed in bwHealthApp, the limited informative value of the single measures needs to be communicated to participants. Regarding the wearable-reported values, the method by which these are calculated from the sensor raw data remains unclear. For enhanced research quality, it is crucial that the manufacturers provide comprehensive and transparent information. In a related manner, all Bluetooth-supported wearable devices should possess the capability to query the data via a system such as bwHealthApp.

Sleep duration was manually configured on the wrist-wearable device. The use of a sensor model capable of determining sleep would be an advancement. The implementation of the in-ear wearable was likely hindered by the challenges posed by the COVID-19 pandemic. The use of a face mask may have contributed to a decline in comfort levels and adherence, which may have contributed to the observed interindividual variability in the quality of values measured by the in-ear wearable.

Despite its limitations, this pilot study makes a substantial contribution to the development of bwHealthApp in the field of personalized oncology.

Future Directions

The results highlight the importance of conducting feasibility studies with new RPM systems. Due to the rapid pace of research and development in this field, it is necessary to continuously develop RPM systems. bwHealthApp offers the possibility of connecting additional wearables. Classic wearables with an extension of biosignals are one option. However, implantable sensors in the port or tumor tissue, which do not require adherence to device use, are also viable options, as gastrointestinal tumors, in particular, are easily accessible by endoscopy. In any case, close cooperation between the medical and technical informatics disciplines is required. This also applies to data analysis, as there are millions of data points available. The use of artificial intelligence should be considered. Future research should analyze the data collected from a homogeneous patient group in a long-term study and examine their correlations with clinical data such as staging data and laboratory values, with the aim of improving outpatient cancer therapy. In this context, future studies should also investigate the clinical process integration and assess the acceptance of RPM by medical staff.

Conclusions

This pilot study on the bwHealthApp system demonstrates the feasibility and acceptance of continuous monitoring via a mobile app and wearables during outpatients' systemic cancer therapy, including targeted therapies. Patients with advanced cancer were able to use the RPM system. They found it acceptable and were generally satisfied with bwHealthApp. The wearable type was an important aspect due to differences between the two devices. This emphasizes the need for further technological development and integration through a flexible system such as the bwHealthApp system.

The collected RWD can be used to further personalize the therapy and care of patients with cancer. The next step is to analyze the app data and clinical data using artificial intelligence. With sufficient data, predictors may be developed to support an automated alert system, offering new possibilities for outpatient cancer treatment.

Abstract

Background: Long-term breast cancer survivors often continue to experience physical and psychological sequelae, despite being cancer-free; these challenges can negatively impact their quality of life and self-efficacy. Mobile health interventions constitute a promising strategy for providing personalized support. However, the feasibility and acceptability of these tools in long-term breast cancer survivors have not yet been sufficiently explored.

Objective: This study aimed to evaluate the feasibility and acceptability of the CUMACA-M, a digital health app designed to improve the quality of life and self-efficacy in long-term breast cancer survivors.

Methods: A single-arm feasibility pilot study was conducted with pre- and post-intervention evaluations. Participants were recruited from the Navarra Breast Cancer Association (Saray), a nonprofit organization supporting individuals with breast cancer in Navarra, Spain. The inclusion criteria included being female, being aged ≥18 years, having been diagnosed with breast cancer, and being disease-free for at least 5 years after primary treatment. The participants used the CUMACA-M app for 3 months. Feasibility was assessed through recruitment and completion rates, whereas acceptability was measured using the System Usability Scale and open-ended qualitative questions. Changes in quality of life and self-efficacy were analyzed with the Quality of Life-Cancer Survivors (QOL-CS) scale and the Self-Efficacy to Manage Chronic Disease Scale. Paired *t* tests were performed for pre-post comparisons.

Results: A total of 23 women (mean age =52.8, SD 6.1 years) participated, with a 100% retention rate. The System Usability Scale score (mean 80.8, SD 15.2) indicated excellent usability. The health advice module received the highest level of satisfaction, whereas the nutrition and physical activity modules received suggestions for improvement. With respect to the clinical outcomes, no statistically significant differences were found between the pre- and post-intervention scores on the QOL-CS (total score: pre=5.96, SD 1.08; post=5.72, SD 1.20; *P*=.07) or the Self-Efficacy to Manage Chronic Disease Scale (total score: pre=6.57, SD 1.90; post=6.26, SD 1.82; *P*=.40). However, a reduction was observed in the QOL-CS spiritual well-being subscale (pre=5.35, SD 1.13; post=4.93, SD 1.22; *P*=.05).

Conclusions: As a pioneering digital intervention for long-term breast cancer survivors, CUMACA-M appears to be a potentially viable and acceptable intervention for this population, as suggested by the high level of usability and absence of dropouts. However, the findings should be interpreted with caution because of the limited sample size and the short follow-up period. The lack of significant changes in quality of life or self-efficacy may be influenced by these constraints. Future studies with larger, more diverse samples and longer follow-up periods are needed to more robustly assess the long-term impact of this intervention.

Introduction

Breast cancer is the second most diagnosed cancer worldwide, with 2,296,340 new cases in 2022, surpassed only by lung cancer [1]. In the same year, breast cancer caused 666,103 deaths, making it the fourth leading cause of cancer death worldwide [1].

Despite the high incidence, advances in early detection, surgical techniques, and personalized treatments have contributed to reducing mortality from breast cancer and reaching net survival

XSL•FO
RenderX

rates close to 90% at 5 years and 80% at 10 years [2-5]. However, despite advances in treatments and increased long-term survival, breast cancer survivors often continue to express needs that are not covered by health services [6,7]. In many cases, treatments lead to persistent side effects and late effects, such as lymphedema, cardiotoxicity, cognitive impairment, pain, and fatigue, which affect survivors' quality of life (QOL) [8-10]. Moreover, emotional problems such as depression, anxiety, and fear of recurrence are common [10-12]. In this context, the digital transformation of health care is gaining increasing relevance because the use of information and communication technologies in the sector allows new forms of access and monitoring for patients with complex needs [13].

The COVID-19 pandemic has accelerated these new realities in access to health services, such as telehealth and telemedicine, from any point and at any distance [13]. Thus, the use of information and communication technologies in health or digital health technologies (eHealth) is proposed as an innovative strategy for improving aspects, such as barriers due to distance, time, and cost, in addition to being a great advantage for allowing access to many patients at the same time and at any time and place [13,14].

Within the field of eHealth, mobile health—which refers to the use of mobile devices, such as smartphones, tablets, smartwatches, and other wireless devices, to support medical and public health practices—is notable [15]. These devices offer multiple functionalities, including telephone calls, sending and playing multimedia content, access to the internet, and support for computer apps, making it easier for patients to self-manage their disease [15].

Numerous digital health interventions have been implemented [16]. However, the evidence of the benefits of these interventions in cancer survivors remains limited [17], with some exceptions of studies that have demonstrated its effectiveness in improving psychological aspects, QOL, and self-efficacy [16-18]. At the international level, successful experiences with personalized digital interventions have been documented. For example, in the Netherlands, a program that provided psychosocial support and promoted healthy lifestyles among patients who had completed primary treatments (eg, surgery, chemotherapy, or radiotherapy) between 1 and 12 months after diagnosis was developed [19]. However, despite advances in this field, mobile health tools designed specifically for breast cancer survivors remain narrow in scope, as evidenced by a systematic review highlighting the scarcity of mobile apps tailored to individual needs [20]. In addition, studies focusing on the population of long-term cancer survivors, that is, people who are free of the disease for at least 5 years from the end of their treatment, are still scarce [21,22].

This study aimed to assess the feasibility and acceptability of the mobile app CUMACA-M (acronym for Care Beyond Breast Cancer, in Spanish), a digital intervention based on artificial intelligence algorithms, to improve the QOL and self-efficacy of long-term breast cancer survivors.

Methods

Overview

This study is a part of a larger clinical trial [23] that uses the methodological framework of the Medical Research Council for the evaluation of complex interventions [24,25]. The Medical Research Council framework consists of four phases: development (phase I), feasibility and piloting (phase II), implementation (phase III), and evaluation (phase IV). This research will focus on phase II or exploratory trials to evaluate the acceptability and feasibility of the CUMACA-M intervention.

Design

This feasibility study involved a single-arm pilot study with pre- and post-interventions [26]. The study protocol followed the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) guidelines and was registered at ClinicalTrial.gov on April 11, 2022 (NCT05322460).

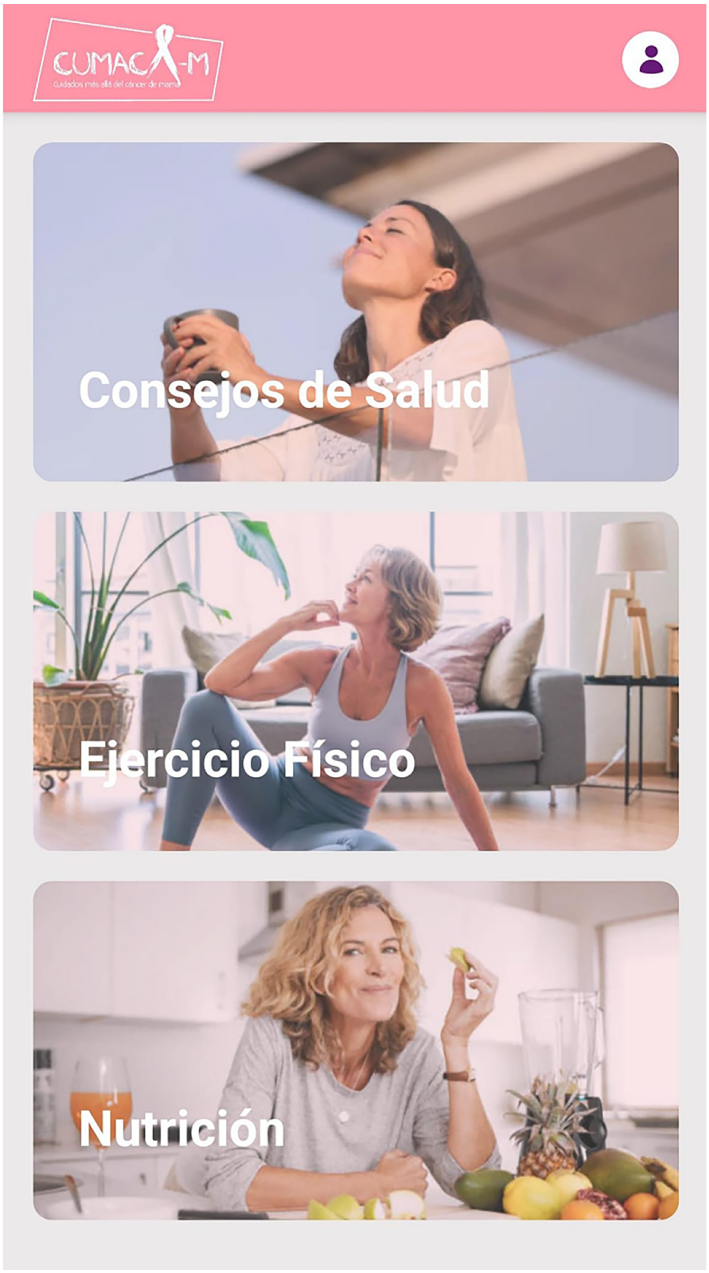
Participants and Settings

Convenience sampling was conducted during the month of June 2024 among women belonging to the Navarra Breast Cancer Association (Saray), a nonprofit organization supporting individuals with breast cancer in Navarra, Spain. The study invitation was disseminated by Saray through its email newsletter and social media platforms (eg, Facebook and Instagram) and during in-person support group meetings. Women interested in participating were invited to contact the research team via email or telephone, with contact details provided in the invitation. Once contact was established, the research team shared detailed study information, confirmed eligibility, and scheduled the informed consent process.

The inclusion criteria were as follows: (1) being a woman, (2) being aged >18 years, (3) having been diagnosed with breast cancer, (4) having completed active cancer treatments (ie, surgery, chemotherapy, immunotherapy, or radiotherapy) in a period of more than 5 years, (5) being free of disease at the time of data collection, (6) having the ability to use the internet, and (7) having a smartphone. The exclusion criteria were as follows: (1) having a diagnosis of cancer other than breast cancer, (2) having a recurrence of cancer or metastasis for which a new treatment was needed, and (3) being actively treated for recurrence or new cancer.

CUMACA-M Intervention

This app was developed within the context of the Spanish project titled *CUMACA-M Project: Personalized digital intervention for long-term breast cancer survivors* with the aim of improving the QOL and self-efficacy of long-term breast cancer survivors [23].



A user-centered design was proposed with a simple and easy-to-navigate interface that required prior registration via email. Artificial intelligence algorithms were incorporated, so the functionalities of the app—including the main modules—could be customized (Table 1); Figure 1). In addition, the app included a notification system with motivational messages.

XSL•FO
RenderX

Table . Description of the main modules of the CUMACA-M app.

Modules	Functionality
Consejos de salud	Health recommendations: This addressed 22 key categories for long-term breast cancer survivors, including anxiety, wellness, cardiotoxicity, exercise, body image, menopause, nutrition, and sexual health, among others. It provides expert-validated health tips available in text, video, podcast, and infographic.
Ejercicio físico	Physical exercise: A personalized training program was presented. The exercises to be performed, and the duration and the repetitions were explained, accompanied by different videos that demonstrated the execution of the different exercises. The app seamlessly integrated with wearable devices for continuous data collection. This module was programmed based on the main international guidelines for physical exercise, physical activity, and health [27,28].
Nutrición	Nutrition: Personalized daily menus were planned. This module was programmed following international recommendations [29,30].

RenderX

Variables and Measurements

The dependent variables analyzed were as follows:

QOL was assessed using the Quality of Life–Cancer Survivors (QOL-CS) scale, originally developed by Ferrell et al [31]. For this study, the validated Spanish version of the instrument was used. The QOL-CS consists of 41 items encompassing four domains: physical well-being (8 items), psychological well-being (18 items), social well-being (8 items), and spiritual well-being (7 items). Each item is rated on a 10-point Likert scale, where 1 indicates extremely poor QOL and 10 represents excellent QOL. The scale has demonstrated high internal consistency, with a global Cronbach α of .93. The α coefficients for the subscales were .77 for physical well-being, .89 for psychological well-being, .81 for social well-being, and .71 for spiritual well-being [31].

Self-efficacy in the management of cancer sequelae was evaluated with the Spanish version of the Self-Efficacy to Manage Chronic Disease Scale (SEMCD-S). This scale consists of 4 items that measure the confidence of individuals in their ability to handle various aspects related to chronic diseases [32]. Each item is scored on a 10-point Likert scale, where 1 indicates "not at all sure" and 10 "totally sure." The SEMCD-S has high internal consistency, with Cronbach α coefficients ranging from .88 to .95, indicating excellent reliability [32,33].

Moreover, the participants' sociodemographic data (eg, age, sex, marital status, educational level, employment status) and clinical data (eg, stage of breast cancer at diagnosis, type of treatment(s) received, time elapsed since the end of active cancer treatment, recurrences, and comorbidities) were collected at the beginning of the intervention, using an ad hoc questionnaire.

The usability of the mobile app was evaluated at 3 months using the System Usability Scale (SUS) [34], the most widely used instrument for measuring the perceived usability of digital products and services [35]. It consists of 10 items on a Likert scale, ranging from 1 ("totally disagree") to 5 ("totally agree") and has shown high reliability and validity in various studies [36].

The total score ranges from 0 to 100, where higher values indicate better usability. A score of 68 points is considered an average user experience, whereas 78.9 points or more represents excellent usability and 51.7 points or less indicates a poor experience [37]. The Spanish version has shown good content validity (0.92) and easy understanding (face validity of 0.94), with a Cronbach α of .812, reflecting adequate internal consistency [38]. The participants also answered 3 open questions about their experience with the app, their perception of use, and possible improvements.

Feasibility was defined as the proportion of participants who were successfully recruited and who completed both the baseline and follow-up assessments (ie, the QOL-CS and SEMCD-S questionnaires) [39,40]. Acceptability was assessed through usability (SUS) and participants' responses to 3 open-ended questions about their experience.

Sample Size

The sample size was estimated following the rules established by Whitehead et al [41] for calculating the sample size of pilot studies on the basis of the minimum desirable effect of 0.075 (standardized difference in QOL), with a standard deviation of 0.18 predicted for the randomized clinical trial. Thus, considering that the SD of this effect (in terms of the QOL variable) was of small intensity ($0.1 \leq d < 0.3$) and that the desired power was 80%, the number of subjects to be recruited was 20.

Data Procedure

Before the CUMACA-M mobile app was used, it was presented, and its use was reported in an initial session. In this session, the participants signed an informed consent form, downloaded the app, registered (with the username and password), and provided an instruction manual. All individuals who attended this session agreed to participate and signed the informed consent form; no refusals occurred at this stage.

Through the app itself, the data were collected through 2 electronic questionnaires in SurveyMonkey. The first collected sociodemographic and clinical information, whereas the second evaluated QOL (QOL-CS) and self-efficacy in disease management (SEMCD-S). The questionnaires were completed in 2 phases, that is, a preintervention phase (baseline) and a postintervention phase, which were carried out at 3 months. For follow-up, a WhatsApp (Meta Platforms, Inc., Menlo Park, CA, USA) distribution list was created, through which an electronic questionnaire was sent at the end of this period. This included the evaluation of QOL-CS, SEMCD-S, and SUS, in addition to open questions about the experience of using the app: "What are your experiences using the app during the study?," "How did you perceive the use of the app?," and "Do you have any suggestions to improve the app?"

Data Analysis

The data were analyzed using descriptive statistical analysis for quantitative variables (mean and SD) and for qualitative variables (frequencies and percentages). To analyze the changes in the variables QOL and self-efficacy in cancer management before and after using the app, a Student *t* test was used for related samples. All the analyses used a level of statistical significance of $P<.05$. The data were analyzed with SPSS (version 27.0; SPSS Inc, Chicago, IL, USA).

In addition, a content analysis was carried out for the open questions about the experience of the participants with the use of the app. All responses were transcribed verbatim into a spreadsheet. An expert in qualitative methods read the texts to gain an overall understanding and identified meaningful units of text, which were coded and organized into three categories: experiences with the app, perceptions of its utility, and suggestions for improvement. The research team then reviewed these categories and their content, reaching consensus on their relevance and accuracy in representing participants' perspectives. Finally, representative quotations were selected to illustrate each category.

Ethical Considerations

This research project complied with the ethical principles established by the Declaration of Helsinki. This study was approved by the Ethics, Animal Experimentation, and Biosafety Committee of the Public University of Navarre (PI-2021/18). Written informed consent was obtained from each participant before the study began. Participants were informed about the objectives of the research, the procedures involved, their right to withdraw at any time without consequences, and the measures taken to ensure confidentiality and data protection.

All data collected were anonymized before the analysis to protect participants' privacy and confidentiality. No personally identifiable information was retained, and data were stored securely in password-protected files accessible only to the research team.

Participants did not receive monetary compensation for their participation. However, they were provided with detailed information about the study and its potential benefits, and their voluntary involvement was appreciated.

Results

Twenty-three women, with a mean age of 52.8 (SD 6.1) years and a range between 42 and 61 years, participated. None of the participants withdrew from the study. Most of the participants were married (16/23, 70%), had university studies (15/23, 65%), and used mobile apps regularly (22/23, 96%; Table 2). With respect to healthy habits, no participants reported tobacco use, whereas 17 (74%) participants used alcohol occasionally. With regard to physical activity, 15 (65%) participants performed between 150 and 300 minutes of moderate physical activity a week, 2 (9%) completed 75 to 150 minutes of intense physical activity, and 5 (22%) performed at least 3 days a week of muscle strengthening and balance exercises (Table 2).

Table . Demographic characteristics and health behaviors of the participants.

Characteristic	Total (N=23)
Age	
Mean (SD)	52.8 (6.1)
Median (range)	53 (42 - 61)
Marital status, n (%)	
Married	16 (70)

150 - 300 minutes of moderate physical activity	15 (65)
75 - 150 minutes of intense physical activity	2 (9)
At least 3 days per week of muscle strengthening and balance	5 (22)

Survival time, defined as the period from the end of the primary treatments, had a mean of 7.7 (SD 2.7) years. Of 23 participants, most (21/23, 91%) had a survival time between 5 and 10 years, whereas 2 (9%) exceeded 10 years (Table 3). Regarding the stage of cancer at diagnosis, 6 (26%) women were diagnosed with stage 1 disease, 5 (22%) were diagnosed with stage 2

XSL•FO
RenderX

disease, 3 (13%) were diagnosed with stage 3 disease, and 9 (39%) did not know what stage their disease was in at the time of diagnosis. Lumpectomy was the most frequent surgical procedure, performed in 9 (39%) participants, and 14 (61%) required the removal of more than 1 node. The primary treatments were diverse, with the combination of chemotherapy and radiotherapy being the most common (10/23 44%). A total of 20 (87%) patients received hormonal therapy. In addition, 21 (91%) did not experience cancer relapse.

Table . Clinical characteristics of the participants.

[a]DK: Don’t know

The classification of the SUS scores is presented in Table 4. The mean score was 80.8 (SD 15.2), corresponding to grade A. Most of the participants (14/23, 61%) reached a score between 84.1 and 100, classified as A+, and 2 (9%) received the lowest score (F).

XSL•FO
RenderX

Table . SUS[a] scores according to Lewis and Sauro [37].

Grade	SUS score range	Values, n (%)
A+	84.1 - 100	14 (61)
A	80.8 - 84.0	1 (4)
A−	78.9 - 80.7	2 (9)
B+	77.2 - 78.8	0 (0)
B	74.1 - 77.1	0 (0)
B−	72.6 - 74.0	0 (0)
C+	71.1 - 72.5	1 (4)
C	65.0 - 71.0	2 (9)
C−	62.7 - 64.9	0 (0)
D	51.7 - 62.6	1 (4)
F	0.0 - 51.6	2 (9)

[a]SUS: System Usability Scale.

Regarding the experience of use during the study, the most common responses described the app as “easy” (n=7), “simple” (n=5), and “intuitive” (n=7). However, some participants highlighted aspects for improvement, such as that the app “helps, but it is not very specific” (n=1), that “it is sometimes confusing” (n=1), or that “it is not excessively complicated but presents difficulties in managing physical exercise” (n=1). Regarding the perception of use, the majority highlighted the ease of use of the app, although some users indicated that certain aspects could be optimized to improve the experience. Finally, in relation to suggestions to improve the app, the most frequent answer was “no” (n=8), including those that indicated “I do not know” (n=2). However, some participants proposed improvements in the nutrition and exercise modules. For the nutrition module, they suggested incorporating more recipes, including seasonal foods, offering simpler recipes, and using more common ingredients. In the exercise module, they recommended expanding the content and offering more personalization. In addition, 1 of the participants proposed the possibility of face-to-face care from professionals.

Table 5 presents the pre- (baseline) and post- (3 months later) intervention scores obtained on the QOL-CS scales. No statistically significant differences were found in the global score or in most of the subscales of the QOL-CS. A reduction in the spiritual well-being score was observed after the intervention (P=.05); however, this finding should be interpreted with caution, given the limited sample size and exploratory nature of the study. For the SEMCD-S scale, no significant changes were observed in any of the items or in the total score (Table 6).

Table . QOL-CS[a] instrument scores (domains/subscales).

Domains/subscales	Pre, mean (SD)	Post, mean (SD)	P value [b]
Physical well-being	6.7554 (1.26046)	6.4946 (1.22618)	.23
Psychological well-being	5.1715 (1.33637)	5.1787 (1.43636)	.96
Social well-being	6.5815 (1.78679)	6.2880 (1.88800)	.10
Spiritual well-being	5.3478 (1.13129)	4.9317 (1.22956)	.05
Total score	5.9641 (1.07612)	5.7233 (1.20420)	.07

[a]QOL-CS: Quality of Life-Cancer Survivors.

[b]Parametric tests were used: t test for paired samples.

Table . SEMCD-S[a] instrument scores.

Item	Pre, mean (SD)	Post, mean (SD)	*P* value [b]
1	7.04 (2.011)	6.48 (1.806)	.20
2	6.30 (2.754)	6.17 (2.329)	.80
3	6.87 (2.138)	6.43 (1.854)	.39
4	6.04 (2.788)	5.96 (1.965)	.86
Total score	6.5652 (1.89979)	6.2609 (1.82077)	.40

[a]SEMCD-S: Self-Efficacy to Manage Chronic Disease Scale.

[b]Parametric tests were used: *t* test for paired samples.

Discussion

Principal Findings

This pilot study evaluated the feasibility and acceptability of the CUMACA-M mobile app, a digital health intervention incorporating artificial intelligence algorithms and designed to improve QOL and self-efficacy in the management of sequelae among long-term breast cancer survivors. Our findings suggest that the intervention may be feasible, as evidenced by full recruitment and a 100% completion rate. All participants completed the evaluations using the QOL-CS, SEMCD-S, and SUS scales, which reflect high adherence and commitment to the study. The initial training session may have contributed to these positive outcomes by reducing potential technical barriers and facilitating user engagement, thereby minimizing dropout and ensuring completion of follow-up assessments. This level of participation is especially relevant because the permanent survival stage presents significant challenges for recruiting participants. In many cases, people who have completed their cancer treatment tend to withdraw from studies related to the disease either because they want to focus on their recovery or because they prefer not to emotionally relive their experience with cancer [42].

In addition, the intervention was well accepted by the participants, as evidenced by the results obtained on the SUS scale and the qualitative responses on the experience of using the app. The high score in the SUS (mean 80.8, SD 15.2) indicates excellent usability of the system, which suggests that the app is well designed and functional for this population. These results are consistent with those of previous studies that evaluated the feasibility of mobile apps targeting breast cancer survivors. For example, Bergqvist et al [43] reported an average score of 82.5 on the SUS (standard deviation not reported), with positive perceptions of its ease of use and added value in daily life. Monteiro-Guerra et al [44] reported an average value of 95.0 (SD 6.3), with a high assessment in terms of its ease of use and impact on promoting physical activity. However, unlike these studies, our intervention is the first designed specifically for breast cancer survivors who are in the permanent or long survival stage (disease-free and more than 5 years from the completion of primary cancer treatment).

On the other hand, the participants identified various strengths of the platform, as well as areas for improvement. In particular, the health tips module received no optimization comments, which can be attributed to the close collaboration with users during its development, a strategy recommended in previous studies [43-45], which probably contributed to the high perceived usability. However, the nutrition and physical exercise modules, which had less participation from users in their design phase, were the subject of observations and suggestions for their improvement. These findings underscore the importance of actively involving the study target population in the process of developing digital interventions to maximize their acceptance and effectiveness.

Regarding the results obtained for QOL and self-efficacy in the management of sequelae, which were evaluated using the QOL-CS and SEMCD-S scales, no statistically significant differences were detected between the pre- (baseline) and post- (3 months later) measurements. These findings suggest that, during the period analyzed, the perceived QOL and self-efficacy of the participants in managing their chronic condition remained stable. These findings can be explained by several factors. First, the stability of the measurements could indicate that the intervention helped maintain the levels of QOL and self-efficacy, avoiding the possible deterioration associated with the time and progression of the sequelae. In addition, 3 months may not be sufficient to observe significant changes in these variables because improvements in the perception of QOL and in self-efficacy usually require longer periods of intervention and follow-up. On the other hand, individual factors, such as previous health status, degree of adaptation to life after cancer, or variability in the use of the intervention, could have influenced the results, attenuating the expected effects.

These results are consistent with those of the scientific literature, which has reported heterogeneous results concerning the impact of digital interventions on the QOL of breast cancer survivors [22,46-49]. While some studies have documented significant improvements in certain domains of QOL [22,46], others have not identified statistically significant differences [22,50], and some research has even reported negative effects associated with intervention [49]. The systematic review of Pimentel-Parra et al [22] reflects this variability, reporting positive effects of digital health in aspects such as physical activity, fatigue, sleep disorders, anxiety, and depression, but without significant differences in other dimensions such as vitality, physical role, or self-efficacy for exercise.

Ultimately, the findings of this study highlight the complexity of evaluating the impact of digital interventions on the QOL of long-term breast cancer survivors. In addition, they highlight the need for a longer period to detect clinically relevant changes

XSL•FO
RenderX

in QOL and self-efficacy for the management of sequelae. Future studies with a longer design and larger sample sizes will allow a more precise evaluation of the impact of these interventions on QOL and self-efficacy for the management of sequelae in long-term survivors of breast cancer. In addition, it is essential to consider additional variables, such as adherence to the intervention, the degree of participation of the users, and psychosocial factors that may influence the results. Likewise, the incorporation of mixed methodologies, combining quantitative and qualitative analyses, could provide a deeper understanding of the experience of the participants and the mechanisms through which these interventions generate changes in their well-being.

Strengths and Limitations of the Study

The strengths and limitations of this study are acknowledged, providing a comprehensive view of its contributions and considerations for future research. First, although the literature suggests that usability studies typically require a minimum of 15 to 20 participants to obtain reliable results [51,52], this study included 23 long-term breast cancer survivors, slightly exceeding the initially estimated sample size by 15%. This greater participation strengthens the validity of the findings and highlights the viability of recruiting and maintaining the commitment of this population in digital health interventions. In this sense, the absence of participant dropout may indicate a favorable level of commitment and acceptance of the intervention over the 3-month period, which could suggest the potential feasibility of implementing similar tools in clinical and community settings for the follow-up of long-term breast cancer survivors. However, generalizability remains limited due to the sample size and specific study context, so caution should be exercised in interpreting these outcomes, and further investigation is needed.

The inclusion of participants with varied ages, health conditions, and levels of technological experience could enhance the relevance of the findings for a broader population of long-term breast cancer survivors, although this diversity does not fully compensate for the limited scope of the sample. The findings may provide a preliminary foundation for future improvements in the design and development of digital support strategies tailored to long-term breast cancer survivorship, with possible apps in follow-up and rehabilitation contexts. Finally, the combination of the SUS with open-ended qualitative questions allowed for a more nuanced understanding of the user experience, highlighting both perceived strengths and areas for further improvement.

However, one of the main limitations of this study is its pilot nature, as it had a relatively small sample size and a short evaluation period. Although the 100% completion rate is an encouraging finding that supports the feasibility of the intervention, it is possible that this result was influenced, in part, by the shortness of follow-up. In fact, previous studies have shown that adherence and completion rates tend to decrease with longer-term interventions due to factors such as user fatigue, loss of interest, or the presence of long-term logistical barriers [50,53,54]. In addition, no objective monitoring of the activity of the users was carried out within the app, which prevents the precise evaluation of the patterns of use and the actual adherence to the intervention. In this sense, future research with longer follow-up periods will allow a more realistic assessment of sustained adherence and the long-term impact of the intervention.

In addition, although long-term breast cancer survivors may experience common side effects and late effects, this study did not include a systematic assessment of whether participants themselves had these experiences. As such, it remains unclear to what extent the sample reflects the broader survivorship population in terms of symptom burden. This limits the ability to draw conclusions about the intervention's applicability or effectiveness for individuals facing persistent treatment-related sequelae. Future studies should incorporate measures to assess these factors and examine their influence on user engagement and intervention outcomes.

Conclusions

This pilot study suggested that the CUMACA-M mobile app may be feasible and acceptable for long-term breast cancer survivors, as indicated by a high completion rate and positive usability feedback. While these preliminary findings are encouraging, the small sample size and the specific context in which the study was conducted limit the generalizability of the results. Further research with larger and more diverse samples is needed to confirm these findings and to better understand the role of co-creation in the development of digital health interventions for this population.

Future studies with larger samples, prolonged follow-ups, and objective metrics of use could more precisely evaluate the impact of CUMACA-M on the QOL and self-efficacy of breast cancer survivors.

Abstract

Background: About 40% of cancers are preventable through evidence-based interventions; however, uptake remains suboptimal. Knowledge and acceptance of primary and secondary preventive measures in the general population is not sufficient. We hypothesized that a web-based tool providing comprehensive, easily accessible, and individualized information on preventive strategies for multiple tumor entities could support informed decisions.

Objective: This study aimed to evaluate an interactive web application offering guideline-based, risk-adapted information on preventive measures for colorectal, breast, and prostate cancer.

Methods: The content of web application was developed based on German S3 guidelines. Evaluation questions consisted of the system usability scale questionnaire and queries developed by the Prevent-Take-up consortium. An initial version was tested by two focus groups comprising general practitioners (GPs), specialists and patients, revised and then made publicly available in GPs' offices, hospitals, and pharmacies. We report on the evaluation of the revised web application. Data were collected from 2022 - 2023. The web application also gathers information regarding family and individual risk factors and offers personalized recommendations (eg, to seek further information). Personal data related to specific recommendations were not stored. Participants receiving a recommendation from the web application were asked to anonymously answer questions about the information provided and the website application's functionality using a 5-point Likert scale. As breast cancer mainly occurs in women and prostate cancer only in men, the questions regarding prevention had intrinsic sex specific items and hence all data were evaluated by sex using descriptive statistics. The main evaluation questions were (1) usability or user-friendliness of the web application for cross-entity cancer prevention and (2) motivation of users to seek further preventive advice by the information received.

Results: Data from the first 101 users (62 female, 38 male, one unspecified; predominantly aged 50 - 70 y) showed high score regarding user-friendliness (female 47/62, 76%; male 25/38, 65%), question comprehensibility (female 54/62, 87%; male 32/38, 83%), and the relevance of recommendations (female 47/62, 76%; male 24/38, 63%). A total of 37/62 (59%) of female and 16/38 (44%) of male participants appreciated the web application's functionality; 29/62 (47%) of female and 14/38 (37%) of male participants reported increased knowledge about prevention and early detection of colorectal, breast, and prostate cancers. Additionally, 44/62 (71%) of female and 18/38 (47%) of male participants expressed willingness to follow-up on the web application's recommendations and seek more information from their GPs.

Conclusions: Our web application for risk-adapted prevention across multiple cancers was rated as user-friendly by participants. Having used the web application, more female participants than males were willing to seek further information on prevention and early detection measures. Overall, our study demonstrates that a web application can be a useful tool to deliver integrated and individualized prevention recommendations.

cancer prevention; website application; oncology; colorectal cancer; breast cancer; prostate cancer

Introduction

Background

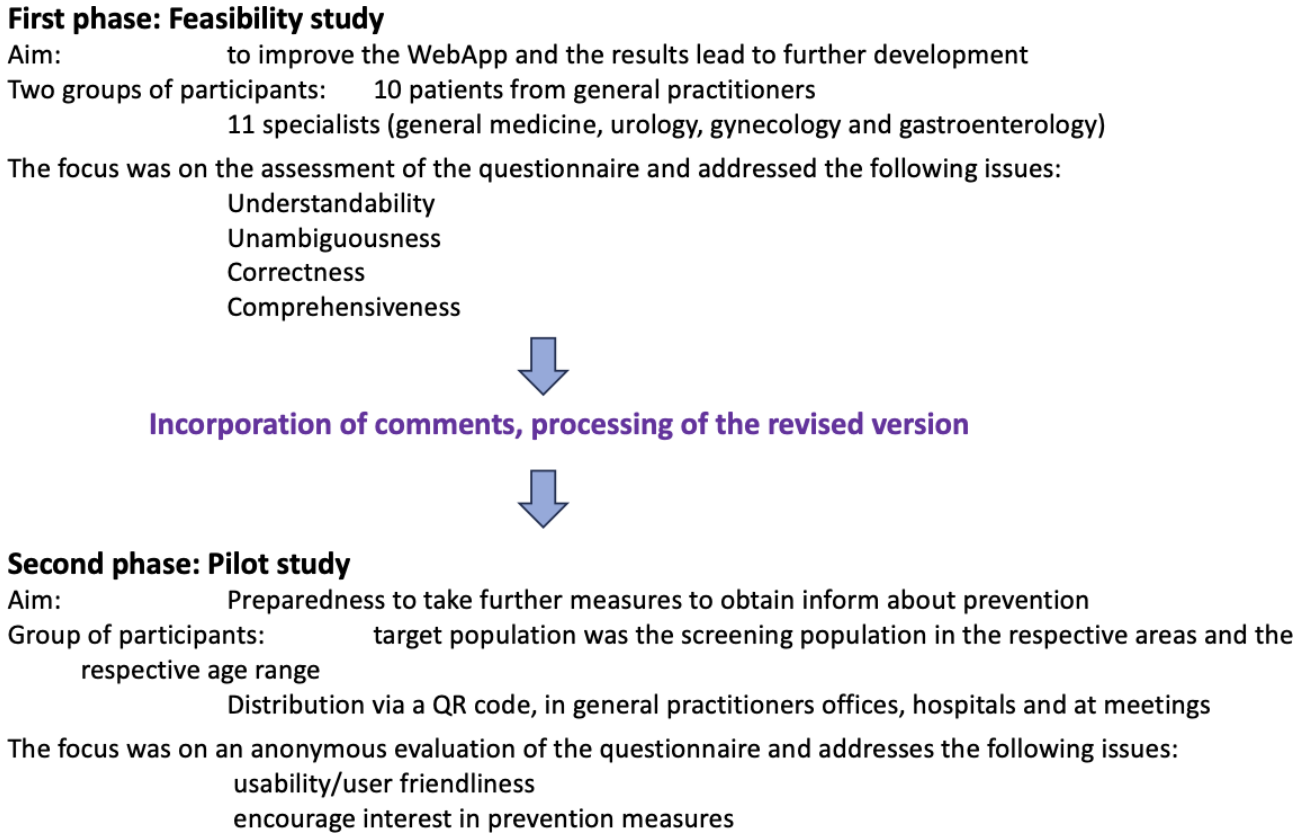
In 2022, cancer was the second leading cause of death in Germany after cardiovascular diseases, with 239,948 fatalities [1] and the total number of new cancer cases remains high. About 40% of all cancer cases could be prevented [2]. For some tumor entities, there are national screening and early detection programs. In case of colorectal cancer, a statutory colonoscopy screening program was established in Germany as early as 2002. This endoscopy program is complemented by the option of fecal occult blood testing. In 2019, the guaiac-based stool test was replaced by fecal immunochemical test (FIT) in the program. The whole program has reduced the cancer-specific mortality rate by around 30% over the last 20 years [3]. A similar screening program was established for breast cancer in 2004, inviting women aged 50-69 years to undergo mammography every two years. In 2023, the program was expanded to include women up to the age of 75 [4]. For prostate cancer screening, every man over the age of 45 is entitled to an annual digital examination of the prostate. However, this particular recommendation is about to be replaced. Colorectal and breast cancer screening in Germany are organized as invitation schemes that start at the designated age of eligibility. Despite these programs, there is still insufficient awareness of preventive measures and screening and a shortage of comprehensive information tools that encompass different tumor types and consider various risk-modifying factors, including smoking, obesity, alcohol consumption, and family history [5-7].

Mobile health (mHealth) is an interesting and ever-expanding resource for disseminating health information and services. In 2016, the World Health Organization mHealth Technical Evidence Review Group developed a checklist for reporting health interventions that utilize cell phones [8]. The CHARISMA study showed that mobile technologies can support medical care services and prevention in a resource-efficient manner [9]. The coronavirus pandemic accelerated mHealth interventions, as digital media became an integral component of the public health care system and acceptance of digital health care services by the public increased [10]. We hypothesized that a comprehensive information on effective and individualized prevention strategies in a single, easily accessible, Web-based tool could improve informed decision-making by the eligible population and potentially encourage the adoption of effective prevention strategies. A centrally administered web portal enables easy access to health care, transfer of knowledge, and the rapid adaptation of health information [11]. Another aspect is the fact that a web application could help to raise awareness for screening and prevention also in harder-to-reach populations [12]. Web application users should be able to assess their individual risk for three common types of cancer, breast, prostate, and colorectal cancer based on recommendations from the current national, German S3 guidelines and receive individualized suggestions. The web application aims at individuals who are eligible for, but have not yet taken any preventive measures or individuals with a higher cancer risk, such as those with a family history of cancer. The web application provides customized information about the individual risk (as assessed by life style factors and family history) as well as decision-relevant information on screening and early detection examinations, including behavior-related preventive measures, their benefits, as well as potential risks associated with the examinations themselves.

Objectives

Here, we describe the pilot evaluation of this web-based, interactive tool for guideline-based, risk-adapted information on preventive measures for colorectal, breast, and prostate cancer by the first 101 anonymous users. The major goals were to assess (1) the usability and user friendliness of the web application on cross-entity cancer prevention and (2) whether the information received through the web application would motivate users to seek more information on preventive measures.

Methods



Development of the Web Application

The web application is structured as an interactive questionnaire for the prevention related content. Rule-based artificial intelligence was used to dynamically adjust subsequent questions based on the participants' real-time responses. This approach aims to reduce the time required for users by narrowing the questionnaire to a set of questions that are personally relevant to the topic. This questionnaire (see Multimedia Appendix 1) and its underlying rule set were developed by a multidisciplinary team based on the recommendations regarding screening and early detection measures for colorectal, breast, and prostate cancer in the respective German S3 guidelines (version 2.1 from 2019 for colorectal cancer [13], version 4.4 from 2021 for breast cancer [14], and version 6.2 from 2021 for prostate cancer [15]). The respective rules are provided in Multimedia Appendix 2. The multidisciplinary team comprised members from the departments of General Medicine, Urology, Gynecology, and Gastroenterology at Ulm University Hospital, as well as experts from the Institute of Medical Systems Biology at Ulm University's Medical Faculty. The application was designed with a focus on straightforward usability, and its responsive design ensures high compatibility across various devices and screen sizes. The evaluation tool was also developed by the multidisciplinary team. It comprised 10 more "technical" questions that were taken from the publicly available system usability scale (SUS) questionnaire [16] that was translated into German. The SUS was supplemented with 10 specific questions regarding the user experience with the web application that was also developed by the multidisciplinary team. The questions were answered on a five-point Likert scale ranging from "strongly disagree" to "strongly agree." Some of the evaluation questions were phrased positively, while others were phrased negatively, and for this reason, they were evaluated individually.

XSL•FO
RenderX

The web application as well as the evaluation questionnaire were first evaluated by two focus groups in a feasibility study. The groups consisted of 10 patients, 50 - 70 years of age with no previous history of cancer from participating general practitioners and 11 specialists from general medicine, urology, gynecology and gastroenterology, respectively. None of the participating doctors had been involved in the app's development. These two groups focused on understandability, unambiguousness, correctness and comprehensiveness of the content as well as the evaluation questions. The individual feedback from the two groups was discussed by the entire Prevent-Take-Up team, and both content-and evaluation-related suggestions for improvement were incorporated into the web application to enhance usability. The results of this evaluation are published elsewhere [17]. The web application was subsequently revised and the revised version was made publicly available to a screening population for phase 2 (Figure 1) which was the topic of this manuscript.

Figure 1. Schema of the feasibility and pilot study.

Recruitment of the Study Population

For recruitment of participants posters and flyers were distributed in general practitioners' offices and hospitals in the State of Baden Württemberg at Ulm University Hospital in southern Germany. In addition, these brochures were also distributed at meetings (ie, Annual conference of the Southwest German Society for Gastroenterology, German Cancer Congress in Berlin) containing a QR code that led to the entire web application questionnaire, comprising both content- and evaluation-created questions. While we were aiming for a screening population which was clearly stated on the promotion material provided, use of the web application was entirely anonymous and we could, therefore, not assess whether this criterion was met. Participants first answered the content-related questions and received a personalized recommendation. Subsequently, the web application asked the participants to provide a voluntary, anonymous feedback on the usability and functionality of the application via this tool. These participants did not receive any compensation for their participation.

Measures

The web application considers sex, age, individual risk and lifestyle factors, including physical activity, alcohol, and nicotine consumption (Table 1), as well as comorbidities and past medical check-ups. Queried previous investigations included colonoscopy, a fecal occult blood test (FOBT), mammography, prostate magnetic resonance imaging (MRI) test, digital prostate examination, or a prostate-specific antigen (PSA) test up to this point in time. Guideline-recommended time intervals for repeating specific screening tests such as mammography or colonoscopy were also considered. A family history of cancer was queried for first-degree relatives (ie, parents, siblings, children). Recommendations for colorectal cancer screening also took into account polyps removed during a previous colonoscopy or the results of a FOBT.

Table . Characteristics of the study population (N=101).

Characteristics	Participants (N=101)
Sex[a], n (%)	
Male	38 (38)
Female	62 (62)
Age range (years), n (%)	
50 - 70	93 (92)
<50	8 (8)
BMI, n (%)[b]	
<18.5	0 (0)
18.5 to <25	29 (29)
25 to <30	44 (43)
≥30	26 (26)
METs[c], n (%)	
>150/ week	77 (76)
Alcohol consumption, n (%)[d]	
No	59 (58)
Yes	41 (41)
1 - 5 days/week	28 (28)
6 - 7 days/week	6 (6)
≤12 g per day	2 (2)
>12 g per day	2 (2)
Nicotine consumption, n (%)	
No	73 (72)
Yes	28 (28)
Red meat consumption, n (%)	
No	59 (58)
Yes	42 (42)
Diabetes mellitus, n (%)	
No	86 (85)
Yes	8 (8)
Don´t know	6 (6)

[a]One person did not specify the sex; a total of 100 out of 101 people provided.

[b]BMI data for 2 persons could not be provided; therefore data for a total of 99/101 is presented.

[c]METs: metabolic equivalent of tasks.

[d]One person did not report alcohol consumption.

The metabolic equivalent of a task (MET) was used as a measure of physical activity [18]. Participants assessed their own physical activity and classified themselves as either “physically active with more than 150 MET minutes per week” or “physically inactive with less than 150 MET minutes per week.” Participants were also asked about nicotine, red meat and alcohol consumption, the frequency of alcohol intake (1 - 5 d or 6 - 7 d per wk) and the amount of alcohol consumed (≤12 g/d for women and ≤24 g/d for men) [19]. Diabetes mellitus was also queried (Yes/No/Don’t know). All answers were taken into consideration for the personalized recommendations. Based on all information provided, the web application recommended to consult a GP regarding specific preventive procedures, if at least one of the recommended preventive measures was outside the recommended timeframe, had not been completed to date, or if alerting symptoms were reported.

Participants were also asked to group themselves according to sex and age (<30, 30 - 50, and 50 - 70 y). BMI was calculated from the height and weight data and categorized according to

XSL•FO
RenderX

the WHO classification as underweight (BMI <18.5), normal weight (BMI 18.5 - <25), preobese (BMI 25 - <30), and obese (BMI≥30) [2]. The medical questionnaire comprises 21 questions, with the option to skip questions, and is provided as an additional file (Multimedia Appendix 1).

Having completed the medical questionnaire, participants were invited to take part in a survey in which they were asked to rate the functionality and user-friendliness of the web application. A questionnaire was developed for this in which the questions from the publicly available SUS questionnaire [16] were supplemented with thematic questions about the web application and agreed upon within the project team. Participants were also asked whether they found the information provided by the website application helpful, if they would use it, and if they would follow the recommendation to seek further medical advice, eg, from their GP.

Results are presented purely descriptively and separately for male and female participants. Participation in screening programs for colon cancer differs between males and females [20]. Due to the fact that breast cancer occurs very rarely in men and prostate cancer only in men, we decided to evaluate the questionnaires by sex to identify possible sex specific differences that could be potentially addressed in further developments of a web application. The only non-descriptive statistic used was to elucidate whether the recommendation to consult a GP was driven by the website application rather than being the result of a random selection. For this purpose, we employed a binomial test to assess this deviation from a random recommendation (statistical software R version 4.4.2).

The trial was registered in the German Clinical Trials Register (DRKS00029631) and the software implementing the Prevent-Take-Up web application is freely available [21].

Ethical Considerations

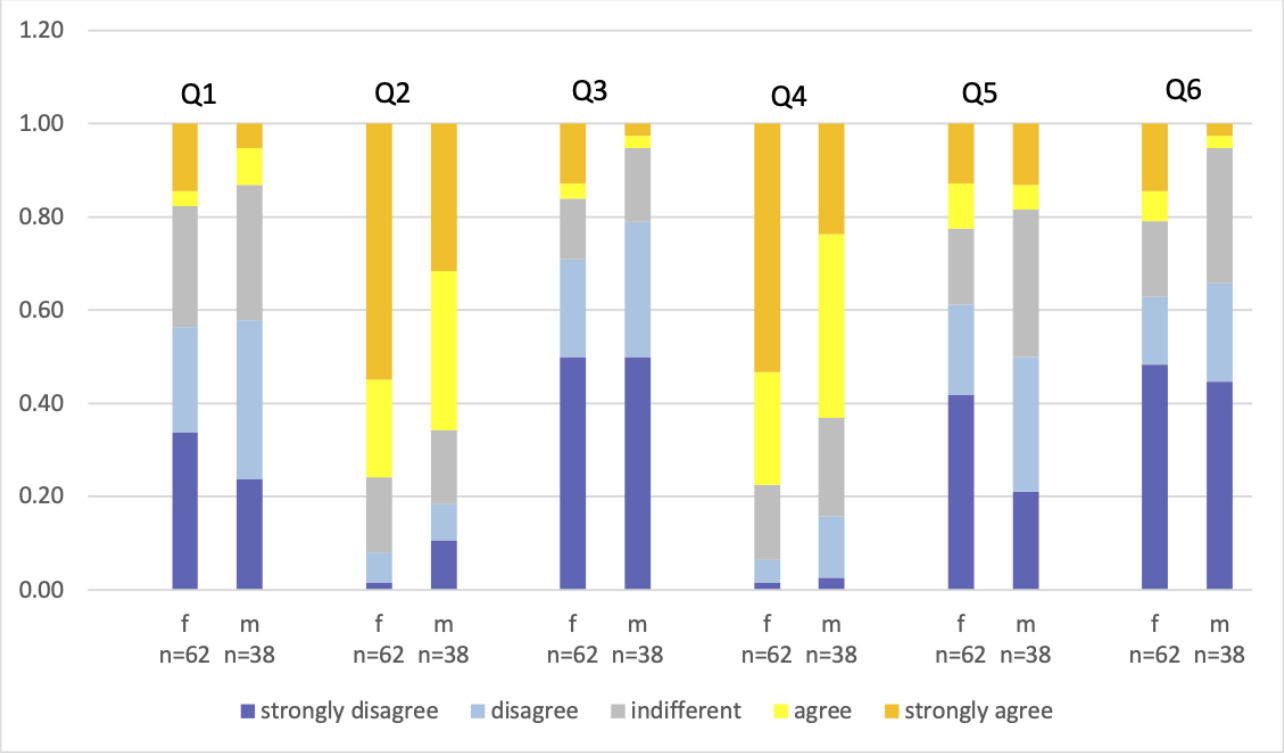
The project was approved by the Ethics Committee of Ulm University (ethics committee No. 122122, 2022). All data were entered voluntarily and anonymously by participants who scanned the QR code and completed the web-based questionnaire. Therefore, a signed consent form was not obtained but completion of the Prevent web application questionnaire was considered as consent to participate. The study data are therefore anonymous, and the participants are unknown and not traceable. These participants did not receive any compensation for their participation.

Results

Baseline Characteristics Analysis

A total of 101 participants tested the web application; 62% (n=62) were female and 38% (n=38) were male; one participant did not specify sex. A total of 91% (n=92) of the participants were older than 50 years and had the age of the screening population; 1/93 participants (1%) did not specify sex, but their age was >50 years. Since participation was entirely anonymous, we would not have been able to verify inclusion or exclusion criteria. However, it was advantageous that individuals younger than the target population participated in the evaluation (8/101, 8%; 4 female and 4 male) as future screening programs may also be available for younger individuals with a family history (eg, of colorectal cancer). Regarding BMI, the majority of the study population was in the preobese range, with a median BMI of 26 (IQR 22.6 - 29.3), and 28.3 (IQR 26.06 - 31.25) for females and males, respectively (Table 1). Overall, 98 of 101 participants (97%) provided a complete dataset, while the response rate for the remaining 3 participants (3%) exceeded 90%.

Assessing Risk Factors



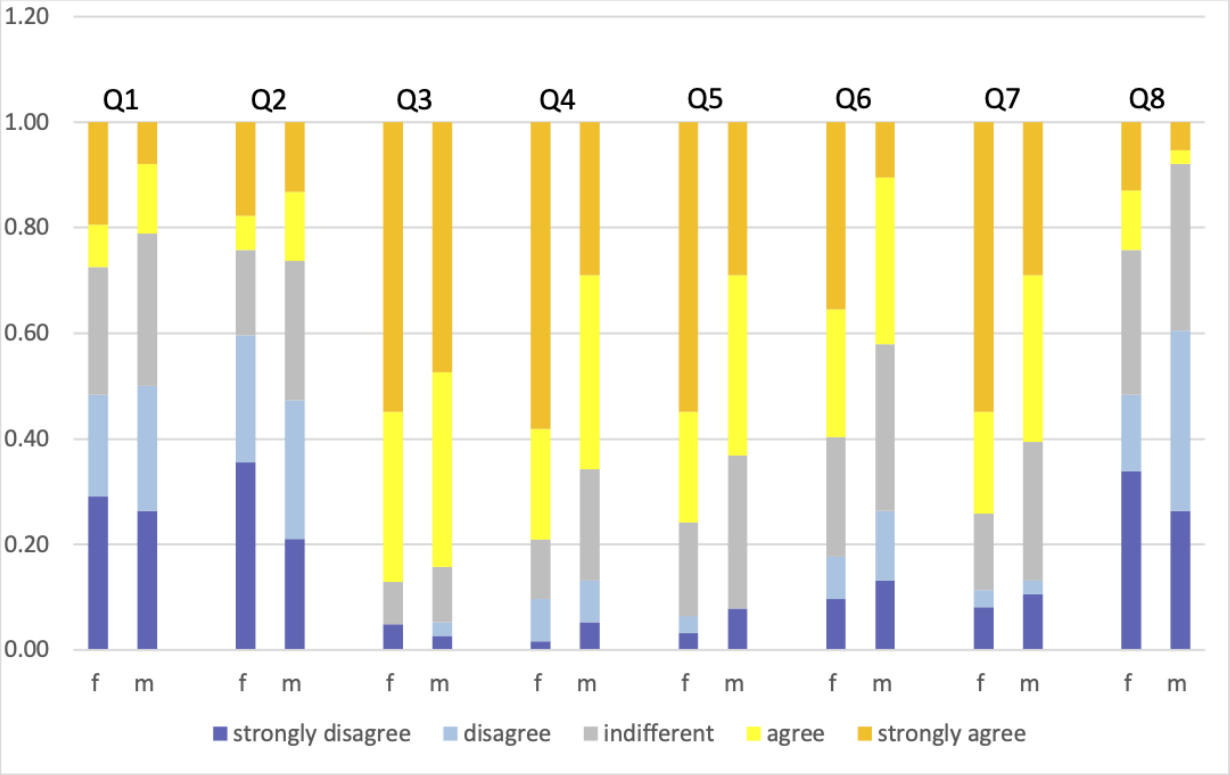
The content questionnaire included several questions on lifestyle factors. Physical activity was assessed asking for the duration of METs. 30/38 (79%) of male and 47/62 (76%) of female participants reported being physically active for more than 150 MET minutes per week. Alcohol consumption was reported by 20/61 (32%) females and 20/38 (53%) males. Specifically, 15/20 (75%) females and 20/38 (65%) males in the “consumer group” indicated consuming alcohol on 1 - 5 days per week, 1/20 (5%) females and 5/20 (25%) males on 6 - 7 days per week. More specific amounts of alcohol intake were reported only by a few participants: 2/20 (10%) females reported a daily intake of less than 12 g, 2/20 (10%) males of up to 24 g of alcohol. Current nicotine use was reported by 19/62 (31%) female participants and 9/38 (24%) male participants. Additionally, 25/62 (40%) females and 16/38 (42%) males consumed red meat regularly. Diabetes mellitus was reported by 2/61 (3%) females and 6/38 (16%) males. 57/61 (92%) female and 29/38 (76%) male participants denied having diabetes mellitus, 2/61 (3%) females and 3/38 (8%) males were unsure about this issue, and 1/61 (2%) female participant did not respond to this question (Table 1).

Evaluation of the Content Questionnaire and the Web Application by the Participants

The main focus of this manuscript is the evaluation of the web application and its content questionnaire by the participants. Usability was rated as “easy” (agree or strongly agree) by 47/62 (76%) females and 25/38 (65%) males. 48/62 (77%) of female and 24/38 (63%) male participants agreed or strongly agreed that most people can quickly learn to use the application. 44/62 (71%) females and 30/38 (79%) males stated that technical support was not necessary for using the application (Figure 2).

XSL•FO
RenderX

Figure 2. Technical usability of the prevent-take-up app. f and m indicate females and males, respectively.



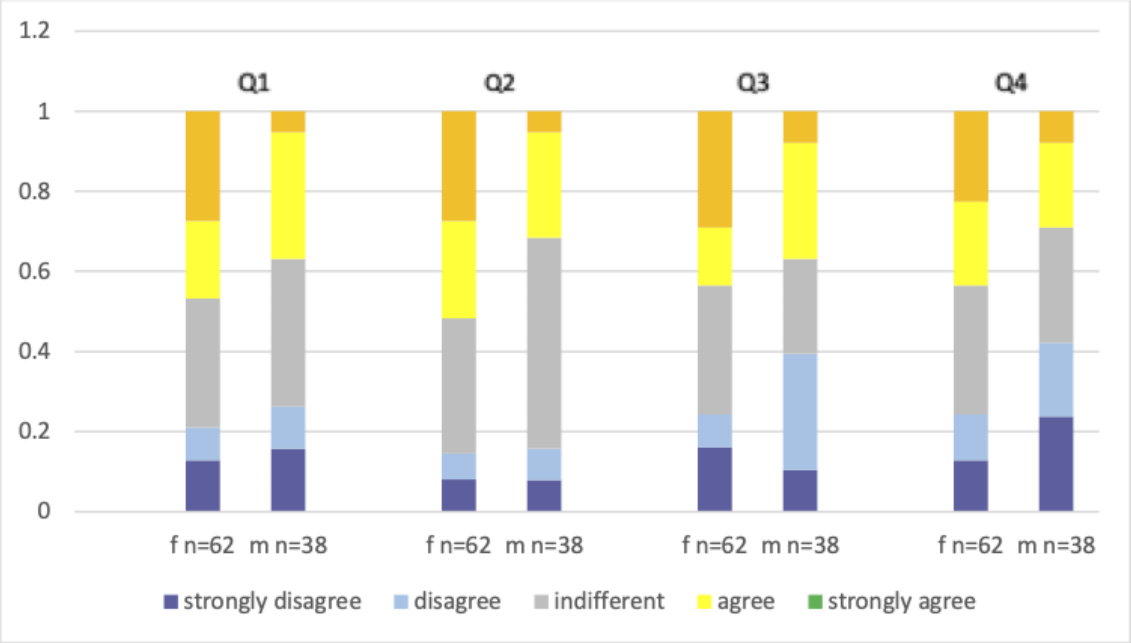
Q1	The website seems unnecessarily complicated.
Q2	I think, the website is easy to use.
Q3	I think, I would need technical support to be able to use the website.
Q4	I think, the most people can learn how to use the website easily.
Q5	The website seems very complicated to use.
Q6	I had to learn a lot to use the website

The majority of female and male participants agreed or strongly agreed that the questions posed (female: 54/62, 87%; male: 32/38, 83%) and the recommendations provided (female: 47/62, 76%; male: 24/38, (63%). Participants had access to additional information on screening and preventive measures within the web application. 49/62 (79%) females and 25/38 (66%) males agreed or strongly agreed that the informative texts in the web application were clear (Figure 3).

XSL•FO
RenderX

Figure 3. Assessment of the questionnaire and functionality. f and m indicate females and males, respectively.

Q1	I think the number of questions is too low.
Q2	I think the number of questions is too high.
Q3	I think the questions on the website are easy to understand.
Q4	I think the information on the website is easy to understand.
Q5	I think the results on the website are easy to understand.
Q6	I find that the various functions of the website are well integrated.
Q7	I feel very safe using the website.
Q8	The website seems too inconsistent to me.



37/62 (59%) of female and 16/38 (44%) of male participants agreed or strongly agreed that the app's various functions were well integrated. 30/62 (49%) of female and 23/38 (59%) of male users totally disagreed or disagreed that the web application appeared too inconsistent while 46/62 (74%) females and 23/38 (60%) males agreed or totally agreed that they felt safe using the web application (Figure 3).

29/62 (47%) of female and 14/38 (37%) of male participants agreed or strongly agreed that the web application improved their understanding of cancer screening and early detection in the respective areas. 32/62 (52%) female and 12/38 (32%) male participants agreed or strongly agreed that they felt more informed about prevention and early detection of breast, bowel, and prostate cancer after using the web application. 27/62 (44%) female and 14/38 (37%) male participants agreed or strongly agreed that they used the web application to learn more about early detection and prevention of cancer. Furthermore, 27/62 (44%) female and 11/38 (29%) male participants agreed or strongly agreed that they would use the app regularly, most likely because changes in individual lifestyle factors over time may lead to different risk assessments (Figure 4A).

XSL•FO
RenderX

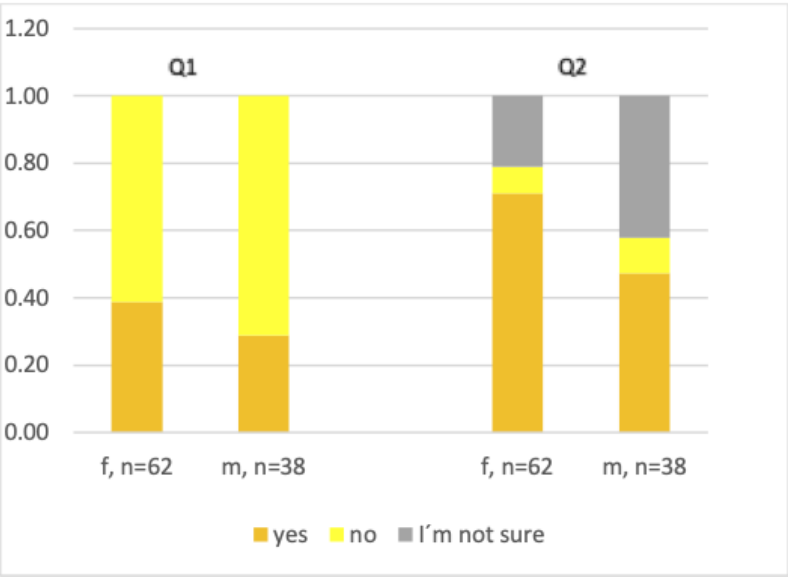


Figure 4. Improvement of the understanding of cancer screening and taking action after screening recommendation. (A) Level of knowledge; (B) Screening recommendation. f and m indicate females and males, respectively.

(A)

Q1	The "Prevent-take-up" website has improved my knowledge of cancer screening and early detection of breast, bowel and prostate cancer.
Q2	After using the "Prevent-take-up" website, I feel well informed about cancer prevention and early detection of breast, bowel and prostate cancer.
Q3	By using the "Prevent-take-up" website, I would like to learn more about the early detection and prevention of cancer.
Q4	I think I would use the website regularly.

(B)

Q1	Did you receive a recommendation from the "Prevent-take-up" application to see a doctor?
Q2	If the "Prevent-take-up" website has recommended that you see a doctor, will you follow this recommendation and see your doctor for a consultation?

24/62 (39%) females, 11/38 (29%) males, and one individual without an indication of sex received a recommendation to consult their GP regarding further information on preventive check-ups based on their "prevention history" as well as

XSL•FO
RenderX

individual lifestyle and risk factors. Binomial testing showed that these recommendations were indeed not given by chance, but driven by the web application algorithm (*P*=.005, two-tailed, binomial test). Furthermore, 44/62 (71%) female and 18/38 (47%) male participants indicated they would follow the application's recommendation to see their GP for more information on preventive measures. Others stated they would not follow this recommendation whereas 13/62 (21%) females and 16/38 (42%) males expressed uncertainty about following the recommendation (Figure 4B).

Of note, in many items of the questionnaire, female participants compared to male participants provided a numerically more positive assessment of the web application and stated greater willingness to follow the recommendations given.

Discussion

Main Findings

This web application was developed to provide low-threshold, cross-entity and individual risk-adjusted information on cancer prevention. It is an evidence-based tool, developed by experts in the respective fields in Germany. The web application does not directly give a medical advice but makes individualized recommendations to seek further advice from their GPs or respective experts. The web application was highly rated by the majority of participants. A majority—at least 71% of female and 47% of male participants—stated that they would take advantage of an information session with their GP after receiving a respective recommendation by the web application.

Comparison With Prior Work

There is an increasing number of apps in the area of cancer prevention, including customized text messages or fotonovela programs that encourage screening uptake, eg, for colorectal or breast cancer [22-24]. The majority of these apps focuses on prevention of a particular tumor or give advice on how to perform a specific preventive test such as an FOBT [25]. Very few apps take into account individual risk factors such as exercise, smoking, obesity, or alcohol consumption when making a recommendation for a preventive test. Lifestyle changes and behavioral prevention can reduce cancer incidence [26]. A meta-analysis showed a 10 - 20 percent reduction in the risk of developing various cancers in physically active individuals [27]. Reporting risk factors such as consumption of alcohol, red/processed meat or low physical activity is more likely to be done anonymously online, rather than in a face to face interview [28]. Thus, a web application like Prevent-Take-up could encourage individuals to take proactive steps toward primary prevention by highlighting the benefits of specific lifestyle changes, such as increasing physical activity. It is well known that knowledge of cancer prevention, screening tests, and individual risk factors can motivate the eligible population to take part in screening [29].

This was the goal of our web application. We did not intend to produce a medical device or a diagnostic tool according to the In-Vitro Diagnostic Regulation. Therefore, the strongest recommendation by the app was to seek further advice from a trusted expert, which was GP for the majority of the population. Structured integration of GPs into an overarching prevention program is an important step to improve informed decision making on participation in cancer screening and preventive measures.

It remains a challenge to disseminate information on prevention to the less informed part of the population. It is remarkable that particularly younger and potentially digitally more savvy people (<50) felt well-informed simply by using the web application, but the numbers are low. Social media may not be the only solution since, in a survey from Canada, no correlation was found between low knowledge of guideline-based screening and participation in screening programs, although participants were willing to link their information to their medical records [30-33]. Therefore, we included GPs as trusted experts in the entire process.

The reported nicotine consumption by 31% of female and 24% of male participants is higher than that reported in the 2021 microcensus (15.7% of women and 22.3% of men) [1] that included all age groups. Individuals using the web application may be less health-conscious. Alternatively, since the survey was mainly advertised in health care facilities, participants of the survey may have been there for treatment of medical conditions potentially also due to nicotine consumption [34].

Generating a web application rather than an app in an app store has significant benefits for an academic group: Updates can easily be made in case of small changes to screening programs; it offers greater flexibility to developers since it is not bound by the regulations imposed by commercial app stores and it is far cheaper to maintain [35].

Strengths and Limitations

A strength of the study is the approach to inform about preventive measures in a comprehensive, cross-entity manner and at the same time take individual risk factors like family history, comorbidities, and lifestyle factors into account to recommend a risk-adapted consultation by the GP. This recommendation could also save the family doctors' time since critical individual topics are already identified and can be directly addressed. Another strength is the involvement of GPs from the beginning in both the design and the realization of the study. GPs are persons of trust and are an important, yet underused, partner in the whole spectrum of cancer prevention. GPs can make a major contribution to informed decision-making.

Our study has also several limitations. First, the participant group was small with only n=101 individuals taking the survey. Second, the individuals who participated in the surveys were probably mainly recruited from general practices where the study was advertised. There might be a bias towards participants with previous conditions such as obesity, and participants may not reflect the average population. Third, participation was anonymous making it impossible to determine whether the participants were representative of the screening population, whether the answers given were true, and disabling any follow-up. The questionnaire could hence only evaluate intention, which does not equate to behavior of taking up a preventive measure.

XSL•FO
RenderX

Finally, 47% of female and 37% of male participants stated that their knowledge of preventive and early detection measures had increased due to the web application. This rate is below 50% and clearly demands further improvements; however, it could also reflect a selection bias due to an already knowledgeable portion of the population participating in the survey.

Conclusions

Prevent-Take-up is a simple web application designed to improve informed decision-making on comprehensive screening for frequent tumor entities using guideline-based recommendations. The web application was highly rated and well accepted by the target population. Thus, Prevent-Take-Up follows a sensible approach.

Future Directions

Translating the content of the web application in various languages could help bridge language barriers and facilitate better communication with GPs and specialists. The web application could also be expanded to include a feedback function that allows participants to report whether the recommendations were followed in an anonymous fashion and the respective outcomes. Finally, the study could be extended to incorporate a larger group and also potentially younger people with a higher risk of cancer due to individual risk factors. The challenge is to reach as many individuals possible who are eligible for different reasons such as age, family or individual risk. In particular, the implementation of strategies to ensure equitable access for different population groups is still challenging [36]. The active involvement of potential users in the development of this web application was crucial and will contribute to the continued improvement of Prevent-Take-Up.

Acknowledgments

The generation of the website application was funded in the framework of the Preventive Medicine Competence Network by the Ministry of Science, Research, and the Arts of the State of Baden-Württemberg, Germany. No generative AI was used in any portion of the manuscript.

TS and HAK share senior authorship.

Data Availability

The app’s source code is available in the GitHub repository [21]. The app itself is accessible at [37].

Authors' Contributions

AK developed the content of the website application and wrote the manuscript, JDS developed the application and wrote the manuscript, TJ developed the content of the application and carried out the first phase, MM developed the content of the application and reviewed the final manuscript, FZ developed the content of the application and reviewed the final manuscript, SL developed the content of the application and reviewed the final manuscript, WJ reviewed the final manuscript, CB reviewed the final manuscript, AB developed the content of the application and carried out the first phase, HAK developed the application and wrote the manuscript, TS had the idea for the program, developed the content of the application, wrote the manuscript and obtained the financial support.

Abstract

Background: Mobile health (mHealth) apps are playing an increasingly important role in health care, including in radiotherapy. However, adherence remains low. One way to increase adherence is to tailor app features to the patients' preferences.

Objective: This study aimed to explore the importance of patient preferences regarding the features of a therapy-supporting app in radiotherapy. In addition, we examined factors associated with the perceived importance of these features.

Methods: A cross-sectional questionnaire study was conducted with patients undergoing radiotherapy between summer 2021 and winter 2022. The subjective importance of 18 features of a treatment-accompanying app was explored using a 5-point Likert scale from 1=not so important to 5=extremely important. Descriptive analyses were used to show the rated importance of app functions. Associations with possible predictors were examined using multiple hierarchical regressions, with age (interval-scaled), gender (dichotomous), previous experience with mHealth apps (dichotomous), education (3-level nominal), and supportive care needs (interval-scaled) as predictors.

Results: A total of 84 radiotherapy patients participated. The average age was 62 (SD 12.5) years. The feature with the highest importance was security against hacking (46/77, 60% extremely important). Explained variances in the regression analyses ranged between R^2=0.25 (The app should give me tips on suitable sporting activities that are possible with my illness) and R^2=−.07 (The app should provide me with information about suitable self-help offers). Previous mHealth usage predicted the importance of 6 features, such as managing appointments (β=.275; P<.05). Decreasing age was related to 6 features, for example, showing test results and laboratory values (β=−.358; P<.05). Other predictors were an increasing age and greater supportive care needs.

Conclusion: Patients undergoing radiotherapy rated app features as having varying levels of importance. The findings may help to tailor mHealth apps in radiotherapy, potentially improving adherence to app usage.

KEYWORDS

patient preferences; radiation therapy; mHealth apps; app features; Digital Cancer therapy

Introduction

The use of mobile technologies is on the rise, with around 4.7 billion smartphone users worldwide [1]. It is therefore no surprise that an increasing number of mobile health (mHealth) apps are available. mHealth is defined as digital technologies offering health services [2,3]. The main uses of mHealth apps for cancer patients are, interalia, disease management, monitoring, supporting healthy behavior, and interpersonal exchange with other patients [2,4]. mHealth apps have shown a high degree of feasibility and patient acceptance among patients with cancer [5] including early detection of cancer relapse [6]. At the same time, more and more health care providers are offering mHealth solutions to accompany

XSL•FO
RenderX

treatments and health services, such as providing information on floor plans of provider sites, individual appointment planning, and legal, medical documents. As an example, the Medical Center – University of Freiburg provides the "Meine Uniklinik" app [My university medical center] for patients and visitors, helps them navigate the hospital campus and their treatment process [7]. Overall, these apps aim to enhance treatment processes and increase patient satisfaction, and thus potentially improve treatment outcomes in the long run [6].

However, many mHealth apps show insufficient patient usage, as patients often stop using the app shortly after download, do not follow usage recommendations, or never use it at all—even when prescribed by doctors [8,9]. This nonusage has been shown to be associated with the limited effects of mHealth interventions [8,10]. Thus, tailoring mHealth apps to individual patient needs has recently gained importance in order to increase usage and app adherence [11,12]. A recent review has found no clear evidence of consistent predictors of mHealth use in patients with cancer [12], even though some research suggests that female gender, increasing age, and a higher education are related to greater usage [13-16]. Other predictors included the number of comorbidities or the experience of pain [12]. Given the unclear evidence on usage predictors, the question of what factors might positively influence usage remains open.

One promising approach to tailoring mHealth apps might be to consider patient preferences for mHealth app features. One study found that the flexibility of mHealth apps to adapt to patient preferences positively influences patients' expectations of app performance [17]. Considering patient preferences is also known to be a key aspect in providing patient-centered care [18,19]. Since care coordination is essential to patient-centeredness [19], which could also be provided through treatment-accompanying apps, understanding patient preferences is relevant. Furthermore, by addressing patient preferences related to care processes, treatment outcomes might be positively affected [18]. However, little is known about patient preferences for mHealth apps accompanying treatment in patients with cancer [20], even though detecting patients' needs before developing a mHealth app is relevant to developing targeted measures [21].

In conclusion, the aim of this study was to explore patient preferences for app features and to investigate the possible associated factors. Specifically, we aimed to explore the following research questions: (1) How do patients undergoing radiation therapy rate the importance of the features of an app accompanying treatment? (2) What factors are associated with the importance ratings of the features?

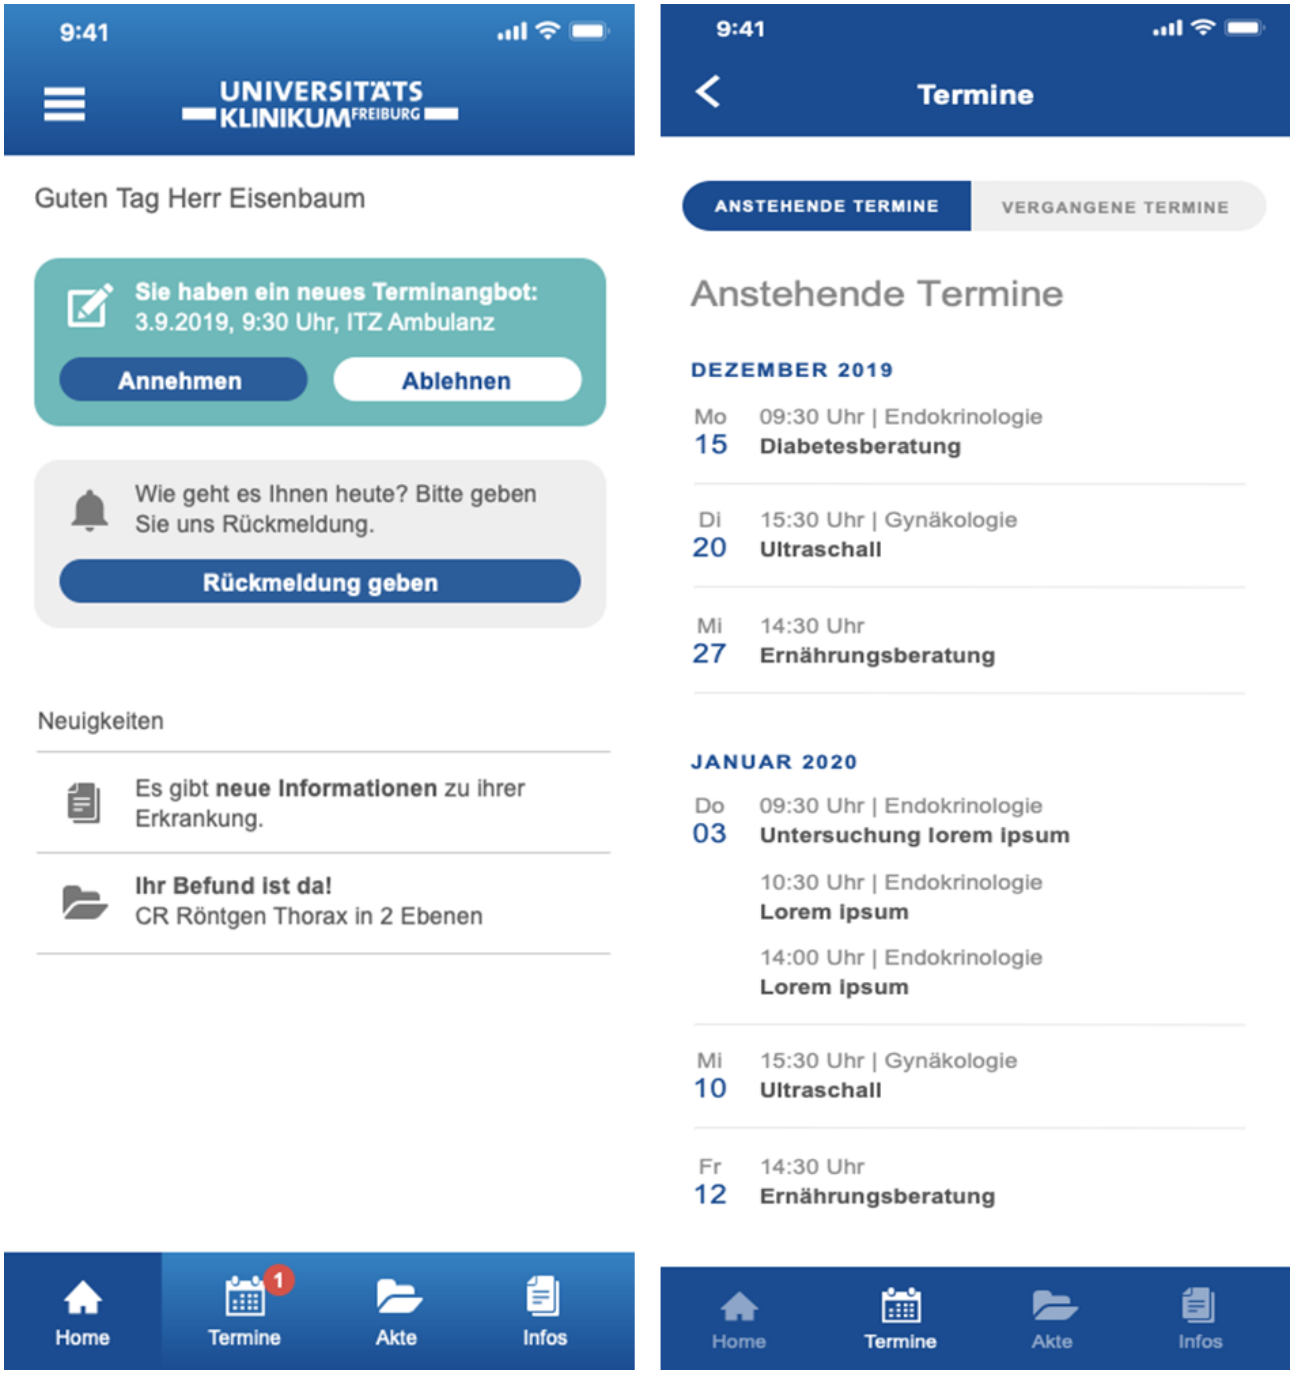
We conducted a quantitative cross-section study. The questionnaire used was based on findings from a qualitative preliminary study. To examine associations, the following factors were investigated: gender, previous use of mHealth apps, education level, age, and supportive care needs.

Methods

Ethical Considerations

This study was conducted at the Medical Center - University of Freiburg. Ethical approval was granted by the University of Freiburg Ethics Council (approval number: 377/19), and the study was registered in the German Clinical Trial Register (DRKS00020362). Written informed consent was obtained from all participants in the preliminary and main studies. Participants received no compensation for their participation. All data were pseudonymized to ensure confidentiality.

Preliminary Study and Questionnaire Development



We conducted a qualitative preliminary study in the summer of 2020 with a total of 4 patients. The number of participants was determined based on practical considerations during the COVID-19 pandemic, where contact was to be limited. Included patients were those visiting the Department of Radiation Oncology at the Medical Center – University of Freiburg for their initial consultation before the start of radiation therapy. The aim of the preliminary study was to assess patients' feature preferences for a mobile app accompanying hospital treatments. For this purpose, qualitative interviews were conducted using a semistructured interview guideline. The guideline began with an open-narrative question, asking the participant to elaborate on their expectations of a treatment app before the initial consultation, immediately after the initial consultation, during treatment, and after the completion of treatment. Afterward, patients were shown an early version of the "Meine Uniklinik" app, a treatment accompanying app developed by the Medical Center – University of Freiburg [7]. Patients were given some time to use the app before the interview proceeded. They were then asked about their first impression of the app and its features, and whether the app aligns with their previously matched expectations. All the interviews were digitally recorded and transcribed verbatim by an external service provider.

We categorized the interview content into different categories. The categories comprised the treatment organization, the therapy process, therapy participation, information about the clinic and providers, emotional support, services, design, and concerns. Based on these categories, items in respect to patient preferences for a mobile app accompanying hospital treatment were developed. For this purpose, one of the authors (RW) developed an initial version of items, aiming to create one item for each feature mentioned by participants. Two of the other authors (EFG and NHN) reviewed the items, with a specific focus on comprehensibility and unidimensionality. Finally, a total of k=18 items were developed as regards feature preferences related to, interalia, the organization of treatment, appointments, and networking with other patients. Example items include "The app should give me information about the therapy process" and "The app should remind me of my follow-up appointments." Answers were given on a 5-point Likert scale from 1=not so important to 5=extremely important. The questionnaire began with pictures of the "Meine Uniklinik" app to give participants an impression of what such an app might look like (refer to Figure 1). For the purpose of publication, the questionnaire

XSL•FO
RenderX

items were translated into English by the author of this manuscript.

Figure 1. Screenshots of the "Meine Uniklinik" app used during the study showing the home screen and the overview of appointments.

The questionnaire was tested with a total of 5 participants. Attending doctors asked these participants for feedback, in particular as to whether all the items were understandable and if the length of the questionnaire was acceptable. All 5 participants rated the questionnaire as acceptable in both length and clarity. Since all the participants rated the questionnaire as acceptable and no changes were made, the 5 participants were included in the final sample.

Further Assessments: Supportive Care Needs

To assess the supportive care needs of participants, the Short-Form Supportive Care Needs Survey [21] in its 9-item short form as described by Girgis and Stojanovski [22], was used. We used supportive care needs as possible associative factors, hypothesizing that the app might be able to provide supportive care. The 9 items describe the psychological, health systems and information, daily living, patient care, and sexuality domains as in the original form. The brief 9-item version is efficient and reliable for clinical samples that have limited time [23]. For analysis, a mean score is calculated and converted to a 0 - to 100-point scale, with 100 indicating greater supportive care needs. Cronbach α was 0.87 in this study.

XSL•FO
RenderX

Sociodemographic Data

Sociodemographic data included gender, age, highest school education, employment status, and previous usage of mHealth apps.

Recruitment of Participants

As part of the study, we aimed to recruit 200 participants during their initial consultations at the Department of Radiation Oncology, Medical Center – University of Freiburg, between summer 2021 and winter 2022. A sample size of 200 was deemed sufficient to explore associations between various factors and the perceived importance of app features. In total, we successfully recruited 84 participants, corresponding to a recruitment rate of 42%. Eligible patients had to be of legal age (≥18 y) and have sufficient German language skills. Attending doctors led the recruitment process by informing potential patients about the study and handing out study information and the questionnaire. Both the study information and questionnaire were paper-based. Participants were allowed to complete the questionnaire directly after the consultation while still at the clinic, or at home, and to then return it at the following appointment. Participants took about 20 minutes to complete the questionnaire. Final questionnaire data was entered into the database using an automated scanning process with a PDF to Microsoft Excel step.

We have no information on patients who were eligible and declined to participate.

Analysis: Description of Feature Preferences

Analyses were conducted at the level of the individual item. First, we conducted a descriptive analysis of each item, describing the subjective importance of the corresponding feature.

Associations With Feature Preferences

Associations with possible predictors were examined using multiple hierarchical regression analyses, with the following factors as predictors: Gender (dichotomous: female or male), experience with mHealth apps (dichotomous: yes or no), highest level of education (dummy-coded), age (continuous variable), and supportive care needs (continuous variable) were chosen as possible associated factors. Assumptions for all the regression models were tested by checking the value of the variance inflation factor, the Durbin-Watson statistic, plots of *ZRESID against *ZPRED and normal P-P plots. All the assumptions were met. All the analyses were conducted using IBM's SPSS Version 29 [22].

Results

Participants

Although 84 patients submitted their questionnaires, data were available in only 82 cases, as 2 participants returned empty questionnaires. One person identified as gender diverse and was therefore excluded from further analyses in view of the small number, resulting in a final sample of 81 patients. Most participants were male (41/78, 52% responses), the mean age was 62 (SD 12.5) years. About 31% (25/81) of the participants had previously used a mHealth app. More information on the participants can be found in Table 1.

Description of Feature Preferences

Participants showed a high diversity in their preferences for app features. For each item, responses were received from up to 77 out of 81 study participants. Overall, 46 out of 77 (60%) participants rated safety against hacker attacks as extremely important, whilst sending notifications about changes in treatment was rated as extremely important by 33 out of 77 (43%) participants. The feature rated least important was the option to network with other patients, with 39 out of 76 (51%) participants rating it as not important. An overview of all items can be found in Table 2.

[a]Not applicable.

Associations With Feature Preferences

Explained variances in the analyses ranged between R^2=0.25 (The app should give me tips on suitable sporting activities that are possible with my illness) and R^2=−.07 (The app should provide me with information about suitable self-help offers), indicating a limited fit of the predictors in some models. Gender and highest education were not significantly related to any preferences.

Previous mHealth app usage was associated with higher importance for 6 preferences. Participants who had previously used mHealth apps stated placing greater importance on the app offering the opportunity to manage appointments (β=.275; *P*<.05), and having a message feature if something changes (β=.342; *P*<.05) as well as an integrated tax call (β=.315; *P*<.05). Furthermore, participants with previous mHealth app usage placed greater value on functions concerning the showing of test results and laboratory values (β=.398; *P*<.01), the offering of information about a healthy diet (β=.575; *P*<.001), and the offering of suitable tips for sporting activities (β=.500; *P*<.001).

Age was related to higher importance in eight preferences in total. With decreasing age, participants had a greater need for the opportunity to manage appointments (β=−.459; *P*<.01), having information about therapy processes in the app (β=-.401; *P*<.05) as well as a feature showing test results and laboratory values (β=−.358; *P*<.05). Moreover, the app should further send messages if something changes (β=−.491; *P*<.01). In addition, it was more important to them that the app was attractively designed (β=−.372; *P*<.05) and should be intuitive to use (β=−.446; *P*<.01).

In contrast, increasing age was associated with the greater importance of 2 features: the app giving information about the timing of the therapy (β=.522; *P*<.001) and also reminding participants about follow-up appointments (β=.597; *P*<.001).

Finally, having higher supportive Care Needs was associated with a greater need for the app to address the patient personally (β=.367; *P*<.01). An overview of all the analyses is given in Table 3.

Discussion

Principal Findings

In this study, we explored patient preferences in respect of the features of a mHealth app accompanying treatment in a university hospital in Germany. Overall, participants in our study rated the features with varying degrees of importance, with the most crucial feature being security against hacker attacks. Other highly rated features related to the process and organization of the treatment, such as the administration and timing of appointments. Decreasing and increasing age, and previous usage of mHealth apps seem to be associated with greater importance being attributed to specific features. Understanding patient preferences might be relevant for increasing the usage of such apps, potentially leading to improvements in treatment processes and health outcomes. Furthermore, as patient opinions are often not considered during the development of mHealth apps in cancer care [20], the results we presented might help to encourage further apps' development. Recent literature shows that tailoring mHealth apps to patient preferences does increase engagement rates in cancer care [24].

Comparison to Previous Work

Overall, participants rated features as being of differing importance, with the most important feature being security from hacker attacks. Other highly rated features related to information on the process and organization of the treatment, such as the administration and timing of appointments. This is hardly surprising, as we did include patients at their initial consultation and there is some evidence indicating that cancer patients have a great need for information about therapy contents and processes at the beginning of therapy [25]. In contrast, participants noted a limited need to connect with other patients or to receive information on self-help resources. This is remarkable as self-help offers and peer-support groups are generally perceived as helpful [26] and are often included in mHealth apps [27]. Interestingly, patients in a previous study concerning the “Meine Uniklinik” app requested this specific

XSL•FO
RenderX

feature for a mHealth app in oncology [28]. It is possible that participants might perceive a treatment-accompanying app to not be an appropriate platform for promoting these services. However, due to the exploratory nature of our study, we cannot draw a conclusion about self-help resources in mHealth apps.

In line with the literature, we found that both increasing and decreasing age groups could be related to the feature importance, whilst there are contrasting results with regard to age [12,29]. In fact, the relationship between age and the adoption of mHealth apps seems to be complicated, with the perceived ease of use becoming more important with age [30]. Surprisingly, we ascertained that a decreasing, rather than an increasing age, was associated with a need for intuitive use and attractive design. Given that both preferences associated with an increasing age are related to the timing and therapy schedule, one might assume that this is the most important need for older patients. Furthermore, we found in our sample that experiences with health apps are related to a greater importance of different kinds of features, for example, the organization of the treatment and information on the illness itself (test results or diet tips). One could hypothesize that, due to previous experiences, participants place greater importance on those features when they have already encountered and therefore know which features are beneficial, or where they are able to transfer previous knowledge of the features to another app.

Notably, higher supportive care needs were only related to the greater importance of the app being personalized, even though the questionnaire assesses concepts like the need for information on laboratory values or behavior changes to increase the quality of life [23,31], which we also included as features in our study. One possible reason might be that patients do not expect these needs to be met by a treatment-accompanying app. Alternatively, the limited sample size may have contributed to supportive care needs being significantly related to only one feature.

As Woldeyohannes and Ngwenyama [17] stated, the flexibility of features is a key factor in influencing app usage. This is in line with the theory on patient preferences, which states that patient preferences are not a stable concept and do change over time [18]. Thus, even though we assessed preferences at only one measurement point, we assume that the preferences for features in a treatment-accompanying app will change during the course of treatment. It is therefore important for the usage and uptake of a treatment-accompanying app for it to be flexible with the features and for these to be adjustable by the patients.

Strengths and Limitations

In this cross-sectional study, we explored patients' preferences for a treatment-accompanying app in radiation therapy. Knowledge about patients' preferences is of relevance to improve usage of mHealth apps and to thus enhance treatment processes. The results might be used to design treatment-accompanying apps for patients undergoing radiation therapy and could thus possibly influence clinical decision-making.

First, we should discuss the assessment of the app features. We based our assessment of features on a qualitative preliminary study to assess only those features relevant to patients. Both patient groups in the preliminary study and main study were briefed either by screenshots of an example app, or the use of an early version of the "MeineUniklinik" app. This could have led to positive and negative effects on the assessment, either by limiting answers to the displayed features or helping patients imagine a corresponding app. For instance, patients had previously stated that a symptom and side effect tracker would be of use [20]. However, no patients in our preliminary study considered this feature to be necessary. Thus, the features assessed in this study require further validation.

Second, we were not able to gather any medical information on our participants, and this has proved to be an important disadvantage of our study. This was due to the COVID-19 pandemic, where no medical resources were available to assess patients' information. However, medical information should be considered in the future, as previous research suggests it is associated with app usage patterns [12].

Finally, the most important limitations are the small sample size, as well as the cross-sectional nature of the study. The latter is especially relevant considering the time instability of patient preferences. Furthermore, due to the small sample size, we decided not to control for multiple testing. However, this limits the interpretation of our results. Future research should focus on the assessment of feature preferences in therapy-accompanying apps using a longitudinal design, as well as focus on bigger sample sizes. These studies should also investigate the time instability of preferences, where possible.

Conclusion

In this paper, we explored how patients undergoing radiotherapy assess the importance of mHealth app features. The most important feature was security from hacker attacks, according to our sample. Age and previous usage of mHealth apps seem to be associated with the greater importance of different features. The findings in this study might be used to develop future apps after further validation, allowing tailoring to the individual patient and, thereby, enhancing patient-centered mobile care in radiation oncology. In this way, treatment processes might be improved, which in turn, might impact treatment outcomes.

Abstract

Background: Insomnia affects the quality of life and health outcomes of cancer survivors. Cognitive behavioral therapy for insomnia (CBT-I) is an effective treatment for insomnia among cancer survivors, but it is not readily accessible due to the limited number of trained providers and the difficulties in providing care across wide geographical areas. Mobile health (mHealth) technologies represent a promising solution; however, these technologies are not tailored to the unique needs of cancer survivors.

Objective: This study aimed to understand the needs and preferences of cancer survivors and test the usability of an evidence-based CBT-I smartphone app called iCANSleep that will be tailored and accessible to cancer survivors.

Methods: A user-centered design (UCD) approach was applied, and cancer survivors were actively engaged in the app's design, usability testing, and prototype refinement. In phase 1, semistructured interviews were conducted with a purposive sample of cancer survivors (n=20) to inform the design of the app and its content. In phase 2, iterative low- (n=8) and high-fidelity (n=7) usability testing was conducted with participants until no further recommendations for change were suggested.

Results: Users suggested several defining characteristics, features, and desired functionalities, including a user-friendly and evidence-based design. They saw increased accessibility and simplicity as advantages of a mobile app but expressed some concerns about data security and losing the accountability that comes with in-person treatment. User testing highlighted the preference for images of real people and diverse stories over graphics and animated videos, and offered suggestions for enhanced navigation. The first iteration of the app was developed using the information gained during the needs assessment and usability testing. Feedback was integrated into the final prototype of the iCANSleep app, which will be tested for feasibility, acceptability, and efficacy.

Conclusions: Cancer survivors desire an insomnia treatment app that is simple, user-friendly, evidence-based, convenient, and secure. The iCANSleep app represents the merging of mHealth principles and best practices with evidence-based insomnia care, allowing for an intervention with minimal access barriers related to cost, geography, and provider availability. Feasibility, acceptability, and efficacy of the intervention will be maximized by following a UCD framework involving the engagement of end users at every design stage.

Introduction

Owing to increased screening, earlier detection, and advances in treatment, more people are living longer after cancer and with active disease [1,2]. The increasing number of cancer survivors (defined as individuals from the time of cancer diagnosis throughout the balance of life [3]) presents new challenges and opportunities for research to better address the long-lasting impacts of cancer and cancer treatment. Among the most common challenges of cancer survivorship is insomnia, which limits recovery [4] and quality of life [5]. Cancer survivors are approximately 3 times more likely to experience insomnia than the general population, and this insomnia can persist for up to 10 years after diagnosis [6-9]. Insomnia among cancer survivors

XSL•FO
RenderX

is associated with many negative health consequences, such as increased pain [10], fatigue [11], perceived cognitive impairment [12,13], and reduced satisfaction with quality of life [5]. Moreover, disrupted sleep can have detrimental impacts on important objective health outcomes, including immune function, treatment response, and disease progression [4,14].

Cognitive behavioral therapy for insomnia (CBT-I) is recommended by the American Academy of Sleep Medicine and the American College of Physicians as the first-line treatment for insomnia [15,16] and has demonstrated effectiveness in several randomized controlled trials among cancer survivors [17-19] and the general population [20-22]. A meta-analysis of 15 trials reporting on 1461 cancer survivors indicated that participation in CBT-I resulted in clinically significant improvements in the time participants took to fall asleep, the amount of time spent awake while in bed, sleep quality, and self-reported insomnia severity [23]. CBT-I is a psychotherapy typically conducted over several weeks through regular sessions with a trained provider, which aims to address the perpetuating thoughts, emotions, and behaviors that contribute to insomnia [24]. Unfortunately, CBT-I remains inaccessible for most Canadians due in part to a shortage of appropriately trained clinicians [25]. Estimates suggest that there are only 752 CBT-I specialists worldwide, with only 5% residing in Canada. Access to qualified face-to-face providers in Canada is further complicated by the fact that a substantial proportion of residents live outside of metropolitan areas [26]. This means that cancer survivors in Canada, many of whom live in rural or remote areas, do not have adequate access to evidence-based treatment for insomnia. Additional barriers include a lack of insurance coverage, high treatment costs, and the difficulty of providing care across large rural areas. Owing to this lack of accessibility, pharmacological interventions, such as benzodiazepines and off-label hypnotics (eg, trazodone), have become the most frequently prescribed treatments for insomnia [27], despite well-documented risks that include tolerance and dependence, as well as withdrawal and rebound insomnia upon discontinuation.

Mobile health (mHealth), which is defined as the use of mobile and wireless technology (tablets, smartphones, etc) to support the improvement of health outcomes, health services, and health research, is a promising solution to the previously noted barriers to accessing CBT-I, especially given the high prevalence of smartphone ownership across age groups and socioeconomic status [28-30]. mHealth interventions are particularly well-suited to promote active engagement with and self-monitoring of chronic conditions, such as insomnia, and are considered by patients with cancer to be highly acceptable and feasible treatments [29]. Unfortunately, many of the currently available apps have been criticized for failing to adhere closely to evidence-based treatment recommendations [31]. iCANSleep will be the first evidence-based insomnia treatment smartphone app tailored to the unique needs of cancer survivors.

The objectives of this study were to (1) conduct a needs assessment with a sample of cancer survivors to inform the appearance, features, and content of the iCANSleep app, and (2) assess the low- and high-fidelity usability of the codeveloped iCANSleep app.

Study Overview

Design

The development of iCANSleep involved a user-centered design (UCD) process and followed a phased, sequential approach as recommended by the Medical Research Council Framework on the development of complex technology-based interventions [32]. UCD is an evidence-based framework for the development of technology-based medical interventions, which is informed by the needs and preferences of a specific group of end users [33]. A UCD process involves the engagement of end users at all stages of the development process, from needs assessment and app design to usability testing. Early involvement of cancer survivors in the design stages of the app allows the identification of features perceived as important to cancer survivors in a CBT-I app and is intended to address the common concerns with mHealth interventions (eg, early abandonment).

Ethical Considerations

Ethical review and oversight were provided by the Health Research Ethics Authority of Newfoundland and Labrador. Approval was obtained for the needs assessment (HREB# 20222228) as well as both low- and high-fidelity testing (low fidelity: HREB# 20230515; high fidelity: HREB# 20231358). All interested participants were screened for eligibility and provided written informed consent. Once enrolled, participants were assigned a study number, and all subsequent information was tied to the study number to protect the identity of the participants. The researchers did not ask for names or any other identifying information during the interviews, but if participants provided such information, this information was not included in any transcripts. The recordings were tied to the study number and were securely erased after being transcribed and checked for accuracy. Questionnaires were emailed to the participants for completion via Qualtrics. Each participant who completed the interview or low/high-fidelity usability testing received a CAD $15 (US $11) digital gift card.

Phase 1: User Needs Assessment

Methods

Participants

Participants were purposively sampled, such that half of the sample reported having experience with in-person CBT-I and half reported no such experience. That was done to capture the perspectives of treatment-naïve and experienced cancer survivors. Cancer survivors who participated in past CBT-I trials were recruited directly from our mailing lists. Individuals without CBT-I experience responded to study advertisements shared through partnering networks and patient support organizations and were eligible to participate if they had (1) a previous cancer diagnosis of any type or stage, and (2) current reported insomnia as indicated by a score of >8 on the Insomnia Severity Index (ISI). A target sample size of 20 participants was selected based on the recognition that previous studies performing needs assessments through semistructured interviews have used similar sample sizes to achieve adequate thematic saturation, with further interviews providing limited novel

XSL•FO
RenderX

information [34]. All participants who expressed interest in the study were interviewed. Reporting of the phase 1 assessment follows the Consolidated Criteria for Reporting Qualitative Research (COREQ) [35].

Procedure

An interview guide was developed by the research team based on a review of the literature and consultation with our industry stakeholders. End users provided feedback and improved the clarity of the interview guide before it was deployed. Eligible individuals participated in virtual interviews about their experiences with insomnia and cancer, their familiarity with smartphone technology, and their needs and preferences for an insomnia treatment smartphone app, using Webex. Interviews were conducted by SK (an experimental psychology master's student with graduate training in qualitative research). Participants were introduced to the interviewer, explained the purpose of the interview, and offered an opportunity to ask questions prior to providing informed consent. Each interview lasted approximately 30 minutes and was attended by the interviewer and participant only. No repeat interviews were conducted. The semistructured interview guide is presented in Multimedia Appendix 1. Interviews were transcribed using NVivo software (Lumivero). Field notes were taken during the interviews, and transcripts were double-checked by the research team to ensure consistency and accuracy. Feasible recommendations for app design were drawn from the identified themes and translated into a set of functional requirements and design guidelines, which were used to develop the app prototype for usability testing. Transcripts were not returned to participants, and direct feedback on the findings was not provided. However, usability testing allowed for further user feedback.

Analysis

Interview transcripts were analyzed, and recurrent themes were identified through thematic analysis. Thematic analysis is a form of qualitative data analysis that is used to analyze patterns in the data and organize them into overarching themes [36]. The process involved 6 steps. In step 1, researchers read the interviews multiple times to familiarize themselves with the data. Then, in step 2, interviews were coded by 2 researchers, and the identified codes were discussed. This involved interpreting, identifying, and categorizing the major ideas and concepts in a passage (codes), and noticing which ideas and concepts are repeated or more central to the experience of interest. Codes are the smallest units of analysis that capture important features of the data, ranging in length from a single sentence or phrase to a paragraph. In steps 3 to 5, the codes were further categorized into overarching core ideas, known as themes, and iteratively grouped and refined by the research team. This process requires multiple reflexive iterations of transcript review, as categories are refined and restructured as more data are analyzed. The process is nonlinear as codes may be established and later updated or refined to fit with a new interpretation of the data. In step 6, the data were presented (*Results* section).

Results

Participants

A total of 22 eligible participants responded to recruitment materials and were enrolled in the study. Technical issues with the audio recordings of 2 interviews rendered their transcripts unusable, and data from these 2 participants were excluded. The final sample of 20 participants (mean age 58.65, SD 15.68 years) included 14 women and 6 men. Of the 20 participants, 10 (50%) had experience receiving CBT-I in a virtual face-to-face format and 10 (50%) did not have previous experience or information about this intervention. Table 1 provides the demographic information of the sample, and Table 2 provides the cancer-specific information of the sample.

Cancer Survivors' Recommendations for mHealth-Based Insomnia Treatment

Three major themes were identified from the participant interviews relating to what features and functionalities they would prefer in the app and the perceived advantages and disadvantages of an app-based insomnia treatment for cancer survivors. Each of these themes was further characterized by several subthemes to best capture key concepts.

Theme 1: Defining the Characteristics, Features, and Functionality of an Insomnia Treatment Smartphone App

Subtheme 1: User-Friendliness

Simplicity and ease of use were highly valued. Cancer survivors reported not wanting to spend too much time "figuring out" the app. Easy navigation included having a few large, clear buttons with apparent functions. CBT-I–naïve participants had mixed feelings about the user-friendliness of in-app reminders such as badges, sounds, and push notifications. While they did recognize the advantages of receiving timely reminders to complete certain tasks, they noted that overuse of these notifications would be perceived as annoying and would discourage long-term use of the app. A colorful, easy-to-understand data visualization was

XSL•FO
RenderX

favored by these participants, particularly one that included information on the displayed variables and their relevance to sleep and insomnia.

Participants found that many apps they had used in the past imposed upon their daily life through irrelevant suggested content, excessive notifications, and intrusive advertising. Apps with heavy use of medical and technical jargon were considered difficult to understand and therefore less usable. This extended to apps that displayed data awkwardly or without explaining what the variables mean or how to understand the data display.

Subtheme 2: Evidence-Based Design

Cancer survivors reported being much more likely to use an app if it was endorsed by the medical community or their local cancer center. Participants liked that the content of the iCANSleep app would be designed by insomnia specialists and that it would deliver the recommended treatment for insomnia according to clinical practice guidelines. Cancer survivors who had no experience with CBT-I highly valued the ability to track their sleep within the app and receive individualized behavioral recommendations (eg, bed and rise time assignments) tailored to their own sleep data. This sentiment was echoed by participants who had experienced CBT-I in the past, and they also appreciated the ability to access curated evidence-based educational materials and resources within the app, rather than searching for similar information online, where it would be intertwined with information from unverified sources.

Subtheme 3: Desired Functionality

Participants with CBT-I experience felt that an app could consolidate several aspects of insomnia treatment. These participants saw the app as a convenient one-stop shop for receiving bed and rise time routine recommendations, tracking sleep diary indices as well as unique circumstances (events, stressors, and subjective sleep quality), seeking evidence-based information and resources on sleep, and receiving peer support through an anonymous forum. Those with CBT-I experience noted that sleep diaries would be more easily completed on a smartphone than using paper and pencils or a desktop computer. Participants also noted that the digital data display would be easier to understand at a glance than paper diaries and that this could be augmented through the thoughtful use of display colors, flags, and info bubbles.

Cancer survivors with and without CBT-I experience also expressed the desire to be able to connect their various wearable devices (eg, Fitbit and a smartwatch). Most participants agreed that the app's ability to provide feedback and praise when certain tasks are completed or goals are achieved through badges, streaks, and other gamification features would augment their experience of the app and encourage its use. Participants with no CBT-I experience desired an insomnia treatment app that included guided meditation, calming sounds, and sleep stories to listen to while falling asleep in order to manage presleep stress and anxiety. This was not endorsed by participants with CBT-I experience.

Theme 2: Advantages of Receiving Insomnia Treatment via a Mobile App

Subtheme 1: Accessibility

The primary advantage identified by cancer survivors for receiving insomnia treatment through a smartphone app was increased accessibility. Participants liked how an app for insomnia treatment could be accessed around the clock, without the need for scheduling appointments at a predetermined hour. Furthermore, the app could be accessed from any location, allowing treatment access when away from home, such as on vacation, and eliminating costs associated with travel to appointments, such as gas, parking, and childcare. One participant commented:

> *I've always got my phone on me, so it doesn't matter where I am if I'm camping or home or whatever. If I'm having trouble, I have techniques, I'll have tools.*

Cancer survivors considered an insomnia treatment app that is available for free download to be highly advantageous compared to standard treatment channels.

> *Something that's actually accessible to people like a smartphone app makes it a lot easier for people to actually access care that they wouldn't necessarily otherwise be able to access.*

One participant, speaking of the many ways an app would be more accessible for them, made the following statement:

> *I think anything that gets it in the hands of people that doesn't require a referral, or you know, $120 every time you go see them...more people are going to use it.*

Subtheme 2: Simplicity

Another major advantage mentioned by cancer survivors about receiving insomnia treatment through a smartphone app was simplicity. Participants with CBT-I experience felt that a properly designed smartphone app would simplify the daily process of tracking their sleep. One participant, speaking of the advantages of a digital sleep diary, made the following statement:

> *It's so much easier….You know, like especially where our phones are pretty much, for the most part, next to our beds, so you can quickly type it in.…First thing I do, I check my email. I can easily plug in the numbers. Boom, it's done.*

Participants also noted that the data display could facilitate the process of identifying trends in their own data. For some participants, using an app was also considered to be easier than finding an appropriate treatment provider. According to 1 participant, the ordeal of seeking out a new mental health professional was a big step to take. The participant commented as follows:

> *…To finally go and see someone about it…it's difficult when you go and you see a therapist three times and realize we're not going to mesh. Like this isn't going to work. And then the thought of having to go and repeat yourself all over again to another person and*

XSL•FO
RenderX

you know, that cycle. If there was an option of having an app that I could try, what's the harm in trying?

Theme 3: Disadvantages of Receiving Insomnia Treatment via a Mobile App

Subtheme 1: Absence of a Therapeutic Relationship

Cancer survivors with experience receiving CBT-I from a provider, albeit virtually, were concerned that by receiving insomnia treatment through a smartphone app, they would miss out on the benefits of having a therapeutic relationship with a trained care professional. The ability to raise concerns or ask questions and receive answers from an experienced clinician was important to several participants, who highlighted the app's relative lack of individual tailoring as a weakness. Some participants felt that the app's ability to deliver cognitive therapy would be limited, and they were looking for a treatment that did more to "analyze" the causes and precipitants of their insomnia, rather than simply provide psychoeducation and behavioral recommendations. One participant commented as follows:

I like face to face. It's a personal preference. I think it allows me to ask questions that I can get answered as opposed to just putting in and they, the app, giving me back the information they think I want.

Subtheme 2: Lack of Accountability

Participants with CBT-I experience reported that accountability to another human helped them remain engaged in past treatments, and they worried that engagement with an insomnia treatment app would be more difficult to maintain. These participants noted that the onus would be on the app user to engage with the app and maintain the daily sleep diary entries, and they felt that it would be easier to forget to complete the diaries or ignore any push notification reminders if there was no other human involved to keep them accountable.

If I didn't feel like it worked right away, I sometimes I have a tendency to give up early. It was helpful with a therapist because I felt that obligation to them. Whereas it might be easier to quit on an app because it's an app and there's nobody to disappoint.

Subtheme 3: Reliance on Technology

Cancer survivors noted that treatment would only be available to people who own smartphones and who are located in a region with cell service. Some raised concerns that older participants or participants located in more rural areas would not be able to access the app. One participant commented as follows:

There are people that because of where they live, don't have the best reception with their phones and their apps. There are still a lot of places here in Newfoundland that are rural and don't have the best reception.

Participants also noted that certain events or circumstances might limit access to treatment, such as adverse weather conditions causing power or service outages. Some participants owned smartphones but expressed concerns that they were not familiar enough with the phone or with using apps to be confident in using an insomnia treatment app. One participant made the following statement:

I'm not that old. I mean, my husband is in his early 80s. I'm going to be 75…I don't feel I don't feel old in any way, except when I pick up one of these [smartphones] and then or this [laptop computer] and then I feel old.

Subtheme 4: Security, Privacy, and Data Ownership

Participants expressed distrust in the privacy and security of most apps, noting that many apps earn revenue through the sale of user data, and they mentioned that even those that do not explicitly sell user data are still vulnerable to unintentional data breaches. As a result, participants desired an insomnia treatment app that could be used while maintaining full anonymity and privacy. Participants with and without CBT-I experience highlighted the importance of being able to access their sleep data, both for privacy reasons and the ability to bring this easily understood information to another health care provider to augment the visit.

Phase 2: Usability Testing of the iCANSleep App

Methods

Basis of Usability Testing

The results from the needs assessment supported a consumer demand for a mobile insomnia intervention (eg, accessible and simple to use) tailored to cancer survivors and informed the defining characteristics (eg, user-friendly and evidence-based design), features (eg, gamification), and functionality (eg, built-in sleep diary and options for symptom tracking) of the app. The needs assessment also highlighted potential issues that would need to be addressed for the app to be acceptable to the users, including security, privacy, and data ownership. Potential users also identified possible limitations of an app-based intervention compared to traditional face-to-face treatment. This information can be used to identify those individuals who may or may not be best suited for an mHealth intervention.

Adhering to the principles of a UCD approach, usability testing of the iCANSleep app used an iterative process of testing the intervention's user interface and prototype among a group of end users, collecting feedback, and using the feedback to redesign the prototype to meet users' needs [37,38]. Current literature supports iterative usability testing to improve the likelihood of effectiveness in a technology-based intervention [33,39]. Both low- and high-fidelity usability testing cycles continued until saturation of recommendations was achieved. Low-fidelity usability testing uses simple design mock-ups of the app interface, usually presented as a digital wireframe, with feedback focusing primarily on basic functionality and design. This approach allows for the early identification of usability and design concerns before developing a prototype, making it a cost-effective way to implement participant feedback. Subsequently, high-fidelity testing uses a functioning prototype of the app, providing realistic user interactions. This final stage

XSL•FO
RenderX

of usability testing helps to solidify the final design and refine the navigation of the app.

Participants

Individuals were eligible to participate if they had (1) a previous cancer diagnosis of any type or stage, and (2) current reported insomnia as indicated by a score of >8 on the ISI.

Procedure

Low-Fidelity Usability Testing

Low-fidelity usability testing involved showing participants a digital wireframe of the app's user interface and soliciting feedback about aspects that are liked or disliked about the premise, design, and presentation of the app. Participants were further queried about suggestions for improvement. All interviews took place through Webex video conferencing software and were recorded. Researchers transcribed interview responses. Participants who participated in the low-fidelity usability testing received a CAD $15 (US $11) digital gift card.

High-Fidelity Usability Testing

High-fidelity usability testing took place following the development of a complete mock-up of the app. During a 30-minute in-person interview, participants were invited to explore the iCANSleep app and provide their impressions of its features and functions. Participants also completed a short questionnaire exploring their interest and willingness to use the app. Following a brief demonstration of the app, users were asked to navigate its contents and complete tasks (eg, make an entry in the sleep diary and locate a specific educational resource) while narrating aloud about the positive and negative aspects of app use. Audio of their voice and video of their hands as they navigated the app were recorded to help identify aspects of the app that were challenging to navigate. Additional information was generated from test participants through semistructured interviews assessing the app's user interface design, content, and functions.

Analysis

Data from the low- and high-fidelity usability testing interviews were transcribed and reviewed. Participants' statements were examined for patterns that indicated usability issues (ie, tasks taking longer than expected). Similar feedback from multiple participants was interpreted to indicate systematic problems with the design, whereas outliers and less common feedback were taken to suggest issues that may affect specific user groups.

Results

Low-Fidelity Usability Testing Results

Eight cancer survivors from across Canada viewed a digital wireframe of the app's design and content and completed semistructured interviews. Participants (6 female and 2 male participants; mean age 53 years) were generally very impressed with the design and layout of the app. Most participants (6/8, 75%) were very interested in trying the app and reported that they would complete all or most of the app's treatment program. Participants appreciated the integration of cancer-specific stories and material; the app's simple, user-friendly design; the use of incentives and reinforcement; and the depth and breadth of its content. In the interviews, participants commented on the comprehensive sleep diary within the app and its apparent simplicity. Participants offered feedback on the presentation of the app and made recommendations to improve the usability of the interface. Suggestions were also made to streamline the onboarding and replace animations with real people. Based on the low-fidelity feedback, the research team removed the onboarding video and animations and replaced them with diverse patient stories to convey the necessary information.

High-Fidelity Usability Testing Results

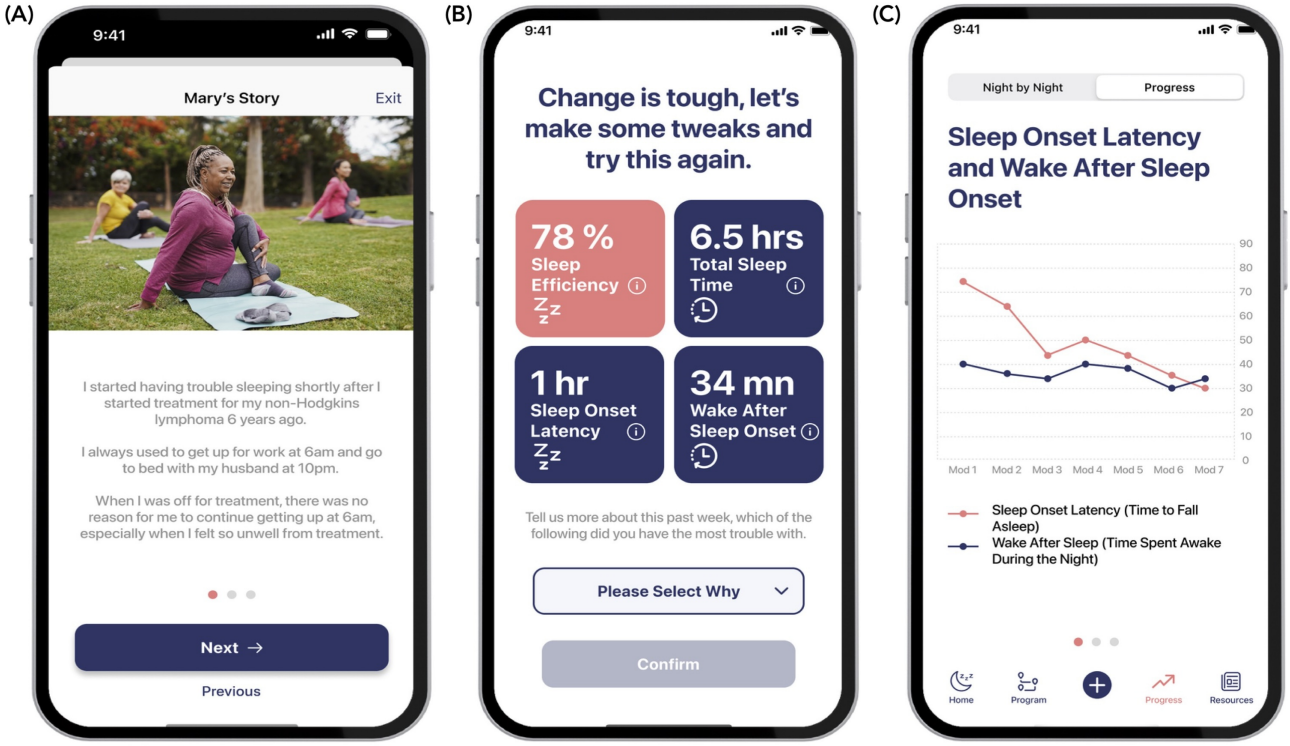
Seven cancer survivors (4 female and 3 male participants) from St. John's and the surrounding areas in Newfoundland attended a 30-minute in-person interview. Most participants (5/7, 71%) reported being very interested in trying the app, and 86% (6/7) indicated that they would complete the program. Additionally, 71% (5/7) reported that they would complete the program even if they did not see immediate results. All participants found the app easy to use and successfully completed all tasks and navigations. Suggestions for improvements included adding more "information" buttons throughout the app to provide additional context, increasing the size of the "information" buttons for better visibility, and organizing the bottom navigation menu. Participants also recommended improvements to the sleep diary, such as providing multiple options (eg, pain, washroom, pets, etc), along with an "other" button for the question "Did something influence your night?" instead of a text box response.

Final Product

Based on the feedback from the user needs assessment and low- and high-fidelity user testing, we codeveloped an evidence-based insomnia treatment smartphone app for cancer survivors called iCANSleep (insomnia treatment for cancer survivors). Feedback from study participants in phases 1 and 2 was shared with the developers and user interface/user experience design members at our partner company, SideKick Interactive, to draw on their expertise and assess the appropriateness and feasibility of incorporating changes. The majority of the changes and updates to the app were driven by our participants to ensure that the needs of our target audience were prioritized. This self-guided insomnia treatment program is based on an established CBT-I treatment program [40] and incorporates evidence-based treatment components (described in Table 3).

XSL•FO
RenderX

Table . iCANSleep app module content overview.



Module	Summary of key components
Module 1: Getting to know your sleep	Introduction to CBT-I[a]; Creating sleep goals and the importance of self-monitoring using sleep diaries.
Module 2: Making your sleep more efficient	Sleep restriction; Creating a buffer zone; Users will receive their personalized sleep program based on sleep diary data from the past week.
Module 3: Making sleep your new habit	Stimulus control therapy; Reinforcing the connection between the bed and falling asleep by using the bed as a cue for sleep and restricting or avoiding other activities in bed.
Module 4: Relaxing into sleep	Relaxation techniques (progressive muscle relaxation, diaphragmatic breathing, etc); The role of relaxation techniques and how to schedule time for relaxation practice.
Module 5: Thinking straight about sleep	Cognitive restructuring; Challenging maladaptive beliefs about sleep, sleep problems, and sleep expectations, and creating realistic expectations and goals about sleep.
Module 6: Taking care of your sleep environment	Sleep hygiene psychoeducation.
Module 7: Sleeping with and beyond cancer	Users will receive strategies to help cope with relapses, strategies to instill motivation, and tools to maintain treatment gains over time.
Supplementary material	The extra resources provided to participants serve as supplementary material. The resources have been designed to address general and cancer-specific sleep questions or concerns raised by participants. Some examples include (1) Pain and sleep; (2) Sleep and exercise; (3) Hot flashes and sleep; (4) Should I take melatonin to help me sleep? and (5) How do cancer treatments affect sleep?

[a]CBT-I: cognitive behavioral therapy for insomnia.

The iCANSleep app allows for daily sleep tracking, provides tailored feedback for sleep improvement based on user-provided sleep data, and acts as an information resource for cancer survivors with insomnia. Figure 1 provides examples of the app's appearance and features. As suggested by users, the app's appearance is clean and uncluttered, with intuitive features and functions. The language is free of jargon, and any unfamiliar terms have an associated definition. Data from the sleep diary are presented to the user nightly each week, and weekly averages are available so that users can visualize their data and progress in the following areas: total sleep time, time spent in bed, sleep efficiency, sleep onset latency, amount of time spent awake at night, and number of awakenings.

XSL•FO
RenderX

Figure 1. Screenshots of the user interface of the iCANSleep app showing (A) a story of a user with lived experience, (B) a weekly sleep summary, and (C) a weekly progress graph. Credit: Image created by the authors using content from Sabrina Bracher/Shutterstock.com.

Much attention was paid to the development of the sleep diary to ensure data accuracy. The development of the diary followed the recommendations of Shaffer et al [41], and it includes features to limit retrospective bias, promote user engagement, and provide data validation checks. Users must provide 5 days of sleep diary data in a 7-day period to allow for sufficient data to inform their individualized sleep recommendations and progress to the next module. Sleep efficiency cutoffs are used to inform the next week's recommended sleep window. If the user's sleep efficiency increases to 85% or higher, the app will offer praise, reinforce progress, and suggest that the user increase their sleep window by 30 minutes. If the user's sleep efficiency is between 75% and 85%, the app will suggest that the user keep the recommended sleep window the same and address problem areas. If the user's sleep efficiency is below 75%, the app will recommend that the user reduce their sleep window by 30 minutes, but never less than 5 hours. It will also provide support and suggest addressing challenges that the user might have encountered.

The lived experiences of cancer survivors are woven into the app onboarding so that users can "see themselves" in the app, and patient stories are used to demonstrate key treatment components. Notifications are limited to reminders to complete the sleep diary in the morning and a reminder to wind down before bed. Several gamification features are incorporated to encourage app engagement, including badges for sleep tracking streaks and awards for sleep improvements. As suggested, the app also features general and cancer-specific sleep information to address common challenges that users may face.

Users expressed concerns about the security, privacy, and ownership of their data. Based on this feedback, the research team is committed to collecting only absolutely necessary data (eg, sleep diary entries). The app also does not have any advertisement features for revenue generation and will not sell user information to third parties. To ensure the privacy of user data, a unique user identification number is generated upon user registration, and sleep data are stored in a secure SQL database that can only be accessed by approved members of the research team.

Discussion

Principal Findings

End users were involved in every phase of this research, including identifying priorities and preferences, development, and feasibility and usability testing, to ensure that the app is relevant and will address their unique concerns. The needs assessment revealed that cancer survivors wanted an app that is simple, user-friendly, evidence-based, convenient, secure, and a "one-stop shop" for all their insomnia-related needs. While all participants who tried the app prototype reported finding it easy to use and successfully navigating through the assigned tasks, they suggested valuable improvements for both organization and content. Participants with no CBT-I experience generally described user-friendly features of apps they had used in the past, requesting features like guided meditation and sleep sounds. Participants with CBT-I experience had a more concrete idea of what the treatment entailed, speaking more about how digital delivery would improve their experience, increase accessibility, and streamline treatment processes, such as completing the daily sleep diary. Phases 1 and 2 of our UCD approach resulted in the development of iCANSleep, an app that merges evidence-based insomnia treatment components with modern mHealth best practices for the delivery of insomnia care.

RenderX

Comparison With Prior Work

An evidence-based app for the treatment of insomnia is desperately needed to combat the multitude of apps that purport to help with sleep. Choi et al [42] reviewed nearly 2500 smartphone apps for sleep, concluding that the vast majority of sleep apps listed for download on common app stores fail to meet acceptable criteria for content, quality, or functionality in sleep self-management. To the untrained eye, finding an evidence-based sleep app through a simple search is thus a task akin to finding a needle in a haystack. Accordingly, there is a great opportunity for an evidence-based app focused on insomnia treatment. As recommended by the Medical Research Council Framework on the development of complex technology-based interventions [32], the next phase in the UCD and development of the iCANSleep app will involve testing the acceptability and feasibility of the app. This will be followed by a clinical trial to properly investigate the efficacy of the iCANSleep app for treating insomnia in Canadian cancer survivors.

Limitations

For receiving insomnia treatment through a smartphone app, cancer survivors highlighted some areas where they perceived disadvantages. These included a lack of a therapeutic relationship between the patient and clinician, a lack of accountability, and a reliance on technology. First, some participants felt that an insomnia treatment app would not have certain aspects of face-to-face treatments, such as individual tailoring and the ability to ask questions. This is a reasonable concern, and the exact trade-off between cost and effectiveness when it comes to therapist guidance versus automation of sleep therapies is currently being debated [43]. Despite past research showing increasing treatment effect sizes in therapies that include more intense therapist involvement [44], other research has shown that automating aspects of treatments can make them much more cost-efficient for producing improvements in sleep [45]. While iCANSleep will have a Frequently Asked Questions page as well as a repository of informational articles, it will not have the ability to flexibly answer individual inquiries or alter treatment based on specific personal circumstances. Moreover, the app might be able to provide some feedback and encouragement through gamification features (eg, badges and streaks), but an in-person clinician may be able to provide more personalized feedback. Second, participants also noted that there would be no clinician to hold them accountable, and the onus would be on themselves to engage with the app and follow its instructions. As such, iCANSleep will not entirely replace face-to-face individual treatment, and there remains a need for well-trained clinicians to offer CBT-I to support cancer survivorship. The iCANSleep app will expand treatment options and potentially allow for the prioritization of face-to-face interventions in patients for whom iCANSleep is not available or desirable. Third, participants recognized the potential for technological issues to arise, which would disrupt their ability to avail of the digital therapeutic service. Access is limited to patients who currently own a smartphone that can connect to cell phone towers, and a failure in any link of the chain (phone, power, internet service, and data) may cause the entire system to be inaccessible. Lastly, reliance on technology can leave patients open to digital risks, such as accidental breach of data, although these risks exist at varying levels for in-person treatments as well. During the development of iCANSleep, security and privacy were prioritized, resulting in a product that does not collect potentially identifiable information.

Clinical Implications

Patients with cancer have identified that once cancer treatment is completed, their specialized care stops, despite still facing cancer-related mental and physical health challenges, including poor sleep. There are not enough CBT-I practitioners to address sleep concerns in cancer survivors. The development of iCANSleep aims to directly address these concerns by making follow-up survivorship care, specifically for sleep, accessible to all. After tests of efficacy are completed and future refinements are integrated, we plan to partner with cancer care authorities and support organizations to offer this treatment app to all cancer survivors.

Acknowledgments

This research has been funded by a Canadian Cancer Society Emerging Scholar Award (Survivorship) (grant #707146). Generative artificial intelligence was not used in any portion of manuscript writing.

Data Availability

Data will be available to investigators whose proposal regarding the use of the data has been approved by an independent review committee. To gain access, data requestors will need to sign a data access agreement.

Abstract

Background: Cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy (CRS-HIPEC) can improve survival outcomes for individuals with gastrointestinal (GI) cancer and peritoneal disease (PD). Individuals with GI cancer and PD receiving CRS-HIPEC are at increased risk for malnutrition. Despite the increased risk for malnutrition, there has been limited study of nutritional interventions for individuals receiving CRS-HIPEC.

Objective: We aimed to test the feasibility, acceptability, and usability of Support Through Remote Observation and Nutrition Guidance (STRONG), a multilevel digital health intervention to improve nutritional management among individuals with GI cancer and PD receiving CRS-HIPEC. We also assessed patient-reported outcomes, including malnutrition risk, health-related quality of life, and weight-related measures.

Methods: STRONG is a 12-week digital intervention in which participants received biweekly nutritional counseling with a dietitian, logged food intake using a Fitbit tracker, and reported nutrition-related outcomes. Dietitians received access to a web-based dashboard and remotely monitored patients' reported food intake and nutrition-impact symptoms. Implementation outcomes were assessed against prespecified benchmarks consistent with benchmarks used in prior studies. Changes in patient-reported outcomes at baseline and follow-up were assessed using linear and ordered logistic regressions.

Results: Participants (N=10) had a median age of 57.5 (IQR 54-69) years. Feasibility benchmarks were achieved for recruitment (10/17, 59% vs benchmark: 50%), study assessment completion (9/10, 90% vs benchmark: 60%), dietitian appointment attendance (7/10, 70% vs benchmark: 60%), daily food intake logging adherence (6/10, 60% vs benchmark: 60%), and participant retention (10/10, 100% vs benchmark: 60%). Most participants rated the intervention as acceptable (8/10, 80% vs benchmark: 70%) and reported a high level of usability for dietitian services (10/10, 100%). The benchmark usability for the Fitbit tracker to log food intake was not met. Compared to baseline, participants saw on average a 6.0 point reduction in malnutrition risk score (P=.01), a 20.5 point improvement in general health-related quality of life score (P=.002), and a 5.6 percentage point increase in 1-month weight change (P=.04) at the end of the study.

Conclusions: The STRONG intervention demonstrated to be feasible, acceptable, and usable among individuals with GI cancer and PD receiving CRS-HIPEC. A fully powered randomized controlled trial is needed to test the effectiveness of STRONG for reducing malnutrition and improving patient outcomes.

KEYWORDS

gastrointestinal cancer; peritoneal disease; cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy; digital health intervention; nutrition; feasibility

Introduction

Malnutrition is commonly observed among individuals with gastrointestinal (GI) cancer and can severely affect disease prognosis, quality of life, and survival [1,2]. Individuals with GI cancer are at high risk of developing peritoneal disease (PD), the metastasis of cancer to the abdominal cavity, which occurs in about 40% of patients with GI cancer [3]. Cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy (CRS-HIPEC) can offer survival benefits for individuals with GI cancer and PD [4,5]. CRS-HIPEC is a 2-step approach that removes all visible cancerous tumors in the abdomen through a surgical procedure, followed by heated chemotherapy during surgery [5]. Due to the invasive nature of this extensive operation, postoperative morbidities are common, including weight loss, which occurs in more than 90% of individuals receiving CRS-HIPEC [6]. Malnutrition, arising from loss of appetite and malabsorption, occurs in about 50% to 60% of individuals receiving CRS-HIPEC, which can negatively affect postoperative outcomes (eg, length of hospital stay, hospital readmission, and mortality) [7-10]. After CRS-HIPEC, patients often experience a decline in nutritional status, heightening the importance of adequate nutritional support in the postoperative period [6,11].

Medical nutrition therapy (MNT), which includes dietitian-led nutritional counseling and additional dietary interventions, has been shown to improve nutritional outcomes for individuals with GI cancer [12,13]. However, multilevel barriers hinder access to MNT and its effectiveness. At the system level, there may be limited outpatient services for nutritional counseling, fragmented oncology and nutritional care, and inconsistent nutrition-screening procedures across clinics [14,15]. For example, a survey among surgical oncologists who specialize in CRS-HIPEC showed that only one-third of providers reported the availability of malnutrition screening at their practice [16]. At the provider level, available dietitians may be lacking, and MNT is not routinely provided to individuals with cancer [14,17,18]. There are also many barriers at the patient level, including the lack of adherence to nutritional programs due to clinical factors (eg, difficulties swallowing, fatigue, nausea, and pain) and nonclinical factors (eg, lack of motivation and time constraint) [19]. Digital nutritional interventions, such as remote monitoring, can help patients overcome barriers to accessing and adhering to traditional nutritional interventions and can improve patient outcomes [20,21]. However, research on digital nutritional interventions for individuals with cancer is limited [22]. There is a need to develop and test digital nutritional interventions, particularly for individuals receiving CRS-HIPEC who are at high risk for malnutrition.

To address this gap, the goal of this study is to pilot test the Support Through Remote Observation and Nutrition Guidance (STRONG) intervention, a multilevel digital health intervention to improve nutritional outcomes. The study aims (1) to assess the feasibility, acceptability, and usability of the STRONG intervention for individuals with GI cancer and PD undergoing CRS-HIPEC and (2) to evaluate patient-reported outcomes, including malnutrition risk, health-related quality of life, and weight-related measures. To the best of our knowledge, this is the first digital nutritional intervention conducted among individuals receiving CRS-HIPEC, who are at high risk of postoperative malnutrition and face unique barriers to accessing and using MNT [7,20,21]. Findings from this study will inform broader interventions to manage cancer-related malnutrition and guide a future randomized controlled trial to evaluate the impact of the STRONG intervention.

Methods

Study Design

We conducted a single-arm feasibility trial of STRONG, a 12-week digital intervention to improve postoperative nutrition. Guided by the Obesity-Related Behavioral Intervention Trials model, the goal of the single-arm study was to identify potential technical issues with digital health delivery, assess the optimal length of intervention delivery, and gather participant feedback on acceptability to inform intervention refinement prior to larger testing in a randomized trial [23]. The intervention was developed based on the Theoretical Domains Framework, a theory used to understand and address multilevel behavior change (ie, patient and clinician behavior) in health care settings [24]. Participants received biweekly MNT (6 sessions) that included nutritional counseling with a registered dietitian and continuous remote monitoring of participants' dietary needs by the dietitian. In addition, participants logged daily food intake using a Fitbit device (Inspire 2) and completed 5 study assessments related to patient malnutrition, nutrition-related symptoms, and quality-of-life outcomes (at baseline and 4, 8, 12, and 16 weeks after study enrollment). Participants provided feedback on the intervention's acceptability and usability (at week 12).

Participants

Individuals who met the following criteria were eligible to participate in the study: (1) older than 18 years, (2) diagnosed with primary GI cancer, (3) diagnosed with PD, (4) underwent curative-intent CRS-HIPEC at Moffitt Cancer Center (Moffitt; with cytoreduction completeness score of 0 - 1), (5) transitioned to a postoperative oral diet, (6) were able to speak and read English, and (7) provided informed consent. Individuals were excluded from the study if they met any of the following criteria: (1) had documented or observable psychiatric or neurological condition that would inhibit with study participation, (2) were undergoing treatment for another primary cancer, and (3) received postoperative parenteral or enteral nutrition.

XSL•FO
RenderX

Recruitment

Potential participants were identified through a collaboration between Moffitt's GI clinic staff and the study coordinators. In addition, we screened the patients' electronic health records (EHRs) to determine their eligibility. Eligible participants were contacted by phone, unencrypted email, videoconference, or in-person meetings to introduce them to the study and determine their interest in participating. The participants who provided informed consent were given study materials and equipment during patient visits or by mail, including (1) a welcome packet and checklist describing the study components, instructions on using and caring for the Fitbit tracker and tablet, and brief instructions on estimating food portion size; (2) a Fitbit tracker; and (3) a study loaned tablet to log daily food intake with the Fitbit application already downloaded and synced. Participants also had the choice of downloading the Fitbit application on a personal device if preferred. Within 3 to 5 days of the participant receiving the Fitbit tracker, one of the study coordinators (RH, OS, and SD-C) contacted the participant to confirm that they were able to use the device. Participants received an introduction to the Fitbit tracker before undergoing CRS-HIPEC. Recruitment occurred from December 2022 to July 2023.

Intervention

Dietitians reviewed the participants' food intake and nutritional assessments and conducted 6 biweekly telehealth or in-person counseling sessions with them. During these visits, the dietitian established individualized dietary plans that included a calorie goal, discussed challenges to dietary intake, and made recommendations for improving nutrition. If a participant did not record food intake for 5 days or more, a study coordinator contacted the participant to discuss barriers to using the Fitbit tracker and to encourage continued tracking. Study assessments were completed on REDCap (Research Electronic Data Capture; Vanderbilt University), a web-based software platform [25,26], on a paper survey, or in person using a tablet during clinic visits.

Measures

Sociodemographic Characteristics

Participants' sociodemographic characteristics were obtained from the EHR and the baseline survey. Information collected included age, sex at birth, race or ethnicity, marital status, primary language preference, whether the participant resided in an urban area (defined by matching the participant's zip code using the 2010 US Department of Agriculture rural-urban commuting area codes) [27], 2022 Area Deprivation Index (ADI; an area-level measure of socioeconomically disadvantaged neighborhoods ranging from 0 to the 100th percentile nationally, with higher percentiles indicating more disadvantaged neighborhoods) [28], insurance type, highest educational attainment, and annual household income.

Clinical Characteristics

Clinical characteristics were obtained from the EHR and included tobacco use, BMI, Charlson Comorbidity Index, and cancer type or histology. The peritoneal cancer index was also measured, which grades the extent of PD on a scale from 0 to 39, with higher scores indicating a more extensive disease [29]. Eastern Cooperative Oncology Group performance status was measured, which captures the extent to which the disease affects a patient's activities of daily living; the grades included in this study ranged from 0=fully active to 4=completed disabled [30]. Cytoreduction completeness score was measured, which captures the extent of the residual tumor, and was used to determine whether the patient underwent CRS-HIPEC for curative intent [31]. The patient's nutritional status was measured by the Patient-Generated Subjective Global Assessment (PG-SGA) Short Form, with scores ranging from 0=no risk to 36=highest risk [32].

Implementation Outcomes

The data on feasibility, acceptability, and usability of the intervention were collected through objective intervention data or measured by a participant survey at the end of the intervention (week 12). Implementation outcomes were assessed against prespecified benchmarks consistent with benchmarks (60% - 70%) used in previously reported single-arm digital health interventions for patients with cancer (Multimedia Appendix 1) [33,34]. The feasibility benchmarks of successful implementation of the intervention within the GI clinic included recruitment rate (≥50%), percentage of participants who completed baseline study assessment (≥70%), percentage of participants who completed 4 of 5 study assessments (≥60%), participant retention at the end of the intervention (≥70%), participant retention at the end of the study period (≥60%), percentage of participants who attended at least 4 of 6 dietitian appointments (≥60%), and percentage of participants who logged food intake for 63 of 90 days (≥60%).

Acceptability, defined as the participant's level of satisfaction with the intervention, was measured by the Acceptability of the Intervention Measure, a 4-item scale (score ranges 0 - 20) [35,36]. A ≥70% response rate with a score >12 on the Acceptability of the Intervention Measure was used as the cutoff for establishing acceptability, indicating that participants on average had a positive experience with the intervention [35].

Usability was assessed in 2 ways. Usability, defined as the extent to which individuals were able to use the Fitbit tracker and application to log food intake, was measured by the 10-item System Usability Scale (SUS; score ranges 0 - 100) [37]. A ≥65% response rate with a score >68 on the SUS was used as the cutoff, indicating that participants on average perceived the Fitbit tracker and application to be easy to use [37]. Usability of the clinical dietitian services, including the dietitian's interpersonal skills and patient-perceived health benefits of the dietitian service, was measured by a validated 8-item scale (score ranges 0 - 24) that has been used in outpatient MNT interventions for patients with cancer [38,39]. A ≥70% response rate with a score >12 was used as the cutoff for establishing acceptability, indicating that participants on average had a positive experience with the dietitian services [39].

Patient Outcomes

To evaluate the secondary aim of this study, patient outcomes were obtained from their EHR or study assessments and included malnutrition risk measured by the PG-SGA, health-related quality of life measured by the Functional Assessment of Cancer Therapy—General [40] and the Functional Assessment of

XSL•FO
RenderX

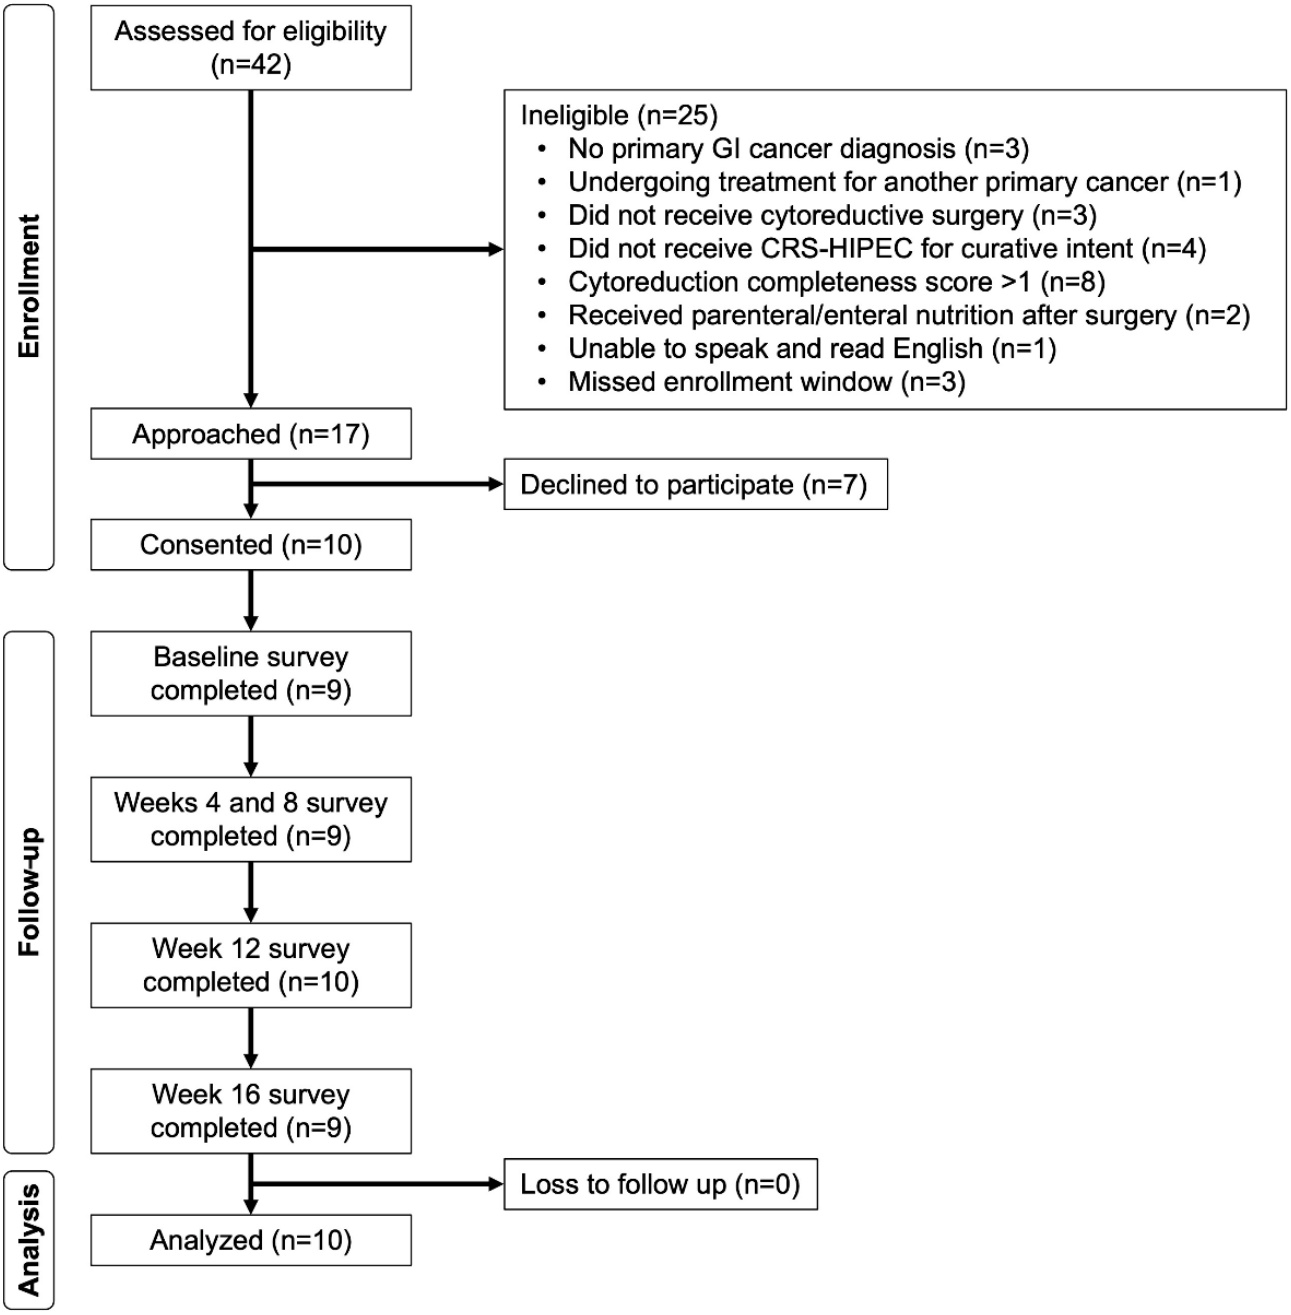
Anorexia/Cachexia Treatment—Anorexia/Cachexia Scale [41], BMI, weight, and 1-month weight change.

Analyses

Descriptive statistics were computed to describe the study sample and assess whether prespecified benchmarks for feasibility, acceptability, and usability were met at the end of the intervention. Given the small sample size, continuous variables were summarized using median and IQR, and categorical variables were summarized using frequency and percentage. Changes in patient outcomes at baseline and the end of the study period (week 16) were assessed using linear regressions for continuous outcomes and ordered logistic regressions for ordinal outcomes. Models included participant fixed effects to obtain within-participant estimates, and SEs were robust and clustered by the participant. We adhered to the CONSORT (Consolidated Standards of Reporting Trials) guidelines for pilot and feasibility studies and study reporting (Checklist 1) [42]. All analyses were performed in Stata (version 18; StataCorp).

Ethical Considerations

The trial (ClinicalTrials.gov NCT05649969) was conducted at a single site, Moffitt, a National Cancer Institute (NCI)–designated comprehensive cancer center. The study was approved by Moffitt's Institutional Review Board of Record, Advarra (protocol Pro00066098). Informed consent was obtained from all participants. To protect participants' confidentiality, deidentified information and pseudonym IDs (eg, Participant 1) were entered into participants' Fitbit profiles. The study staff maintained a separate password-protected file behind Moffitt's firewall linking participant IDs to patient identifiers (eg, name and medical record number). Paper questionnaires were stored in a locked file cabinet in an office with a locked door. Only the study team had access to participant research data, and only trained staff with appropriate approvals had access to patient medical records. Participants were compensated with a US $25 gift card for completing each of the 5 study assessments; participants who completed all 5 assessments received an additional US $25 gift card.



Results

Sample Characteristics

Among the patients (n=42) screened for eligibility, 25 patients were deemed ineligible (Figure 1). Of the 17 patients approached, 10 patients consented to participate in the study. All 10 participants completed at least 1 assessment, and no participants were lost to follow-up.

Figure 1. CONSORT diagram of the single-arm feasibility trial of the STRONG intervention. CONSORT: Consolidated Standards of Reporting Trials; CRS-HIPEC: cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy; GI: gastrointestinal; STRONG: Support Through Remote Observation and Nutrition Guidance.

Study participants had a median age of 57.5 (IQR 54.0 - 69.0) years; 8 (80%) participants were female, and 10 (100%) were non-Hispanic White (Table 1). In total, 6 (60%) participants were married, 1 (10%) had never been married, and 3 (30%) were divorced. All participants spoke English as their primary language and resided in an urban area. The median ADI of participants was in the 30th percentile nationally (IQR 24-32), with a higher ADI indicating a more disadvantaged neighborhood. In total, 4 (40%) participants received health insurance through employment, 4 (40%) received public insurance, 1 (10%) had direct-purchase insurance, and 1 (10%) did not provide insurance-type information. The highest education attained by participants was some college for 3 (30%) participants, a bachelor's degree for 3 (30%) participants, or a graduate or professional degree for 4 (40%) participants. Participants' annual household income ranged from US $35,000 to ≥US $100,000.

In total, 8 (80%) participants never smoked tobacco, and 2 (20%) were former smokers (Table 1). The median BMI of participants was 28 (IQR 27.3-29.5), and participants had a median Charlson Comorbidity Index of 7 (IQR 7-9). A total of 6 (60%) participants were diagnosed with appendiceal cancer, 2 (20%) with colorectal cancer, and 2 (20%) with peritoneal mesothelioma. The median peritoneal cancer index was 21.5 (IQR 13.0-25.5). Participants were all fully active or able to carry out light or sedentary work, with a median Eastern Cooperative Oncology Group performance status of 0 (IQR 0-0). No participants at baseline were assessed to be at low

XSL•FO
RenderX

malnutrition risk, 2 (20%) were at medium risk, and 7 (70%) were at high risk.

Feasibility

Among the eligible patients (n=17) who were approached to participate in the study, 10 (59%) consented to participate (Table 2). In total, 9 (90%) participants completed the baseline assessment and completed 4 of 5 assessments. All participants completed the assessment at the end of the intervention (week 12), and 9 (90%) participants completed the follow-up assessment at week 16. A total of 7 (70%) participants attended at least 4 of 6 dietitian appointments, and 6 (60%) participants logged food intake for at least 63 of the 90 days (median logged 76, IQR 15 - 87 days). Adherence to logging food intake decreased slightly over the span of the intervention, from 7 (70%) participants meeting the benchmark number of days logging food intake in the first 30 days (median logged 29, IQR 15 - 30 days) to 5 (50%) participants meeting the benchmark in the last 30 days (median logged 15, IQR 0 - 27 days; not shown in table).

Table . Feasibility outcomes of the STRONG[a] intervention.

Outcome	Benchmark (%)	STRONG intervention, n/N (%)
Recruitment		
Eligible patients who consented	≥50	10/17 (59)
Study assessment completion		
Participants who completed baseline assessment	≥70	9/10 (90)
Participants who completed 4 of 5 study assessments	≥60	9/10 (90)
Retention		
Participants retained at the end of the intervention (week 12)	≥70	10/10 (100)
Participants retained at the end of the study period (week 16)	≥60	10/10 (100)
Intervention adherence		
Participants who attended at least 4 of 6 dietitian appointments	≥60	7/10 (70)
Participants who logged food intake for 63 of 90 days	≥60	6/10 (60)

[a]STRONG: Support Through Remote Observation and Nutrition Guidance.

Acceptability and Usability

Among the 10 participants who completed the week 12 assessment, 8 (80%) rated the intervention as acceptable (benchmark score >12), with a median score of 18 (IQR 16 - 20; Table 3). In total, 5 (50%) participants rated the Fitbit tracker and application as usable for logging food intake (benchmark score >68), with a median score of 68.8 (IQR 54.4 - 90). All participants (100%) were satisfied with the dietitian services (benchmark score >12), with a median score of 23.5 (IQR 17.8 - 24.0). One participant reflected on the high acceptability of the dietitian services and said, “The program added a lot of value. It helped with my recovery, especially with getting the right nutrition. It has been really great!” Another participant conveyed the value of the digital nature of the STRONG intervention, expressing “The ZOOM meetings were wonderful because I am over an hour from the hospital. The [nutritionist]

XSL•FO
RenderX

was also a great encourager and contributed to my healing process."

Table . Acceptability and usability outcomes of the STRONG[a] intervention (N=10).

Outcome	Benchmark	STRONG intervention
Acceptability		
Acceptability of the Intervention Measure	≥70% response rate with score >12	8 (80)
Usability		
Fitbit	≥65% response rate with score >68	5 (50)
Dietitian services	≥70% response rate with score >12	10 (100)

[a]STRONG: Support Through Remote Observation and Nutrition Guidance.

Patient Outcomes

Compared to baseline, average PG-SGA malnutrition scores saw a decrease of 6 points (*P*=.01), with a corresponding reduction in patients with high malnutrition risk (*P*=.03; Table 4). Functional Assessment of Cancer Therapy—General scores increased by an average of 20.5 points (*P*=.002), and Functional Assessment of Anorexia/Cachexia Treatment—Anorexia/Cachexia Scale scores increased by an average of 7.4 points (*P*=.03), indicating an improvement in participants' health-related quality of life. There was no change in participants' average BMI or weight, suggesting a stabilization of weight loss. This is supported by a 5.6 percentage point increase in the average 1-month weight change (*P*=.04), in which participants saw a slight weight gain compared to the previous month at week 16.

Table . Changes in patient outcomes between baseline and the end of the intervention.

Patient outcomes (n=9)	Baseline	Week 16	*P* value[a]
Patient-Generated Subjective Global Assessment Short Form score, mean (SE)	11.7 (3.8)	5.7 (4.3)	.01
Low risk, n (%)	0 (0)	3 (33)	.03
Medium risk, n (%)	2 (22)	5 (56)	.03
High risk, n (%)	7 (78)	1 (11)	.03
Functional Assessment of Cancer Therapy—General score, mean (SE)	70.4 (15.4)	90.9 (10.5)	.002
Functional Assessment of Anorexia/Cachexia Treatment—Anorexia/Cachexia Scale score, mean (SE)	28.9 (4.3)	36.3 (7.8)	.03
BMI (kg/m^2), mean (SE)	27.5 (5.5)	26.3 (4.2)	.09
Weight (lb), mean (SE)	172.3 (29.1)	165.3 (22.0)	.09
Weight change since 1 month ago (%), mean (SE)	−5.2 (4.8)	0.4 (3.1)	.04

[a]*P* values of continuous outcomes were computed from linear regression models. *P* values of ordinal outcomes were computed from ordered logistic regression models. All models included participant fixed effects. SEs were robust and clustered by the participant.

Discussion

Principal Findings

The goal of this trial was to evaluate the feasibility and acceptability of the STRONG intervention for individuals with GI cancer and PD undergoing CRS-HIPEC. Our findings demonstrated that the STRONG intervention was feasible to be implemented with high participant recruitment, adherence, and retention to the intervention. Participants rated the intervention favorably and found the dietitian services to be both acceptable and usable. This rating is consistent with previous pilot studies assessing the implementation of mobile phone–based nutritional intervention for individuals with cancer [43,44]. Patient outcomes, including malnutrition risk, health-related quality of life, and 1-month weight change, saw marked improvement. Given that this study was a single-arm intervention without a comparison group, we were unable to attribute the changes in patient outcomes to the intervention alone without considering the effects of cancer treatment and disease progression. The successful implementation of STRONG in this study, positive feedback from participants, and promising improvements in patient outcomes suggest that a future, fully powered trial with a comparison group is warranted. Our team is currently evaluating potential improvements to STRONG and assessing alternative food logging approaches in preparation for a randomized controlled trial of STRONG.

Comparison With Prior Work

Malnutrition screening, counseling, and related interventions remain underused in cancer care [45,46]. Nutritional counseling has been shown to improve the nutritional status, quality of life, and survival for individuals with GI cancer [47,48]. Digital nutritional interventions show clear benefits over traditional MNT, including efficiency, accessibility (eg, reduced transportation barriers), and the ability to remotely monitor patients outside of a traditional clinic visit [22]. Digital tools can also help individuals maintain adherence to nutritional interventions [14]. In our study, despite undergoing a complex surgical procedure, participants were able to adhere to the dietitian visits and food logging in the postoperative period. We hypothesize that this may be facilitated by strong support from the clinic team. Members of the surgical and dietitian teams encouraged patients to participate in the intervention and periodically checked on participants to monitor their progress through the intervention. This study is innovative in that individualized and remote monitoring of dietary needs bridges the gap between the clinical need for close, in-person patient follow-up and the substantial barriers for this patient population to access nutritional support.

Prior studies have shown that digital nutritional interventions are feasible and effective for achieving weight loss among survivors of cancer [49,50]. However, there has been limited research on the use of digital health interventions for individuals with malnutrition to maintain weight or to prevent weight loss. To the best of our knowledge, this is the first digital nutritional intervention conducted among individuals receiving CRS-HIPEC, who have increased risk for malnutrition and face unique barriers to accessing and using traditional MNT [7,20,21].

One study that assessed food-intake tracking with a Fitbit device among individuals with colorectal cancer undergoing surgery found decreased acceptability of the intervention in the postoperative period due to the complexity of the Fitbit application [51]. In our study, we also found declining adherence to tracking food intake over time. The benchmark for tracking food intake was not achieved and was driven primarily by 3 participants who logged 0, 3, and 12 days over the course of the intervention. The decline in adherence to tracking food intake was driven primarily by 2 participants who logged 12 and 24 days over the first 30 days of the intervention, followed by no additional days logged over the rest of the intervention period. It was unclear why these participants were disengaged with tracking food intake, as they did not provide any qualitative feedback.

Further research is needed to investigate why the usability of Fitbit may be low (eg, differences in digital literacy) and what strategies could be used to improve usability. One potential explanation is the choice of the usability measure. Our study team used a generic SUS that was not targeted to mobile health specifically [52]. In future studies, we plan to include mobile health–specific measures of usability to see how that may affect usability ratings. Another potential explanation is that study participants did not have sufficient education on how to use the Fitbit. Since this pilot study, our team has added teach-back sessions to the Fitbit training. Additionally, our team has created a paper version of the food log as an alternative for patients who cannot manage electronic food logging even after training. A third hypothesis is that participants may only need to food log for a certain amount of time before learning enough about their dietary patterns to manage their nutrition. Further study is needed on the optimal time needed for food logging for malnutrition self-management.

Future digital health interventions should assess the eHealth literacy of participants and make efforts to address participant concerns about the potential complexity of digital interventions [53,54]. One approach may be to target participants with low eHealth literacy with additional technical support and resources to ensure equal and inclusive participation in the intervention [53]. Another approach to improve adherence to food tracking may be to adopt a tracking system designed for patients with cancer (eg, the Automated Self-Administered 24-Hour Dietary Recall developed in collaboration with the NCI) [55]. Recent developments in image processing technology can also be leveraged to reduce the burden on participants in tracking food intake [56]. For example, artificial intelligence–enabled applications such as MyFitnessPal, Fastic, and Noom enable food tracking through capturing photos of the foods via a smartphone [56]. However, the feasibility of these technologies for individuals with cancer has yet to be fully explored.

Limitations

Our study should be considered in light of the following limitations. First, this is a single-arm feasibility study conducted at an NCI-designated comprehensive cancer center. Therefore, the study findings may not be generalizable to other settings. Second, the study sample is small and consisted only of non-Hispanic White participants, limiting generalizability to other patient populations. There is a critical need to test the intervention in a more diverse population, across a wider range of settings, and on a larger sample. Additionally, our study focused on extending nutritional support in the postoperative setting, which has been previously recommended for individuals receiving CRS-HIPEC [57,58]. Further research is needed to test nutritional interventions for this population prior to surgery, which may improve CRS-HIPEC tolerance and reduce the likelihood of nutrition-related, postoperative complications [57,58]. Finally, this study was a single-arm trial without a comparison group. Findings on changes in patient outcomes over time cannot be solely attributed to the effect of the intervention without considering the effects of cancer treatment and disease progression. A larger, fully powered randomized controlled trial is needed to rigorously evaluate the impact of STRONG on patient outcomes.

Conclusions

Our study demonstrated that STRONG, a digital health intervention aimed at improving nutritional management for individuals with GI cancer and PD receiving CRS-HIPEC, is feasible, acceptable, and usable. Future studies are needed to establish the effectiveness of the STRONG intervention and to evaluate its implementation in more diverse patient populations and settings.

Acknowledgments

This study was funded by a Moffitt Cancer Center Innovation Award that was awarded to BDP and KT. Generative artificial intelligence tools were not used in any portion of the manuscript writing.

Data Availability

The datasets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

YCL drafted the manuscript and conducted the data analyses. RH served as a study coordinator for the trial. BDP and SPD helped conceptualize the study and assisted with patient recruitment for the trial. JM served as the study dietitian for the trial. EH served as the research project manager for the trial. OS and SDC served as a study coordinator for the trial. JBP, JD, and AAT helped conceptualize the study. KT helped conceptualize the study, obtained funding for the study, and provided overall scientific direction for the study. All authors reviewed the final draft of the manuscript and provided feedback.

Conflicts of Interest

None declared.

Abstract

Background: Survivors with head and neck cancer (HNC) face challenging treatment consequences that can lead to severe disruptions in swallowing and result in weight loss, malnutrition, and feeding tube dependence. Caregivers (family or friends who provide support), therefore, often encounter distressing nutritional caregiving burdens and feel unprepared to provide adequate support at home.

Objective: The purpose of this mixed methods study was to develop a mobile support app to support HNC caregiving with an emphasis on nutritional support following treatment.

Methods: We assessed perspectives on nutritional recovery challenges and mobile support app preferences in (1) a national panel of oncology dietitians using a web-based cross-sectional survey and (2) survivors with HNC completing treatment within the past 24 months and their nominated caregivers using dyadic semistructured interviews. Descriptive statistics for survey data were synthesized with thematic analysis of interview data to characterize nutrition-related perceptions and intervention preferences; results were integrated, and themes were translated to high-priority main menu domains and subdomains for a mobile app for caregivers.

Results: Surveys were completed by dietitians (n=116, 100%; female n=87, 50%, with >10 years practice experience). Interviews included survivors with HNC (n=15; 12/15, 80% male, and 6/15, 40% with oropharynx cancer) and their caregivers (n=13; 11/13, 85% female, and 10/13, 77% spouses). Dietitians, survivors, and caregivers perceived that the majority of nutritional concerns assessed (eg, swallowing, feeding tube management, weight maintenance, and caregiver distress about nutrition) were very or extremely important to caregiving in the 6 months following treatment conclusion. The caregiving tasks rated highest in importance by dietitians included tracking nutritional concerns (n=113, 97%), working together as a team on nutritional concerns (n=104, 90%), and making care decisions (n=102, 88%). Five themes emerged from dyadic interviews, including types of nutritional challenges faced, that competing symptoms were difficult to separate from nutritional challenges, the emotional challenges related to nutrition and recovery, the diverse set of medical and support tasks taken on by caregivers, and information and resource needs in caregivers. Qualitative interview and survey themes guided the content of the Healthy Eating and Recovery Together (HEART) app with an intake tracker and sections for nutrition recovery support, other competing caregiving tips, peer support, and caregiver self-care.

Conclusions: Results pinpointed optimal content for a mobile app for caregivers of individuals with HNC and support the acceptability of implementing the HEART app following HNC treatment.

Introduction

Approximately 522,846 people were living with oral cavity, pharynx, and larynx cancers in the United States in 2021 [1,2]. With increasing numbers of survivors with head and neck cancer (HNC), it is imperative that survivorship concerns are addressed [3,4]. Survivors with HNC face extremely difficult treatment consequences that impair their nutritional well-being [5]. Specifically, HNC and its multimodal treatments [6] can result in oral health problems related to swallowing, speech, mucositis, and dry mouth [7] that disrupt nutritional intake during and after treatment. Most survivors with HNC experience weight loss during treatment [8-11]. Population-level analyses using Surveillance, Epidemiology, and End Results data have estimated that approximately half of patients with HNC need a feeding tube and 40% - 45% of survivors with HNC experience dysphagia-related morbidities up to 2 years following treatment [12]. These nutritional recovery challenges impair the quality of life substantially [13-17].

Nutritional challenges in survivors with HNC also impact their caregivers [18,19], family members, and friends who provide cancer-related support. Relative to caregivers for people with other cancer types, caregivers of people with HNC confront unique support tasks such as feeding tube management, meal preparation, and speech support [6,19-22]. Caregivers report feeling unprepared for their roles in nutritional caregiving, sometimes experiencing a disconnect between survivors' goals and their own, and experiencing significant unmet needs as caregivers [23-29]. While interventions for caregivers caring for a loved one with cancer have been designed and tested [30-33], few evidence-based interventions are available to support caregivers of people with HNC with a focus on nutritional caregiving tasks in the early posttreatment period. Challenges in providing high-quality comprehensive support to caregivers of people with cancer include cost (financial and time) and competing demands while caring for a loved one [34-36], complexity of survivors' needs [20], and high prevalence and extent of emotional concerns among both survivors and caregivers [37,38].

Digital health strategies may overcome some of these barriers and offer a promising way to reach and support caregivers of survivors with HNC, particularly during the transition from cancer care to home, a critical point at which in-person interventions may not be feasible [39]. Research is growing on the feasibility, acceptability, and efficacy of digital health interventions for caregivers of people with cancer, with encouraging results for interventions designed to decrease burden and improve mood [39-45]. To guide the development of a mobile app to support nutrition-related caregiving among caregivers of people with HNC, this mixed methods study characterized nutritional challenges and caregiving tasks and intervention preferences in HNC oncology dietitians and survivor-caregiver dyads.

Methods

Study Design

Using a concurrent parallel mixed methods design [46], this study included a cross-sectional, web-based survey of a national panel of oncology dietitians and semistructured interviews with survivors with HNC and caregivers. We selected a mixed methods approach to facilitate gathering the perspectives of three groups, including dietitians, survivors with HNC, and caregivers [46]. A mixed methods approach also allowed for a more comprehensive understanding of the unmet needs of caregivers of people with HNC to drive the selection of content in a supportive care app to address those needs. Our team included researchers with expertise and training in HNC, cancer survivorship, oncology caregiving, and mobile health. We used a team approach to reflexivity with discussion and attention to the potential of the research team's background to influence research findings.

The purpose of this mixed methods study was to characterize nutritional challenges and caregiving tasks and intervention preferences in HNC oncology dietitians (quantitative) and survivor-caregiver dyads (qualitative and quantitative). We concurrently collected survey data from dietitians. Both quantitative and qualitative data were considered of equal priority and were analyzed separately and then integrated using the merging technique [47] as described below. Data were collected between April and September 2018. The GRAMMS (Good Reporting of A Mixed Methods Study) checklist was used to guide the mixed methods approach and reporting [48] (Checklist 1). Multimedia Appendix 1 provides the interview guide and surveys.

Dietitian Surveys

A convenience sample of dietitians was recruited by posting a study notice on the listserv for the Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics. Dietitians were eligible for the 15-minute web-based survey if they reported providing care for patients with HNC in the past 6 months; the survey was hosted on REDCap (Research Electronic Data Capture; Vanderbilt University). The 67-item survey was developed by the study team. All items were optional, and participants could return to the survey over time if requested. The survey assessed demographic (race, ethnicity, sex, and age) and practice (credentials, years practicing as a dietitian, practice setting, and number of patients with HNC seen per week) characteristics. In addition, perceptions of the importance of posttreatment concerns in caregiving (0=not at all important to 4=extremely important) and perceived importance and difficulty (0=not important or difficult at all to 4=extremely important or difficult) of a variety of support tasks for caregivers of people with HNC, guided by the transactional model of caregiving were assessed (eg, tracking nutritional intake, changes and patterns in symptoms, and making care decisions [49]). Other measures included ratings of nutritional support resource needs (0=not at all to 4=extremely) in caregivers of people with HNC (eg, screening process to identify caregiver nutritional concerns, assessment tool to identify caregiver distress, and educational materials) and barriers to

XSL•FO
RenderX

addressing support needs (1=not a barrier at all to 4=major barrier) in caregivers of people with HNC (eg, time, caregiver interest, lack of evidence about the value of caregiver programs, and leadership). Participants then reviewed example app screens and then answered questions about the preferred focus of app content (eg, increasing caregivers' awareness of the importance of addressing nutritional challenges, changing caregivers' attitudes about improving nutritional status, and encouraging help-seeking for nutritional support) using an adapted version of the app-specific subscale in the Mobile App Rating Scale [50] (1=strongly disagree to 6=strongly agree) and an open-ended question. Finally, participants completed an open-ended question asking them to describe any specific suggestions they had for the development of a mobile support app for HNC caregivers.

Dyad Interviews

Survivors with HNC who completed treatment with curative intent 6 - 24 months prior to enrollment and were free of disease, and their caregivers, were recruited at the Medical University of South Carolina Hollings Cancer Center, with initial screening for eligibility by chart review. Inclusion criteria included being 18 years or older, completing treatment for stage I-IVA HNC (mucosal squamous cell carcinoma of the oral cavity, oropharynx, hypopharynx, and larynx), and experiencing nutritional challenges at the end of treatment as assessed by a 6-item screen. Survivors were excluded if they were unable to identify a primary caregiver, and survivors and caregivers were excluded if they either did not speak English or were cognitively impaired. After mailing a study letter and determining eligibility via phone screen, dyadic interviews were scheduled. Informed consent documents were signed, and dyadic interviews were conducted in person by 2 female investigators with training in qualitative methods (KS and MS). Interviewers did not know the participants and were not involved in their clinical care. Interviews were continued until we reached saturation in themes [51]. They were conducted in a private room, audio-recorded, and lasted approximately 45 minutes. Field notes were taken to provide interview observations.

We developed a semistructured interview guide using a cancer survivorship quality of life framework [52] to examine participants' reflections on the physical, emotional, and social challenges they experienced at the end of treatment and in the 6 months following treatment conclusion, with an emphasis on nutritional challenges and caregiving. Survivors and caregivers were asked to describe their emotional and physical well-being at the end of treatment. They were asked specifically about nutritional challenges, expectations they had about intake abilities, and the caregiver's role in nutritional recovery. Finally, they were asked about caregiver needs and suggestions for resources to better meet their needs at the end of treatment. Participants then viewed a set of example app screens (eg, nutrition tips, recipes, and stress management advice) on a tablet, after which they provided feedback on the content and format of a future app. After the interview, survivors and caregivers completed separate brief paper-based surveys assessing demographic (age, race, sex, and education), clinical (stage, treatment type, and nutritional status at the end of treatment), and technology access (home computer and smartphone) characteristics. They also completed ratings of the importance of caregiving tasks (0=not important to 4=extremely important) and ratings of agreement (1=strongly disagree to 6=strongly agree) about the benefits of checking in with caregivers after treatment, providing support messages to caregivers, and the importance of providing practical information to help with patients' nutritional recovery.

Ethical Considerations

Study procedures were approved by the Medical University of South Carolina Institutional Review Board (Pro00066211). A waiver of written informed consent was granted for dietitian surveys; after reading a study statement, participants advancing to the survey implied consent. Dyads completed written informed consent before completing interviews and received a copy of the signed consent for their records. All screening and survey data were stored in password-protected databases. The underlying databases were hosted in a secure data center. All data were identified only by code number (participant IDs). Dietitians completing surveys were entered into a lottery to receive a US $25 gift card to thank them for their time. Survivors with HNC and caregiver participants each received a US $50 gift card.

Statistical Analysis and App Development

Descriptive statistics were used to characterize survey data on dietitian and survivor-caregiver dyad demographic characteristics, perspectives about posttreatment, and caregiving challenges, and app preferences using R (R Core Team) [53]. Interviews were transcribed and analyzed using rigorous content analysis methods for systematic theme identification [54] in NVivo software (QSR International) [55]. Transcripts were coded by pairs of independent coders (KS, JO, and HK) and regrouped and reorganized until the investigators agreed on categories. This initial inductive theme identification process was followed by team meetings to finalize themes and guide implications for the intervention design. We sought trustworthiness in the qualitative data analysis approach by including prolonged engagement with the data, triangulating data, and using an audit trail to finalize themes [56]. Quantitative and qualitative data were analyzed separately, and then a data synthesis integration step was used to guide app development [57]. We selected the mixed methods integration approach of merging [47] and brought our quantitative and qualitative results together for elaboration. For example, the quantitative results (eg, perceptions and preferences of dietitians, survivors, and caregivers) were merged with key themes identified in interviews used to offer a more in-depth understanding of appropriate content for the app. Our interdisciplinary team of HNC clinicians, researchers, and developers completed a set of planning meetings to translate study results into app content by discussing the meaning of themes, identifying potential similarities and differences across themes, and mapping the themes to content using a consensus-based approach. The app development method was an agile approach, specifically rapid application development or rapid application building, which focuses on timely delivery in a fast-paced environment with the use of prototyping and iterative development [58]. The research team worked closely with the development team to review and

XSL•FO
RenderX

test evolving prototypes; a final prototype was pretested with 2 caregiver volunteers who were not involved in interviews or development activities.

Results

Participant Characteristics

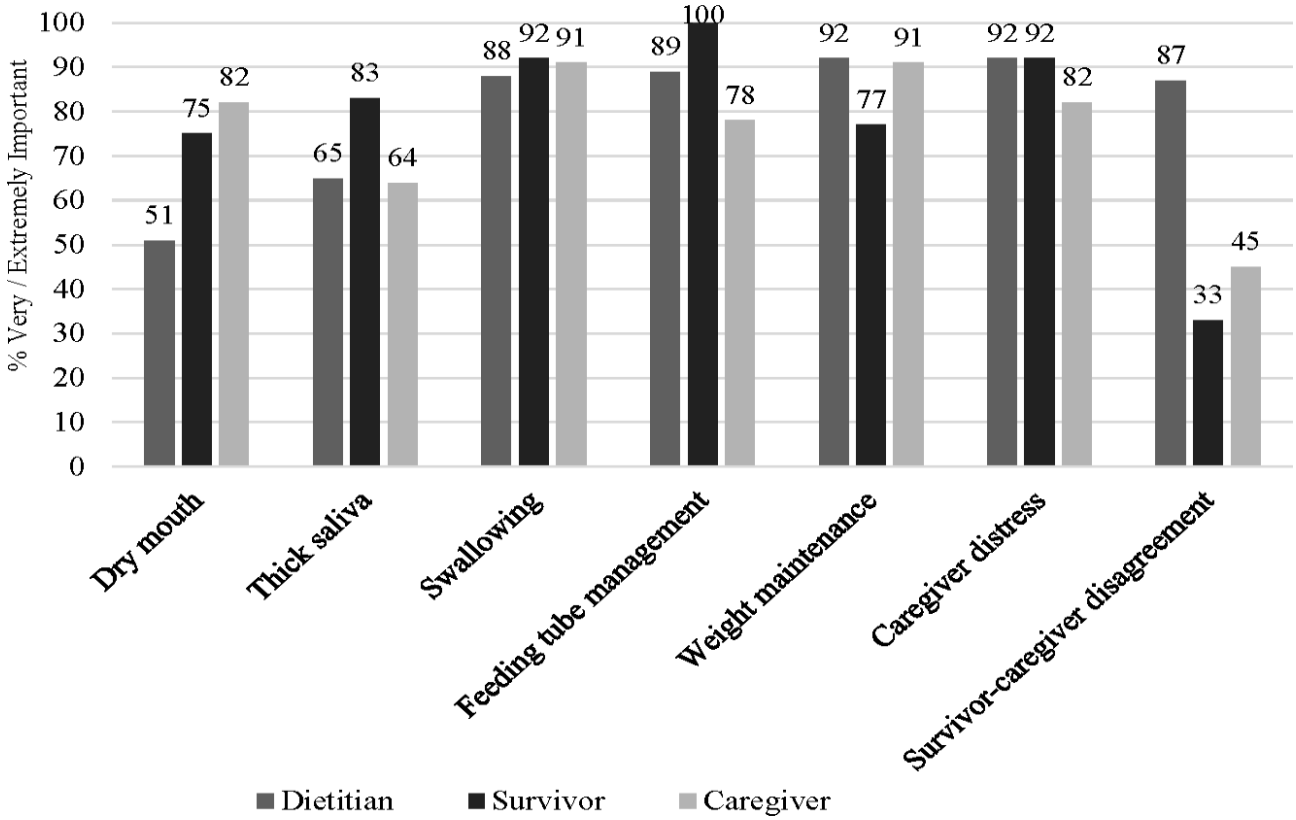
Dietitians

All dietitians (n=116, 100%) were female, and the majority were registered dietitians (n=115, 99%) and White (n=110, 95%). Most practiced more frequently in the outpatient (n=107, 92%) versus inpatient (n=23, 20%) setting; options not mutually exclusive. Half had more than 10 years of experience working with patients with HNC, and most (n=87, 75%) cared for 1 - 10 patients with HNC per week.

HNC Dyads

A total of 50 survivors mailed a study letter. Several (n=15, 30%) were ineligible due to exclusion criteria, while others declined (n=20, 40%) due to scheduling conflicts prohibiting attendance at the in-person interview, lacking interest or reporting being too ill, or overwhelmed to participate. In total, 15 survivors enrolled in the study and nominated a caregiver. All survivors completed the in-person interview and 11 survivors were accompanied by their caregivers (8 spouses and 3 children). Scheduling conflicts precluded interview completion for 4 caregivers in person, 2 of whom were interviewed independently by phone (n=13 caregivers overall).

Most survivors (n=12, 80%) were male, while most caregivers (n=10, 77% spouse) were female (n=11, 85%). A total of 83% (n=19) of survivors and 87% (n=20) of caregivers were White, and age varied from 28 to 79 years (mean age 66, SD 15.1 for survivors and 61, SD 16.6 for caregivers). A total of 20% (n=3) of survivors and 27% (n=3) of caregivers had a high school or lower education. The most common cancer types included oropharynx (n=6, 40%) and oral cavity (n=3, 20%). Most survivors had surgery (n=14, 93%) and radiation (n=12, 80%); not mutually exclusive. One-third (n=5, 33%) had a liquid diet and approximately half (n=7, 47%) had a feeding tube at the end of treatment. Finally, most participants had a home computer (n=13, 87% survivors; n=13, 100% caregivers) but fewer survivors than caregivers had a smartphone (n=11, 73% vs n=10, 90%).



Posttreatment Challenges

Perceptions of HNC Nutritional Concerns in Caregiving

In the 6 months following treatment completion, dietitians, survivors, and caregivers perceived that the majority of nutritional concerns assessed were important to caregiving (Figure 1). The caregiving concerns rated most important (ie, very or extremely) by dietitians included weight maintenance (n=107, 92%), feeding tube management (n=103, 89%), caregiver distress about nutrition (n=103, 89%), and swallowing (n=102, 88%). The caregiving concerns rated as most important by survivors included feeding tube management (n=8, 100%), swallowing (n=14, 92%), and caregiver distress about nutrition (n=14, 92%). The caregiving concerns rated most important by caregivers themselves included weight maintenance (n=10, 91%), swallowing (n=10, 91%), caregiver distress about nutrition (n=9, 82%), and dry mouth (n=9, 82%).

XSL•FO
RenderX

Figure 1. Dietitian, survivor, and caregiver perceptions of the nutritional concerns in caregiving after treatment. This figure reports data from dietitian (n=116), survivor (n=15), and caregiver (n=11) surveys. Each caregiving concern endorsed at the very or extremely important level is graphed for dietitians, survivors, and caregivers.

Perceptions of HNC Caregiving Tasks

Most dietitians perceived all evaluated caregiving tasks to be very or extremely important to survivors' recovery. The highest-rated caregiving tasks included tracking nutritional concerns (n=113, 97%), working together as a team on nutritional concerns (n=104, 90%), and making care decisions (n=102, 88%). Relative to importance, most dietitians did not perceive that the measured caregiving tasks were overly difficult for caregivers to perform. The caregiving tasks most frequently endorsed as very or extremely difficult included navigating the health system (n=45, 39%), making care decisions (n=44, 38%), and interpreting changes in nutritional status (n=40, 34%).

HNC Recovery Challenges

Dyadic interviews identified 5 unique themes, which are described below with example quotes from survivors and caregivers shown in Textbox 1.

XSL•FO
RenderX

Textbox 1. Themes identified in interviews with survivors with head and neck cancer and their caregivers.

Nutritional challenges were expected but extremely frustrating with weight loss and disrupted intake caused by texture/taste, swallowing, dry mouth and sticky saliva concerns

Exemplary survivor quotes:

- Well, the issue for me is that, I mean I couldn't taste food and water tasted really weird. So I basically ate because I knew I was supposed to. Not because I enjoyed it.
- [My wife] said, “Baby, please eat, eat something.” Cause I mean, I'm doing my best...I'm trying, I'm trying, I'm trying, and I'm trying but I wish I could just eat something.
- Peg tube blockages [happened because] protein powder didn’t dissolve well, gurgling, irritation. Part of lining of my wound started sticking out and ached. After hospital discharge, I was given a nutrient solution from a medical supply company and then had diarrhea, night sweats, and projectile vomiting. Lost 26 pounds.

Exemplary caregiver quotes:

- I kept weighing him and you know in the back of your mind you know that losing weight is a sign of cancer and you really, in your mind you know it's gone, you think it's gone. But there's that worry that maybe it's not really gone and that's why his weight is still going down. So that really confused me about his weight.
- But what bothered me was that he won't eat or couldn't eat and he lost a lot of weight. He looked terrible, and he didn't have energy. I didn't know what to fix when we get home. I tried to do mostly liquid stuff but there's only so much liquid stuff you can do. The thing is, they had pulled all of his molars before the surgery, because they figure if he had a radiation, it would have to have his teeth fit. Well, with no teeth, you can't chew.
- It did affect him quickly and he dropped the weight like a ton of bricks. It was a challenge to get anything down him and it was like I wanted to do things on his schedule but it was just really, really difficult. We tried this and we tried that and we tried you know, tried several different things.

Other competing symptoms were common and difficult to separate from nutritional challenges

Exemplary survivor quotes:

- Well, the pain had a lot to do with that. Your neck, shoulders, arms and hands are in lots of pain and discomfort.
- When I finished everything, I think the last two weeks for me were the worst, where the radiation had really taken on where it had in my jaw because I could probably open my mouth the width of my finger.
- I had two really bad sores in my mouth that didn't make it fun to eat anything. When I started again occasionally, I would get some irritation from eating crunchy foods.
- I couldn't raise my arms up above my shoulders… I think my taste was coming back and the physical therapy really, I mean, that really turned me around. I started feeling a lot better. They really rehabbed my shoulders.

Exemplary caregiver quotes:

- And the sores that was on his neck kind of bothered me. Some nights he couldn't sleep normally. You know, you just go to sleep but he couldn't.
- It was more helplessness than anything. There's not anything you can do for him. You can't force him to eat because the pain was there.
- His stomach was upset a lot. After the radiation was over for a period of time after the radiation was over. It was just miserable. And also he is having [GI] issues.
- But as far as some of the other issues as far as being nauseous, we had to deal with that. The doctor gave her medicines for that, another big one is constipation. Oh, that one is a tough one.

Emotional challenges related to nutrition and recovery were common

Exemplary survivor quotes:

- Oh, yeah, confused, I mean the cancer just takes the world, just takes a lot out of yourself and I wondered if I'm going back to work and how I'm going to feel at the end of the day, for how long I would be able to see my brand new granddaughter.
- I'm still at the point where anything - I'm still afraid…because you know I still do have a lump down there, I know every time I swallow my saliva I know it’s there and I can feel it and it's - that's one thing that's always going back of my mind.
- Emotionally, I was depressed especially after the radiation specifically. Physically, I couldn't swallow. I couldn't eat. It was the most egregious treatment I ever had my life and if I knew what the outcome was going to be I would have never done it.

Exemplary caregiver quotes:

- I was with her through her depression. I think, I was depressed along with her. Seeing my mother not being able to eat or any of that and on Sundays we have Sunday dinners at her house so, we went ooh, about a good two, three months without having Sunday dinner at mom's unless one of us had to go over and cook.
-

XSL•FO
RenderX

Depression lingered, it's always in the back of your mind - is it coming back? Or did they get it all? Or those kinds of things and then what's going to be next?

- At the end of treatment I was a basket case. I checked on him constantly when he slept.

Caregivers take on a diverse set of medical and support tasks

Exemplary survivor quotes:

- Well my wife made up a chart and we had everything, I want to say laminated, definitely a plastic cover over it which was a good thing. We had it all laid out there [to monitor intake].
- But I mean-- patience. Because we're going to fight back, not meaning to be mean. But we're hurting. We're just trying to get back—we're trying to get better. I would just say, frustration. That'd be a better word. Because it is frustrating. And you seem to take it out on the ones you love the most.
- I know I relied on them a lot to get me and to help me get to the tub, to get me out of the tub. At that time, it wasn't easy. If I was this big, they wouldn't have been-- it would take a couple of them.

Exemplary caregiver quotes:

- I went to the grocery store and I just went up and down the aisle trying to find something that he could eat.
- You wouldn't believe what I've learned to do from the last year. Changing IV's. Trained to do those things. There's nothing I wouldn't do for him anyway, but I was nervous I would maybe do something wrong and harm him accidentally.
- Knowing that he's like a glass half empty kind of guy, I tried to keep everything - I didn't... not that I didn't think about it, but I just kept thinking positive. That they got it all.
- You need someone who have their best interest at heart. There's times that she's not in her right state of mind with everything that is going on so, we go to these doctor's appointments or we go to certain things, you have to have someone that is there that's going to ask the doctors the question.

Caregivers need information about what to expect with nutritional challenges and recovery

Exemplary survivor quotes:

- [My caregiver] was given a calorie intake document for a day and that was what we're trying to keep at, but there's no real specifics given us - as to how we should accomplish that.
- Yeah, I think seeing a nutritionist would have been a plus. That was never approached to us. Maybe while I was in the hospital. Given some kind of program to try to keep certain calories or what kind of foods and how to build up to.
- I think that we should have been counseled about … a feeding tube. There was no plan. There was no nutritional plan. So, full disclosure and a plan to support that disclosure would have been great. And early on in the planning – you need it in the treatment planning phase.

Exemplary caregiver quotes:

- It would be nice to have a list of do's and don'ts, a list of things that have worked for patients in the past like, you know. Puddings, Jell-O's, more common-sense and anything but having a list would be really nice when you're in a grocery store and going, okay, he's gonna need blank, blank, blank and blank.
- Well, I think they should give you a folder with all the instructions for about everything. Nutrition, food to eat, everything that needs to be done on our way. Or even we didn't know you had to have this port flushed.
- Okay, I think what could be helpful...it seems to me, if somebody can be pre-briefed as to what difficulties they may have with the-- like the chewing aspects and the saliva aspects, and what things that people have found in general that might be worth avoiding, that would be a helpful thing.

Theme 1: Nutritional Challenges Were Expected but Extremely Frustrating With Weight Loss and Disrupted Intake Caused by Texture or Taste, Swallowing, Dry Mouth, and Sticky Saliva Concerns

Both survivors and caregivers reported an array of nutritional challenges at the end of treatment that required special diets and feeding tubes. With challenges in swallowing, texture, and taste during recovery, dyads reported difficulty finding diets that were satisfying and tolerable, and often caregivers experienced distress in encouraging their loved ones to eat. Shopping, cooking, and communicating and negotiating with one's loved one around intake were also commonly reported challenges. Weight loss was reported by all survivors and caused significant distress, particularly in caregivers. The routine around feeding was reported to be very tedious.

Theme 2: Other Competing Symptoms Were Difficult to Separate From Nutritional Challenges

Survivors experienced many symptoms in addition to and related to nutritional concerns. For example, participants reported fatigue, mobility challenges, nausea, sores, and pain, and recovery challenges that often exacerbated nutritional and caregiving concerns. The array of symptoms caused frustration in survivors and worry in caregivers.

XSL•FO
RenderX

Theme 3: Emotional Challenges Related to Nutrition and Recovery Were Common

The emotional challenges faced by survivors and caregivers included frustration, fear, uncertainty, confusion, and depression. They reported frustration associated with eating challenges and the persistent focus on feeding and symptom management. Some participants reported worry and fear about survivors not regaining functional abilities. Relatedly, confusion and uncertainty about the future were commonly described by both survivors and caregivers. Caregivers expressed fear about weight loss and choking, as well as their ability to care for their loved ones. Both survivors and caregivers reported depression and other psychosocial concerns, and both also emphasized the importance of caregiver well-being.

Theme 4: Caregivers Take on a Diverse Set of Medical and Support Tasks After Treatment Completion

Caregivers focused on practical, nutritional, and emotional support tasks. Common practical tasks included providing transportation to and attending health care appointments, helping a loved one get around, and managing medications and stoma and IV care. Common nutritional support tasks included monitoring weight loss and intake, grocery shopping, researching recipes, preparing meals, and caring for feeding tubes. Emotional support tasks included supporting survivors' frustration with recovery and nutritional challenges and trying to keep a positive attitude. It was common for caregivers to report distress about support challenges, and they sometimes faced resistance from their loved ones around eating. Caregivers described a dynamic process of being persistent, creative, and patient.

Theme 5: Caregivers Need Information and Resources About What to Expect and How to Cope With Nutritional Challenges

Caregivers described feeling unprepared to support nutritional recovery and said they would have benefited from additional resources and support at the end of treatment. They emphasized the importance of early education during the treatment planning process to provide a better understanding of what to expect, resources and tools to support food preparation, and tips to help monitor intake. Survivors and caregivers both highlighted interest in meeting with a dietitian, yet also raised concerns about information overload.

Caregiver Needs and App Recommendations to Support Caregivers

Dietitians endorsed caregivers' time constraints (100/116, 86%) and caregivers being overwhelmed (102/116, 88%) as major barriers to meeting caregivers' needs. They also endorsed oncology clinics lacking designated staff to coordinate caregiver resources (70/116, 60%), higher priority care issues (n=72/116, 62%), and clinical team time constraints (n=70/116, 60%) as barriers. In light of unmet needs and to better support caregivers' provision of quality nutritional support to survivors with HNC, dietitians rated the importance of a variety of services and resources. While all 8 proposed services were rated by the majority (≥60%) of dietitians as very or extremely important, the highest ranked services or resources included a clinic referral process to link caregivers to appropriate nutritional resources (104/116, 90%), educational materials about diet (92/116, 79%), one-on-one counseling about nutrition (103/116, 89%), and training in nutritional support and symptom management (90/116, 78%).

Dietitians' responses to an open-ended question after reviewing example app screens yielded suggestions for new app content, including recipe recommendations, intake tracker, encouragement about caregiving tasks, and support for the caregiver's own well-being. Exemplary quotes include:

> *Caregivers want recipes! Tips for sore mouths, mucositis and dry mouth ... trouble-shooting enteral tube issues, constipation tips.*
>
> *Specific tips on adding high-calorie foods for weight maintenance (low in acid, soft/liquid). Same for high protein foods for tissue healing and muscle mass maintenance/recovery. Tips for frequent eating until appetite improves or side effects diminish (nausea, early satiety).*
>
> *Having exercises listed that can maintain muscle strength would be great. Also, a tracking device for the number of tube feedings completed and fluid intake would be helpful.*
>
> *It is important for the caregiver to have one set number to call for info. So many times, they try to get info from the internet which isn't always helpful.*
>
> *Support for caregivers themselves knowing they are not alone and such a big part of success moving forward.*

Survivors and caregivers' survey responses indicated that dyads were in strong agreement that checking in with caregivers after survivors complete treatment (12/15, 80% and 9/11, 82%, respectively) and providing support messages to caregivers (11/15, 73%, and 10/11, 91%, respectively) would be helpful. In addition, dyads were in strong agreement that it is important to provide practical information to caregivers to help survivors' nutritional recovery (15/15, 100%, and 10/11, 91%, respectively).

Feedback from dyads' responses to open-ended questions after reviewing example app screens included keeping the content simple, providing tips about what foods to avoid, providing recipes and dynamic nutrition information as needs change, including tips from other survivors with HNC and caregivers, and emphasizing support for caregiver well-being and self-care. Examples of exemplary quotes include:

> *This is like your personal resource right here at your fingertips - you're not alone. Let them know you're here if they need you. Simplicity is important.* [Caregiver]
>
> *Provide more advice about foods you can eat and problems with specific types of food groups…practical information with step-by-step directions. Food suggestions based on symptoms.* [Survivor]

XSL•FO
RenderX

Prepare caregivers for the possibility that the patient may not like the same dishes caregivers prepared before and not to take this personally. [Caregiver]

Encourage caregivers to ask for support from others: Doesn't mean you're less of a person [if you ask for help]. You need all the help you can get and a lot of the time you don't want to ask for it. [Caregiver]

It is important to ask about how the caregiver is doing; I feel guilty for not asking how she was doing. In general, we are in the dark; anything that brings some light into the room is helpful. [Survivor]

Data Synthesis: App Development

Building on results from all surveys and interviews underscoring the high need and interest in a comprehensive caregiver app, we designed the Healthy Eating and Recovery Together (HEART) app. The overall goal of the app was to support caregivers of survivors with HNC as they transition to the home setting after completing treatment and decrease their unmet needs and caregiver burden. The study investigators evaluated qualitative themes from dyad interviews side by side with quantitative themes observed in dietitian and dyad surveys. Team meetings were used to identify similarities in themes that were translated to high-priority main menu domains and subdomains for the app. The integration of survey and qualitative data resulted in an expansion of the findings, as the qualitative themes provided a detailed understanding of quantitative findings about caregivers' unmet needs and responsibilities as caregivers. The research team worked closely with the development team to review and test evolving prototypes, and a final prototype was pretested with 2 caregivers. The app was updated with feedback over the course of these steps (eg, we updated icons, modified menu choices, added instructions to components, reordered messages, and modified color choices). HEART includes educational information, caregiving tips and encouragement, and resources, with 4 elements, including survivor nutritional support, intake tracker, caregiver toolkit, and support videos (Table 1 provides more detailed descriptions and sample screenshots). The app also provides caregivers with notifications twice a week to check in with them about their concerns and deliver real-time resources mapped to current concerns. Two main areas in the app's content included a focus on survivor-caregiver teamwork and support of caregivers' own well-being.

Table . Content of the HEART[a] app.

App section	Content	Results guiding content	Screenshot
Nutritional support	Tips and encouragement for supporting a loved one with nutritional intake	A need for coverage of a broad array of topics to support the dynamic nutritional recovery process with content on common issues, recipes, and oral care support.	
Intake trackers	Supports tracking of feeding tube, liquid diet, and solid food in real time to monitor quantity, tolerability, and preferences, with the ability to share the intake journal with others.	Caregivers experience distress in monitoring intake and need a simple, convenient way to support monitoring.	
Caregiver toolkit	Emphasis on caregiving tasks and how caregivers can take care of their own physical and emotional well-being with tips and relaxation techniques	Caregivers feel unprepared for their roles as caregivers and face significant burdens, often overlooking their own well-being.	
Support videos	Survivor, caregiver, and clinician videos to support nutritional recovery and well-being	Interest in social support and increased interaction with dietitians and other survivors and caregivers.	
My resources	Stores biweekly prompts and tailored resources	Participants desire real-time connections and resources that are dynamically matched to their changing needs during recovery and caregiving.	

[a]HEART: Healthy Eating and Recovery Together.

Discussion

Principal Results

Survivors with HNC and their caregivers face exceptionally difficult posttreatment concerns that negatively impact their quality of life [28,59-61]. Caregivers are often tasked with addressing survivors' nutritional challenges in the home setting, yet many are unprepared for these caregiving tasks [20,24]. Getting adequate nutritional intake, maintaining a healthy weight, and managing physical symptoms and emotional distress are imperative for survivors of HNC during the posttreatment period; yet, there is a paucity of tools available to support survivors and their caregivers in meeting these goals [31,32]. This study addressed this important survivorship care gap, specifically the availability and accessibility of high-quality interventions to support nutritional caregiving. Recognizing the

XSL•FO
RenderX

value of stakeholder input in intervention development [62-64], we used mixed methods to assess the perspectives of survivors, and then also used responses from caregivers and oncology dietitians to guide the development of an app to support caregivers at the end of treatment. Previous studies have emphasized the acceptability of apps for cancer caregivers while also calling for more formative research to ensure their suitability [43,44,65,66]. While we intended to focus this tool on nutritional caregiving support, study results led to a more comprehensive product focused on nutrition and other survivor recovery concerns, plus caregiver self-care. The final HEART app includes nutrition support with an intake tracker, along with tips and encouragement for other caregiving areas (daily support, emotional support, and medical support), support videos from peers and clinicians, and a caregiver toolkit (taking care of yourself and relaxation exercises).

To guide app development, dietitians provided their perspectives on caring for and supporting HNC dyads. They endorsed a broad array of important nutritional concerns for HNC caregiving, including swallowing, feeding tube management, weight maintenance, and caregiver distress about nutrition. They also perceived that there were multiple nutritional care tasks that were important to survivors' recovery, including monitoring nutrition, making care decisions, and working together with their survivors as a team to manage nutritional concerns. While most dietitians did not rate these care tasks as extremely difficult for caregivers to manage, the number of tasks endorsed was substantial, and the importance to survivors' recovery was rated highly, indicating that an app intervention would likely need to be complex and cover a comprehensive set of nutritional concerns. These results suggest that an app should help caregivers be flexible and skilled in multiple nutritional care tasks. Additionally, dietitians' perceptions regarding potential survivor-caregiver mismatch on nutritional goals were consistent with previous studies [18,26], which may suggest that a focus on teamwork in dyads would be beneficial in an app [67,68].

HNC survivor-caregiver dyads in this study confirmed the challenges reported by dietitians in both surveys and interviews. First, survey results highlighted similar nutritional caregiving concerns after treatment in survivors, caregivers, and dietitians. Second, interviews confirmed the types of nutritional challenges experienced and the emotional toll they take on dyads, consistent with previous studies [5,6,69,70]. Results also highlighted that nutritional caregiving tasks were compounded by other competing HNC recovery concerns (eg, support for pain, mobility, pain, fatigue, and emotional challenges); it was difficult for caregivers to focus on nutrition without considering these additional concerns. As highlighted in previous research, caregivers take on a multitude of caregiving tasks and need resources matched to these responsibilities [14,19,20], again supporting the coverage of a broad array of HNC caregiving [20] content in an app.

Dietitians also endorsed high barriers to meeting caregiver needs, including clinician time constraints and a lack of designated staff to coordinate resources. While increasing research has prioritized interventions to meet caregiver needs [31,71], cancer care settings are not adequately resourced to address their needs [72,73]. Technology tools such as the HEART app may be a promising approach to address these barriers and complement other interventions to support caregivers [39,74]. Dietitians in this study endorsed a broad variety of strategies and content to include in an app to support caregivers. Dietitians tended to prefer high-resource strategies for inclusion in an app, such as intake tracking, training, screening processes, educational resources, and counseling. Survivors and caregivers confirmed interest in an app for caregivers with check-ins, support, and practical tips. Both dietitians and dyads recommended the provision of recipes and support for caregivers' own well-being. Dietitians uniquely recommended an intake tracker, while dyads uniquely recommended tips from peers.

While mobile health intervention development and testing to support caregivers of people with cancer is growing and shows evidence of promising acceptability, adherence, and some improvements in short-term outcomes such as caregiver burden [41-43,45,65,75,76], more research is needed in this area to better understand caregiver adoption and engagement in these interventions, impacts on caregiver psychosocial and health outcomes, and best practices for disseminating such intervention in practice using rigorous methods. Of key importance, few studies have focused on HNC caregiving and nutritional support. Apps to support caregivers of people with HNC also have the potential for supporting and addressing HNC dietitian time constraints by supporting their recommendations outside of the clinic; more research is needed in this area.

Strengths and Limitations

The strengths of this study include its mixed methods approach with data collection from multiple perspectives, including those who had experienced HNC recovery, served as an HNC caregiver after treatment, and provided clinical care for HNC survivor-caregiver dyads. The integration of survey data and qualitative data allowed for the examination of similarities and unique findings across qualitative and quantitative themes, ultimately allowing a deeper understanding of perspectives to guide the HEART app. Dietitians were recruited from across the United States, and qualitative interviews with dyads were used to supplement surveys and provide a more in-depth understanding of survey results. The app's focus on nutritional support, particularly after the end of treatment, is innovative and would help address an area of major concern for HNC providers, survivors, and caregivers. In the context of changing digital health use patterns over time, it is important to note that an important limitation of this study is that the data were collected in 2018. However, it is notable that digital health use and engagement rates have increased over time, and this expanded reach and growing societal acceptance of these tools are therefore encouraging [77]. Other limitations of this study include recruitment of dyads from only one medical center, recruitment of a convenience sample of dieticians, and a modest sample size for interviews, all of which limit the transferability of findings. In addition, we experienced a lack of diversity in clinical and sociodemographic factors for surveys and interviews. We selected a parallel convergent approach for data collection and analysis and followed with an integration approach (merging) to synthesize our mixed methods data; while a sequential approach may have allowed more iterative app

XSL•FO
RenderX

development and testing, this approach was selected to facilitate rapid technology development.

Conclusions

In summary, this study identified the optimal content for a mobile support app for caregivers of people with HNC and supported the acceptability of implementing this intervention at the end of treatment. Future steps include evaluating the implementation of the HEART app and its impact on survivor and caregiver outcomes. It will be important for a future study to rigorously test the HEART app in a prospective clinical trial.

Abstract

Background: Due to multifaceted outpatient regimens, children receiving hematopoietic stem cell transplants (HCTs) are at high risk of medication nonadherence, leading to life-threatening complications. Mobile health (mHealth) interventions have proven effective in improving adherence in various pediatric conditions; however, adherence intervention literature on HCT is limited.

Objective: This study aimed to assess the usability of a mHealth intervention (BMT4me) designed to serve as a real-time, personalized tool for medication management or adherence, symptom tracking, and journal keeping.

Methods: Following a mixed methods approach, 14 caregivers (n=11, 79% female; n=10, 71% White) of children aged 2 - 18 (mean age 8.51, SD 5.18) years in the acute phase (first 100 d) post-HCT were recruited. Caregivers were asked to use the BMT4me app for 100 days or until weaning of the immunosuppressant medications to measure usability. The System Usability Scale (assessing functionality and acceptability), reaction cards (assessing desirability), caregiver satisfaction (assessing satisfaction) with the app, and semistructured interviews (assessing participant experience using the app and feedback regarding features) were conducted at two time points, at enrollment and study completion.

Results: The mean System Usability Scale score was 86.15 (SD 12.81) at enrollment and 73.13 (SD 16.13) at study completion, with most participants reporting the app easy to use and accepable during both time points. At enrollment, 80% (n=12) of caregivers reported that the app was effective in motivating them to stay on schedule, and 87% (n=13) indicated they would recommend it to others. At study completion, 75% (n=6) of caregivers found the app helpful for tracking their child's medication schedule, and 64% (n=5) would recommend it to others. Caregivers described the app as "accessible," "useful," and "valuable." Qualitative interviews during both time points revealed caregivers' positive reactions to the app, particularly regarding medication reminders, tracking symptoms, and notes features, while also providing suggestions for improvements, such as integrating the BMT4me app with electronic medical records, incorporating educational content, adding fields for recording vital signs, and important phone numbers.

Conclusions: The BMT4me app demonstrated promising usability as a mHealth intervention among pediatric patients undergoing HCT. Caregivers considered the app user-friendly and valuable, with positive feedback on its features, such as medication reminders and symptom tracking. Despite minor reported issues with app functionality, the overall acceptance of the app suggests its potential to support families in managing complex treatment. The findings from this study will inform the feasibility of testing in larger randomized controlled trials.

Introduction

Pediatric hematopoietic stem cell transplants (HCTs) are an intensive life-saving treatment for several malignant and nonmalignant disorders [1]. However, HCT often requires a long hospital stay that is stressful for the children and their caregivers [2]. Symptom and medication management are important components of the HCT experience, and it is critical for caregivers to adhere to recommendations and communicate with the care team [3]. After discharge, caregivers must follow complex medication regimens with various dosages and frequent dose adjustments, increasing the risk for nonadherence [4,5]. In the pediatric HCT population, 52% to 73% [2,6,7] of patients do not take medications as they are prescribed during the treatment course. Therefore, medication adherence is a primary concern for health care providers and caregivers after pediatric HCT [8,9]. Many factors impact medication adherence rates, including patient-related factors, forgetfulness, therapy side-effects, complexity and length of treatment, and route of administration [10-13]. Although medication adherence in pediatric HCT is understudied and interventions are limited, research in other pediatric chronic conditions has demonstrated the potential of mobile health (mHealth) interventions in improving medication adherence [14-16].

As smartphones become nearly ubiquitous in daily life, mHealth interventions can improve families' ability to manage their child's medical care [17,18]. Recent estimates show that over 5 billion people have access to mobile phone services around the world [18]. Additionally, a study of adults with chronic diseases suggests that mobile apps as mHealth intervention tools are more effective for improving medication adherence than non-mHealth interventions [19]. mHealth interventions have resulted in better clinical outcomes (eg, increase in health-related quality of life, symptom management, and decrease in readmissions and treatment anxiety) [20-22] through behavior change and enhancement of adherence to treatment [23-25]. mHealth interventions allow individuals and caregivers to track medication doses and symptoms, make notes of discussion points with their health care team, and find educational resources and support networks [26-29]. However, such interventions have yet to be tested to promote medication adherence among children in the acute phase post-HCT (ie, hospital discharge to day 100) [30].

This paper reports a longitudinal mixed methods pilot study examining the usability of a mHealth intervention (BMT4me) with caregivers of children in the acute phase following HCT. This intervention helps caregivers to record and track their child's medications, set reminders, report symptoms, and take notes on their child's progress. The goal is to inform future refinement of the intervention, a feasibility trial, and a pilot randomized controlled trial examining efficacy.

Methods

Study Design

Data are from a longitudinal mixed methods study to assess the usability of a newly developed mHealth intervention for pediatric post-HCT medication management. The study was conducted at a large Midwestern children's hospital from September 2021 to January 2023. Eligible caregivers were identified from the HCT clinic schedule and inpatient HCT unit based on the following eligibility criteria: (1) English-speaking, (2) 18 years of age or older, (3) having a child between 2 and 18 years of age undergoing allogeneic HCT, and (4) having a smartphone (either Android or iPhone) at recruitment and during the study period. All 20 caregivers of children who received HCT during the study period and met the eligibility criteria were approached for participation. A total of 15 caregivers consented to participate in the study, while 5 caregivers declined due to reasons including being busy with caring for the child and not being comfortable using the apps in general. One caregiver withdrew after initial consenting, resulting in a final cohort of 14 caregivers.

Ethical Considerations

The study was approved by the Nationwide Children's Hospital Institutional Review Board (approval STUDY00000910) and was designed in accordance with the ethical standards laid out by the Declaration of Helsinki. Eligible interested participants provided informed consent prior to enrollment and were assigned ID numbers for confidentiality. Recordings of qualitative interviews were destroyed after completion of the transcription, and identifying information in the transcripts was removed. All participant information has been anonymized in this paper, including the text, tables, and figures. Upon completion of the study, all participants received a US $20 gift card as compensation.

Measures

Demographic Data Form

Caregivers self-reported the child's and their own background characteristics, including age, sex, race, ethnicity, education level, and family income at the time of study enrollment.

System Usability Scale

Caregivers rated 10 items on a 5-point Likert scale to evaluate the functionality and acceptability of the BMT4me app. Total scores range from 0 to 100, with scores >68% considered above average [31]. Internal consistency (Cronbach α=0.91) and convergent validity (r=0.81 with a 7-point scale of "user-friendliness") have been well established [32,33].

XSL•FO
RenderX

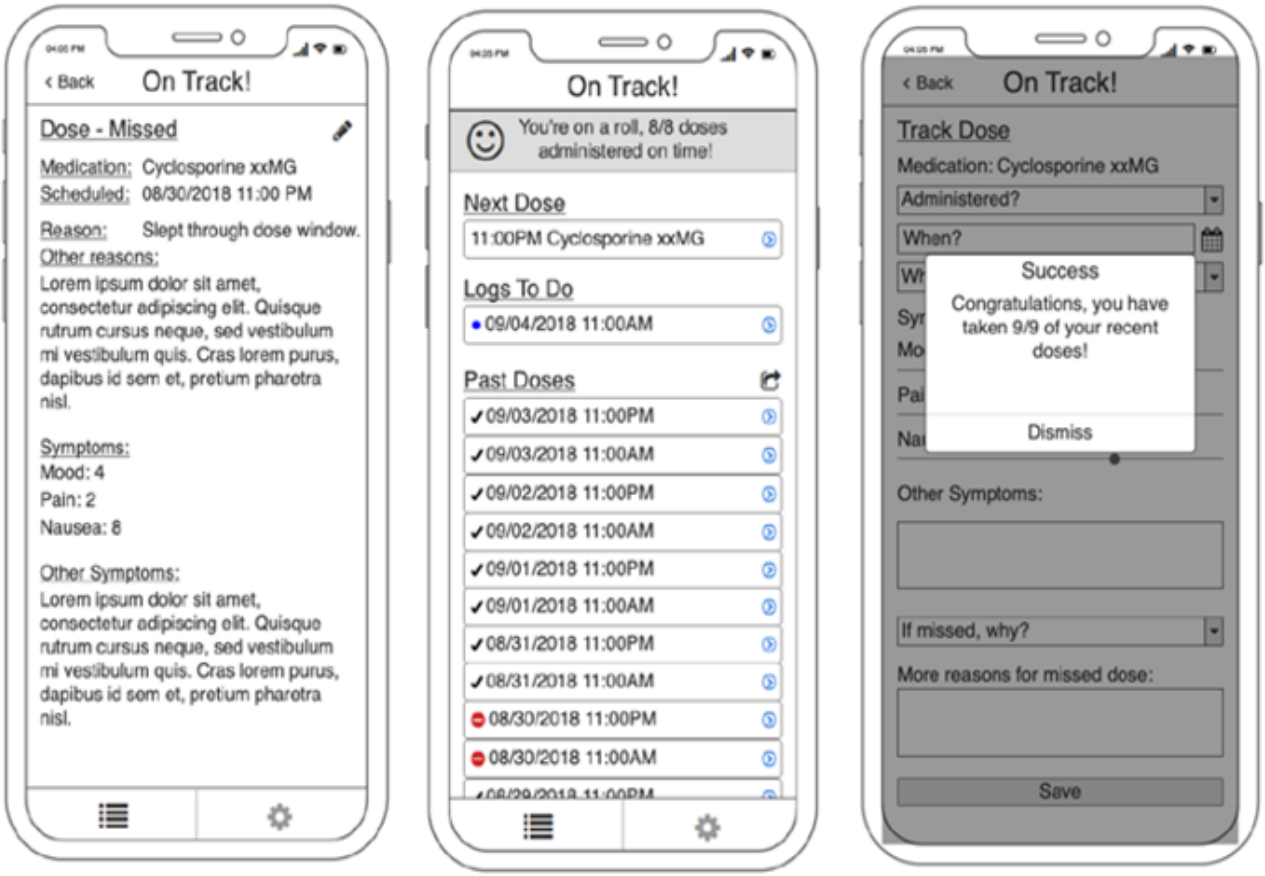
Caregiver Satisfaction

Investigators developed a 9-item survey to obtain feedback regarding caregiver app use, benefits, burdens, barriers, suggested modifications, and overall satisfaction. Questions were rated on a 1 to 4 scale, with higher total scores indicating greater caregiver satisfaction.

Reaction Card

Reaction cards were developed by Microsoft as part of a "desirability toolkit" to elicit immediate reactions, thoughts, or opinions from individuals regarding a particular tool or technology [34]. Using a reaction card of 55 listed words, caregivers provided feedback on the desirability of the BMT4me app. The words and the number of times they were chosen were summarized to indicate the overall attitude toward the app. Higher frequencies of positive words indicated greater usability, while higher frequencies of negative words indicated lower usability [35].

Qualitative Interview



Qualitative nterview guides were developed using a combination of literature review, expert consultation, and pilot testing to ensure relevance and clarity. Questions were designed to elicit in-depth perspectives on key study themes while allowing for flexibility in participant responses. A semistructured format was used to balance consistency across interviews, with the opportunity for participants to elaborate. The semistructured interviews were transcribed verbatim and analyzed using NVivo software (QSR International).

BMT4me App

The development of the BMT4me app (Figures 1 and 2) followed a user-centered, multiphase iterative approach. This method actively involved patients, caregivers, and health care providers at every stage of the app's creation. Initially, a wireframe (Figure 1) was designed, serving as a simple visual representation of the app's structure and content [36].

Feedback was then collected from caregiver and child dyads, which informed the creation of the BMT4me app prototype (Figure 2). Afterward, health care providers assessed the prototype, and feedback led to further refinement of the app.

Figure 1. Version 1 of mobile health app wireframes.

XSL•FO
RenderX

Figure 2. Revised BMT4me app prototype.

The BMT4me app was developed for both iOS and Android devices as a real-time, personalized medication management or adherence tool, and to track medication, symptoms, and side effects. Medications, doses, and schedules can be manually typed into the app by the user or entered using the image-to-text feature, which converts the medication label into text. Through pop-up notifications, the BMT4me app reminds caregivers of the medication doses and schedule, while also recording the time medication was taken and reasons for missed doses. Symptom ratings are represented by emojis on a slider scale of 1 to 10. Additional features include a note section to upload pictures and for recording any details of care to communicate with the provider. In the case of shared caregiver responsibility, the app can be installed on separate devices using the same sign-in code to sync information in real-time between caregivers. Amazon Web Services were used for data storage and app database management.

Procedures

If eligible, recruitment occurred either before or on the day of the child's discharge following HCT or at the first HCT clinic visit postdischarge. Trained research staff introduced the study, and interested caregivers provided written informed consent prior to participation.

To facilitate app login and use, participants received a unique QR code for activating the BMT4me app on their smartphones, and the research team helped with installation. Understanding and engagement with the app were evaluated in the following steps (further explained in [37]).

Step 1: Unobtrusive Observation to Measure the Intuitiveness of the Interface (10 - 15 Min)

Ease of Navigation

This was how quickly and accurately participants were able to find features and complete tasks, as well as any moments of hesitation or confusion when navigating the menu and buttons.

Task completion

This was how quickly and accurately participants found features or completed tasks such as inputting medications, symptoms, or notes.

Error frequency

This included mistakes made while interacting with the app, such as tapping the wrong button or misunderstanding the instructions.

Flow and Progression

This was how naturally participants moved through the app interface without guidance.

Caregivers were encouraged to interact with the app independently, without guidance from the study staff, to evaluate the intuitiveness of the app's interface. During this phase, research staff observed and recorded participant progress related to the other steps described below.

Step 2: Interactive Observation (10 - 15 Min)

After observing independent app use, the research team started to interrupt the participants and ask questions regarding observed cues. Caregivers were encouraged to share their thoughts and criticisms of the app. The discussion was based on individual participant cues, and preprescribed questions were not possible.

XSL•FO
RenderX

Step 3: Debriefing (15 - 20 Min)

Caregivers were asked to share their experience with the app, including the app's interface and content, as well as thoughts on incorporating the app into their daily routine. Feedback regarding the strengths and weaknesses of the app was also collected.

Step 4: Passive Use Observation

To ensure caregivers understood the app, research staff provided a detailed introduction, answered participant questions, and had the caregivers practice adding medications and tracking symptoms. Participants were invited to continue using the BMT4me app at home for 100 days or until the child had been weaned off the immunosuppressant medications. Participants' passive use data on app use and phone activity was digitally logged

Caregivers then evaluated the usability of the BMT4me app at the beginning and end of the study, using the System Usability Scale (SUS), Caregiver Satisfaction, and Reaction Card assessments. SUS, Caregiver Satisfaction, and Reaction cards were completed after participants independently interacted with the app for 5 - 10 minutes during enrollment. Participants completed enrollment measures in the hospital prior to discharge, and they had an option to complete them either electronically via REDCap (Research Electronic Data Capture; Vanderbilt University) on a study iPad or using paper and pencil. Exit measures were completed electronically, where participants were emailed the survey link. Participants were invited to continue using the BMT4me app at home in the acute phase post-HCT (100 d or until the child had been weaned off the immunosuppressant medications) because the risk of nonadherence and complications such as GVHD is highest during that time. The BMT4me app collected daily data on medication-taking, the time medication was taken, reasons for missed doses and barriers, symptoms, and notes. Passive use data on phone activity and app use were digitally recorded and sent to the research team by software developers each week. During the study, research staff followed up with participants weekly to provide technical app support if needed.

Upon completion of surveys, semistructured interviews were also conducted in-person, both at the beginning and end of the study, to explore app use experiences, helpful features, suggestions for future improvements, and barriers encountered while using the app at home. To schedule the interviews, participants were contacted by research staff via phone call or email. During their child's clinic visit, semistructured interviews, lasting approximately 15 - 20 minutes, were conducted by research staff trained in qualitative interview methods. The study investigator conducted fidelity checks to ensure consistency across the research staff's qualitative interview techniques. All interviews were audio-recorded for analysis.

Data Management and Analysis

Data cleaning and verification were completed using Excel (Microsoft Corp), and the data were then analyzed using SPSS software (version 26; IBM Corp). Descriptive statistics (frequencies, means, and SDs) summarized quantitative data, including demographic characteristics, BMT4me app activity, and survey responses. During the passive observation period, passive data modules recorded phone activity and caregivers' app use (such as time, date, and duration of use). Descriptive statistics were applied to analyze the phone activity, and correlation analysis was conducted to examine use patterns over time. Usability and acceptability of the BMT4me app were assessed by averaging total scores from the SUS. The proportion of participants who enrolled and completed the study was examined to assess the feasibility of the intervention.

Semistructured interviews were transcribed verbatim for content analysis and were organized and coded using NVivo software. Initially, the study team read the transcripts to familiarize themselves with the data. Afterward, the team generated an initial list of codes to align with study questions, and later, the codes were sorted to create a thematic framework. For consistency and accuracy, themes and code groups were then revised systematically by the team's identified coders (MS, MK, and Kathryn A Vannatta), and the thematic framework was adjusted to reflect any changes. Once the review was complete, final codes and themes were reviewed by the study's principal investigator (MS), and any disagreements were resolved through consensus with the coding team. Finally, findings were interpreted and reported in relation to existing literature.

Results

Participants

Initially, 15 caregivers were enrolled in the study (Table 1). Among them, 10 (67%) were approached at discharge and 5 (33%) at the first BMT follow-up visit postdischarge. One caregiver opted out after consenting for the study, and 2 were lost to follow-up, one at week 2 and the other at week 3, both due to transfer of care to another institution. Most caregivers were female (n=11, 79%), White (n=10, 71%), non-Hispanic (n=13, 93%), married (n=9, 64%), and had a college-level education (n=8, 57%). More than half of caregivers reported an annual family income of ≤US $75,000 (n=8, 57%). All caregivers were biological parents of the children. The sample of children was mostly male (n=10, 71%), White (n=10, 71%), and non-Hispanic (n=13, 93%).

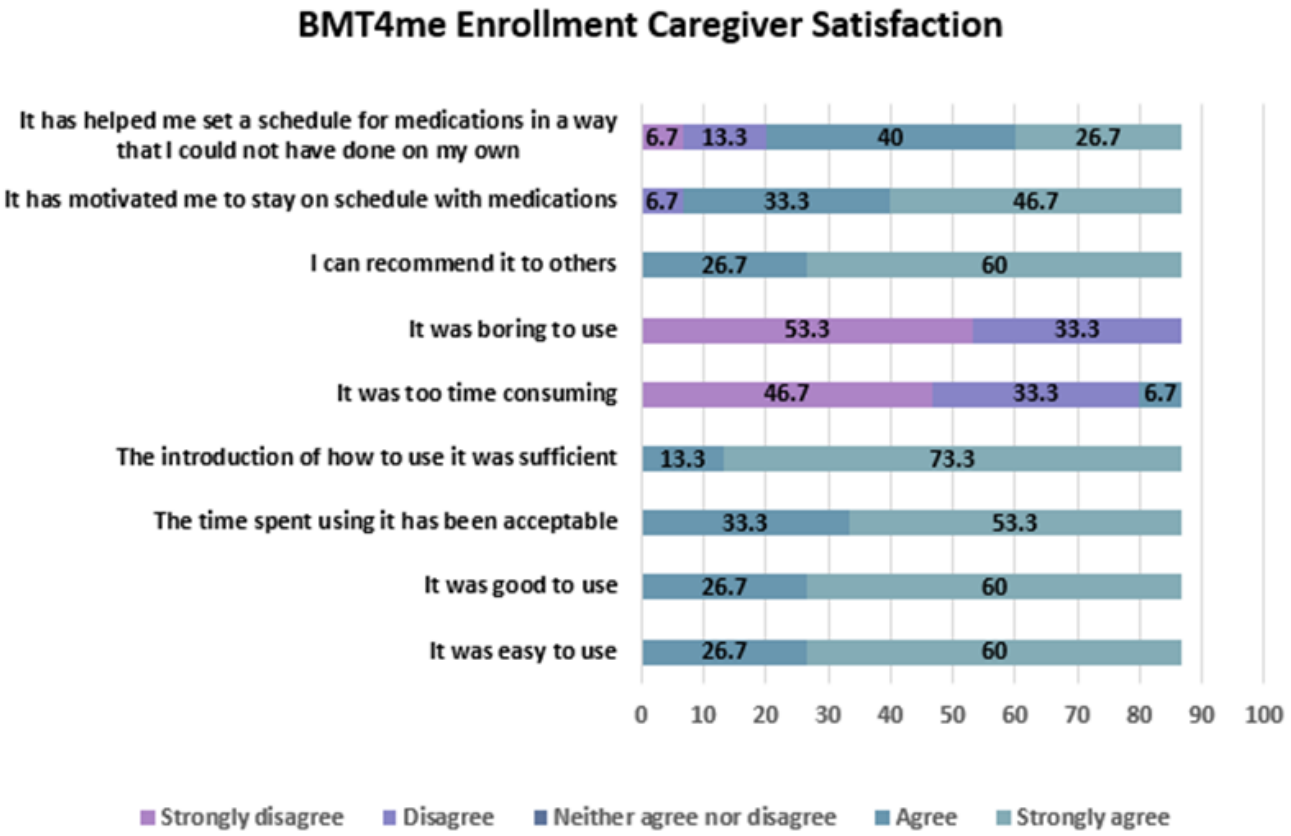
Usability

SUS

At enrollment, the average SUS score was 86.15 (SD 12.81), and the median was 87.5 (IQR 62.5 - 97.5). On individual items, caregivers reported that the app was quick to learn (n=13, 93%), they were confident using the app (n=11, 79%), the app was easy to use (n=11, 79%) and that they would like to use the BMT4me app (n=13, 93%; Figure 3).

Figure 3. Enrollment SUS survey responses from caregivers. SUS: System Usability Scale.

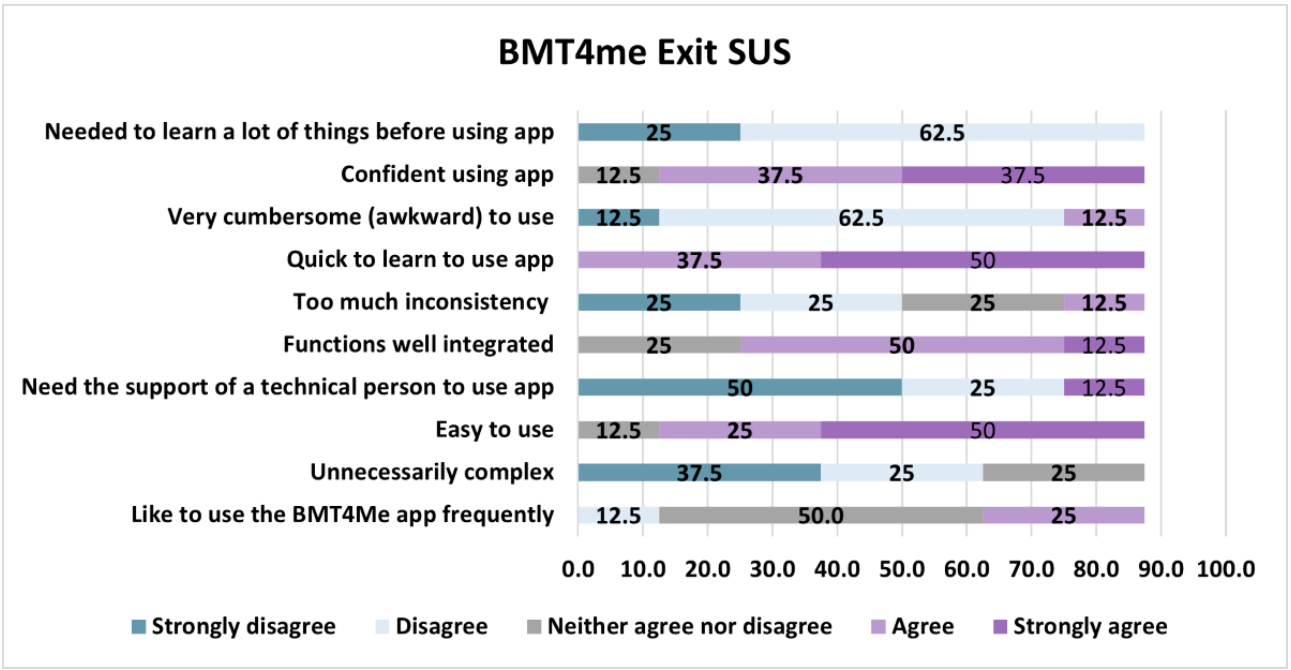


Caregiver Satisfaction

Participants reported that the BMT4me app was easy to use (n=13, 87%) and effective in motivating them to stay on schedule with medications (n=12, 80%). Most did not find it time-consuming (n=12, 80%) or boring (n=13, 87%). Caregivers indicated they would recommend the app to others (n=13, 87%) and felt it helped them maintain their child's medication schedule in ways they could not have managed on their own (n=10, 67%; Figure 4).

XSL•FO
RenderX

Figure 4. Enrollment caregiver satisfaction survey responses.



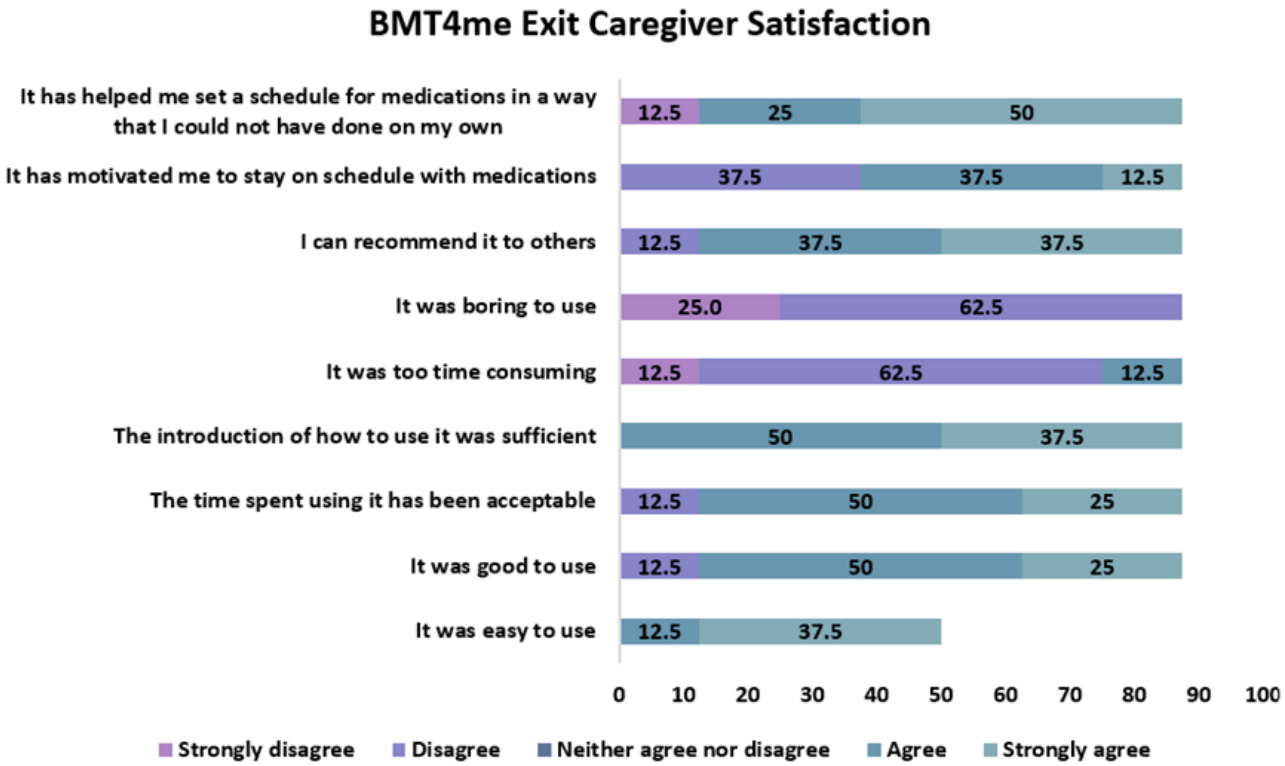
Reaction Cards

Most caregivers expressed a positive reaction after their initial use of the app with the top three endorsed reactions being the app was accessible (n=11, 73%), useful (n=11, 73%), and easy to use (n=10, 67%), which received the highest percentage of responses (Multimedia Appendix 1).

SUS

At study completion, the mean SUS score was 73.13 (SD 16.13), and the median was 75.0(IQR 50 - 86.3). On individual items, caregivers reported the app was quick to learn (n=7, 88%), they were confident in using the app (n=6, 75%), app was easy to use (n=6, 75%), and that features were well-integrated (n=5, 65%; Figure 5).

Figure 5. Exit SUS responses from caregivers. SUS: System Usability Scale.



XSL•FO
RenderX

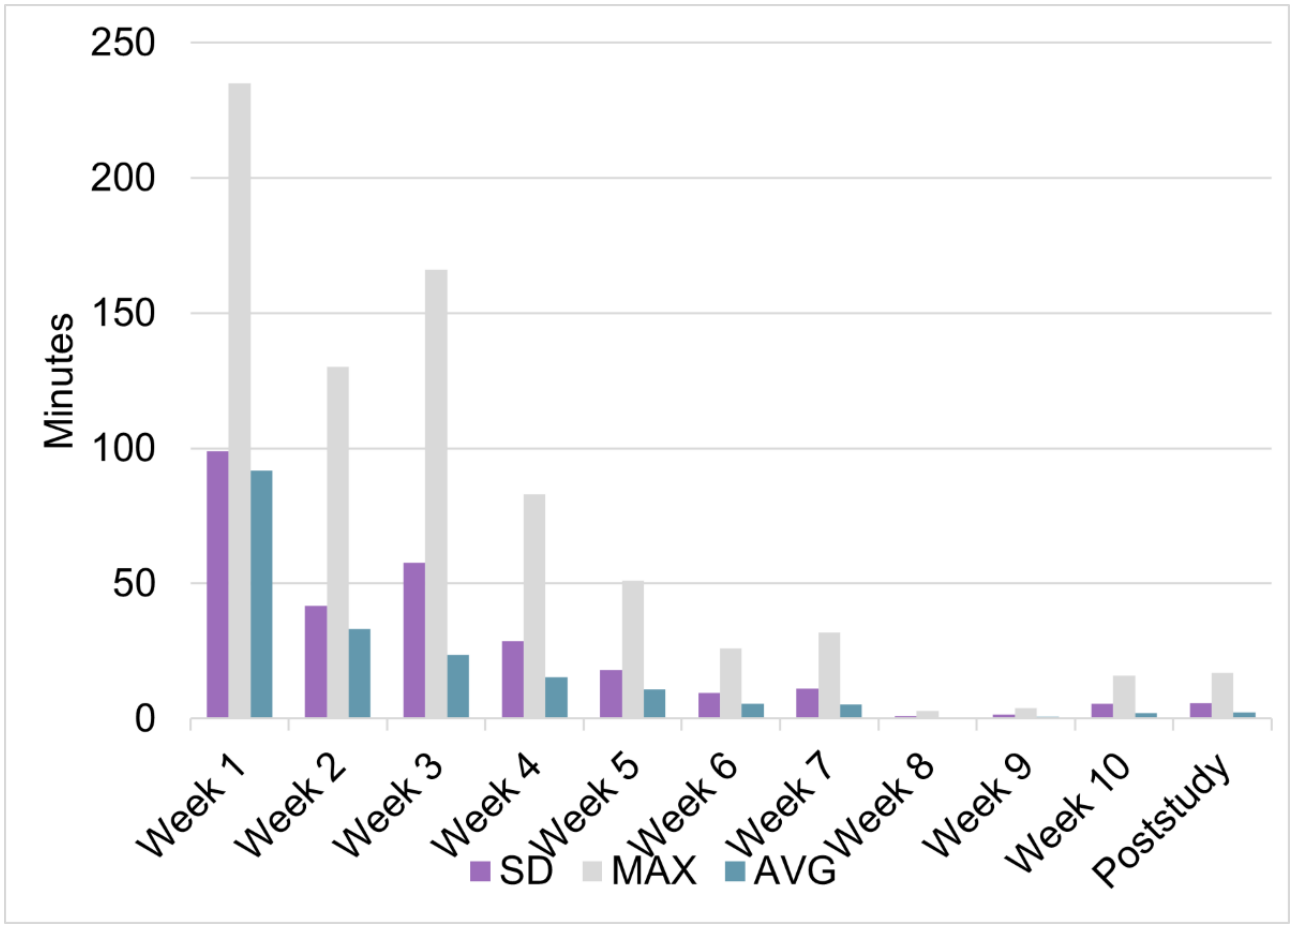
Caregiver Satisfaction

Caregivers reported that the app was helpful in keeping track of their child's medication schedule (n=6, 75%), while also being good to use (n=6, 75%) and not boring (n=7, 88%). A total of 6 caregivers indicated that they would recommend the app to others (n=6, 75%; Figure 6).

Figure 6. Exit caregiver satisfaction survey responses.

Reaction Cards

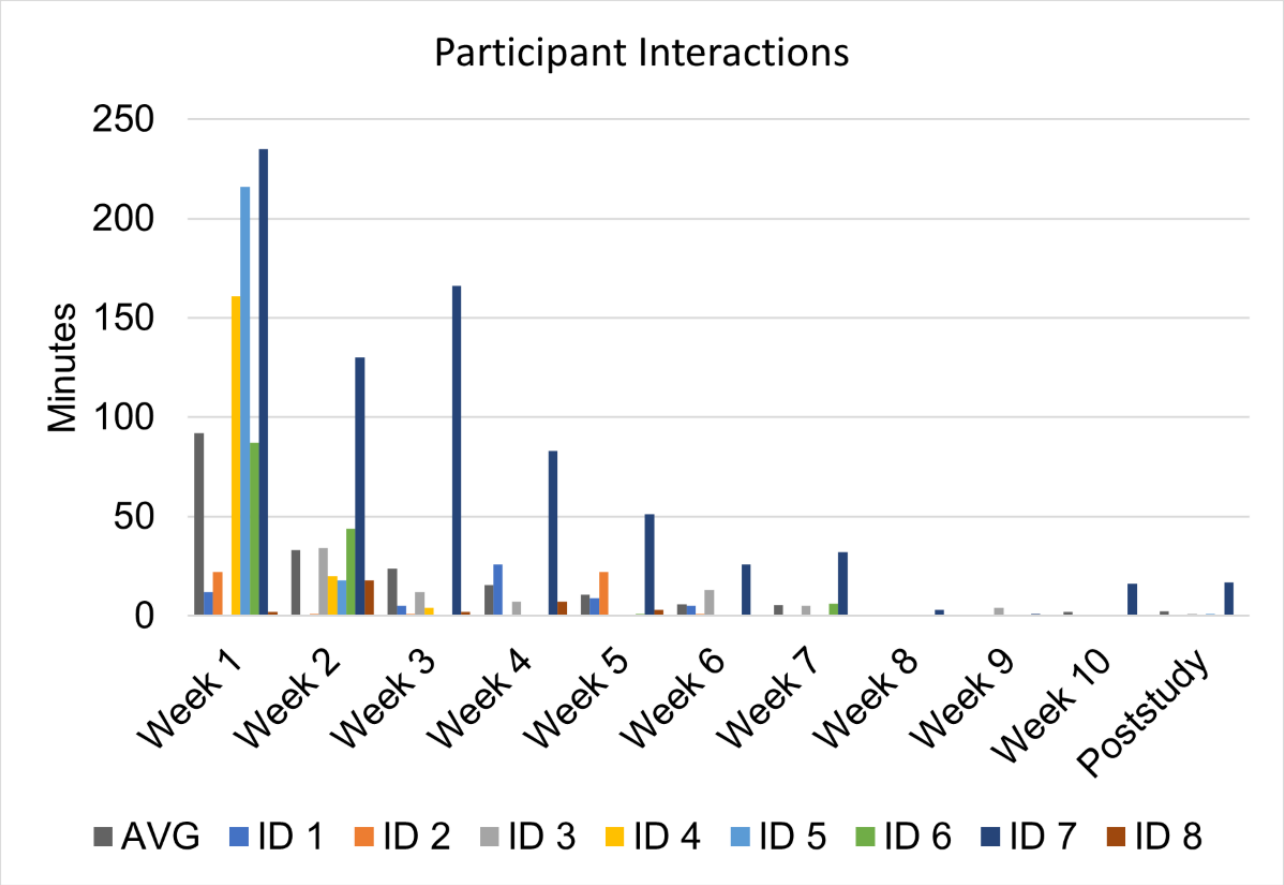
After a few weeks of interaction with the app at home, most caregivers expressed positive reactions to the app. The top three endorsed reactions were accessible (n=7, 88%), useful (n=7, 88%), and valuable (n=7, 88%), which received the highest percentage of responses (Multimedia Appendix 2).



Feasibility

Of the 14 caregivers who successfully installed the app, 7 (50%) caregivers did not use the app after the initial sign-in, 2 (14%) caregivers added their child's regimen, and 5 (36%) caregivers used the app for at least 1 week. In total, 2 (14%) caregivers used the app for 1 week, while the other 3 (21%) caregivers used the app until study weeks 2, 6, and 7, respectively (Figures 7 and 8).

Descriptive analyses were conducted for the app data (Multimedia Appendix 3) . A total of 1579 app engagement activities were recorded, of which 286 (18%) were for "loading the app," suggesting the number of times enrolled caregivers either attempted logging in or opening the app. The "creating a medication" feature, indicating medication entry into the app, was used 172 (11%) times. The feature "create a dose" was used 552 (35%) times, reflecting the number of times a medication was either entered or edited. A total of 100 (6%) responses were registered for the "take-all-doses." The "take-all-doses" feature pertained to the number of times enrolled caregivers registered on the app that their child took all their prescribed medications. The note feature was used 24 (2%) times. Caregivers used the app to enter their child's symptoms 22 (1%) times. Four of the enrolled caregivers used the note feature at least once.



XSL•FO
RenderX

Figure 8. Weekly app engagement by individual user.

Semistructured Interviews

Our qualitative analysis of both enrollment and exit semistructured interviews found that medication reminders were highly favored by 43% (n=6) of families, while recording side effects and symptoms were reported by 21% (n=3) of participants, and writing notes was favored by 14% (n=2). Participants also suggested several new features for the app (Table 2). Half of the families (n=7, 50%) recommended integrating the app with electronic medical record (EMR) to automatically add prescribed medications and appointments and to allow providers to review app activity for pattern identification. EMR is a secure member website that allows patients to access their health information, view appointments, medical test results, and medication therapies, and communicate with their providers [38]. Additionally, 14% (n=2) of families suggested including educational content about common symptoms posttransplant and a search field for medications and their uses. Another 14% (n=2) recommended a field for recording vital signs, such as temperature and blood pressure. Finally, 14% (n=2) proposed adding important contact numbers such as pharmacies, providers, and support groups to the app.

Table . Features suggested by participants.

Features families suggested	Value, n (%)
Integrate with EMR[a] to automatically add prescribed medications and appointments to the app, as well as allowing the provider to review app activity to identify patterns.	7 (50)
Including educational content such as frequently experienced symptoms after transplant, and a field to look up medications and for what they are used.	2 (14)
A field for recording vitals such as fever and blood pressure on the app.	2 (14)
Include important numbers in the app, such as pharmacy, provider, and support groups.	2 (14)

[a]EMR: electronic medical record.

During the enrollment interviews, 3 key themes regarding usability and features of the app were identified (Table 3). Ease of use was the most frequently recurring theme. Participants repeatedly highlighted the intuitive design, which made navigation and operation simple, especially for those who were less technologically skilled. Several participants remarked that grandparents, who lack digital proficiency, could use the app without any issues. Another significant theme was the app's

XSL•FO
RenderX

ability to keep families "on track" with medication schedules and doses. Caregivers expressed enthusiasm for using the app at home to manage a variety of medications and doses and record symptoms. Participants appreciated the ability to mark off administered medications and track notes, finding the digital logging of all information in one place helpful.

Table . Participants' reflections on the use of the BMT4me app.

Themes identified from qualitative interviews	Quotes from enrollment interviews	Quotes from exit interviews
Easy to use	• "It's very simple. Even if my mom had to do that, I think it would be simple for her to use it." [ID 5] • "It looks straightforward and easy to use." [ID 3]	• "It was pretty easy to use. It's pretty intuitive, I think. I think it's easy to pick it up and just start entering things, which is very helpful. Like, it's pretty straightforward." [ID 3] • "It's really pretty self-explanatory. So easy usage which is always nice because if it's complicated, you kind of don't want to deal with it, you know, human nature kind of thing." [ID 11]
Keep us on track	• "I think it'd be useful to help keep us on track. Hopefully not forget any doses." [ID 6] • It seems like it could help to keep on schedule and just like simple reminders of what to do, certain things especially get put and medications." [ID 13]	• "I think having something to be able to keep track of things for you is the number one way to get to have success with them after care because when I left the hospital, like the first time after he had his treatment, I was completely overwhelmed. It was like, how am I going to keep track of all of this stuff?" [ID 3] • "It was nice because if you just didn't realize what time was, it would ring and kind of let you know like, hey, it's time to take medications that so just getting into the swing and kind of getting used to taking all that medication too so." [ID 2]
Helpful	• "I think it would be helpful. You know, just having it. To mark off you've taken it or having the option to have notes to look back on. Have it all on one place and you always have your phone with you, so." [ID 2] • "Yeah, I mean, especially if she's taking a lot of meds I don't remember, like knowing like getting a reminder would probably help you." [ID 8]	_[a]
Technical difficulties	–	• "The other thing I noticed that sometimes it reminded me, sometimes it didn't." [ID 3] • "It says symptoms recorded and it says what time when the dose was taken at nine p.m. But then you can go back and look, it says it was given at eight p.m." [ID 1]
Nontech preferences	–	• "You got a pencil and the journal, you know I can easily, you know, erase. And I just like to have everything in front of me on one page. I'm a visual person and then like going next to next page, you know?" [ID 5] • "I have it in my head, I know what it is to do, so I don't really need it." [ID 13]

[a]Not applicable.

Upon study completion, families reiterated the app's ease of use and its effectiveness in maintaining medication routines (Table 3). Participants described the app as easy and self-explanatory, allowing them to quickly enter information and interact with it. They emphasized that simplicity was highly desirable, as a complicated interface would deter use. Additionally, participants noted that the app's ability to help them stay on track with medication regimens was helpful, particularly when life's demands could interfere with their child's medication schedule. However, new themes also emerged during the exit interviews. One notable theme was technical difficulties. Some families reported experiencing glitches or

XSL•FO
RenderX

issues with the app's functionality, which occasionally hindered their ability to fully use the app. Another emerging theme was a preference for nondigital methods. A subset of families expressed a preference for traditional, paper-based methods of managing health care routines. These participants indicated that while the app offered useful features, they were more comfortable with paper-based tracking and reminders.

Discussion

Principal Findings

The BMT4me app was developed in collaboration with health care providers, caregivers, and patients to aid in medication management, improve adherence monitoring, and track symptoms or medication side effects in real-time [37]. This pilot study aimed to evaluate the usability of the BMT4me app among caregivers of children during the acute phase post-HCT. The caregiver-reported mean SUS score of 73.13 (SD 16.13) at study completion indicated a favorable perception among caregivers, surpassing the threshold of 68 and demonstrating above-average usability. Most caregivers found the app easy to learn and use, with well-integrated features, fostering confidence for independent use at home. These findings are consistent with prior research emphasizing the significance of intuitive design and user-friendly interfaces in mHealth apps [39,40].

The positive usability feedback suggests that the app's design and features were well-received, enhancing caregivers' confidence in managing their child's complex medication regimen [41]. Engagement with the app generally depends on user motivation, perceived value, and satisfaction. As highlighted by Kim et al [42], technology must be both useful and enjoyable, with perceived value and satisfaction stemming from the overall user experience [42]. Caregiver satisfaction emerges as a critical factor for sustainability. Similar to existing literature, out of the participants who use the app regularly, the satisfaction with the BMT4me app was high [43,44]. Most caregivers in this study reported the app as helpful for tracking their child's medication schedule, finding it easy to use, and expressing willingness to recommend it to others. These sentiments were further echoed in qualitative interviews, with caregivers affirming the app's ease of use and effectiveness in navigating their child's post-HCT journey.

Current literature highlights a preference among users for mHealth apps that allow communication with health care providers [45]. This aligns with this study, where 50% (n=7) of caregivers recommended integrating EMR with the BMT4me app and including important contact numbers to facilitate easy communication with health care providers through the app. Including educational content in the mHealth apps has been shown to be preferred among individuals with chronic illnesses [46-48]. This trend was similarly observed in this study, with 14% (n=2) of our participants suggesting the inclusion of information on frequently experienced symptoms after HCT, along with details about medications and their uses.

While initial reactions to the app were positive, the sustainability of long-term use among our sample was constrained. Several caregivers stopped using the app beyond the initial sign-in phase, highlighting potential barriers such as technical challenges, time constraints, feeling overwhelmed, inconvenience, or perceived lack of necessity. Identifying and addressing these barriers is crucial for optimizing app design and implementation strategies to foster sustained engagement among caregivers. Notably, a significant proportion of participants used the app for the first few weeks postdischarge, establishing medication-giving routines before stopping the use. This suggests that the BMT4me app may serve as a valuable resource in assisting families with establishing medication administration habits, particularly during the initial phase of treatment. Some caregivers also expressed the potential value of the BMT4me app in the broader oncology population and wished to have access to it earlier in their child's treatment journey. The app's ability to accommodate the transition from a simple to a complex medication regimen, characterized by frequent changes in medications and dosages, underscores its potential utility beyond the HCT context.

Caregiver feedback on the BMT4me app indicated a generally positive experience from enrollment to study completion, however, some areas showed declines. The mean SUS score decreased from 86.15 to 73.13, reflecting a decrease in overall usability satisfaction; nevertheless, it surpassed the 68% cut-off for usability. Initially, 73% (n=11) of caregivers found the app accessible and useful, and 67% (n=10) found it easy to use [31]. These ratings improved with continued interaction, with 88% (n=7) later describing the app as accessible, useful, and valuable. Caregiver satisfaction measure showed minimal change from enrollment to completion, demonstrating high caregiver satisfaction throughout the study.

Analyzing app engagement activities provided insights into caregivers' usability patterns and preferences. For instance, some features demonstrated more active engagement than others, such that creating and administering doses suggested active engagement in medication management, while note-taking and symptom tracking exhibited low utilization. Therefore, there are potential areas for improvement to better address caregivers' diverse needs and preferences. This observation aligns with existing literature, which often highlights the importance of user-centered design in health apps to enhance engagement and adherence [49]. Studies have shown that while medication management tools are frequently used due to their direct impact on patient care, features like symptom tracking and note-taking require more intuitive interfaces and clear benefits to encourage consistent use. By addressing these gaps, developers can create more effective and comprehensive health management tools that cater to the varied needs of caregivers, ultimately improving patient outcomes [23,50,51].

Overall, this study underscores the importance of user-centered design with a mixed methods approach. By using multiple methods of data collection and data sources, we gained an in-depth understanding of patients with HCT and their families' complex needs. The results suggest that while the BMT4me app has significant potential, there are critical areas that require attention for sustained engagement and effectiveness. Future development should focus on overcoming technical challenges, enhancing the perceived value of lesser-used features, and ensuring the app remains a supportive tool throughout the entire treatment journey. By addressing these gaps, the BMT4me app

XSL•FO
RenderX

can be optimized to better meet the evolving needs of caregivers and patients and improve their health outcomes and quality of life.

Limitations

In addition, this study is not without limitations. First, the use of a single pilot recruitment site may restrict the generalizability of our findings. Although we included a diverse group of children who received HCT at this institution, the small number of caregivers may not represent the broader population. The demographic characteristics of our caregiver (female, White, and non-Hispanic) and child (male, White, and non-Hispanic) cohorts are consistent with other studies in this population [52-54]. However, while our cohort reflects the typical demographics of the pediatric HCT population and their caregivers, it is important to acknowledge that our results may be limited in their broader generalizability. Future research should aim to include a more diverse sample to ensure that findings are relevant across different demographic groups. Furthermore, our recruitment was limited to English-speaking caregivers, due to the app only being available in English. Future versions of the app should be developed in multiple languages to allow for more inclusive recruitment and to examine the app's usability across diverse linguistic and cultural groups. Including caregivers who speak other languages could have enriched the diversity and applicability of our findings. Another limitation is the variability in the timing of app distribution. Participants received the app at different stages of their HCT journey, some on the day of discharge and others after discharge. This inconsistency could have influenced their established medication routines, potentially affecting the outcomes such that participants who were recruited after discharge were less likely to use the app due to already having a system in place for medication management. Additionally, technical issues with the app were noted, which could have impacted the user experience and the app's usability and sustained engagement. Addressing these barriers is crucial for optimizing the app's design and ensuring sustained use. Future improvements should focus on enhancing technical stability, expanding user-centered features, and increasing accessibility to diverse populations.

Conclusions

Despite these limitations, we demonstrated the usability of the BMT4me app among caregivers of children undergoing HCT. This study extends the literature by providing insights into caregiver technology expectations and needs and highlights the potential of mHealth tools to manage medication adherence at home. Notably, 50% (n=7) of caregivers expressed that integrating the app with EMR would be helpful, benefiting both caregivers and health care providers by streamlining access to medication-taking patterns and updating medication regimens. Furthermore, there is potential to adapt this work for children with other chronic conditions, extending the benefits of the BMT4me app beyond the HCT context. The study findings offer valuable insights into the feasibility of conducting a larger randomized controlled trial, potentially leading to significant improvements in adherence and clinical outcomes in children post-HCT.

Acknowledgments

We would like to thank the families who generously participated in this work. We are also grateful for the support of the Information Technology Research and Innovation group at the Nationwide Children's Hospital, specifically Brannon Oiler, Brandon Abbott, and John Luna, for app design and development. We would also like to thank Dr Kathryn A Vannatta for her assistance in qualitative coding. This research was supported by a grant from the National Institute of Nursing Research of the National Institutes of Health (K99 NR019115). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. No generative artificial intelligence was used to write the manuscript.

Abstract

Background: Digital interventions for supportive care during cancer treatment incorporating electronic patient-reported outcomes (ePROs) can enhance early detection of symptoms and facilitate timely symptom management. However, economic evaluations are needed.

Objective: This study aims to conduct a cost-utility analysis of an app for ePRO and interactive support from the perspective of the payer (Region Stockholm Health Care Organization) and to explore its impact on patient health care utilization and costs.

Methods: Two open-label randomized controlled trials (RCTs) were conducted, including patients undergoing neoadjuvant chemotherapy for breast cancer (B-RCT; N=149) and radiotherapy for prostate cancer (P-RCT; N=150), recruited from oncology clinics at 2 university hospitals in Stockholm, Sweden. EORTC QLQ-C30 scores were mapped to EQ-5D-3L to calculate quality-adjusted life years (QALYs). Intervention and implementation costs and health care costs, obtained from an administrative database, were used to calculate incremental cost-effectiveness ratios (ICERs) in 3 ways: including all health care costs (ICERa), excluding nonacute health care costs (ICERb), and excluding health care costs altogether (ICERc). Nonparametric bootstrapping was used to explore ICER uncertainty. Health care costs were analyzed by classifying them as disease-related or acute.

Results: In both RCT intervention groups, fewer QALYs were lost compared with the control group (P<.001). In the B-RCT, the mean intervention cost was €92 (SD €2; €1=US $1.03). The mean cost for the intervention and all health care was €36,882 (SD €1032) in the intervention group and €35,427 (SD €959) in the control group (P<.001), with an ICERa of €202,368 (95% CI €152,008-€252,728). The mean cost for the intervention and acute health care was €3585 (SD €480) in the intervention group and €3235 (SD €494) in the control group (P<.001). ICERb was €49,903 (95% CI €37,049-€62,758) and ICERc was €13,213 (95% CI €11,145-€15,281); 22 out of 74 (30%) intervention group patients and 24 out of 75 (32%) of the control group patients required acute inpatient care for fever. In the P-RCT, the mean intervention cost was €43 (SD €0.2). The mean cost for the intervention and all health care was €3419 (SD €739) in the intervention group and €3537 (SD €689) in the control group (P<.001), with an ICERa of –€1,092,136 (95% CI –€3,274,774 to €1,090,502). The mean cost for the intervention and acute health care was €1219 (SD €593) in the intervention group and €802 (SD €281) in the control group (P<.001). ICERb was €745,987 (95% CI –€247,317 to €1,739,292) and ICERc was €13,118 (95% CI –68,468 to €94,704). As many as 10 out of the 75 (13%) intervention group patients had acute inpatient care, with the most common symptom being dyspnea, while 9 out of the 75 (12%) control group patients had acute inpatient care, with the most common symptom being urinary tract infection.

XSL•FO
RenderX

Conclusions: ePRO and interactive support via an app generated a small improvement in QALYs at a low intervention cost and may be cost-effective, depending on the costs considered. Considerable variability in patient health care costs introduced uncertainty around the estimates, preventing a robust determination of cost-effectiveness. Larger studies examining cost-effectiveness from a societal perspective are needed. The study provides valuable insights into acute health care utilization during cancer treatment.

Introduction

Managing symptoms during cancer treatment is essential for patients' quality of life, workability, and performance [1]. Symptoms such as pain, fatigue, and gastrointestinal problems commonly lead to emergency department visits [2]. Emergency department visit rates appear to be higher among patients with cancer than in the general population, although the magnitude or underlying reasons for this remain understudied [3].

Electronic patient-reported outcome (ePRO) interventions have gained recognition as convenient and safe tools for promoting the early detection of symptoms and adverse events [4,5]. Collecting ePROs has demonstrated high acceptance [6-8], long-term feasibility [9], and positive outcomes related to physical and psychological symptoms [10-15], as well as increased survival [16]. ePROs are also suggested to help mitigate unplanned acute care and unnecessary hospitalizations during cancer treatment; however, this assertion requires more robust empirical confirmation [17,18]. In our studies, the use of the interactive app Interaktor was associated with a decreased symptom burden during radiotherapy (RT) for prostate cancer [19], neoadjuvant chemotherapy (NACT) for breast cancer [11], and up to 6 months after surgery for pancreatic cancer [20].

Health economic evaluations are essential for supporting the implementation of cost-effective interventions [21,22] and guiding decision-makers [23]. A cost-utility analysis (CUA) is one type of health economic evaluation that compares the costs and health outcomes of medical treatments or care by estimating the cost required to improve a unit of health outcome [24]. Quality-adjusted life years (QALYs) is a generic measure of disease burden that accounts for both life quality and quantity. One QALY corresponds to 1 year of perfect health, while 0 represents death [25]. In Sweden, the National Board of Health and Welfare (NBHW) has defined a cost per QALY of €9685 (€1=US $1.03) as low, more than €48,423 as high, and more than €96,846 as very high [26].

Most health economic evaluations of ePRO interventions have focused on patients with advanced or metastatic cancer [27]. Lizée et al [28] demonstrated the cost-effectiveness of ePRO from a national health insurance perspective, despite increased costs, due to associated survival benefits. Velikova et al [29] evaluated the cost-effectiveness of ePRO for patients undergoing systemic treatment for colorectal, breast, or gynecological cancer, comparing the cost per additional QALY gained at 18 weeks after randomization from both health care and societal perspectives. The analysis considered costs for the intervention manual, software maintenance, and patient time off work but excluded intervention development costs. No significant cost differences were observed between the intervention and usual care groups. The study indicated a 55% likelihood of cost-effectiveness at the National Institute for Health and Care Excellence cost-per-QALY threshold.

This study was conducted alongside 2 randomized controlled trials (RCTs) of the ePRO intervention Interaktor during NACT for breast cancer (B-RCT) and RT for prostate cancer (P-RCT). The primary aim is to evaluate the cost utility of the app for ePRO and interactive support from the health care provider's perspective (Region Stockholm Health Care Organization). Additionally, the study examines the impact on patients' health care utilization and associated costs.

Methods

Ethical Considerations

The research was approved by the Swedish Ethical Review Authority (permit numbers 2013/1652-31/2 and 2017/2519-32). Written informed consent was obtained from all patients at the time of study inclusion. Data were deidentified to protect participants' privacy. Patients received written and verbal information about their right to opt out without affecting their subsequent care. No compensation or payment was provided for participation.

Study Design

Between 2016 and 2019, Interaktor was evaluated through 2 parallel prospective open-label RCTs, with symptom burden as the primary endpoint, measured using the EORTC QLQ-C30 version 3.0 [30]. Patients were consecutively recruited from oncology clinics at 2 university hospitals in Stockholm, Sweden. Eligible and interested patients met with a researcher who provided detailed information about the trial. Refer to the previously published study protocol and clinical effectiveness article [11,31] for details on the eligibility criteria, intervention design, and randomization process. No changes were made to

XSL•FO
RenderX

the methods after the protocol was registered (NCT02479607 and NCT02477137) and the trials commenced.

Samples

One RCT included a sample of patients with breast cancer treated with NACT (B-RCT), and the other included a sample of patients with prostate cancer treated with RT (P-RCT). In both RCTs, patients were randomly allocated to the intervention or control group. In the B-RCT, there were 74 patients in the intervention group and 75 patients in the control group. Of these, 69 (93.2%) in the intervention group and 71 (94.7%) in the control group completed the follow-up and were considered complete cases (Multimedia Appendices 1 and 2). In the P-RCT, a total of 150 patients were randomly allocated to the intervention (n=75) or control (n=75) group. Of these, 58 (77%) in the intervention group and 56 (75%) in the control group completed the follow-up questionnaires and were considered complete cases [32] (Multimedia Appendices 2-4). The sample size for both RCTs was estimated based on an effect study conducted with patients receiving RT for prostate cancer [19], with symptom distress as the primary outcome. The effect size difference (Cohen d=0.54) indicated that, for 90% power at P<.05, 71 patients were required in each group.

Intervention and Standard Care

The Interaktor smartphone and tablet app is an ePRO intervention designed for daily symptom reporting and interactive support during cancer treatment. It includes a symptom questionnaire, graphs of symptom reporting history, self-care advice related to disease and treatment-associated symptoms, and links to websites with additional information. Oncology ward nurses are alerted via SMS text messages when severe symptom levels are reported. Nurses can access patients' reports through a web interface, which facilitates patient-clinician communication. Depending on the alert, nurses contact the patient within 1 hour or 1 day. The Interaktor versions used in this study did not include any institutional affiliation display or logo.

Patients in the intervention group reported daily via the Interaktor app on weekdays, starting from their first day of treatment and continuing until 2 weeks after treatment in the B-RCT (mean treatment duration: 15 weeks in both groups) and, until 3 weeks after treatment in the P-RCT (mean treatment duration: 5 weeks in both groups). In the intervention groups, registered nurses at the patients' oncology units responded to the symptom report alerts. Additionally, a researcher was available to assist with any technical questions or issues. Outside office hours, patients were advised to contact health care personnel according to the standard procedure of their oncology clinic. The intervention and app content remained unchanged during the evaluation process. Patients received daily reminders if a report had not been submitted. A comprehensive description, including screenshots, has been published previously [7].

All patients, in both the intervention and control groups, received standard care, which included an assigned contact nurse and a visit with the physician before treatment.

Data Collection

Before randomization, patients self-reported sociodemographic characteristics, including education level, marital and occupational status, and baseline outcomes via questionnaires. In the B-RCT, follow-up (via postal questionnaires) occurred 2 weeks after the end of NACT or the day before surgery, whichever came first. In the P-RCT, follow-up was 3 weeks after the conclusion of RT. Medical history and clinical treatment data were obtained from the patients' medical records, including comorbid conditions, tumor histopathology, cancer stage, and prostate-specific antigen score before treatment initiation, as well as the type and number of cancer treatments planned and completed, and reasons for discontinuing or altering treatment. Data on mortality and cause of death were obtained from the Stockholm and Gotland Regional Cancer Centre and the Swedish NBHW (Multimedia Appendix 5).

Health Care Utilisation and Costs

Administrative data on each patient's health care utilization and costs, from the first day of treatment and for 6 months thereafter, were obtained from the Stockholm Region Council administrative database (VAL). The database includes variables on primary care and emergency department visits (VAL-OVR) and hospitalizations (VAL-SLV) for Stockholm Region Council patients [33]. Health care costs were estimated using a variable (SIMKOST [simulerad kostnad/simulated cost]) that calculates the cost of visits based on the profit and loss account for the respective care branch. SIMKOST reflects approximately 90% of the costs for individuals' visits to outpatient care and 99% of the costs for inpatient care (Multimedia Appendix 6). Intervention costs were based on a fiscal estimate provided by the company that developed the app, expressed as a 1-time implementation/startup cost of €5212, with weekly licensing costs per capita of €39 for nurses and €2.25 for patients (Multimedia Appendix 6).

Data Analysis

Statistical Analysis

Data were handled using Microsoft Excel 2016 with the add-in XL-STAT, IBM SPSS Statistics version 27, and STATA 16 (StataCorp LP). Clinical trials with an RCT design should be analyzed using the intention-to-treat (ITT) principle [34], so missing values were imputed as the mean per group and time [32]. Health care utilization and cost values were imputed for 2 patients in each intervention group (B-RCT and P-RCT). In the P-RCT, EORTC dimension scores were imputed at baseline for 2 patients per group, and at follow-up for 15 patients in the intervention group and 20 patients in the control group. In the B-RCT, follow-up values were imputed for 5 patients in the intervention group and 4 patients in the control group. Distribution normality was assessed using skewness and kurtosis. All costs were adjusted for inflation from 2019 to 2022 [35] (×1.0764) and converted from Swedish kronor (SEK) to Euros (€) using the average exchange rate for April 2022 of 10.3257 SEK=€1 [36]. Nonparametric bootstrapping (1000 replications) was used to test nonnormally distributed variables, calculate the incremental cost-effectiveness ratios (ICERs), and explore sample uncertainty regarding the mean ICERs [37].

Health Outcome

EORTC QLQ-C30 [30] dimension scores were mapped onto EQ-5D-3L [38] health state utilities using a response mapping algorithm [38,39] (Multimedia Appendix 4). The original algorithm includes British utility weights [40], which were replaced with Swedish weights according to Burström et al [41] for this study. The mean predicted EQ-5D value (EQ-5DP) before treatment minus after treatment was used to measure effectiveness, with a smaller reduction in mean EQ-5DP indicating better outcomes.

Intervention Costs

The overall startup cost was divided by the total number of patients diagnosed and treated with the respective treatment regimens in the Stockholm Regional Council and Gotland Region for the years 2016-2018 (518 patients with breast cancer treated with NACT and 683 patients with prostate cancer treated with RT). Given that system updates may incur additional costs beyond the license fees, a time frame of 3 years was considered reasonable. The estimate assumed 5 nurses per 100 patients, with no additional costs for nurses to handle symptom alerts. Based on each patient's number of weeks in treatment (wt), the intervention costs were calculated per equations (1) and (2) for B-RCT and P-RCT, respectively:

$$(5212/518) + ([39 \times 5/100] \times [wt]) + (2.25 \times wt) \quad \textbf{(1)}$$

$$(5212/683) + ([39 \times 5/100] \times [wt]) + (2.25 \times wt) \quad \textbf{(2)}$$

Cost-Utility Analysis

Stochastic CUAs [42] were conducted for each RCT by calculating ICERs in 3 different ways. For ICERa, each patient's intervention cost, along with all health care costs from randomization through 6 months, was included. For ICERb, each patient's intervention costs, plus acute health care costs from randomization and the subsequent 6 months, were considered. Given the considerable variation in patient health care costs, which introduced substantial uncertainty in the cost-effectiveness estimates, a third ICER (ICERc) was calculated by dividing the intervention group's intervention costs minus the control group's intervention costs by the difference in QALYs lost between the 2 groups. The rationale behind this approach is that patients' health care utilization during cancer treatment is influenced by multiple factors, and a much larger study would be necessary to demonstrate a significant reduction in health care costs. Therefore, it was deemed appropriate to assess cost-effectiveness under the assumption that health care costs are not substantially affected. To capture the gradual change in the quality of life during treatment, QALYs lost were calculated linearly as follows: ([EQ-5DP after treatment minus EQ-5DP before treatment]/2) × (individual treatment duration in weeks/52). For visualization, bootstrap values of the incremental intervention costs and incremental health outcomes (QALYs) were plotted on cost-effectiveness planes.

In the P-RCT, the RT treatment was standardized with minimal variation between patients, so RT costs were excluded from both CUAs. By contrast, the B-RCT did not allow for standardized subtraction of treatment costs, so all health care costs were included. The analysis was conducted from the payer perspective (Stockholm Region Council) and focused on the patient's treatment duration (less than 1 year), meaning that no discounting of costs or results was applied. The cost per QALY, as defined by the Swedish NBHW, was used to evaluate cost-effectiveness.

ICERa=[(intervention costs + IG total health care costs) – (CG total health care costs)]/(IG change in QALY – CG change in QALY)

ICERb=[(intervention costs + IG acute health care costs) – (CG acute health care costs)]/(IG change in QALY – CG change in QALY)

ICER=[(IG intervention costs) – (IG intervention costs)]/(IG change in QALY – CG change in QALY)

Exploration of Health Care Utilization and Costs

Within each RCT, variables for total and acute health care visits and costs were generated by summing each participant's visits and costs, conditional on the VAL variable AKUT (acute) being marked as yes or no. Additionally, variables for health care utilization related to the respective cancer treatments were created through a qualitative analysis of the International Statistical Classification of Diseases and Related Health Problems (ICD) codes, using a conventional and summative approach [43]. All ICD codes for acute outpatient and inpatient visits within each RCT were compiled in Excel sheets, and the occurrence of all unique codes was counted. These ICD codes were either grouped or coded based on similarities into predefined and emerging categories. Examples of these categories include fever/neutropenia (D709C, R502, R508, and R509), gastroenteritis/colitis (K521 and A047), anemia (D649), urinary tract infection (N390), and urinary problems (R339, N390, R301, N390X, N304, N109, T830, R391, R319, and N300; Multimedia Appendix 7).

Each patient's visits and costs, according to the categories, were calculated to create variables used as dependent outcomes in multivariate regression analysis. Depending on the level of overdispersion, Poisson, negative binomial, or binary logistic models with a log-link function were fitted [44]. The variable "Group" was coded as control=0 and intervention=1. Prior studies have suggested an association between diminished performance status [45,46], the presence of multiple chronic diseases in older individuals [47], and increased costs. Therefore, the continuous variables—age at inclusion, Charlson Comorbidity Score, and Baseline EQ-5DP score—were included as covariates. The reference category was arranged in ascending order. For the B-RCT, each patient's number of NACT cycles was included as an independent variable. By contrast, for the prostate cancer trial, treatment was standardized, and all patients underwent a similar number of treatments.

Results

B-RCT

Health Outcome

The mean EQ-5DP before treatment was 0.86 in the intervention group and 0.87 in the control group. After treatment, the mean EQ-5DP was 0.84 in the intervention group and 0.80 in the

XSL•FO
RenderX

control group (*P*=.036, effect size=0.099). A statistically significant difference was observed in the mean changes in EQ-5DP from before to after treatment between the intervention and control groups (*P*=.012, effect size=0.042). The greatest difference in change was observed in the Anxiety/Depression dimensions (Multimedia Appendix 8). The CONSORT (Consolidated Standards of Reporting Trials) checklist is presented in Multimedia Appendix 9 (also see Multimedia Appendices 1 and 3).

Cost-Utility Analysis

The intervention group patients had a mean QALY loss of –0.004 (SD 0.002) from before treatment to after treatment, while the corresponding figure for patients in the control group was –0.012 (SD 0.002; *P*<.001). The mean cost for the Interaktor app per patient was €92 (SD €2). The mean total cost for the intervention and all health care was €36,882 (SD €1032) for patients in the intervention group and €35,427 (SD €959) for control group patients (*P*<.001). The ICERa was €202,368 (€SD 811,136; 95% CI €152,008-€252,728). The mean cost for the intervention and acute health care was €3585 (SD €480) in the intervention group and €3235 (SD €494) in the control group (*P*<.001). ICERb was €49,903 (SD €207,042; 95% CI €37,049-€62,758; Table 1). Lastly, when health care costs were excluded from the analysis, the ICERc was €13,213 (SD €33,327; 95% CI €11,145-€15,281; Table 1).

Exploration of Health Care Utilization and Health Care Costs

The mean outpatient cost for patients in the intervention group was €27,571 (SD €6392), while in the control group, it was €26,348 (SD €5800). In both groups, approximately 2% of the outpatient costs were attributable to acute care: €554 out of €29,321 (1.9%) in the intervention group and €562 out of €26,348 (2.13%) in the control group.

In the intervention group, 13 out of 74 (18%) patients had an acute outpatient visit for fever, with a total of 34 visits. In the control group, the corresponding proportion was 9 out of 75 (12%), with a total of 21 visits. Additionally, 7 out of 74 (9%) patients in the intervention group had an unplanned admission from outpatient to inpatient care, accounting for 37 unplanned admissions. In the control group, 6 out of 75 (8%) had an unplanned admission from outpatient to inpatient care, totaling 29 unplanned admissions.

The mean inpatient cost per patient was €9207 (SD €5254) in the intervention group and €9093 (SD €5460) in the control group. Approximately one-third of all inpatient care cost was acute in both groups (€2932/€9207, 31.85% in the intervention group and €2665/€9093, 29.31% in the control group). The most common diagnoses during acute inpatient care episodes in both groups were fever, gastroenteritis/colitis, anemia, and urinary tract infection. The variable group (intervention/control) was not associated with the number of visits for fever, gastroenteritis/colitis, anemia, or urinary tract infection, nor were age, health-related quality of life (HRQOL) before treatment, comorbidities, or the number of NACT (Table 2).

[g]Neoadjuvant chemotherapy treatments

Negative binomial multivariate regression analysis revealed that the independent variable group (intervention/control) did not significantly affect the predicted log odds of patients' health care costs (*P*=.949). For acute outpatient health care costs, the analysis showed that age, health-related quality of life at baseline, and comorbidities significantly predicted costs. Older age (*P*=.002) and better health-related quality of life (*P*<.001) were associated with lower acute outpatient health care costs. By contrast, a higher number of comorbidities was associated with increased acute health care costs (*P*=.02; Table 3).

P-RCT

Health Outcome

The mean EQ-5DP before treatment was 0.88 in the intervention group and 0.89 in the control group. After treatment, the mean EQ-5DP was 0.87 in the intervention group and 0.88 in the control group (*P*=.51). The mean difference in EQ-5DP from before to after treatment was not statistically significant between the intervention and control groups (*P*=.94). The most prominent differences in change were observed in the dimensions of Pain/Discomfort and Anxiety/Depression (Multimedia Appendix 5).

Cost-Utility Analysis

The intervention group patients scored a mean QALY loss of –0.0008 (SD 0.0006), while the corresponding figure for the control group was –0.0009 (SD 0.0006; *P*<.001). The mean total cost of the Interaktor intervention per patient was €43 (SD €0.2). The mean total cost, including the intervention and all health care, was €3419 (SD €739) for the intervention group and €3537 (SD €689) for the control group. The ICERa was –€1,092,136 (SD €35,155,229; 95% CI –€3,274,774 to –€1,090,502). The mean total costs for the intervention and acute health care were €1219 (SD €593) in the intervention group and €802 (SD €281) in the control group. The ICERb was €745,987 (SD €16,006,924; 95% CI –€247,317 to €1,739,292). Lastly, when health care costs were excluded from the analysis, the ICERc was €13,118 (SD €1,314,743; 95% CI –€68,468 to €94,704; Table 4).

Exploration of Health Care Utilization and Health Care Costs

The mean outpatient cost for patients in the intervention group was €2077 (SD €1386), while in the control group, it was €2488 (SD €2403); €121 out of €2077 (5.83%) outpatient cost in the intervention group was for acute care, compared with €126 out of €2488 (5.06%) in the control group. In both groups, 25 patients (33%) had an acute outpatient care visit.

Acute outpatient care for urological problems was required by 5 of 75 (7%) patients (7 visits) in the intervention group and 6 of 75 (8%) patients (14 visits) in the control group (Table 5). Regarding acute outpatient visits for urological problems that resulted in unplanned admissions from outpatient to inpatient care, this occurred for 1 patient in the intervention group (1 admission) and 2 patients in the control group (3 admissions).

[g]Intervention/Control; reference category=Control

[h]*P* value for the independent variable in the Binary Logistic Regression Model.

The mean inpatient cost was €1321 (SD €5460) in the intervention group, compared with €1049 (SD €4240) in the control group. In the intervention group, €1054 out of €1321 (79.79%) inpatient care costs were attributed to acute care, while the corresponding figure in the control group was €684 out of €1049 (65.20%). The most common diagnoses during acute inpatient care episodes in the intervention group were R060 dyspnea (4 episodes) and I214 acute subendocardial infarction (3 episodes). In the control group, the most common diagnoses were N390 urinary tract infection (3 episodes) and anemia D630/D649 (2 episodes).

Negative binomial multivariate regression analysis revealed that higher HRQOL before treatment was associated with a decrease in the number of outpatient care visits (*P*=.002). Multivariate binary logistic regression indicated that higher HRQOL before treatment was negatively associated with both having an acute outpatient care visit for urological problems (*P*=.02) and having an inpatient care episode (*P*=.04). Therefore, patients with better HRQOL before treatment were less likely to have an acute outpatient visit for urological problems and less likely to experience an inpatient care episode (Table 5).

Discussion

Principal Findings

In both RCTs, patients in the intervention groups experienced fewer QALYs lost compared with those in the control groups. In the B-RCT, the quality of life of patients in the intervention group decreased significantly less during treatment compared with the control group; however, this was not observed in the P-RCT. The reduction in QALYs lost was achieved with a low intervention cost per patient. Unfortunately, while ICERs are particularly valuable for guiding decision makers, the ICERs from this study are somewhat difficult to interpret due to uncertainty, as illustrated in the cost-effectiveness planes. The variability in the ICERs arose from differences in patients' health care costs. When health care costs were excluded from the analysis, the RCTs showed ICERs slightly above the NBHW threshold for a low cost per QALY but still well below what the NBHW considers a high cost per QALY. These findings are encouraging and support the conceptual foundation of ePRO [48].

Comparison With Prior Work

Although the P-RCT showed a decrease in QALYs lost, the difference was relatively small. This finding is not uncommon. Snoswell et al [49] reviewed 25 cost-utility studies of telehealth interventions that reported costs from the health system perspective and changes in HRQOL. About one-third of these studies demonstrated cost savings and changes in effect, but most QALY improvements were marginal (range 0.0006-0.12). The authors concluded that this may be partly due to HRQOL instruments being neither sensitive nor appropriate for detecting the effects of changes in health service delivery. Demonstrating substantial cost savings from ePRO during curative cancer treatment may be challenging, given the relatively short time frame and the high variability in health care utilization, which necessitate large sample sizes. However, because productivity loss due to morbidity and mortality represents the most significant societal cost of cancer [50], further research should explore whether life quality improvements enable patients to continue working during treatment or return to work earlier and to a greater extent after treatment. Such a cost-effectiveness analysis could reveal societal cost savings.

There are a few studies available to compare with our findings, as CUAs of ePRO interventions remain limited [27]. We did not identify any studies evaluating the cost-effectiveness of ePRO during first-line curative cancer treatment. However, some studies have been conducted in the context of follow-up and advanced cancer care. For instance, Nixon et al [51] and Lizée et al [28] reported relatively low ICERs for ePRO in cancer survivors, whereas Van der Hout et al [52] found a small positive effect on HRQOL but no significant differences in direct or indirect medical costs among cancer survivors.

Evidence suggests that ePRO can reduce health care utilization [27]. For example, ePRO has been shown to positively impact outcomes such as emergency room visits, hospitalizations, and readmissions [27]. However, not all studies demonstrate these effects. Barbera et al [53], in a study conducted during adjuvant chemotherapy for breast cancer, did not observe a reduction in hospitalizations or readmissions. Similarly, Wheelock et al [54]

XSL•FO
RenderX

investigated the impact of ePRO during follow-up care after breast cancer treatment and found no reduction in health care resource use, including oncology-related appointments, physician visits, or medical tests. Lizée et al [28] observed a higher number of follow-up clinic visits in the ePRO intervention group compared with the control group. However, the intervention group also experienced longer overall survival, allowing more time for follow-up visits.

The study highlights the heterogeneity of the cancer population and the variation in health care use not only between but also within patient populations. For instance, nearly 104 of 149 (69.8%) patients treated for breast cancer made acute outpatient visits, whereas only about one-third (50/150) of patients with prostate cancer required such visits. This may be linked to the continuous health care contact that patients undergoing external RT maintain. In the context of older patients receiving cancer treatment, Nipp et al [55] demonstrated that age moderated the positive effects of ePRO on both ER visits and survival in patients with advanced cancer.

By analyzing ICD codes documented during health care visits to regional health care organizations, this study revealed that 5 of 75 (7%) intervention group patients and 6 of 75 (8%) control group patients undergoing treatment for prostate cancer had an acute outpatient visit for urological problems. Similarly, 4 of 74 (5%) intervention group patients and 11 of 75 (15%) control group patients treated for breast cancer had an acute outpatient visit for gastrointestinal symptoms. However, health care visits to general practitioners' clinics and health centers lacked ICD codes, meaning these figures may not fully capture the patients' health care utilization for those symptoms.

In this study, intervention group patients treated for breast cancer had more acute outpatient visits for fever/neutropenia, although the difference was not statistically significant. A similar increase in neutropenic events was observed by Absolom et al [10], who evaluated an intervention for patients undergoing chemotherapy, which aligns with national recommendations for managing chemotherapy patients presenting with this symptom [56]. In this study, the number of acute inpatient care episodes for fever/neutropenia was similar between the intervention and control groups.

Previous research has shown that health care utilization and costs during cancer treatment are complex [45]. This study examined whether age, comorbidity, and health status significantly influenced patients' health care utilization. As expected, the results suggest that health status has some impact on health care consumption. In the B-RCT, higher HRQOL before treatment was associated with reduced acute outpatient costs. In the P-RCT, higher HRQOL before treatment was associated with a lower likelihood of having an acute outpatient visit or inpatient care episode. Considering the results showing a smaller decline in quality of life among intervention group patients, these findings suggest that patients using the app receive timely and appropriate care, leading to more effective and prompt management of symptoms and adverse events associated with cancer treatment. This interpretation aligns with previously reported positive effects on health-related quality of life and symptom burden [11,19,20].

Limitations

The study presents unique and highly relevant findings for modern outpatient-based, personalized cancer care. A key strength is its randomized design, although some limitations should be noted. First, the ICERs must be interpreted with caution due to the uncertainty illustrated in the cost-effectiveness planes. Regarding costs, additional expenses for nurses handling alerts were not included, as staff interviews indicated that no increase in working hours was necessary (unpublished data). A similar assumption was made in the study by Nixon et al [51]. A recent study of a similar intervention also concluded that the intervention did not increase hospital clinicians' workload [10]. Finally, the Swedish valuation system assigns higher values to most conditions than the British system, presumably because it is based on patients' valuations of their conditions rather than, as in the British case, the public's valuations of hypothetical conditions [57]. Accordingly, the results regarding intervention effectiveness may have differed.

In the P-RCT, the dropout rate was notably high, potentially reducing the statistical power to detect significant differences. The reasons for nonresponse to outcome questionnaires remain unknown. Importantly, all patients used the app daily as instructed, with an adherence rate of 80% [6]. Although debated, imputation aims to accurately estimate the overall data distribution [58]. It is suggested that imputing missing values exceeding 10% increases the risk of bias [34,58]. By contrast, the use of ITT analysis is highly recommended in RCTs [34]. Although there is no specific threshold for missing values in health economic studies, it is emphasized that patterns of missing data should be reported [32]. The sample in our study is too small to analyze patterns, but the ITT principle presumably assumes missing data are random, though other mechanisms may also have contributed [59]. Based on the study design and sample size, a simple imputation method was applied in this study [57].

Health care costs were missing at random due to an administrative error, and values for no more than 2 patients per group were imputed. The risk of overestimating costs due to right-skewed data is therefore small. Given that the data on the EORTC dimension scores are approximately normally distributed, the imputation method appears to be accurate. Nevertheless, further studies are needed.

Conclusions

At a low weekly cost, the intervention reduced QALYs lost. The cost-effectiveness of the intervention, as defined by the ICER in relation to the Swedish NBHW, varied depending on the costs considered. For patients with breast cancer, the intervention was cost-effective when nonacute health care costs were excluded, whereas for patients with prostate cancer, cost-effectiveness was achieved when all health care costs were included. This suggests that the intervention has the potential to achieve cost-effectiveness. However, larger studies are needed, as there was considerable uncertainty regarding the ICERs due to significant variations in patients' health care costs.

Patients in the intervention group with breast cancer had more acute health care visits for neutropenia/fever, whereas more

XSL•FO
RenderX

patients in the control group were hospitalized for gastrointestinal symptoms. Only a few patients with prostate cancer were hospitalized for urological problems. These findings highlight the previously demonstrated positive effects on patients' symptom burden and suggest that the intervention may facilitate timelier and more effective symptom management. Future studies should assess cost-effectiveness from a societal perspective.

Acknowledgments

We thank Dr. Tracey A. Young and Dr. Clara Mukuria for kindly providing the original mapping algorithm syntax. We also extend our gratitude to the Region Stockholm Health Care Administration and the Confederation of Regional Cancer Centres for their supportive assistance with registry data. The study was supported by the Swedish Cancer Foundation (grant 160298), the Swedish Research Council (grant 521-2014-2723), the Kamprad Family Foundation for Entrepreneurship, Research, and Charity (grant 20150015), the Swedish Research Council for Health, Working Life and Welfare (grant 2014-04713), and Karolinska Institutet (internal grant).

Data Availability

The data sets generated and analyzed during this study are not publicly available as they contain information that could compromise the privacy and consent of the research participants. However, the transformed data are available upon reasonable request from the authors.

Abstract

Background: Palliative care is crucial for patients with life-threatening and serious diseases such as cancer, as it addresses their physical, psychosocial, and spiritual needs. Hematological malignancies significantly contribute to global cancer cases, impacting both older adults and children. To meet the increasing demand for palliative care, electronic patient-reported outcome (ePRO) interventions offer valuable insights into patient monitoring and treatment decision-making. The MyPal project developed a digital ePRO solution to improve palliative care by enabling structured symptom reporting and promoting physician-patient communication.

Objective: This study aims to explore the perceptions, opinions, and needs of adult and pediatric patients with cancer, caregivers, and health care professionals (HCPs) regarding low-fidelity versions of the MyPal project's digital solution, which is designed to improve palliative cancer care.

Methods: A qualitative, cross-sectional study was conducted using 12 prepilot focus groups (FGs) across 4 European countries (Greece, Italy, Germany, and the Czech Republic) at participating hospitals and research centers. The FGs, held in person, included 61 participants, including 27 (44%) adult patients with chronic lymphocytic leukemia or myelodysplastic syndromes, 19 (31%) children with hematological malignancies or solid tumors and their parents, and 15 (25%) HCPs specializing in oncology and palliative care. A semistructured discussion guide, informed by vignettes and user personas, was used to facilitate discussions. Sessions were audio recorded, transcribed, and analyzed using thematic analysis to identify and extract themes and subthemes from the FG discussions.

Results: Three main themes emerged from the FG discussions. The first theme, *improved care*, showcased the project's potential to enhance health care through patient-reported measures by improving symptom monitoring, streamlining decision-making, and strengthening physician-patient communication. Patients and caregivers valued the ability to report symptoms remotely, reducing unnecessary hospital visits, while HCPs appreciated having structured patient data to guide treatment. The second theme, *digital communication framework*, revealed that while participants recognized the benefits of digital tools, they had concerns about data security, privacy, and clarity regarding communication protocols. Questions emerged about how and when HCPs would review

XSL•FO
RenderX

and respond to patient-reported data. In the third theme, *applicability for use in health care*, participants emphasized the importance of the system's ease of use, particularly for older patients and young children. Concerns were raised about the potential intrusiveness of the system, particularly regarding notification frequency and the impact on daily life. HCPs highlighted workload challenges, suggesting the need for a structured alert system to prioritize urgent cases.

Conclusions: Our findings indicate that ePRO-based interventions such as MyPal can improve palliative care by facilitating communication and patient monitoring. However, addressing privacy concerns, optimizing usability for diverse populations, and ensuring seamless integration into clinical workflows are critical for successful adoption. Insights from this study will inform future development and optimization of eHealth interventions in palliative care.

Introduction

Background

Palliative care plays a vital role in the holistic treatment of patients with life-threatening and serious diseases such as cancer. Palliative care takes a multidisciplinary approach, focusing on preserving and enhancing the quality of life (QoL) for patients with life-threatening illnesses and their families [1]. Its primary aim is to prevent and alleviate distress through the early recognition, evaluation, and management of physical, psychological, emotional, and spiritual challenges. In addition, the World Health Organization emphasizes the importance of providing support systems to help patients maintain an active life throughout their disease trajectory [2]. As the global population ages, the demand for palliative care continues to grow due to the increasing prevalence of complex chronic diseases and progressive conditions, such as cancer [3,4]. To address these needs effectively, innovative interventions are essential.

Hematological malignancies (HMs) account for approximately 6.5% of all cancers worldwide and predominantly affect older individuals, with a median age of diagnosis of approximately 70 years [5-7]. Due to the chronic and often aggressive nature of these diseases, patients with HMs experience a significant symptom burden and diminished QoL compared to the general population [8]. This deterioration in QoL, coupled with the high prevalence of distressing symptoms, such as pain and fatigue, underscores the need for comprehensive palliative care approaches in this patient group. Furthermore, while cancer in children is relatively rare, it remains the leading cause of disease-related death in pediatric populations [9]. Among pediatric cancers, HMs are the most frequently diagnosed and profoundly impact not only young patients but also their families and caregivers [10]. Given the distinct challenges faced by pediatric patients, palliative care plays a critical role in symptom management and improving their overall well-being and QoL throughout their disease trajectory [11].

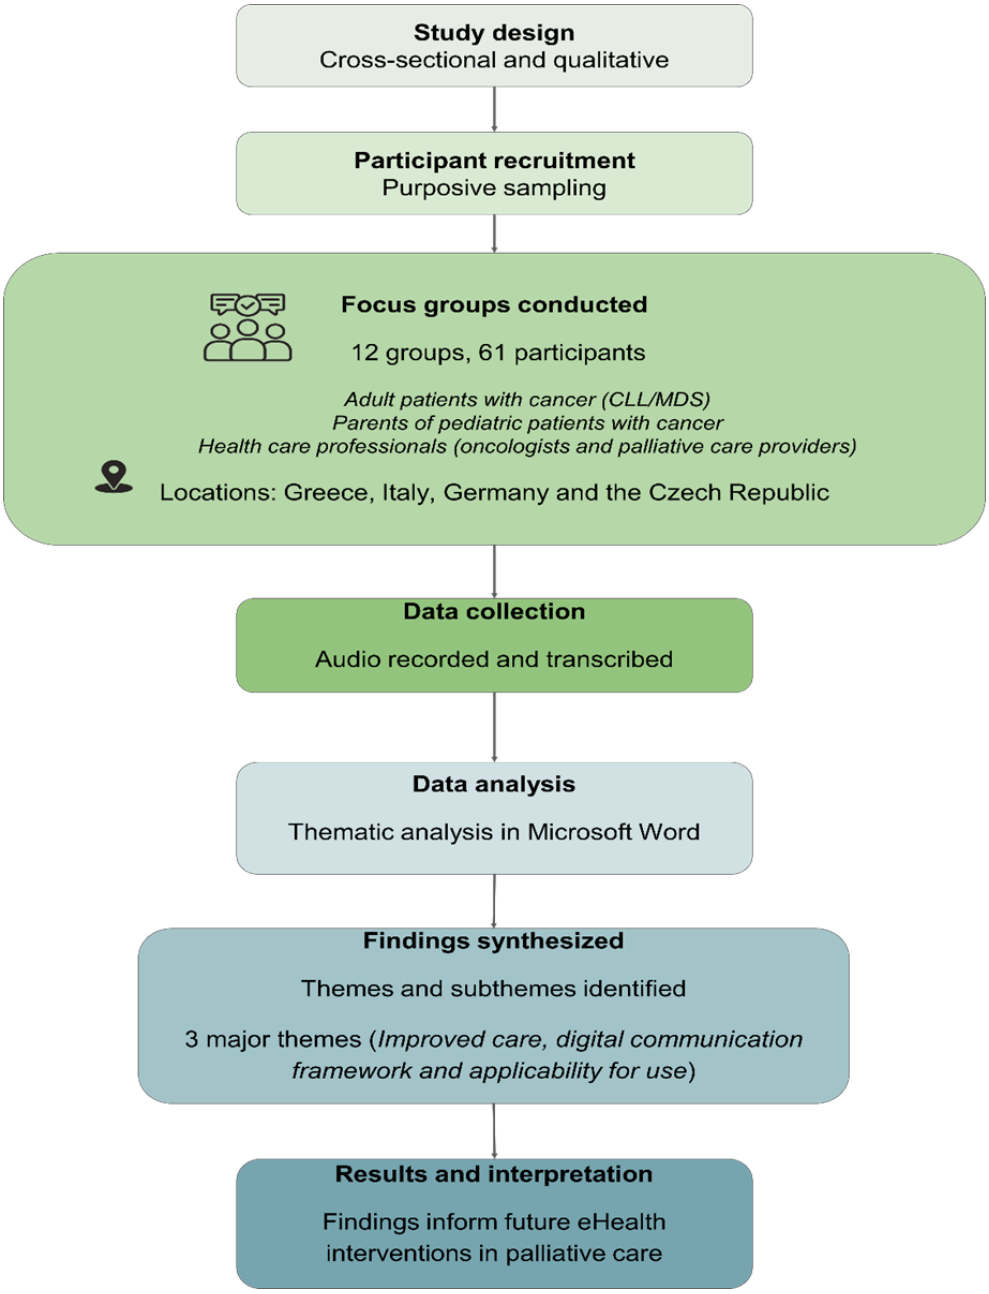
With the growing demand for palliative care and the limited number of specialized health care professionals (HCPs), it becomes critical to identify methods to optimally use available resources [12]. Palliative care is a resource for anyone living with a serious illness. It extends beyond end-of-life support, integrating early into the disease trajectory alongside active treatment to improve symptom management, psychological well-being, and overall QoL [12]. One promising approach is the use of electronic patient-reported outcomes (ePROs), which have been integrated into various palliative care interventions for patient monitoring, providing reliable data and improving the quality of care delivered to patients with cancer [13]. eHealth tools and applications offer promising solutions for enhancing patient monitoring and care coordination. However, their adoption is hindered by barriers, such as low engagement among older adults and disease-specific usability factors [14]. Participatory design [15], which actively involves patients in developing eHealth tools [16], resources [17], or systems [18], has shown potential to enhance user acceptability, usability, and the feasibility of interventions in palliative care [19]. While usability concerns exist for older adults, children face distinct engagement challenges, as demonstrated in the MyPal4Kids study [20]. Younger children often benefit from engaging, gamified designs, whereas older children may find such approaches too simplistic, leading to disengagement. Tailoring eHealth tools to the developmental and cognitive needs of different age groups is essential to optimize usability, engagement, and effectiveness.

MyPal Project

Building on these principles, the MyPal project is a collaborative Horizon 2020 research project, funded by the European Commission, aiming to use eHealth technologies in order to support patients with cancer and HCPs. The main goal of MyPal is to develop and clinically assess new ePRO-based interventions for the palliation of patients with cancer in order to improve their QoL [21]. The project, through the MyPal digital solution, targets both adults with chronic HMs via an ePRO-enabled mobile app and pediatric patients with leukemia or solid tumors via a serious game tablet app, along with their caregivers. The digital solution also comprises a web-based HCP portal. The pediatric patient's app is characterized as a "serious game" because it serves a purpose beyond entertainment, aiming to engage pediatric patients in their care journey by improving health literacy, encouraging symptom reporting, and fostering adherence to treatment protocols. The MyPal project has committed to both adopting a patient-centered approach and adapting technology in order to cater to fundamentally different profiles of patients of different age groups as well as levels of digital and health literacy. Therefore, during the MyPal intervention design and protocol development, not only the

XSL•FO
RenderX

context of health care provision, that is, current clinical practice for patients with cancer, their interaction with HCPs, and provision of palliative care but also users' personal needs were considered.



Objective

The purpose of this study is to explore the perceptions, opinions, and needs of HCPs, adult patients with cancer, and caregivers of pediatric patients with cancer regarding the MyPal digital solution, a palliative care eHealth solution. Specifically, we aim to understand users' views on system functionalities, benefits, challenges, and potential improvements.

Methods

The chronological steps of the study process are presented in Figure 1.

Figure 1. Study flowchart depicting the overview of the study process from design and participant recruitment to focus groups, data collection, analysis, and key findings. CLL: chronic lymphocytic leukemia; MDS: myelodysplastic syndrome.

Study Design

This study used a cross-sectional qualitative methodology, using focus group (FG) discussions to explore the perceptions of patients, caregivers, and HCPs regarding MyPal, an ePRO-based digital solution for palliative care (NCT04370457) [8]. This study was conducted in 5 clinical sites across 4 European countries (Greece, Italy, Germany, and the Czech Republic).

It involved 3 participant groups: (1) adult patients with chronic lymphocytic leukemia (CLL) or myelodysplastic syndromes (MDSs), (2) children with HMs or solid tumors and their parents, and (3) HCPs working in participating clinical sites.

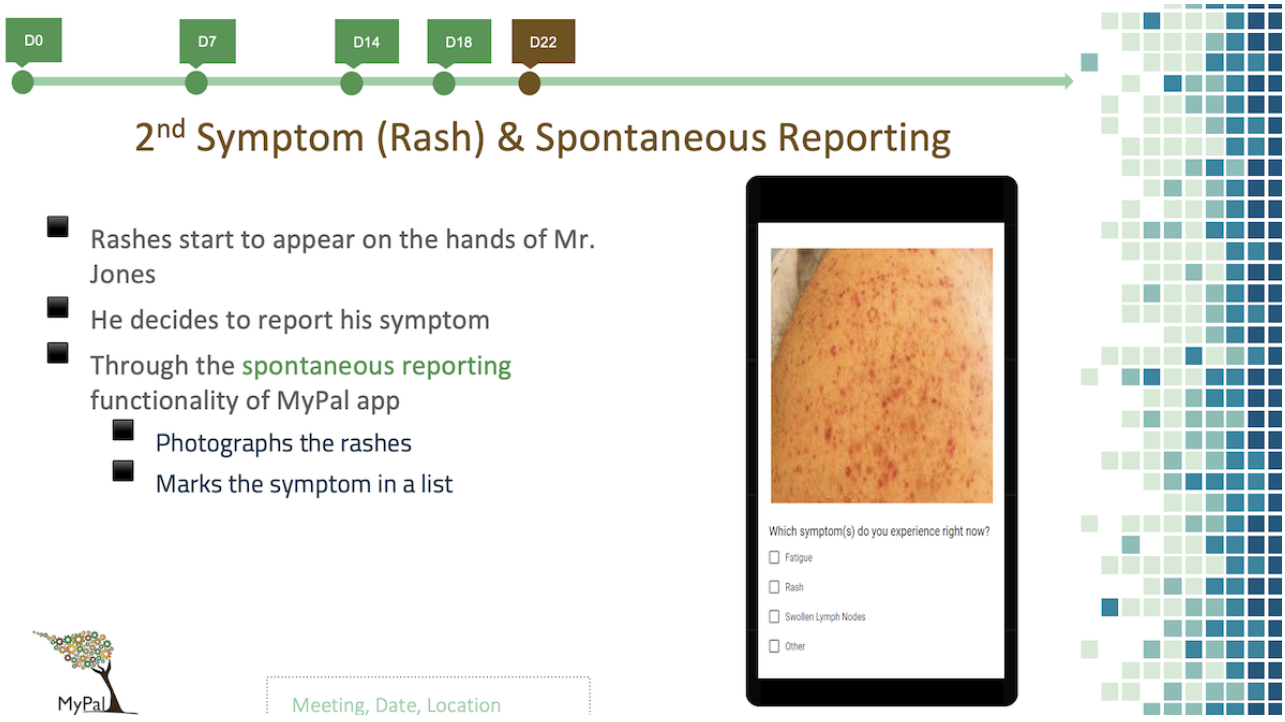
Each FG was moderated by an interdisciplinary team, comprising professionals experienced in health care (LS: female physician; MM: male PhD candidate; AS: female physician; TA: male physician; EK: female PhD candidate; and C Karamanidou: female PhD graduate) and psychosocial work at each clinical site. The moderators received previous training and possessed experience in conducting and leading FGs within the fields of health care and health psychology and had no previous relationship with the participants, who were solely informed of their professional roles and qualifications. The interviews were conducted in each country's native language (Greek, Italian, German, and Czech). They took place in an assigned meeting room within each of the 5 hospitals (Università Vita-Salute San Raffaele [USR; Vita-Salute San Raffaele University], Universität des Saarlandes [USAAR; Saarland University], Medizinische Hochschule Hannover [MHH; Hannover Medical School], Fakultní nemocnice Brno [BRNO; University Hospital Brno], Panepistimiako Geniko Nosokomeio Irakleiou [PAGNI; University General Hospital of Heraklion]) and in one research center (Centre for Research and Technology Hellas [CERTH]) where participants' privacy was protected.

Participant Recruitment

Recruitment was carried out by the principal investigators from each clinical site. Invitations were extended in person, via email, or by telephone to patients, HCPs, and parents of young patients. Specifically, participants for each participant group were recruited if they fulfilled the following criteria: (1) patients with CLL or MDS, (2) HCPs who worked in palliative care units or oncology units, and (3) parents of young patients (with or without their children) with solid tumors or HMs. The participants were recruited through the hospital units where they worked or were being looked after. This study used a mixed sampling method to recruit participants. HCPs were recruited using purposive sampling, targeting those with experience in palliative care or oncology, while patients with CLL or MDS and parents of young patients were recruited via random sampling. For the purposes of participant recruitment, a screening paragraph was developed to help HCPs from each participating site recruit participants in a standardized way:



> *Within the context of a project called MyPal funded by the European Commission we are organizing a number of focus groups discussions. We are interested in developing a digital health system for cancer patients [or for HCPs looking after cancer patients] and we would very much appreciate your input as our design should ideally correspond to the needs of patients [or HCPs] like yourself. Let us know whether you would be interested in taking part.*

Development of FG Content

Overview

A series of vignettes was developed by a female (C Kakalou) and a male (CM) software engineer, with expertise in eHealth and participatory design techniques, and a female health psychologist (C Karamanidou). These vignettes presented more than 1 imaginary end users (called personas) of the system and targeted each participant group (Multimedia Appendix 1). Each vignette introduced a persona and illustrated how it interacted with the MyPal app and all its components from enrollment to the clinical trial up until its end (Figure 2).

Figure 2. Vignette for adult patient.

On the basis of the vignettes, discussion guides were created in order to assist the elicitation of participants' perceptions and judgments in a semistructured way (Multimedia Appendix 2). The discussion guides included showing the user a scenario divided into episodes and then asking relevant questions to the participants. Importantly, all key materials (the discussion guide, the user scenario, and the consent form) were provided to FG participants in English.

XSL•FO
RenderX

Training Workshop

Aiming at maximizing consistency in the conduct of FGs and the analysis of the data across every clinical site, the Institute of Applied Biosciences (INAB) at the CERTH developed a 2-hour training workshop, which was delivered online to all MyPal participating clinical sites and partners (Multimedia Appendix 3). The workshop was recorded so that those who could not be present could view it at their own time.

The workshop was held after the completion of the first 2 FGs in Greece. The aim of the workshop was as follows: (1) to present the rationale behind interacting with potential users to elicit needs and preferences via FG discussions and (2) to present the process that must be followed to ensure consistency among sites.

FG facilitators were given a list of necessary materials (ie, recorder) and conditions that had to be met (ie, private room) in order to successfully conduct a FG on the premises of their organization (ie, hospital ward). Particular emphasis was placed on the recruitment of FG participants and the role of the moderator, both of which were discussed at length as they could have an impact on the integrity of the methodological design. Examples of each were presented and discussed on the context. For example, certain questions from the discussion guide were phrased as open-ended questions to avoid judgment, etc.

Following this, managing the FG discussion itself was discussed with the workshop attendants. Specifically, with regards to group dynamics, attendants were advised to pay attention to nonverbal language; manage "airtime" among members; as well as use techniques to invite, reflect, or summarize.

Finally, 3 examples from the FGs conducted in Thessaloniki were presented. Attendants had the opportunity to comment on the role of the moderator and their choice of intervention at each instance as well as the sequence or the manner the questions were posed. Furthermore, attendants were able to observe from a bird's eye view the stages of the process the group undergoes after the introduction of a new item on the agenda by the moderator, namely exploration, unison, and solution. Key references on the conduct of FGs [22] and a step-by-step thematic analysis guide [23] were provided as supplementary material.

Data Collection

The FGs initially featured a presentation of the appropriate vignette, followed by a specific discussion on this vignette based on the discussion guide. At the beginning of each session, the aim of the MyPal project was introduced, followed by an explanation of the session's structure.

None of the participants refused to participate or dropped out during or after the FGs. All FG discussions were conducted exclusively with the researchers and participants present. Each FG was audio recorded and lasted approximately 2 hours. Data collection was considered complete once participants' accounts had been analyzed, and the resulting conceptual structure was determined to be sufficiently rich and detailed to address the research questions and meet the analytic objectives of the study. During the FGs, no field notes were taken, transcripts were not returned to participants, and no repeat FGs were conducted as the spontaneous and instinctive nature of participants' responses was considered essential for capturing the authenticity of their experiences. Transcription and translation followed a systematic approach to preserve accuracy and consistency. Initially, all discussions were transcribed in the original language of the FG (Greek, Italian, German, or Czech). Each research team was responsible for translating the transcripts and the participants' quotes into English, ensuring that the original meaning and context were accurately conveyed. To maintain consistency across sites, translations were reviewed within each team, safeguarding the fidelity of participants' narratives in the final dataset.

Data Analysis

The qualitative data were analyzed using thematic analysis, which is an established method of management and analysis of qualitative data in applied health research [24] and usability for mobile apps [25]. The initial inductive coding was carried out independently by the research team of each participating site. Subsequently, the coded data were consolidated to ensure consistency and facilitate cross-site analysis. The aggregation and the final analysis for this study were conducted by a male clinical psychologist (DK) with previous experience in thematic analysis using an inductive approach. The analysis was performed in Microsoft Word.

Ensuring uniformity of the FG analysis in the different participating sites was the primary concern of the research team. To address this challenge, the clinical psychologist consolidated the codes generated from different countries, and thematic analysis was applied to identify central themes and subthemes. This process facilitated the generation of a cohesive and integrative analytic outcome that adequately accounted for the diversity present within the dataset. Among the main reasons behind choosing this method of analysis were its suitability for exploring and identifying patterns in qualitative data, particularly participant perceptions, which aligned with the aim of this study; the multidisciplinary research teams involved, which facilitated a comprehensive interpretation of the data; the sample composition, which included clinical, patient, and lay representations, requiring a method capable of capturing multifaceted views regarding specific features of the MyPal digital solution; and the complexity of the dataset, which was generated via the collection of data in 4 different countries and languages, requiring a flexible and robust analytic framework. According to the guidelines by Braun and Clarke [23,26,27], the steps that were followed were as follows:

1. Familiarization with the qualitative data was carried out through listening to the FG discussions.
2. Inductive coding of the FG data to generate preliminary concepts was conducted. These codes were developed at a national level. Examples of preliminary codes generated were "The physician has the chance to evaluate signs and symptoms of which the patient is not aware" and "It is easy, to the point, immediate."
3. Inductive codes were sent to the INAB at the CERTH, and the final stages of analysis were performed on the aggregated data.

XSL•FO
RenderX

4. The initial codes were clustered by the clinical psychologist into overarching categories that reflected conceptual patterns across the data (subthemes and themes).
5. The external heterogeneity and internal homogeneity of the developed categories were reviewed in a multidisciplinary research team (health and clinical psychologists [C Karamanidou and DK], eHealth [CM and C Kakalou], and usability experts [PB]) and refined until consensus was reached.

While the thematic analysis was conducted on aggregated data from all participating countries, initial coding was performed at the national level to account for local context and language. During the consolidation phase, the clinical psychologist leading the analysis reviewed the codes from each country to identify both shared and divergent patterns. Although some nuances specific to cultural or health care contexts emerged during coding, no substantial thematic differences were identified that warranted separate country-level themes. This decision was further validated through discussions with the multidisciplinary research team, ensuring that the core concepts identified were consistent across sites. Thus, aggregation was deemed appropriate to provide a comprehensive overview of stakeholder perceptions. Nonetheless, potential differences in system adoption and perception across countries are expected to emerge more clearly during the evaluation phase of the MyPal project.

Ethical Considerations

The integration of ePROs via mobile apps has raised ethical concerns regarding inclusion criteria, information provided to participants, free and voluntary consent, and respect for their autonomy. These have been carefully addressed by a multidisciplinary team. Data processing, dissemination, and the use of the study findings will take place in full compliance with European Union data protection law. A participatory design was adopted in the development of the digital solution, involving FGs and discussions with patients to identify needs and preferences.

Before the interviews, participants were informed about the study's objectives. They were required to sign a consent form outlining the measures taken to protect their confidentiality; the processes for anonymizing, storing, and managing the data; and their rights to refrain from answering specific questions or withdraw from the study at any time. Ethics approval for the study was obtained from the research ethics committee of the INAB at the CERTH and the research ethics committee of San Raffaele (8/2020), Thessaloniki "George Papanikolaou" Hospital (849), Karolinska Institutet (20.10.2020), University General Hospital of Heraklion (07/15.4.2020), and University Hospital of Brno (01-120220/EK). The study adhered to the principles in the Declaration of Helsinki and complied with the European General Data Protection Regulation. Special attention was given to safeguarding participants' identities and maintaining the confidentiality of their narratives. Because qualitative data often contain detailed personal experiences and sensitive information, all transcripts were deidentified, replacing real names with pseudonyms or participant codes. Any contextual details that could reveal participants' identities were removed or generalized to ensure anonymity. Access to raw transcripts was strictly limited to the research team members responsible for data analysis, and all files were securely stored in encrypted databases. Participation in the study was entirely voluntary, and no form of compensation was provided.

Results

Overview

A total of 61 participants took part in 12 FGs (3-8 participants per group), which were conducted across 5 clinical sites in 4 European countries (Greece, Italy, Germany, and the Czech Republic; Table 1). Participants included adult patients with CLL or MDS, children with HMs or solid tumors and their parents, and HCPs specializing in palliative care or oncology. Among them, 27 (44%) were adult patients (men: n=15, 56%; women: n=12, 44%; age: mean 61, SD 11), most had received treatment (n=25, 93%), with several in relapse or partial remission, while others were treatment naive (n=2, 7%). Detailed demographic and clinical characteristics of all participant groups are summarized in Table 2, including age, sex, and professional roles where applicable.

Of the 61 participants, the parent and child FG included 10 (16%) children (boys: n=8, 80%; girls: n=2, 20%; age: mean 13.50, SD 1.75 y) diagnosed with leukemias, lymphoma, sarcoma, or epidermolysis bullosa (all undergoing active treatment) and 9 (15%) parents (mothers: n=6, 67%; fathers: n=3, 33%; age: mean 43, SD 3 y). In addition, 15 (25%) HCPs (men: n=5, 33%; women: n=10, 67%; age: mean 42.50 y; SD: 3.75) participated, including oncologists (n=9, 60%), nurses (n=3, 20%), and other HCPs (n=3, 20%), such as a physiotherapist, a social worker, and a psychotherapist, with experience in oncology settings, pediatric hemato-oncology or

XSL•FO
RenderX

palliative care. The FGs varied in size and were structured to capture diverse perspectives on the MyPal digital solution.

Three themes and 7 subthemes (Figure 3) were developed from the FG data. The first theme (improved care) portrayed participants' perceptions and opinions regarding MyPal's potential to improve health care using patient-reported measures and outcomes, which can both enhance monitoring and decision-making, improve physician-patient communication, as well as highlight areas of intervention (eg, psychological distress), which can easily go unnoticed in clinical practice. The second theme (digital communication framework) highlighted participants' need for more explicit clarification of the boundaries, roles, and procedures regarding MyPal's digital communication framework and their concerns regarding the privacy of their personal data. The third theme (applicability of use in health care) described the importance of the system's ease of use, presented participants' feedback regarding MyPal's burdensomeness, and presented participants' ideas on how to enhance its acceptability for health care use.

Figure 3. Main themes and subthemes identified through the thematic analysis methodology.

Themes and subthemes are presented in more detail subsequently, along with relevant quotes from the FGs, which further support and illustrate the presented concepts. The quotes' descriptions include the participant group, the clinical site, and the specific functionality of the MyPal digital solution on which participants commented, that is, patient-reported outcomes, smart bracelet, personalization, general judgment, facial recognition and voice recognition, and game (for the MyPal-CHILD study only).

Improved Care

Facilitation of Medical Practice

Patients, parents, and HCPs reported that MyPal could promote an easier and more efficient way of symptom monitoring and reporting, especially through the patient-reported measures. Emphasis was placed on the convenience of reporting symptoms via the app, without having to visit the hospital or call the physician:

> *I think it helps, because patients don't want to visit the doctor every month, so reporting from home will be easier and less stressful.* [General judgment; adult patient FG, parent and child FG, and HCP FG; USAAR]

Patients highlighted that by self-reporting their symptoms, they would become better at self-monitoring and enable their health care team to keep better track of their condition. Specific functionalities, such as photo reporting and the smart bracelet, were emphasized as a means for more accurate reporting:

> *The patient may not describe or may not be able to accurately describe a symptom, for example, a rash. A photo is far more explanatory.* [Patient reported outcomes; adult patient FG; CERTH]

> *It is very useful, I'll be constantly monitored.* [Smart bracelet; adult patients; USR]

HCPs pointed out the value of having immediate access to accurate patient data that can help in the documentation of patients' states (eg, symptoms and side effects). In addition, some mentioned that the collected data could help with more efficient decision-making in medical practice:

> *This system could help with some decisions, like how often to monitor a patient.* [Smart bracelet; HCPs; PAGNI]

On the contrary, some HCPs mentioned that they would be hesitant to shape their decisions based on the collected data and becoming informed about patients' symptoms through the app and not by physically examining the patient would cause them to feel uncertain and worried regarding the symptoms' importance:

> *For me, as a doctor, remote monitoring would not be to my liking. My experience has shown that if you do*

XSL•FO
RenderX

> *not see the patient, you can be sure what he has, you cannot feel safe with the recordings.* [Smart bracelet; HCPs; PAGNI]

Improved Physician-Patient Communication

Every group of participants highlighted the fact that MyPal could improve physician-patient communication through the fast and direct reporting of symptoms. Of note is that both patients and HCPs among many different FGs mentioned that MyPal could alleviate patients' fear of burdening their physicians and enable them to report more symptoms without hesitating:

> *It's helpful for patients who hesitate to disturb their physician, because they don't know whether their symptoms are important.* [Patient reported outcomes; HCPs; CERTH]

In one FG with HCPs, the value of MyPal questionnaires that would be used to personalize health care to each patient's profile was more than emphasized. HCPs described how by getting to know each patient more through MyPal, they could tailor their communication to their specific needs:

> *By using MyPal you can understand how a patient might be feeling when sometimes they become demanding in our appointments. Knowing things about them and their experiences might enable us to respond to their questions more promptly. This might address their issues, even remotely.* [Personalization; HCPs; PAGNI]

In addition, some HCPs mentioned that the discussion guide and communication training functionalities of the app could be helpful in better equipping them to respond to their patients' needs. However, many participants noted their preference for more personal contact via the phone or in person and felt that communicating only via MyPal could be depersonalizing:

> *I would prefer more calls and more personal contact.* [General judgment; HCPs; USAAR]

> *Children have their favorite doctors and they like contacting them directly. But they do not exclude the contact with the app.* [Communication; parents and children; BRNO]

Upholding Holistic Care

HCPs, patients, and parents highlighted MyPal's potential to support patients not only regarding the physical aspects of their condition but also the emotional and psychological aspects. According to participants, frequent reporting through the app could mitigate the anxiety about the disease and make patients feel secure and reassured without having to contact their physician. In addition, reporting data regarding patients' emotional challenges could promote holistic health care and improve patients' QoL:

> *It would provide important information regarding how the patient is feeling. This might help because if we know that one is not fine, next time we could spend more time with them. If we notice that one is depressed, we could refer them to a psychologist. You can't treat someone who is depressed and miserable. This isn't good, even for their medical treatment. So, when you have access to this information, you can use it as you wish.* [Patient-reported outcomes; HCPs; PAGNI]

> *It might be helpful in addressing aspects that would normally not be addressed without data from MyPaL.* [Communication; HCPs; MHH]

Patients, parents, and HCPs highlighted that the app could provide patients with a sense that they are not alone and their health care team is there for them and takes note of their everyday struggles:

> *I think that this is psychotherapeutic for the patient, at times when they have no one to talk to. It mostly helps the patient, not us.* [Patient-reported outcomes; HCPs; PAGNI]

In addition, some patients mentioned that the personalized education functionalities of the app could be a relief and save them from the stress of searching on the internet:

> *It is reassuring. This app is personalized and tailored to my needs. I would be more relaxed, less anxious.* [Personalization; patients; USR]

Concerning children with HMs, their parents commented that the serious game could act as a distraction and attenuate their pain as well as become a channel for fun and communication with peers. In addition, some parents and HCPs commented that the app might motivate children to be more active physically and empower them to better address emerging issues:

> *It would help physically and psychologically, by motivating them to stay active regarding their health issue and deal with it in better ways.* [General judgment; HCPs; PAGNI]

Finally, patients and HCPs in Greece highlighted the need for cooperation with mental health specialists in order to provide support for the psychological issues that would be reported by patients through the app:

> *It would provide us with valuable insights into what the patient is experiencing [...] If we notice that they are depressed, we could refer them to a collaborating psychologist. You can't treat a sick person who is depressed and unhappy.* [Facial recognition; HCPs; PAGNI]

> *Need to speak immediately with a specialist, perhaps even a mental health professional.* [Facial recognition; patients; PAGNI]

Digital Communication Framework

Need for Clarification of Roles, Boundaries, and Procedures

The description of MyPal raised several questions and concerns for participants. Patients and HCPs expressed their confusion regarding the use of telephone calls while using MyPal, that is, in which instances they could contact their physician via phone and in which instances they should report their symptoms via the MyPal mobile app. In addition, patients expressed the need to know who will be the HCP that receives their reported

XSL•FO
RenderX

information and how often they will be viewing the reported symptoms and reply:

> *Is it possible to get a response at night hours, when something happens?* [Communication; parents; BRNO]

> *If I experience something at 4:00 a.m. and record it, when will the doctor be able to review it? Will they be notified and check it in the morning?* [Communication; patients; PAGNI]

Furthermore, several patients expressed the need to receive feedback from their HCPs after submitting information to the app. Patients would like to receive immediate feedback tailored to their unique reported symptoms instead of automatic responses. Along these lines, parents mentioned the need to be able to receive confirmation that things are under control when their children submit information about their symptoms. In 1 FG, patients also expressed the need for personalized medical advice:

> *For instance, if you have high blood pressure, use less salt, or consider walking more.* [General judgment; patients; PAGNI]

By contrast, HCPs made the point that patients should be informed explicitly that the MyPal digital solution is not for emergency situations and that they should make a call or go to the hospital in such cases.

Finally, both patients and HCPs raised concerns regarding the appropriate interpretation and clinical value of the data captured by the face recognition and the smart bracelet utilities of the app:

> *If I have a fight with my husband and my facial expression is changing, this is not due to the disease.* [Facial recognition; patients; USR]

> *I would trust more seeing the patients' face myself, rather than leaving the system to estimate.* [Facial recognition; HCPs; USAAR]

> *We cannot know what the measurements reflect.* [Smart bracelet; HCPs; USAAR]

Privacy Concerns

Every group of participants perceived that the smart bracelet and face and voice recognition utilities would invade their privacy, along with personal questions that could potentially be included in the MyPal questionnaires for personalization purposes:

> *One could feel as being constantly watched, like in George Orwell's book, a sort of Big Brother. Too much personalization could be misunderstood.* [Personalization; patients; USR]

They also expressed their concerns regarding the security of their personal data and highlighted the need for safeguarding their confidentiality. Some mentioned that the face and voice recognition could be acceptable only under the condition that the patients could choose when to enable it:

> *Another question involves the sensors, microphone and camera. If one goes to the toilet, will the camera film that?* [Facial recognition; parents and children; USAAR]

> *If I had control over the timing of the recordings...yes.* [Facial recognition; patients; CERTH]

Applicability for Use in Health Care

Importance of the Ease of Use

Some patients and parents wondered whether patients with CLL, who are generally older, will have the necessary technical skills to be able to use the MyPal digital solution:

> *The main criticism on the tool is that patients with CLL are generally elderly and they are not very familiar with this technology. If I think of my mother, who is 84 years old, I see this issue.* [General judgment; patients; USR]

The same issue was raised for children and people who do not have a smartphone. By contrast, other patients viewed the MyPal digital solution as an opportunity to become familiar with technology:

> *Technologies are the future and it is necessary to move with the times when it comes to health.* [General judgment; patients; BRNO]

Finally, patients showed appreciation for features that could facilitate the ease of use even more, such as conversational agents (eg, chatbot) or voice-activated functionalities.

Concerns About the System's Intrusiveness and Burdensomeness

Participants raised concerns regarding the intrusiveness of the MyPal digital solution in many FGs. Frequent notifications for the completion of PRO measures were perceived as a constant reminder of CLL, which would burden patients and interfere with their everyday life, both practically and emotionally:

> *They would remind the patient that he is ill even at times when he may not be conscious of it.* [Personalization; patients; CERTH]

Participants suggested that receiving notifications and having to fill PRO measures should be sparse and personalized to their preferences to not tire them out and make them lose their motivation to use the MyPal digital solution. The intervals suggested by the participants varied. For some, weekly reporting was considered acceptable, while for others, monthly reporting was considered more acceptable. Wearing a smart bracelet was considered a burden by some, while others believed it was completely acceptable.

In addition, a few participants expressed their concern regarding addiction to the app and spending too much time on the mobile phone, especially regarding young children.

Of note were HCPs' concerns regarding the time they would have to spend using the MyPal digital solution. With few exceptions, having to look at the extra information that MyPal added to clinical practice was perceived as an extra workload. In addition, having to respond to patients, read the spontaneously reported messages, document their progress according to PROs,

XSL•FO
RenderX

and fill the patient's search engine with appropriate educational material was perceived as highly burdensome:

> *How will MyPal be added to the regular business day of physicians who already have packed schedules for example if there are incoming SMSs because of parental reports? We already have a good system, perhaps in other countries this may be helpful, but how will it be incorporated here? We ask parents to call at the ward in case of problems, how will the use of the app be integrated? It will be difficult, I don't know how it can be integrated.* [Patient reported outcomes; HCP; MHH]

In addition, HCPs highlighted that they would not want to feel that they are constantly on a call or receive notifications during their free time:

> *If I am not at work, I wouldn't want to receive a notification that a patient is not well.* [General judgment; HCP; USAAR]

Along these lines, HCPs suggested developing a smart notification system, which could incorporate patients' data and notify physicians only under certain conditions. Alternatively, some suggested the development of a traffic light system, which would categorize patients' reported data according to their severity. This would allow HCPs to quickly track important patient data without having to review the whole dataset.

> *If there is an alert for data [red light and green light] it could take only a few minutes.* [Patient reported outcomes; HCPs; USAAR]

Discussion

Principal Findings

This study explored the perceptions of patients, caregivers, and HCPs across 12 FGs in 5 clinical sites spanning 4 European countries regarding MyPal, an ePRO-based digital palliative care solution. Three major themes emerged highlighting both the potential benefits and challenges of integrating digital tools into palliative care: (1) *improved care*, emphasizing MyPal's potential to enhance symptom monitoring and physician-patient communication; (2) *digital communication framework*, highlighting privacy concerns and the balance between digital and direct interactions; and (3) *applicability for use*, focusing on usability, intrusiveness, and workload considerations for HCPs.

Overall, participants acknowledged MyPal's potential to enhance symptom monitoring, communication with HCPs, and holistic care delivery. They appreciated the convenience of remote reporting and the structured feedback offered by the system. Their perceptions highlight the dual potential of MyPal. On the one hand, participants recognized its value in enhancing symptom monitoring, improving patient-HCP communication, and supporting holistic care. By contrast, concerns emerged around issues of usability, digital burden, privacy, and the potential for depersonalized care. For example, participants expressed concerns about time investment, effort, and potential disruption to daily life or professional routines. Excessive notifications and complex use requirements could deter engagement, ultimately reducing the effectiveness of the intervention. Previous research has shown that high notification frequency can lead to app abandonment, with engagement declining when users perceive digital tools as intrusive [28]. Given that app-based interventions for chronic diseases report dropout rates of up to 43%, minimizing burden is critical in maximizing sustained engagement [29].

Participants also emphasized the importance of a balanced approach that integrates digital tools alongside traditional care practices to maintain the personal connection between patients and HCPs. Concerns about usability and engagement were also noted, particularly among older adults and those with limited digital literacy. While privacy and security emerged as central barriers to adoption, the findings suggest that building trust in eHealth technologies and providing user control over monitoring features are crucial to fostering long-term engagement.

Overall, the results indicate that while eHealth tools such as MyPal have significant potential to improve palliative care, success hinges on addressing concerns related to digital burden, privacy, and maintaining a sense of human connection. These insights provide a foundation for exploring how digital interventions can complement existing care practices, which is further elaborated in the subsequent sections.

Privacy, Security, and Usability Considerations

During the early stages of the analysis process, it was evident that privacy and security concerns were among the most pressing issues raised by participants, particularly regarding facial and voice recognition features. Even when reassured about data protection measures, many participants remained unwilling to accept such monitoring functionalities. Previous research suggests that the acceptance of digital health technologies depends heavily on patient trust and transparency in security protocols [30]. Studies emphasize that both patients and HCPs must be educated on these measures to alleviate fears and improve confidence in eHealth tools [31-33]. In addition, presenting security systems in a clear and comprehensible manner has been shown to enhance user acceptance and engagement with digital health systems [34]. Beyond security, participants expressed concerns about feeling constantly monitored without control over when and how data collection occurs, a factor that has been previously identified as a barrier to adoption, as many users perceive continuous monitoring as an invasion of privacy and prefer having control over when data are recorded [35]. Addressing these concerns is critical for increasing trust and ensuring the long-term adoption of ePRO interventions. Another key issue was usability and accessibility, particularly for older adults and individuals with physical limitations. Participants noted that small font sizes, complex interfaces, and navigation difficulties could hinder engagement. Previous studies highlight how older users often struggle with digital interfaces primarily designed for younger populations, underscoring the need for age-friendly designs that accommodate diverse user capabilities [36]. To enhance accessibility, future iterations of MyPal should prioritize intuitive design, customizable interfaces, and features that ensure ease of use across all patient demographics.

XSL•FO
RenderX

Implications

Another crucial element to consider in future eHealth palliative care solutions is patients' and caregivers' wishes to receive personalized feedback regarding the data they or their children submit. While ePROs augment the reporting experience, in many cases, they lack the feedback element [37], creating miscommunication issues. Therefore, the incorporation of feedback elements could optimize the user experience by making app-based reporting feel more meaningful and immediately relevant to patients, as they would receive an outcome based on their interaction with the app (eg, a message that "the doctor has seen your submission and will answer through the app in 24 hours at the latest"). In addition, by adding a co-design approach, miscommunication issues are severely limited [16]. Finally, this study did not explore any differences in perception among the participating clinical sites. Future research may address such differences to explore palliative care applications in different settings.

Strengths

This study offers a multinational perspective by collecting data from 4 European countries, allowing a diverse range of viewpoints from different health care systems. The use of qualitative FGs provided an in-depth exploration of user perceptions, generating rich insights into the experiences of patients, caregivers, and HCPs. In addition, the inclusion of multiple stakeholder groups ensured a holistic understanding of the feasibility, benefits, and challenges of implementing digital palliative care solutions.

Limitations

First, our sample may have consisted of participants with an interest in or familiarity with digital technology and the development of eHealth solutions, which may have introduced bias. As a result, individuals with low digital literacy, who may face greater challenges in using such tools, were underrepresented. Given that poor digital literacy can significantly impair interactions with HCPs and limit the benefits of digital health services [38], future studies should include a more diverse sample that explicitly accounts for varying levels of digital literacy.

Second, the first coding step, the inductive coding of FG data, was conducted separately at a national level by different investigators. This approach may have introduced subjective biases related to individual assumptions and analytic styles. However, to mitigate this, the aggregated initial codes were later organized into overarching categories, ensuring consistency across all participating sites and participant groups. This process helped standardize the interpretation of data and minimize potential discrepancies.

Third, the number of FGs conducted may have limited the diversity of perspectives captured. Although the study aimed to conduct at least 1 FG per user group in each country, thematic analysis suggested that additional FGs could have provided further insights. Given that palliative care needs and digital health adoption may vary across cultural and health care settings, increasing the number of FGs in future studies may help elicit a broader range of opinions and experiences.

Fourth, the validity of the FG content was another limitation. While the discussion guides were carefully designed by experts in psychology and software engineering within the MyPal project consortium, they were not directly validated by all stakeholders, such as patients and caregivers. Ensuring FG content is aligned with stakeholder-specific experiences and routine interactions with the MyPal system could improve the relevance of the findings and provide more targeted insights for future iterations of the tool.

Fifth, only limited background information was collected from FG participants, specifically age, sex, and professional role (for HCPs). Additional characteristics were excluded, such as time since diagnosis, comorbidities, current medications, or years of professional experience, primarily due to methodological constraints of the cross-national design, including heterogeneity in data availability across study sites and varying participant willingness to disclose medical or professional information. These limitations could have affected data reliability and comparability, further supporting their omission in a study primarily focused on perceptions, opinions, and needs of an eHealth solution. Future research should consider collecting more detailed personal and clinical data to better contextualize participant input. Furthermore, language barriers and the remoteness factor posed challenges in the study design. Conducting FGs in multiple languages required translation efforts, which introduced delays, and potential nuances might have been lost in translation. In addition, coordinating a multilingual consortium created logistical complexities, as experts from different countries had to communicate in a nonnative language while designing FG materials. This process increased the time and effort needed for study preparation and may have introduced subtle inconsistencies in content delivery. Finally, although no major thematic differences emerged across countries, the possibility of subtle cultural or systemic variations being underrepresented due to data aggregation cannot be entirely ruled out. Future research could address this by incorporating bilingual analysts or using artificial intelligence–driven translation validation methods to enhance accuracy and efficiency.

Comparison to Prior Work

A key insight from this study was the value participants placed on maintaining the physician-patient relationship through MyPal. While digital tools were seen as beneficial for enhancing communication, there was skepticism regarding features that could lead to a depersonalized experience. Previous studies have shown that maintaining "real-person" contact is crucial for patient satisfaction, and the acceptability of mobile health consultation apps remains limited due to concerns about impersonal interactions [39]. To address this, future eHealth solutions should integrate the participatory design paradigm to align digital interventions with patients' and caregivers' needs, ensuring they complement rather than replace in-person interactions [15,34]. In addition, participants emphasized the need for clearer guidelines on the use of MyPal, particularly regarding when to report symptoms via the app versus seeking direct medical attention. A previous study indicated that digital health interventions must clearly define user roles and expected outcomes to ensure effective engagement and adherence [40].

XSL•FO
RenderX

Without such clarity, users may struggle to understand how the tool integrates into their health care, potentially reducing its effectiveness.

Conclusions

This study provides important insights into the feasibility, benefits, and challenges of implementing ePRO-based digital interventions in palliative care. While MyPal was perceived as a valuable tool for symptom monitoring and communication, concerns regarding usability, data security, and clinical integration must be addressed for successful adoption. Findings reinforce the need for patient-centered eHealth interventions that complement, rather than replace, direct interactions in palliative care. The participatory design approach used in this study played a crucial role in ensuring meaningful stakeholder involvement, fostering patient empowerment, and promoting long-term engagement with the technology. Future work should focus on refining digital solutions based on user feedback to optimize engagement and clinical impact.

Acknowledgments

This research was supported by the MyPal project, which has received funding from the European Union's Horizon 2020 research and innovation program (grant 825872).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to privacy and General Data Protection Regulation requirements. However, they are available from the corresponding author on reasonable request.

Authors' Contributions

DK and PB contributed to methodology and writing the original draft. LS, MM, AS, TA, and EK contributed to methodology and implementation. CM contributed to conceptualization, methodology, and writing the draft. C Kakalou contributed to methodology, results, and reviewing the manuscript. MV contributed to the writing, revising, and reviewing the manuscript. C Karamanidou contributed to supervision, conceptualization, methodology, and reviewing the manuscript. All authors contributed to the paper and approved the submitted version.

Conflicts of Interest

LS is an advisory board participant of AbbVie, AstraZeneca, BeiGene, Johnson&Johnson, and Lilly Data Monitoring Committee. CM contributed to this work before joining the European Commission, which funded the MyPal project. He was not involved in the evaluation or funding of the project in his European Commission role. All other authors declare no conflicts of interest.

Abstract

Background: Online self-management interventions for cancer survivors are increasingly being used, but engagement is often difficult for patients. Given the importance of engagement for intervention effectiveness, identifying patient-reported barriers and facilitators is essential.

Objective: The aim of this study was to qualitatively examine barriers and facilitators influencing engagement with an online self-management intervention, offered with or without guidance, for cancer survivors experiencing chronic painful chemotherapy-induced peripheral neuropathy (CIPN).

Methods: Patients who took part in the Embrace Pain randomized controlled trial, conducted between December 2021 and July 2024, were invited to participate in this study. Eligible participants were adults with chronic painful CIPN, based on criteria including pain, completion of chemotherapy, and European Organisation for Research and Treatment of Cancer QLQ-CIPN20 Questionnaire (ie, cancer-specific measure of sensory, motor, and autonomic neuropathy). The Embrace Pain randomized controlled trial involved evaluating an online self-management acceptance and commitment therapy intervention for pain interference in daily life, with some participants receiving email guidance and others not. Thereafter, 12 patients experiencing chronic painful CIPN participated in semistructured interviews. Data were analyzed using thematic analysis. An inductive coding approach was applied, and Atlas.ti (Lumivero) was used for coding.

Results: In total, 2 themes and 17 codes emerged from the data, namely 7 codes for barriers and 10 codes for facilitators. Barriers included program schedule, burden, lack of guidance, irrelevance, mindfulness exercises, usability, and missing content. Facilitators included usability, recognition, positive self-management, program schedule, symptom management, relevance, guidance, experiential exercises, mindfulness exercises, and value-based living. Program schedule, guidance, mindfulness exercises, and usability proved to be barriers for some, while others indicated that they were facilitators for their use.

Conclusions: Participants' perceptions of the intervention varied, with engagement influenced by individual circumstances. These variations highlight the importance of personal context in shaping both uptake and effectiveness, indicating a need for tailored approaches to address diverse needs and challenges faced by participants.

KEYWORDS

chemotherapy-induced peripheral neuropathy; cancer; online intervention; engagement; facilitators; barriers

Introduction

The use of online interventions for patients with cancer is growing due to their benefits in costs, accessibility, availability, traveling, stigma, and psychological burden [1,2]. Previous studies into online interventions have often demonstrated positive patient outcomes [3,4], including patient groups with long-term consequences of cancer and treatment, such as patients

XSL•FO
RenderX

with cancer undergoing chemotherapy-induced peripheral neuropathy (CIPN) [1]. However, studies into online health interventions raise significant issues regarding the intended use [5,6], and thus the implications for effectiveness. Research on eHealth usage is often primarily centered on adherence (ie, a quantitative behavioral approach to usage and the extent to which users benefit optimally from the intervention [7,8]). This approach neglects the qualitative dimensions of use that are critical for achieving individual health goals and therapeutic benefit [8-11]. Engagement offers a broader conceptualization, encompassing both behavioral adherence and subjective experiences such as motivation, satisfaction, and perceived relevance [8,12]. Considering engagement in online interventions is therefore crucial to maximize the effectiveness of online interventions [5,12,13].

Several studies have explored factors influencing user engagement with online interventions. One systematic review proposed an integrative framework for engagement in digital behavior change interventions, identifying 3 key determinants: intervention design (eg, content and delivery), contextual factors (eg, setting and population), and the targeted behavior [12]. Although this framework has yet to be empirically validated, it highlights the importance of considering variables that affect intervention uptake. A systematic scoping review evaluating concepts and components of engagement similarly emphasized the role of content and design in affecting engagement and adherence [8]. These considerations are particularly relevant for online self-management interventions targeting chronic symptoms, such as CIPN, where symptom management involves ongoing, complex, and time-consuming tasks [14]. This highlights the need to explore the various factors that affect user engagement in studies developing such online interventions.

In recent years, research on patients' experiences of online self-management interventions has grown. A systematic review of both quantitative and qualitative studies identified a range of personal and psychological predictors of engagement, including the availability of guidance and sufficient time to complete the intervention [15]. The study concluded that personal and psychological factors, such as the need for guidance and sufficient time to complete the intervention, influence its use. In addition, intervention-related and technical factors, such as impersonal content and technical difficulties, were found to negatively impact user engagement [15]. Additional qualitative research has identified various facilitators and barriers to engagement. A study exploring the experiences of patients with neck and lung cancer, participating in a guided self-management intervention for psychological distress, reported both negative (eg, low levels of motivation and self-discipline) and positive experiences (eg, coaching support and engaging with assignments) [16]. However, since the intervention was offered in both print and online formats, no technology-specific insights could be derived. In contrast, another qualitative study focused exclusively on an online self-management intervention for cancer-related distress and identified 5 overarching influencing factors: illness-related, psychological, personal, intervention-related, and computer-related aspects [17]. Another study has qualitatively explored barriers and facilitators of an online mindfulness-based cognitive therapy for patients with cancer, finding factors of treatment setting, format, therapist, and patient characteristics [18]. In conclusion, these findings highlight the complex and multifaceted nature of engagement with online interventions. Previous research has demonstrated that incorporating guided elements, such as feedback, clear explanations, motivational support, and reminders, can enhance both user engagement and intervention effectiveness [19,20]. This underscores the need to understand the factors that shape patients' engagements and experiences.

It is unclear whether previously studied influencing factors to engagement in online self-management interventions are generic. Evaluating individual interventions is crucial for optimal effectiveness. Therefore, this qualitative interview study aims to explore the barriers and facilitators influencing engagement with Embrace Pain, an online self-management intervention designed for cancer survivors experiencing chronic painful CIPN [21]. This analysis is part of a larger randomized controlled trial (RCT), assessing the effectiveness of the intervention, which is based on acceptance and commitment therapy (ACT) compared with a waiting list condition (WLC) on pain interference in daily life [22].

Methods

Study Design (Qualitative Study Embedded in RCT)

This qualitative study included in-depth semistructured interviews to examine the barriers and facilitators that cancer survivors with chronic painful CIPN experienced in using an online self-management intervention for cancer survivors with chronic painful CIPN, called Embrace Pain [21]. The interviews focused on individuals' subjective experiences regarding their use of Embrace Pain.

Positionality of Research Team

The positionality of the research team is presented in Table 1.

XSL•FO

Table . Positionality of the research team.

Research person initials	Credentials	Occupation	Gender	Experience and training
DvdG	PhD (Medical and Clinical Psychology)	Postdoctoral researcher	Woman	Research experience on eHealth and cocreation
MvdL	PhD (Clinical Psycho-Oncology)	Endowed professor and licensed mental health psychologist	Woman	Clinical and research experience on efficacy and working mechanisms of psychological interventions in oncology, with special attention for online interventions
TS	PhD (Clinical Psychology)	Full professor	Man	Research experience on stress and trauma in relation to mental disorders
HT	PhD (Clinical Psychology)	Researcher and teacher	Woman	Research experience on psychosocial influences on quality of life, functioning, and mental health in chronic pain
FM	PhD (Medical Psychology)	Associate professor	Woman	Research experience on quality of life in cancer patients (with CIPN[a])

[a]CIPN: chemotherapy-induced peripheral neuropathy.

Overview of Embrace Pain

The online self-management intervention Embrace Pain includes psychoeducation and all ACT processes. Patients learn to perform value-oriented activities in daily life with pain, to reduce pain avoidance and increase pain acceptance. ACT is a third generation of cognitive behavioral therapy (CBT) [23]. The main therapeutic goal of ACT is to focus attention on personally valuable activities by stimulating pain acceptance, as an alternative to (experiential) avoidance. ACT has been proven effective for several types of chronic pain [24,25] and is increasingly implemented in global cancer care [26,27]. However, there had been no previous research on ACT for CIPN, although a study into cognitive and behavioral intervention for CIPN had demonstrated positive results [1]. Due to similar aspects and the greater suitability of ACT compared with CBT for the current patient population, it was expected that the current ACT-based intervention would yield positive effects [22].

An overview of the intervention of the main study is illustrated in Table 2 [21,22]. The RCT's method, including an overview of the intervention, was previously published in a protocol paper [22] along with a qualitative paper describing the patient-centered development [21]. Effects of the RCT were still pending at the time of writing. Furthermore, within this study, there were 2 arms, namely the guided ACT group and the WLC group. The only distinction between the guided and unguided groups was the provision of guidance through therapeutic email communication. Despite this, the content of the intervention administered to both groups was identical, which is why both groups were examined in this study. Participants could engage with the intervention autonomously by navigating through it individually. The guidance provided was minimal and had a low threshold, consisting solely of an asynchronous chat function.

XSL•FO
RenderX

Table . Overview of Embrace Pain.

Intervention	Details
Aim	Learning patients to manage their symptoms and pursue psychological flexibility
Duration	8 weeks
Modules	6 (1: “Chronic neuropathic pain”, 2: “On the way to values”, 3: “Away from my values”, 4: “On the road with skills”, 5: “Taking a new road”, 6: “On the road to values: from day to day”)
Investment	2 hours per week
Content	Theory, exercises, mindfulness, metaphors
Multimedia	Text, illustrations, audio files
Groups	ACT[a]: Embrace Pain, including asynchronous therapeutic email guidance WLC[b]: Embrace Pain after 5 months, excluding asynchronous therapeutic email guidance
Software	Karify/Avinty (ISO 27001 and NEN 7510 certified)

[a]ACT: acceptance and commitment therapy.

[b]WLC: waiting list condition.

Recruitment

Participants were selected from the group of participants in the RCT of this project, which was conducted between December 2021 and July 2024 [22]. Inclusion and exclusion criteria are described in the protocol paper previously published [22]. Inclusion criteria regarded being 18 years or older, being identified as having painful sensations by a clinician or self (ie, aching, burning, “pins-and-needles,” shock-like, painful tingling, numbness, and cramps), and experiencing sensations for at least 3 months. Furthermore, a score of 3 or higher on an 11-point pain intensity scale (numeric rating scale), the pain was not present before the administration of chemotherapy, chemotherapy concluded at least 6 months ago, and a score of 1 or higher on the European Organisation for Research and Treatment of Cancer QLQ-CIPN20 Questionnaire was required. The RCT included a total of 112 participants, of whom 25 were invited to participate in an interview. In a previously administered questionnaire within the RCT, patients indicated their willingness to participate in an interview at a later stage. Those who responded affirmatively were considered potential interview participants. Potential interview participants were approached via email within a month after completion of the intervention. Not all patients who expressed willingness in the questionnaire were invited to participate in an interview, because recruitment was stopped when data saturation was reached. During participant selection, efforts were made to ensure a balanced distribution between the guided and unguided groups, as well as gender distribution. It was decided to include both guided and unguided participants, as it was anticipated that the strengths and areas for improvement of the Embrace Pain intervention would exhibit significant overlap between both groups. Efforts were also made to include participants with different levels of engagement, attempting to include both patients with high and low engagement levels. This was estimated by one of the researchers (DvdG), who was aware of the patients’ usage by accessing user data in the intervention’s online system. Excluded were patients who had not activated their account of the intervention Embrace Pain and who were unable or unwilling to participate in an online video call via Microsoft Teams. Patients were able to participate regardless of the time elapsed since they had completed the intervention. Participants sometimes had previous contact via email or phone regarding their participation in the RCT. Some participants had participated in a previous interview with the same researcher (DvdG).

Development of Interview Guide

The interview scheme was based on 2 qualitative studies into subjective cancer patients’ experiences of online self-management interventions [16,17]. It is important to note that these studies followed the definition of adherence, while the operationalization of these studies fits the concept of engagement and of the subjective experience of use as defined in our study. Furthermore, the input from previous patient interviews regarding user needs in the context of this online intervention [21] was used as input for the interview scheme. The final semistructured interview scheme is presented in Table 3.

XSL•FO
RenderX

Table . Semistructured interview scheme.

Category	Questions
Motivation to participate	• Why did you decide to participate? • Did you have any doubts about participating? Why (not)?
Reason for nonusage	• Were you able to complete the training? If not, why did you quit the training? • What influenced you to quit training?
Experiences with intervention content	• To what extent did you find the training relevant and of decent quality? • How was your experience with the (1) information sections? (2) exercises? (3) quotes? (4) audio fragments? (5) time investment? (6) mental workload? • Were there components that made you want to put more or less time and energy into the training? If so, which ones? • Which parts did you find difficult and why?
Experiences with intervention technology	• What do you think of the online format of the training? • To what extent did you experience problems using a computer, tablet, or phone? • To what extent did you experience problems using the online environment?
Experiences with supervisor (if applicable)	• What was your experience with the guidance you received during the training?
Personal circumstances	• What personal circumstances may have increased your use of the training? • Were there any circumstances in your personal life that made it difficult to attend the training? How did you deal with these?
Experiences of intervention effects	• Do you feel the training was worthwhile? Why (yes or no)? • How did the training change your thoughts and behaviors? • Did the training help you to cope better with the neuropathy? Why (not)?

Data Collection

Interviews were conducted by 1 interviewer with each participant. Interviews were conducted by one of the authors (DvdG) between September 21, 2022, and December 19, 2023. Interviews took place via video calling through Teams. Recruitment for interviews stopped when data saturation was reached [28], indicating that additional interviews yielded no novel information, with recurring topics consistently emerging.

Data Analysis

Thematic analysis was used for analyzing the data [29]. Audio of the interviews was recorded and transcribed verbatim by 1 author (DvdG) and by a Psychology postgraduate student from Tilburg University. These students contributed to the research study in the context of their data collection task as part of their master's program. They were mentored by FM or HT in writing their thesis on a related topic and did not contribute to the development of this manuscript. Transcripts were not returned to participants for comment and correction because of the potential burden on patients. DvdG reviewed the transcriptions to confirm accuracy.

All transcripts were inductively coded, deriving themes directly from the data. Text fragments were coded when they involved barriers or facilitators in the use of the online training Embrace Pain from the patient's perception. When patients discussed potential barriers and facilitators relevant to other patients but not applicable to their situation, these were not coded. The analysis began with open coding, where the primary themes of facilitators and barriers guided the coding process. Once all transcripts were coded, an initial codebook code was reviewed and adjusted if necessary. Axial coding was then applied to explore how the codes related to the themes' facilitators and barriers. This process was repeated once for verification. Subsequently, the frequency with which each code was mentioned, as well as the number of participants who mentioned each code, was calculated. Ultimately, condensed meaning units were generated for every text fragment that was coded, capturing the core message of each quote. This approach facilitated a comprehensive understanding of the data, organized around the identified themes.

Interviews were coded in Atlas.ti 23 (Lumivero). One transcript was coded by DvdG and FM independently. Differences in coding were thoroughly discussed to ensure consistency and accuracy. Following these discussions, a consensus was reached regarding the appropriate coding approach. Subsequently, DvdG undertook the coding of the remaining transcript, which was performed inductively as well. In cases where uncertainties arose, these were addressed through further discussion to ensure

XSL•FO
RenderX

clarity and agreement on the coding process. Due to the differences in background and expertise of DvdG and FM, these discussions were conducted in a manner that allowed for as objective an evaluation as possible.

Ethical Considerations

This study was approved by the Medical Research Ethics Committee Brabant, the Netherlands (#NL78436.028.21) and the Ethical Review Board of Tilburg University (School of Social and Behavioral Sciences), the Netherlands (#TSB_RP70). Participants signed informed consent upon enrollment in the RCT that included the interview component. Participants did not receive financial compensation for participating in either the interview or the RCT. Only anonymized data were used in the study. Each participant was given a participant number. This number was kept in a secure password-protected document along with the necessary personal information (name, date of birth, email address, date, and time of interview). Only DvdG had access to this file. For all elements of subsequent procedures, including audio files, transcription, and coding, participant numbers were used. This means that no personal information was available in the transcription and analysis process.

Results

In total, 13 patients participated. However, 1 participant was excluded because of cognitive problems. This eventually resulted in 12 participants, of which 67% (n=8) were female and 33% (n=4) were male. Of these participants, 58% (n=7) were part of the guided ACT group, while 42% (n=5) were part of the WLC and therefore did not receive guidance. In total, 9.3% (n=112) of the participants from the RCT took part in this qualitative study. Participant characteristics are provided in Table 4. Characteristics regarding intervention and usage are presented in Table 5. Interviews lasted 20-30 minutes.

Results can be divided into 2 overarching themes: barriers and facilitators to engagement. Furthermore, 7 codes emerged from the data for barriers and 10 codes for facilitators. An overview of all strategies is presented in Table 6. While the exact numerical values are not the main focus, the table illustrates the facilitators and barriers that were more or less commonly experienced by participants.

Barriers

The most common barrier identified was the program schedule. Many patients indicated having insufficient time for completion:

> *I did find 8 weeks of training too tight. … Especially with the effects of cancer, you do have days when you feel bad. And now you had to keep going because of the time frame.* [P2]

Furthermore, many patients indicated that the timing was unfavorable due to personal schedule or holidays.

> *I suddenly had to start, but you have to be able to plan ahead. By then a week had passed. That made me feel rushed.* [P3]

> *We spent about three weeks on vacation during that period. That also takes you out of it and makes it harder to get going again.* [P12]

Another barrier mentioned by several patients was the overall burden of the intervention. Some patients indicated that it was confronting to work on the training:

> *You do also get into a deeper layer. I had a bit of a problem with that, too. … I became aware of something of which I thought 'oh I left that behind me a long time ago'.* [P3]

Also, some patients indicated physical limitations or cognitive limitations due to chemo brain:

> *Because I have some cognitive impairments, processing is difficult. I understand it, but I also forget it very quickly, so I have to go back often.* [P10]

Burden is also related to remembering to attend the training during the intervention period, as indicated by some patients:

> *At the end I ran out of time, also a little bit due to my chemo brain. Then I forget I'm doing that training.* [P11]

Many patients indicated barriers related to guidance. Several patients who did not receive guidance expressed a need for some form of guidance to be able to ask questions:

> *Sometimes I had questions and then I couldn't ask those questions. … Sometimes I found that quite difficult.* [P5]

Some other patients indicated that they would have preferred guidance for motivation or reminders:

> *It would have helped if once a week or so there was an email with: 'Is it all working out? Do you have any questions? This is the end date when you should be finished.'* [P11]

Furthermore, 1 patient who did receive guidance indicated that the delivery of guidance (ie, by email) was not as required:

> *...ie, enjoy talking [verbal communication] to someone and then you also get more motivation from them. Like: the coach comes into play, and I have to do well.* [P6]

Furthermore, several patients indicated that irrelevant content was a barrier. This meant that some patients experienced no connection to their own situation:

> *What I always find difficult is when it comes to your partner. I am a mother with adult children who is divorced and who lives alone. I can't do anything with examples related to partners.* [P2]

In addition, some patients indicated that they were already familiar with the content:

> *Well I have found that I do a lot of things already. A lot of things were not new to me.* [P5]

Several patients reported experiencing barriers related to the included mindfulness exercises. This relates to the length (P7) or quantity (P9) of mindfulness.

> *All those mindfulness exercises, I did that occasionally but most of it I didn't do. Certainly not the longer exercises.* [P7]

> *I think the training is put together well, but that meditation thing maybe there shouldn't be too much emphasis on that. It does make sense, but not two of those assignments.* [P9]

Some patients reported experiencing barriers regarding usability. Some patients indicated difficulties navigating through the training:

> *At one point it said, 'look back at how that went'. Then I think 'yeah I'm not going to look back'.* [P9]

Also, one patient indicated that the lack of face-to-face communication was a barrier:

> *The emotion in the communication is not there.* [P1]

Furthermore, one patient indicated problems logging in:

> *There were a few email addresses and then I didn't know exactly how to get to the right address to log in.* [P7]

Finally, barriers were reported by a few patients due to missing content. One patient indicated that the exercises contained insufficient explanation and examples:

> *I found the exercise about the areas of life difficult. … Maybe it would be good to mention in the first exercise 'if you don't get there, you can still do the alternative exercise.'* [P3]

Another patient indicated that they missed the opportunity for peer contact:

> *I would like to hear other people's response. … I think if you are in a group where you also hear what the others are saying, you can have a lot of support from that.* [P5]

Facilitators

A facilitator that many patients mentioned was usability. Several patients indicated benefiting from the flexibility of the training, allowing them to use it at their convenience, pausing when needed:

XSL•FO
RenderX

> *It was nice. Sometimes on the tablet, sometimes briefly on the phone. You can put it away again for a while.* [P12]

Several patients also indicated that the freedom in the training facilitated their use:

> *I could look back. I did that regularly. Then I looked back a few sessions to continue.* [P8]

Also, a few patients indicated that the training was easy to use:

> *I found the course very doable online. It was clear and straightforward. The structure was consistent, and I could find everything very easily.* [P2]

Furthermore, many patients indicated recognition as a facilitator. Several patients indicated that they found recognition in the fictitious personas:

> *I am reminded of the example given in training of a tennis player who had back pain. If he played tennis hard, he would forget the pain. I feel the same way.* [P1]

Several patients also indicated that the examples and personas clarified the information and theory that was provided:

> *When you see practical examples like this, it also indicates how differently you can deal with it. That supports the theory. I really liked that combination.* [P11]

In addition, many patients indicated facilitators related to positive self-management. For several patients, the training was a way to find reflection:

> *Well, for me, the most important thing was the insight that I put a lot of limitations on myself. I knew that, but it went much further than I actually realized.* [P10]

Also, several patients indicated that they appreciated being able to further develop themselves through the training:

> *Here you learned about negative thoughts and what can help you turn that around. I also found that helpful.* [P3]

Furthermore, some patients indicated that they received confirmation of their coping through the training:

> *A lot of things I was already doing. ... It was often just confirmation for me.* [P5]

Many patients indicated the program schedule as a facilitator, which was mainly related to the flexibility of the program schedule. This is mainly related to being able to work on the training whenever and wherever the patient wants:

> *You can grab it at your own time when you have time for it. You just sit down for it and you don't have to leave the house.* [P4]

Some patients appreciated the option to pause or request extensions for the training, particularly during personal circumstances that temporarily hindered use:

> *During the training I found out that the cancer is back. Then I took a break from it.* [P10]

There were also some patients who indicated that they valued being able to make their own choices about completing the exercises:

> *In the mindfulness part, you got these 20-minute sessions, and you got a shorter one. Actually, you were supposed to apply both, but then I backed off. ...Then I chose to do the shorter one.* [P9]

Several patients indicated symptom management as a facilitator. Several patients felt that participation in training might improve their symptoms:

> *I've tried quite a bit to combat neuropathy and anything I come across is welcome to me.* [P1]

Furthermore, some patients indicated that they liked getting tips:

> *I had gotten tips from you guys that I could just apply to that as well. That generally works pretty well I must say.* [P12]

There were also some patients who experienced psychoeducation as a facilitator:

> *I often really enjoyed reading about the theory about mechanism of a human being of why we do things and what the effect is if you choose to avoid the pain. I found that very useful to read.* [P11]

Finally, certain elements in the training were identified as facilitators by several patients. Several patients indicated that the relevance of the training was a facilitator because this made it possible to apply the training to one's own situation:

> *It was relevant because I do have the symptoms. Regardless of where they come from. … The complaints are there, and you only refer to them.* [P10]

Furthermore, several patients liked the option for guidance for various reasons, such as motivation, clarification of information, and feedback:

> *I really liked that I had that online guidance. ... That does keep it going. I knew she [guide] would respond every Friday, and I would fill in some things in advance.* [P3]

In addition, several patients indicated that they experienced both experiential exercises (P5) and mindfulness exercises (P8) as facilitators.

> *Yes, I liked those because then you get to know yourself better and you see what you are doing.* [P5]

> *Especially that 4 min breathing exercise where you focus on breathing in and out and where the air goes. I sometimes did it in bed at night after completion of the training, because the neuropathy is more pronounced then.* [P8]

Content related to value-based living was also perceived by several patients as a facilitator:

> *You never think about that so much. You get sucked into all the things that maybe you don't feel like doing. This made you look at: 'What are your values? What*

XSL•FO
RenderX

do you like to do? What are the things that are important to you?' That impressed me. [P9]

Discussion

Principal Findings

This study qualitatively examined barriers and facilitators to engagement of an online self-management intervention for cancer survivors with chronic painful CIPN. Participants generally reported more facilitators than barriers. Facilitators most often related to the perceived ease of use of the intervention, feelings of recognition and validation, the opportunity to actively engage in self- and symptom management, and a favorable program schedule. In contrast, commonly reported barriers included an unfavorable program schedule, perceived burden, lack of guidance, and content irrelevance. Notably, some factors, such as the program schedule, were described both as facilitators and barriers, underscoring the influence of individual preferences and circumstances. Factors seem to include a combination of mainly psychological, intervention-related, and technology-related characteristics. Furthermore, certain aspects are related to illness or individual circumstances. These findings align with previous research on barriers and facilitators [17,18], as well as theoretical frameworks like the conceptualization of engagement in digital behavior change interventions [7,12].

This study revealed that many patients felt a strong sense of recognition in the online intervention, which is likely related to the inclusion of quotes and personas added to make the program more personal, which were based on real patient experiences [21,30,31]. These patient experiences, depicted in a first-person narrative, can contribute to the feeling of social support that can help alleviate feelings of isolation for patients in coping with symptoms [32-34]. However, patient experiences shared by individual users may contain unbalanced information or misinformation [35]. In this online intervention, therefore, researcher-written narratives based on experiences shared by patients were incorporated. This can be seen as an accessible and controlled way of incorporating patient experiences in online interventions to increase the sense of social support.

Furthermore, this study has shown that many patients perceived participating in the online intervention as a pleasant way of engaging in positive self-management. Self-management empowers cancer survivors to enhance their health and well-being [36]. Previous research has shown that theoretically based self-management interventions for various types of chronic diseases, including cancer, can positively influence outcomes such as quality of life, coping, health goals, self-regulatory skills, and self-efficacy [36-39]. Self-efficacy for symptom management in patients with cancer is defined as "the ability to implement behaviors to prevent, recognize, and relieve symptoms" and is a vital component in enabling patients to effectively self-manage their cancer-related symptoms [40,41]. Self-efficacy empowers patients to change their self-management behaviors and helps patients set realistic goals in coping with the symptoms [40,42]. This closely aligns with the acceptance of symptoms and the pursuit of a value-driven life, which reflects the ACT-based approach of the online intervention used in this study. This alignment may help explain why active engagement in positive self-management and symptom management emerged as a frequently reported facilitator in this study.

While for many patients, the flexibility of the training program was a facilitator, many patients experienced the training program as a barrier. In this case, this is related to both unfavorable start time and insufficient time to complete the training due to personal situations, in the context of the study. This aligns with previous studies regarding the use of online psychological interventions, which have shown that time-related factors (eg, not having enough time or being too busy) deteriorate adherence and engagement [15,17,43]. It is important to mention that in this study, the start of the training was not aligned with the participants in advance. In the study, participants received an invitation at the start, and had 8 weeks for completion, which was only extended upon request. Based on this study's results, it is recommended to initiate online interventions in coordination with participants. In addition, it is suggested that the intervention's total duration is sufficiently long, incorporating several weeks of flexibility in scheduling (eg, 9 weeks for an online intervention with 6 components). It can also be considered to allow unlimited access to the intervention. We also recommend that participants be encouraged to contact the contact person or supervisor of the online intervention if they encounter problems, so that it can be assessed when an extension of access is needed to avoid dropout.

Furthermore, barriers identified in this study included the burden and chemo-brain that patients may suffer from. Chemo-brain is known to be a consequence of chemotherapy, which is characterized by self-perceived thinking and memory problems [44]. In this study, for example, patients reported that the training was too stressful or that they had concentration problems. However, this does not only apply to chemo-brain, but also to other physical and mental symptoms caused by cancer or cancer treatment, which causes people to have more difficulty performing daily activities. These may include fatigue, which increases the need for more frequent breaks, or disease-related fear, which may make individuals more vulnerable and prone to heightened feelings of fear in general. Thereby, having a higher age with additional physical and cognitive challenges, which is often the case in cancer survivors, can make this more difficult. Therefore, a low cognitive effort of the online intervention is necessary for proper understanding of the content and effective use [45]. This can be achieved by dividing the intervention into short, manageable sections to reduce the complexity on the pages and to provide simple navigation between pages and sections [45]. Patients also indicated that they valued the ability to schedule the use of the intervention within the provided time frame of the training themselves, as well as the ability to pause when needed, which has also been shown in previous qualitative research regarding computerized CBT for depression [46]. This is also relevant for personal situations of participants, for example, in case of receiving a new cycle of chemotherapy treatment during the intervention period. During the study, it became evident that not all participants were fully aware of this optional flexibility in the schedule. For instance, 1 participant did not report

XSL•FO
RenderX

receiving a new cycle of chemotherapy, which ultimately limited her time to complete the intervention due to restricted access, as a modified schedule had not been discussed. This also applied to, for example, holidays or family issues, which aligns with earlier research [11]. Given the complex circumstances participants often encounter, it is essential, in addition to providing an intervention that considers factors such as breaks and division into manageable sections, to engage in dialogue with users to identify an approach that aligns with their individual needs, ensuring the intervention is as adaptable as possible.

In terms of guidance, patients who had access to it indicated finding it valuable, despite not all of them using it consequently. Among those without access to guidance, some expressed a clear need for it. For example, these patients would have appreciated the opportunity to ask questions for clarification on information or exercises, as well as to discuss personal circumstances that made engaging with the online intervention more challenging. Previous research has shown that online interventions with guidance compared with nonguided versions result in better outcomes in satisfaction, usage, and adherence [19,20,47]. Also, an earlier study examining a self-guided online CBT intervention for patients with CIPN suggests that counseling could be a useful addition [1]. However, a systematic review examining engagement with online psychological interventions found that preferences for guidance varied greatly, ranging from a need for intensive support to enhance engagement to a preference for no guidance to maintain anonymity and freedom [15]. Therefore, offering optional guidance rather than mandatory support appears to be recommended.

Limitations and Strengths

Some limitations of this study should be mentioned. First, no results were available from patients with very low engagement levels, since these people were reluctant to participate in interviews. Several attempts were made to include these patients, but despite these efforts, they remained unwilling to take part, and some potential respondents did not respond at all. It was not possible to engage in discussions with individuals who were dissatisfied or who had discontinued participation prematurely, suggesting that this group was unwilling to discuss their experiences with us. The sample in this study is therefore not representative of the entire user group. Barriers that might exist with low-engaged patients, such as lack of time and low levels of motivation [15,17], were therefore not completely reflected in this study. Furthermore, people with low levels of use might also comprise patients who realized they were already proficient in managing their symptoms and consequently discontinued the intervention. Unfortunately, obtaining insights into this matter was not possible because these patients did not participate in the interviews. Therefore, the results of this study must be interpreted with caution. Second, there was a lot of difference in the time between intervention completion and the interview. Possibly, patients with a longer period between the intervention and interview may have remembered fewer details of their experience with the intervention, which could have also affected the results of this study. Third, the results of this study may be less applicable to other self-management interventions. Each intervention has its characteristics in terms of tasks, technology, and users, all of which affect ultimate use [7,48-50]. Consequently, the experiences encountered by patients also vary. Fourth, the study sample included highly educated and highly motivated patients who experienced little or no difficulty with language and the use of technology. Therefore, the transferability of the results to groups with lower education levels and lower technology literacy levels might be limited. Fifth, no participant checks were performed because of the possible burden on patients. However, in terms of validating the results, it is desirable to perform participant checking in future studies.

Some strengths should also be emphasized. First, interviews were semistructured, enabling patients to freely express their individual experiences without being constrained by the interview's format. The core questions were addressed in all interviews, leading to a consistent structure across all interviews. Second, interviews were conducted with patients from all conditions, including both those who received therapeutic email guidance and those who did not. This enabled the assessment of the experienced barriers and facilitators associated with the availability or unavailability of guidance. Third, interviews took place via video call, enabling vulnerable and disabled patients with cancer to participate without being hindered by, for example, physical limitations.

Conclusions

This study qualitatively identified facilitators and barriers to engagement in an online self-management intervention for cancer survivors with chronic painful CIPN. Facilitators and barriers varied greatly and were dependent on personal situations. Recommendations could be given in terms of recognition, program schedule, burden, and guidance. Consideration of such recommendations following qualitative evaluations is imperative to ensure careful implementation in practice.

Abstract

Background: Systematic symptom management is a crucial component in patient-centered cancer care. Despite the development of numerous electronic patient-reported outcome measure (ePROM) tools, integrating these tools into clinical practice remains challenging. Engaging key stakeholders, including patients, in the development of ePROM tools is pivotal to fostering the adoption of such tools. As part of an innovation and implementation study aimed at enhancing efficiency and patient-centered care (PCC) through the development of digital PCC pathways, we explored the perspectives of patients with cancer on current clinical practice regarding symptom management and PCC, as well as their needs and preferences related to ePROMs.

Objective: This study aims to explore the perspectives of patients with cancer on PCC and symptom management, including their experience with current clinical practice and their views on how ePROMs might enhance patient-centered follow-up.

Methods: A 2-stage qualitative design was used. In stage 1, semistructured individual interviews were conducted to gain an in-depth understanding of patients' experiences with current clinical practice, including perceived challenges and unmet needs. Stage 2 involved structured interviews to further explore patients' perspectives on the potential role of ePROMs in enhancing patient-centered follow-up.

Results: A total of 10 patients were included in the study, participating in either or both stages. Two main themes were developed through a reflexive thematic analysis process: (1) symptom management in the shadow of disease-centered care, and (2) ePROMs: bridging holistic care and disease management. Theme 1 highlighted how patients made sense of symptom management within a health care context primarily focused on disease treatment and progression. Their narratives revealed that biomedical concerns often dominated clinical encounters, while patients' broader lived experiences and symptom-related needs were marginalized. Patients shared an understanding that it was their own responsibility to redirect the focus of clinical consultations toward symptoms. While they generally expressed satisfaction with the care received, they also described a sense of unmet needs that remained unaddressed. The second theme explored how patients made sense of the potential role of an ePROM tool in supporting more patient-centered cancer care. Their accounts revealed both perceived barriers and facilitators to its use, shaped by the expectations and needs that contrasted with current clinical practices. Central to this was a belief, emerging through engagement with the conceptual tool's functionalities, that it could enable a more holistic approach to care, extending beyond physical symptom to encompass the lived experience of cancer.

Conclusions: Patients often felt personally responsible for ensuring that their symptoms were addressed, indicating shortcomings in follow-up and communication. ePROMs were identified as a promising tool to strengthen PCC by amplifying patient voices and enabling more holistic and responsive follow-up. Integrating ePROMs into routine care may improve symptom visibility, foster shared understanding between patients and health care professionals, and support more equitable care delivery.

Introduction

Patient-centered care (PCC) has emerged as a critical component of high-quality cancer care. PCC is an approach to health care that prioritizes individual patients' preferences, needs, and values, ensuring active involvement in all treatment and care decisions [1]. Previous research has shown that PCC improves patient well-being, satisfaction with and quality of care, self-efficacy, and trust toward health care professionals (HCPs) [2,3]. Despite extensive knowledge about the benefits of adopting a PCC approach, cancer care remains predominantly tumor-centered, with a primary focus on diagnostics and treatment [4,5]. This narrow focus often limits attention to the broader needs and experiences of the patient.

A central component of PCC is the systematic assessment of symptoms. Effective symptom management can enhance quality of life (QoL), facilitate early symptom detection, and may even contribute to improved overall survival [6]. Traditional cancer care, however, has primarily focused on curing the disease or controlling its progression, often at the expense of recognizing and addressing the broader symptom burden experienced by patients. Moreover, previous research suggests that symptoms are frequently undetected or underestimated by HCPs [7,8]. Discrepancies between clinician-reported and patient-reported symptoms have also been identified [9,10], alongside a tendency for patients to underreport their symptoms [11]. Therefore, strengthening PCC by prioritizing symptom assessment alongside conventional clinical treatment is of vital importance, as it facilitates a more holistic and patient-centered approach to cancer care. Actively involving patients and implementing systematic symptom management are, thus, essential strategies for achieving PCC in oncology.

Patient-reported outcome measures (PROMs) enable the direct collection of data regarding patients' health status, including symptoms, QoL, and nutritional status [12]. Prior research indicates that PROMs enhance patient empowerment by fostering self-reflection, supporting individualized treatment, and facilitating shared decision-making [13]. When used in clinical practice, PROMs can bolster self-management and satisfaction with care and facilitate more effective patient-clinician communication [14-16]. In addition, PROMs can help identify supportive care needs and address sensitive or unexpected concerns [17-19]. Recent digital advancements have facilitated the development of numerous electronic patient-reported outcome measures (ePROMs), which have the potential to enable more efficient and accurate data collection from patients [20]. ePROMs can enhance data integrity, demonstrate cost-effectiveness, reduce administrative workload, and facilitate comparable or expedited completion times [21,22]. In addition, patients report high acceptability and satisfaction when using ePROMs, both in routine care and research settings [14,23].

Although the use of ePROMs in cancer care is increasing, there remains limited knowledge about how patients' perspectives on PCC and symptom management can inform the development of these tools. Further research is needed to understand how ePROMs can be designed to reflect patients' values and needs and to support more patient-centered follow-up in clinical practice. Moreover, understanding how ePROMs are implemented and used in clinical settings is essential for ensuring the development of tools that contribute meaningfully to the delivery of PCC in oncology. Therefore, this study aims to explore the perspectives of patients with cancer on PCC and symptom management, including their experiences with current clinical practice and their views on how ePROMs might enhance patient-centered follow-up. The insights gained will inform the development and implementation of ePROMs that are relevant, feasible, and meaningful in real-world clinical settings.

The aim was addressed through the following research questions: (1) What are the experiences of patients with cancer regarding symptom management and PCC in outpatient cancer treatment and care? (2) What are the perspectives of patients with cancer on the perceived usefulness of ePROM tools in enhancing PCC, and what factors influence their willingness to use such tools?

Methods

Design

A 2-stage, qualitative design was adopted [24]. In stage 1, semistructured individual interviews were conducted to gain an in-depth understanding of patients' experiences with current clinical practice, including perceived challenges and unmet needs. In stage 2, structured interviews were carried out to further explore patients' views on the potential role of ePROMs in enhancing patient-centered follow-up. This approach enabled a nuanced exploration of both experiential and evaluative dimensions [25,26], offering valuable insights into how ePROMs might be designed and implemented to more closely align with patients' values, needs, and expectations.

Setting

The study presented in this paper was conducted as part of the Norwegian MyPath-MATRIX project. Details of the main project have been published elsewhere [5,27]. In short, this project is a subproject of the MyPath-EU project, a multicenter, international implementation study funded by the European Commission [28,29]. The MyPath-MATRIX project aims to enhance PCC by developing and implementing PCC pathways supported by health and information technology (digital PCC pathways) at 3 oncology outpatient clinics in Norway [27]. One part of the care pathways is to assess patients' symptoms and functioning through an ePROM tool.

XSL•FO
RenderX

A pivotal component of the digital PCC pathways is the systematic collection of information from patients regarding 6 core areas: pain, fatigue, nutrition, physical function, social function, and psychological distress [28]. Building on the previously used computer-based symptom assessment tool, Eir software (NTNU and St. Olavs Hospital) [30,31], the MyPath ePROM tool is currently under development to support personalized follow-up in cancer care. The tool is designed to assess patients' well-being, symptoms, and functioning, including nutrition and psychological aspects. It uses an adaptive format: based on patients' initial responses, it generates tailored follow-up questions to ensure a comprehensive and personalized assessment, thereby facilitating targeted interventions and support [29]. In this study, participants were presented with a conceptual version of the MyPath ePROM tool during the second interview stage. The tool was introduced using a PowerPoint presentation containing screenshots that illustrated the tool's interface, example questions, and response options. This allowed participants to visualize how the tool might function in practice and to provide feedback on its content, design, and perceived usefulness in supporting person-centered follow-up in cancer care.

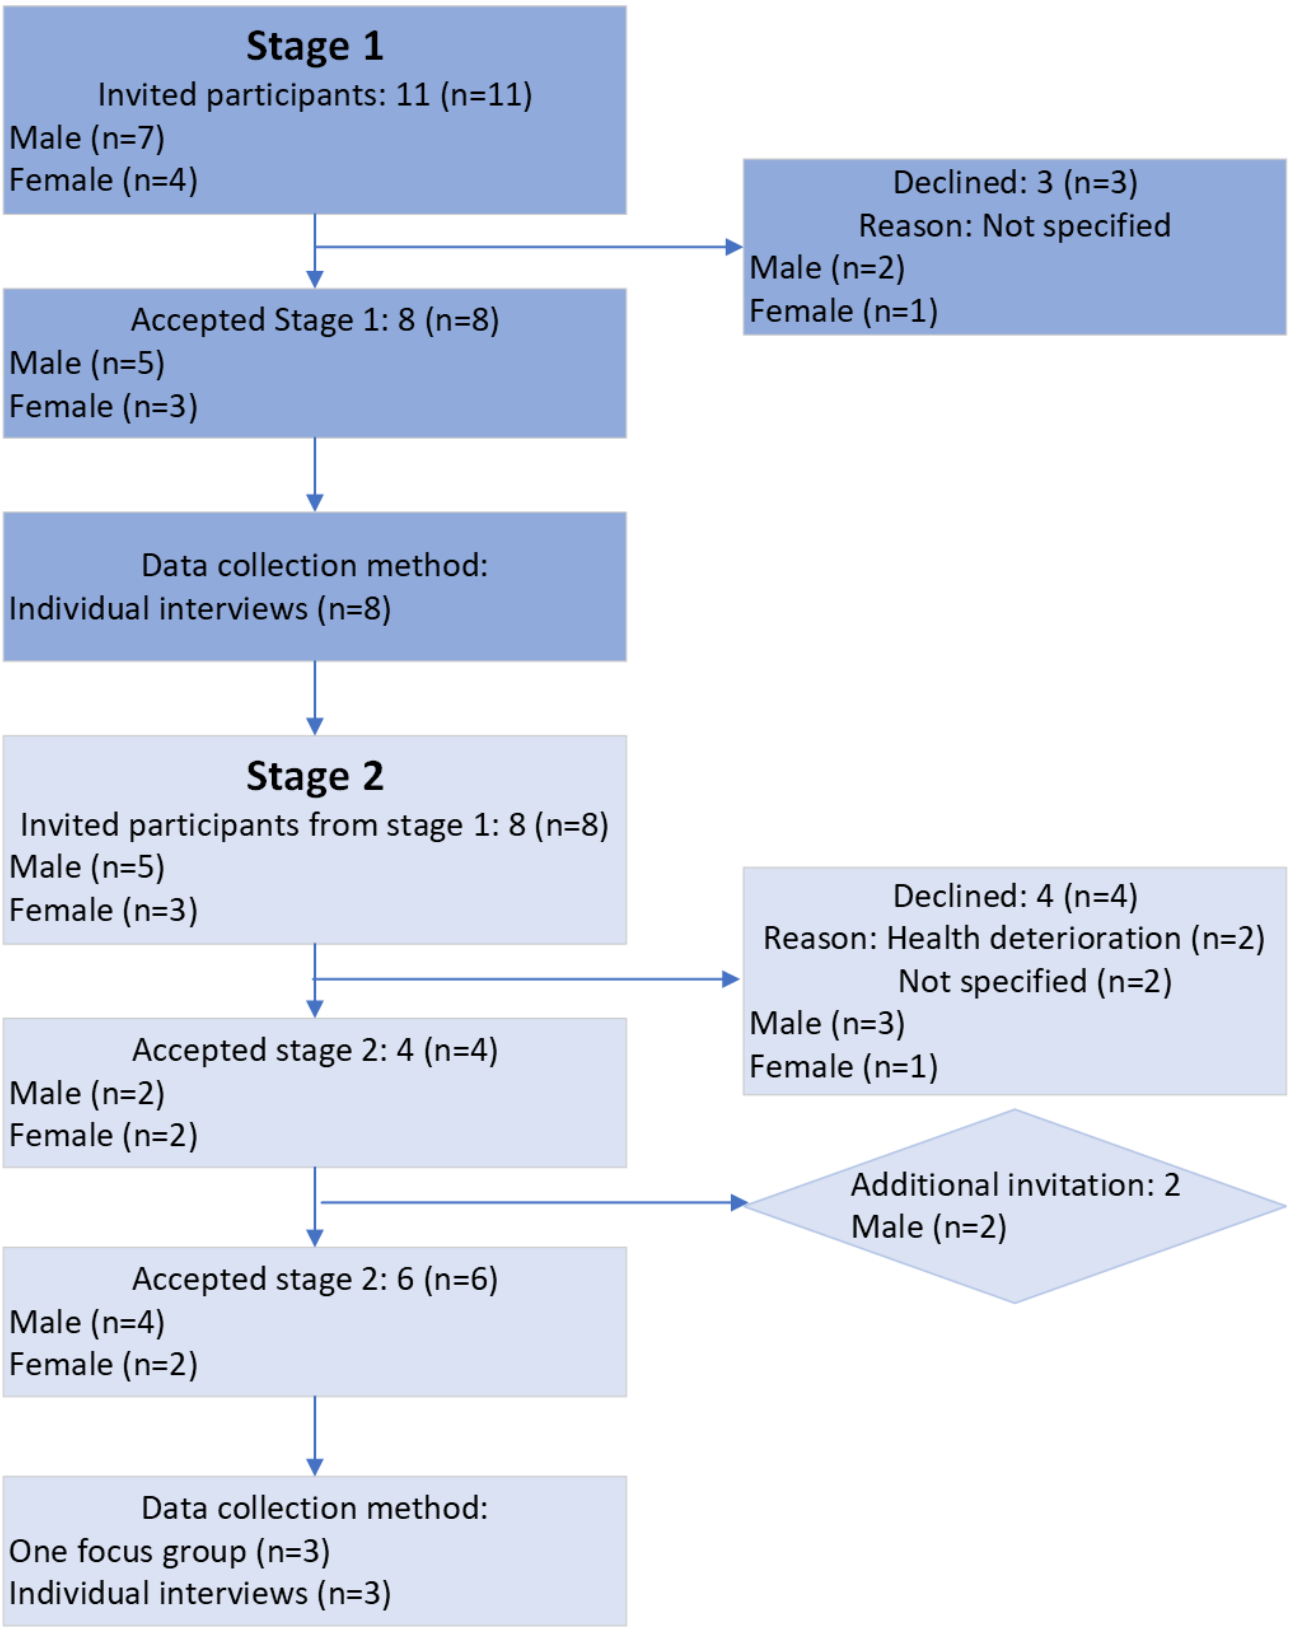
Recruitment

All participants were recruited using a purposeful sampling strategy [24] based on specific inclusion and exclusion criteria (Textbox 1). Six oncologists from 2 oncology departments in Norway (4/2) were asked to identify patients who met the eligibility criteria. Their role was limited to distributing information sheets to these patients and asking whether they would be willing to be contacted by the researcher (TSS). The oncologists did not participate in the recruitment process beyond this initial step.

Textbox 1. Inclusion and exclusion criteria for adult patients with cancer participating in a qualitative study conducted at 2 Norwegian hospitals.

Inclusion criteria

- Age: ≥18 years
- Gender: All
- Medical care: Undergoing active chemotherapy or having one of the following cancer diagnoses: gastrointestinal or urologic
- Scope of treatment: Curative and palliative
- Language: Norwegian, spoken and written
- Consent: Able to provide informed consent



Exclusion criteria

- Patients who, due to their health conditions, were deemed too frail or ill to participate in an approximately 60-minute interview

In stage 1, 11 patients agreed to be approached for inclusion in the study. Of these, 8 agreed to take part. In stage 2, the 8 participants from stage 1 were invited to continue. Four consented to further participation, while the remaining 4 declined. To ensure sufficient data for stage 2, an additional 2 participants were recruited, resulting in a total of 6 participants in the second stage. In total, 13 patients consented to be contacted, and 10 patients ultimately participated in at least 1 stage of the study (Figure 1). Among these, 3 were women and 7 were men. The mean age was 65 years, ranging from 48 to 73 years.

XSL•FO
RenderX

Figure 1. Flowchart of participant inclusion and progression in a 2-stage qualitative study. The study was conducted among adult patients with cancer receiving curative or palliative treatment at 2 Norwegian hospitals between February and September 2024. Data were collected in 2 stages through individual interviews and 1 focus group. The figure illustrates participant inclusion, gender distribution, declined participation, and allocation to stage 1 and stage 2.

Data Collection

Stage 1 focused on exploring patients' experiences with symptom management and PCC. Eight individual interviews were conducted using a semistructured interview guide. The interviews lasted between 33 and 86 minutes (mean duration 56 minutes). The guide was designed to allow flexibility in

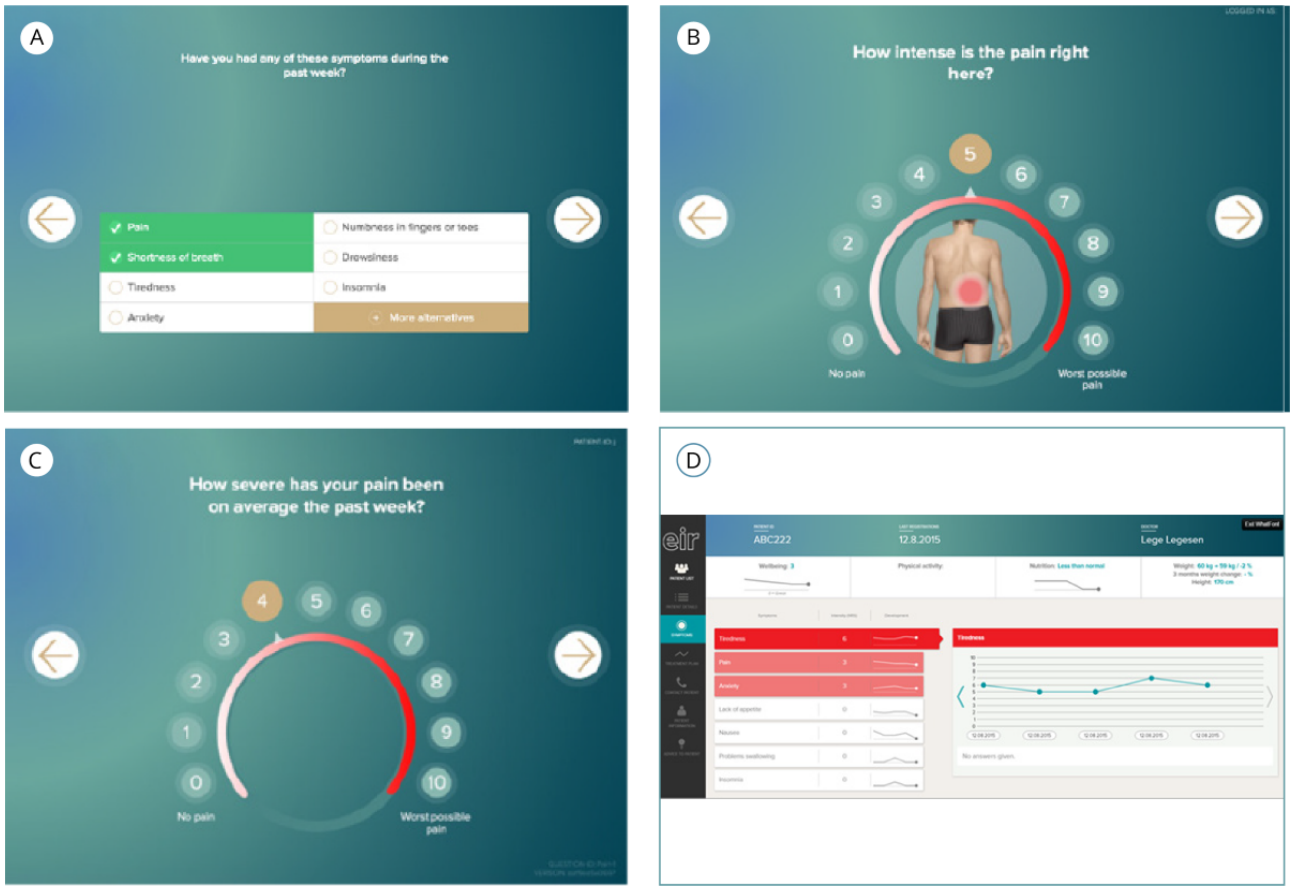
XSL•FO
RenderX

questioning, enabling the interviewer to adapt follow-up prompts based on each participant's responses [32].

The interview guide comprised three overarching themes, each explored through open-ended questions: (1) patients' experiences with PCC, (2) current practices in symptom follow-up, and (3) perspectives on the use of a digital tool to support symptom management and PCC. Follow-up questions such as, "Could you give an example of what you just mentioned?," or "Could you elaborate on what you mean by...?" were used to encourage deeper reflection and elaboration. This approach facilitated the generation of rich, nuanced data on participants' lived experiences and expectations [33]. The guide, including key themes and primary questions, is available in Multimedia Appendix 1.

In stage 2, data collection was initially planned to include focus group (FG) discussions; however, due to participants' reluctance to attend sessions outside of their already scheduled clinical appointments, only 1 FG was conducted (n=3). In addition, 3 individual interviews were carried out. The FG lasted 106 minutes, while the individual interviews ranged from 56 to 71 minutes. In stage 2, patients were presented with a conceptual version of the ePROM tool, comprising preliminary visual representations of proposed content and functionalities. This version was not intended for clinical implementation but served as a prototype to facilitate discussion and elicit feedback on design elements, usability, and relevance. The materials were used to prompt reflection on participants' needs and preferences and to assess the perceived value and usefulness of such a tool in their care context.

The interview guide used in stage 2 was structured, in contrast to the semistructured format used in stage 1. It was designed to align closely with the visual materials presented during the interviews, enabling a focused exploration of participants' responses to specific features and concepts. Topics included perceived needs and preferences for digital symptom–reporting tools, as well as feedback on the design, content, and functionality of the proposed ePROM interface.



The increased specificity of the guide, combined with targeted follow-up questions, facilitated deeper insights into participants' perceptions and expectations. These insights were subsequently incorporated into the MyPath-MATRIX project to inform ongoing tool development. Selected excerpts from the visual materials are shown in Figure 2A-D. The complete interview guide, including all questions but excluding the visual content, is available in Multimedia Appendix 2.

All interviews were conducted between February and September 2024 at locations chosen by the participants. One interview was conducted via Zoom (Zoom Communications, Inc), 1 took place at the university premises, and the remaining interviews were held in meeting rooms at outpatient clinics. The first author (TSS), an experienced female cancer nurse and PhD student, conducted all individual interviews. The FGs were moderated by the first author (TSS), with the last author (MHM), an experienced female nurse and qualitative researcher, serving as comoderator. All interviews were audiotaped and transcribed verbatim. To ensure participant anonymity, transcripts were deidentified by the first author (TSS) using unique participant codes. Participants who took part in both stages 1 and 2 were assigned the same participant codes; however, interviews conducted in stage 2 were marked with "S2" to distinguish them. Any potentially identifiable information was removed during the transcription process [25].

As this study used reflexive thematic analysis (RTA), the concept of data saturation was not used to determine sample size or to guide the conclusion of data collection [34]. Instead, data collection was concluded based on the richness and diversity of the material, alongside practical considerations related to participant availability and the overall study design.

Figure 2. Excerpts from the visual presentation of the conceptual electronic patient-reported outcome measure tool presented to patients in stage 2. (A) Example of symptom selection interface allowing patients to indicate various symptoms; (B) Example of pain mapping including localization and intensity (scale 0 - 10), where each marked pain location is assessed individually; (C) Example of symptom rating (here: pain) on a numerical scale from 0 to 10, performed by rotating a virtual wheel; (D) Overview screen for health care professional following completion of the patient's symptom assessment.

Data Analysis

The data were analyzed as 1 dataset using RTA as described by Braun and Clarke [35,36]. The 6 steps in RTA guided the transition from data engagement to coding and theme development. The process was iterative, moving back and forth between different phases, rather than being a linear progression from start to finish [35].

In the first phase, the first author (TSS) immersed herself in the data by listening to the audiotaped interviews and thoroughly reading and rereading all transcripts. In the second phase, the first author (TSS) coded all data systematically using NVivo (version 14; QRS International). We adopted an inductive, data-driven approach, openly coding the data and identifying meaningful units from the participants' responses. During this phase, the first and last authors (TSS and MHM) worked closely together, engaging in discussions to review, rename, and create new codes when necessary to better capture the data's nuances. Data extracts that reflected nuanced aspects of patients' perspectives and experiences were selected and interpreted to support theme development [35]. As the focus shifted from codes to themes, the analytic process continued with the first author (TSS) clustering multiple codes to generate initial themes and patterns across the entire dataset. Three authors (TSS, MHM, and TL) engaged in in-depth discussions about the created codes, clusters, and initial themes to explore potential shared meanings within the collected data [35]. In the fourth phase, we engaged in an iterative and reflexive process of moving between data extracts, the full dataset, and the developing themes. This process facilitated the identification of patterns of shared meaning across participants, allowing us to construct themes that captured nuanced understandings of symptom management, PCC, and the perceived role of ePROMs in enhancing patient-centered follow-up. Preliminary themes were discussed multiple times, leading us to reorganize and refine them to enhance their richness, coherence, and distinctiveness [35]. Thematic maps were created for each theme, supporting the visualization of the analytic narrative, including connections and boundaries within and between themes, and clarifying the overall thematic structure [35]. In phase 5, themes were refined, defined, and named. The first author (TSS), in close collaboration with all authors, wrote an abstract for each of the 2 final themes, which further developed the analysis. The themes were then reviewed and validated by the entire team to ensure accuracy and coherence. In the final phase of analysis, the first author (TSS) wrote the report, with all authors providing critical input.

Ethical Considerations

Participants received both written and oral information about the study prior to providing written informed consent [37]. This included details about the study's purpose, as well as how interview data would be securely stored and anonymized.

XSL•FO
RenderX

Participants were also informed about the researchers conducting the interviews, including their professional backgrounds and current institutional affiliations. Anonymization was carried out during the transcription phase, where each participant was deidentified using a unique code. Only the interviewers (TSS and MHM) have access to participants' identities. To further ensure privacy, all information that could potentially identify individuals, such as departmental affiliations, names of medical personnel, and other contextual details, was anonymized. Transcriptions and audio recordings are securely stored on servers approved for handling sensitive research data. All procedures complied with established ethical standards for research involving human participants [38]. The MyPath-MATRIX project was submitted to the Regional Committees for Medical and Health Research Ethics (REK) but was deemed to fall outside the scope of REK's mandate (REK Sør-Øst/633827). This study received ethical approval from the institutional Data Protection Officer at both sites. No participants received any compensation for their participation.

Results

The analysis led to the development of 2 main themes, with a total of 5 subthemes (Table 1).

Table . Overview of the thematic analysis process, following Braun and Clarke's reflexive approach [35].[a]

Theme and subtheme	Refined codes (excerpts)
Symptom management in the shadow of disease-centered care	
Patient responsibility and reluctance in symptom reporting	• Responsibility for symptom reporting placed on patients • Patients do not expect proactive inquiry from clinicians • Avoiding symptom disclosure to not "nag"
Perceived quality of care versus unmet needs: a paradox	• Absence of structured symptom assessment routines • Feeling that essential needs are unmet • Open-ended questions are asked but not always sufficient
Side effects—a necessary evil	• Side effects are expected and normalized • Life after cancer is changed • Enduring side effects as necessary for survival
ePROMs:[b] Bridging holistic care and disease management	
ePROMs—a conceptual facilitator for holistic focus	• Heightened awareness of psychosocial and emotional needs • ePROMs—A facilitator to ease the burden of remembering • ePROMs support holistic self-reporting
Perceived challenges—a barrier to utilization	• Perceived value of ePROMs depends on HCP[c] engagement • Difficulty assigning numerical values to symptoms • Digital tools must be quick and easy to use

[a]Overview of theme development based on interviews and 1 focus group, with patients with cancer receiving curative or palliative care. The first column presents the themes, constructed through interpretive engagement with the data, and the subthemes, representing patterns of shared meaning across data extracts. The second column provides excerpts of refined codes, which were developed and adjusted following reviewer's feedback to better capture the conceptual meaning of the data.

[b]ePROMs:electronic patient-reported outcome measures.

[c]HCP: health care professional.

Theme 1: Symptom Management in the Shadow of Disease-Centered Care

Overview

This theme captures how patients in the study made sense of symptom management within a health care context primarily oriented toward disease treatment and progression. Their accounts revealed that regular consultations tended to focus on the biomedical aspects of cancer, while symptom management and broader experiences of living with cancer were often overlooked or marginalized. A shared understanding emerged among patients that it was their own responsibility to redirect the focus of consultations toward symptoms and concerns. This was evident in how they described prioritizing these issues during clinical consultations. We conceptualized this aspect as a subtheme of Theme 1, titled "Patient Responsibility and Reluctance in Symptom Reporting."

A second subtheme, "Perceived Quality of Care Versus Unmet Needs—A Paradox," illustrates how patients expressed feeling adequately supported and cared for by HCPs. This sense of being well looked after appeared to reduce their expectations for symptom-focused follow-up. However, their accounts also revealed that this sentiment coexisted with an awareness of unmet needs, particularly regarding aspects of their experience that extended beyond the disease and its treatment.

The third subtheme, "Side Effects—A Necessary Evil," reflects how patients distinguished between treatment-related side effects and symptoms of the cancer itself. While side effects were acknowledged and often discussed in clinical encounters, symptoms not directly linked to treatment were less frequently

XSL•FO
RenderX

addressed. This contributed to a shared understanding that such symptoms were an inevitable part of living with cancer and not something they could expect support for.

Subtheme 1: Patient Responsibility and Reluctance in Symptom Reporting

This subtheme reflects a shared understanding among patients that initiating conversations about symptoms was largely perceived as their own responsibility. This sense of responsibility was shaped by the open-ended questions posed by HCPs, which placed the burden on patients to determine what to disclose. Patients described how this dynamic contributed to a reluctance to report symptoms unless they were clearly linked to treatment or directly inquired about.

> *You can go into absolutely everything. Both mental and physical. [...] Because it's quite an open question you get about how things are going. Then it's really up to me to address [the various symptoms and ailments].* [#P7]

Meetings with HCPs, particularly consultations with physicians, were often brief and focused on disease progression as indicated by imaging results or other tests. This focus reinforced the perception that symptoms not directly related to treatment were outside the scope of clinical concern. Moreover, it contributed to a pattern in which patients managed many aspects of their symptom burden independently and sometimes expressed low expectations that HCPs would address these issues.

> *But I don't quite see why they should do that, in a way? [ask questions about all aspects of having cancer]. Because I handle that myself, so it's fine.* [#P5]

At the same time, patients appeared to protect the limited time available in consultations, often hesitating to raise concerns they perceived as peripheral to the main clinical agenda.

> *We need to be mindful of the physicians' time- we can handle some symptoms on our own.* [#P9]

While many patients viewed the physician's role as primarily focused on diagnosis and treatment, there was a recurring uncertainty about who was responsible for addressing the broader impact of living with cancer, including symptom and side effect management. This uncertainty regarding professional roles was expressed in varied ways. Some patients associated it with not knowing who should maintain a holistic perspective, referred to as "the human aspect," while others raised such concerns sporadically during clinical encounters, leaving it to HCPs to decide whether to engage with these issues further.

Subtheme 2: Perceived Quality of Care Versus Unmet Needs—A Paradox

Patients noted the absence of a systematic focus on symptom management and yet did not interpret this as a shortcoming in their follow-up within specialist health care services. They described feeling well cared for and consistently encountered accommodating and friendly HCPs, which reinforced their confidence in the quality of care. Despite expressing high satisfaction with their treatment and follow-up, patients also conveyed a sense that something was missing, specifically, attention to aspects of their experience not directly related to the disease or its treatment. This created a paradox between the perceived quality of care and their unmet needs.

Despite patients' overall satisfaction with their care, it became evident that unmet needs persisted. A shared sense of gaps in the management of specific symptoms emerged, suggesting that positive and respectful interactions with HCPs, although appreciated, did not fully compensate for the absence of a structured approach to symptom management.

> *The examination of patients who come [to the hospital] must be much more precise. There must be many more questions.* [#P2]

Patients who had consistent contact with the same HCPs conveyed a shared sense that continuity fostered a sense of security and provided a stable framework throughout their care trajectory.

> *Since I've had the same doctor here for so long, we've talked a lot about many different things. Both about a bit of anxiety and… Many things. But of course, if you constantly, or often, have to deal with a new doctor and such. Because then he doesn't know you as well and so on.* [#P1]

In contrast, those who frequently interacted with unfamiliar HCPs expressed that a lack of continuity contributed to feelings of insecurity and made it more difficult to raise personal concerns or discuss broader aspects of their experience.

A shared focus on the physical aspects of having cancer was evident in both participants' accounts and their interactions with HCPs. The psychological aspect, however, was largely absent from follow-up care, contributing to a sense among patients that something was missing. While the biomedical aspects of care were perceived as thorough and effective, patients noted a lack of structured attention to the broader dimension of care, highlighting a gap in the overall support provided.

> *It's just a CT scan. And a blood test. That's it. Nothing else. [...] The healthcare system is good at curing the disease. But they are not good at follow-up afterwards.* [#P10]

SubTheme 3: Side Effects—A Necessary Evil

Across patients' accounts, cancer treatment was consistently associated with considerable side effects that significantly impacted daily life and overall well-being. While these effects were often accepted as an unavoidable part of treatment, they were also described as having a profound impact on QoL, limiting patients' ability to engage in everyday activities.

> *I hardly notice any difference from one day to the next. But I'm terribly short of breath. [...] I try to go for walks and such...but it's all about resting. Resting, resting, resting. [...] Completely different [life than before]. Now it's the end of mountain hikes, that's for sure.* [#P3]

Side effects were commonly framed by patients as something to be tolerated, an unavoidable consequence of treatment that had to be endured. This perspective reflected a shared

XSL•FO
RenderX

understanding of side effects as a necessary evil, closely tied to the belief that enduring them was part of the cost of receiving curative or disease-controlling treatment.

> *Of course, when you take chemotherapy over two days, it does something to me. It does. There's no doubt about it. But it's something I have to face.* [#P6]

Patients' accounts reflected a pronounced emphasis on treatment-related side effects during interactions with HCPs. However, several patients distinguished between side effects and symptoms of the illness itself. This differentiation, reinforced by the clinical focus on side effects, contributed to a shared understanding that symptoms were an inevitable part of living with cancer and, as such, not considered a priority for discussion or intervention.

> *It's not such a big problem, I think, for me. This I can live with. There are things that are much worse. […] it is that I don't want to bother them. That's how it is. But I do bring up things that are more serious.* [#P8-S2]

Among patients who had lived with cancer for an extended period and had encountered others with the disease, a tendency to downplay their own symptoms was evident. This appeared to stem from comparisons with others perceived to be suffering more severely. Such perceptions contributed to a reluctance to raise personal concerns with HCPs, driven by a fear of being a burden or taking up too much of the professionals' time.

Theme 2: ePROMs: Bridging Holistic Care and Disease Management

Overview

This theme explores how patients made sense of the potential role of an ePROM tool in enhancing patient-centered cancer care. Their accounts highlighted both perceived barriers and facilitators to its use. Patients expressed various expectations and needs they believed the tool could help address, often contrasting these with current clinical practices. A central aspect of this was the belief, shaped by the presentation of the tool's functionalities, that it could support a more holistic approach to care, extending beyond the physical consequences of cancer. This perspective is developed in the subtheme "ePROMs—A Conceptual Facilitator for Holistic Focus," reflecting how patients envisioned the tool as a means of promoting attention to the whole person.

Alongside these expectations, patients also identified a range of anticipated challenges related to the tool's use. These perceived challenges, which stood in contrast to the potential benefits they described, are captured in the subtheme "Perceived Challenges—A Barrier to Utilization."

Subtheme 1: ePROMs—A Conceptual Facilitator for Holistic Focus

Patients anticipated that using an ePROM tool could enhance the focus on all aspects of their being. Several described how completing the assessment in advance might help HCPs see them as whole individuals, rather than solely as patients defined by their disease. This expectation was shaped by the presentation of the tool's functionalities and reflected a desire for care that acknowledged emotional, psychological, and social dimensions alongside physical health.

> *[...] to see the person as well. Not just the disease. That is, the cancer thing. And not just be like on a conveyor belt.* [#P4]

Simultaneously, patients highlighted the value of completing the ePROM assessment in the peace and quiet of their home prior to consultations. This opportunity for reflection was seen as contributing to a more holistic sense of care. One patient envisioned that this process could help them be more honest about their own situation, as the use of the tool would shift some responsibility onto the HCP to engage with the full scope of their responses:

> *It might be better to write it down, and then they [HCPs] can bring it up if they think it's worth discussing or not. [...] What I might have kept inside. If I can't say it, then it's... Yes, check it off and sit at home in peace and quiet to do it [...] It's easier to check it off, because then they can maybe see if it's worth discussing or not. They can evaluate it.* [#P8-S2]

In addition, several patients anticipated that the use of an ePROM tool could help bring greater attention to the psychological dimensions of living with cancer. Their accounts reflected a belief that such a tool could legitimize the view that a cancer diagnosis encompasses more than physical illness alone, thereby encouraging a more holistic approach to care.

> *I felt a bit happy when you brought the form [symptom assessment]. Because I felt like, wow. I should have had this from the beginning. Then I could have explained more about what's inside here [points to head]. Not just that they draw blood from your hand.* [#P6]

Patients expressed that they did not expect the tool to require substantial training, instead conveying a sense that its use would be intuitive and straightforward. They also emphasized its ease and efficiency, identifying this as a key facilitator in terms of practical implementation and everyday usability.

Subtheme 2: Perceived Challenges—A Barrier to Utilization

Among some patients, a pattern of meaning was constructed around concerns related to control and timing in relation to illness focus. Digital tools involving prompts or notifications were described as potentially interfering with the ability to choose when to engage with illness. The possibility that these tools might demand attention at unwanted times was seen as a disruption of personal boundaries, making it more difficult to manage when and how illness became present in everyday life. This perceived loss of control contributed to a broader sense that digital tools could increase the focus on illness in daily life, forming a potential barrier to their use:

> *The way it has been until now, it has been a lot of it [focus on the disease]. This [the ePROM tool] must not require too much [time and attention].* [#P5]

XSL•FO
RenderX

Patients' accounts highlighted concerns related to digital literacy and equitable access. Limited familiarity with digital tools was positioned as a potential barrier to engaging with ePROMs. Within this pattern, the importance of voluntary participation was emphasized, alongside concerns that older individuals or others who do not currently use digital technologies might face challenges in accessing and using such tools.

> *One should consider training for those who clearly don't have it [experience with digital tools]. And maybe also without them having to ask for it, because it's not so easy for many to ask. But to have an offer here that doesn't require too much.* [#P7]

Several patients described difficulties in accurately rating individual symptoms using a 0‐10 scale. Uncertainty was expressed about how to position oneself on the scale and what score might be considered significant by HCPs in terms of triggering interventions. Within this pattern, training in how to use such scales was considered essential to prevent them from becoming a barrier to engaging with ePROMs.

Another pattern of meaning emerged regarding the HCP's approach during consultations. Patients emphasized that if they were to invest time in completing ePROMs beforehand, it was essential that the tool's purpose was made clear and that it was actively addressed during the consultation. The perceived relevance and integration of the tool into the clinical encounter were seen as key factors influencing its acceptability.

> *[...] And a prerequisite is that the doctors use it too. That we don't sit at home and spend time filling this out, and the doctors don't read it.* [#P4-S2]

Patients also highlighted the importance of maintaining physical contact with their HCP. They expressed that the use of such a tool should serve to complement, rather than replace, existing practices.

Discussion

Principal Results

This qualitative study aimed to explore the perspectives of patients with cancer on PCC and symptom management, including their experiences with current clinical practice and their views on how ePROMs might enhance patient-centered follow-up. The analysis generated 2 interrelated themes, which together highlight the complex interplay between patients' lived experiences and their expectations of care.

Theme 1 identified considerable gaps in current clinical practice, particularly concerning symptom management and the delivery of PCC. On one hand, patients described experiencing burdensome symptoms and expressed uncertainty regarding who held responsibility for addressing the broader, more holistic dimensions of cancer care. On the other hand, they reported low expectations that oncologists would, or indeed could, engage with such concerns, perceiving them as beyond the traditional remit of oncology. The challenges and limitations identified in current symptom management appear to directly inform patients' needs and expectations regarding the use of an ePROM tool. In theme 2, which may be interpreted as a response to the biomedical orientation described in theme 1, patients expressed a desire for a more holistic and patient-centered approach to cancer care. They envisioned ePROMs as a way of bridging this gap by legitimizing and structuring attention to symptoms and aspects of well-being that are frequently overlooked in current practice. The thematic relationship reflects how patients' experiences of unmet needs influence their perceptions of digital tools designed to enhance follow-up.

While patients generally viewed ePROMs as a promising tool for capturing the lived experience of cancer and facilitating more patient-centered consultations, subtheme 2 of theme 2 revealed a nuanced ambivalence regarding their emotional impact. Patients' accounts highlighted concerns that regular digital symptom tracking might act as a persistent reminder of illness, thereby intensifying psychological distress and unwanted focus on their condition.

These findings underscore the importance of implementing ePROMs in a way that ensures that the data collected are not only integrated meaningfully into clinical practice but also supported by clearly defined professional roles. The themes reflect a clear desire among patients for a redistribution of responsibility, shifting the burden of symptom management from patients to HCPs. Such a shift not only addresses the emotional and practical challenges patients face but also signals a broader need to reconfigure clinical routines to better accommodate holistic, patient-centered approaches to cancer care.

Comparison With Prior Work

The primary focus in cancer care remains on treating the disease, curative measures, and life prolongation, often relegating patient-centered approaches to the background [4]. Our findings indicate that this tumor-centered focus is also prevalent among patients. Consequently, symptom management tends to be deprioritized. Among patients with advanced cancer, Monsen et al [39] found that symptoms not directly assessed were reported significantly less frequently than those that were explicitly addressed. Furthermore, time constraints during clinical encounters have been identified as a barrier to raising awareness of non−tumor-centric issues [40], alongside patients' limited intention to initiate discussions about symptoms with clinicians [41]. This is particularly concerning given the symptom burden experienced by some patients with cancer [42,43] and the potential consequences of unaddressed symptoms [6,44]. In addition, patients with cancer often report a range of unmet needs [45,46]. Thus, these findings highlight the need for a transformation in clinical encounters within cancer care to enhance PCC, particularly through the implementation of systematic symptom management.

Previous research shows that integrating PCC approaches, including systematic symptom management, into clinical care can significantly improve overall care quality and patient outcomes [6,47,48]. This study found that systematic symptom management is neither routinely performed nor expected by patients, despite being an unmet need. Addressing the tumor-centric focus and aligning care with patients' views on symptom importance may enhance symptom management and support the integration of ePROMs. Simultaneously, this

XSL•FO
RenderX

approach could foster PCC and shared decision-making by equipping patients with the necessary competence and understanding to effectively manage their roles [1,49]. Given that symptom burden is a common challenge across many chronic and complex conditions, these insights may also be applicable to other patient populations beyond oncology.

Our findings suggest that patients felt a considerable responsibility for raising symptom-related concerns themselves. The use of open-ended questions by HCPs appeared to reinforce this perception, indicating that broader issues related to the cancer experience were often left for patients to initiate. Prior evidence has shown that the systematic use of (e)PROMs often supports HCPs in the early detection of symptoms, thereby preventing poor outcomes [50-52]. Our findings indicate that the perceived lack of focus on symptoms from HCP reinforces the burden on patients, heightening their sense of responsibility for symptom management and reinforcing a tumor-centered approach. This dynamic may ultimately hinder the implementation of PCC.

Although patients were generally satisfied with their follow-up care, they identified potential for a more holistic and patient-centered approach through the use of ePROMs. The power imbalance between patients and HCPs is a well-documented barrier to PCC [53]. Systematic use of ePROMs has the potential to highlight key concerns [19,22,54]. In addition, this approach may enable patients to shift some of the responsibility for follow-up onto HCPs, thereby supporting more comprehensive and continuous care. In a previous review, Darley et al [55] found that remote symptom management and self-report technology, along with feedback from HCPs, facilitated the feeling of being taken care of and placed responsibility for addressing symptoms and follow-up with HCPs. Other studies have shown that the feelings of patients with cancer being in control and more involved in their own care increase significantly when using ePROMs [14,56]. Implementing ePROMs could significantly reduce the burden on patients by increasing the focus on all symptoms, while simultaneously shifting some of the responsibility for further focus from patients to HCPs.

At the same time, patients acknowledged that ePROMs could introduce challenges not present in current practice. Some expressed concern that prompts to complete symptom reports, such as phone notifications, might draw unwanted attention to their illness in everyday life, particularly when they preferred not to focus on the disease. Similar findings have been reported elsewhere [57]. However, in contrast to this and our findings, the use of telehealth has generally not been found to increase burden for most patients [58]. This may suggest that, while awareness of this potential burden is important, the use of ePROM is unlikely to be perceived as intrusive or overwhelming by the majority of patients, provided it is implemented in meaningful ways that support PCC.

Patients in this study stressed that if they were to allocate time and effort into filling out ePROM, they expected the HCPs to address the issues raised during consultations. Other studies have found that, despite patients filling out PROMs in advance, doctors often did not address the questionnaire in their encounter with the patient [54]. In a previous study, we found that there was a need for a transformation in how patient consultations were conducted to leverage the benefits from using ePROMs [59]. Raising awareness about the need for a cultural shift among both patients and HCPs is crucial to fully realize the potential benefits of systematically using ePROMs in cancer care.

Future Implications

Despite patients reporting high levels of satisfaction with current cancer care, there remains a need for systematic symptom assessment and follow-up. HCPs must be aware of this and recognize that patients may underreport their symptoms and experiences. A deeper understanding of why patients potentially adopt a tumor-centered focus, and the underlying reasons they may not view symptom management as a priority, could inform the development of strategies to prevent these perceptions from becoming barriers to the successful implementation of ePROMs. Although this study focused on oncology, the emphasis on unmet symptom-related needs and the potential of ePROMs may be transferable to other clinical contexts where symptom burden is similarly underaddressed.

Furthermore, we found that patients did not anticipate needing extensive training to use the tool if they had some degree of digital literacy. However, they found it challenging to quantify their symptoms and score them on a 0-10 scale. This could be a potential barrier to use and may create bias in the assessment. Therefore, implementation in clinical practice, along with comprehensive training, becomes especially important.

Involving patients in qualitative sessions that simultaneously explore current practices can enhance understanding of their preferences and needs, while also providing deeper insight into the requirements for successful implementation of ePROM tools. Moreover, patients in this study distinguished between side effects, viewed as a necessary evil of treatment, and symptoms. Future research should explore this distinction, as it could be crucial for realizing the full benefits of using ePROMs to facilitate a more patient-centered approach to cancer care.

Strengths and Limitations

Strengths of this study include its qualitative design, which enabled rich, in-depth insight into patients' perspectives on PCC and symptom management. However, we acknowledge certain limitations, which should be considered when interpreting the results [24]. First, conducting the study within the Norwegian cancer care context may influence the transferability of the findings. Norway's publicly funded health care system, characterized by universal access and a strong emphasis on digital health integration [60], may differ from systems with limited eHealth infrastructure or more fragmented care. However, while these contextual factors may shape patients' experiences, the core findings, particularly regarding unmet needs and the perceived value of ePROMs, are likely to be relevant across settings where similar gaps exist.

The relatively small sample size (n=10) may limit the breadth of perspectives captured, although qualitative research prioritizes depth over generalizability [34]. In addition, the use of a specific ePROM prototype may constrain transferability to other digital

XSL•FO
RenderX

tools with different interfaces or functionality. Finally, we did not assess patients' level of digital literacy, which could have influenced their engagement with and perceptions of the tool.

Conclusions

This study offers important insights into how patients with cancer perceive current approaches to symptom management and PCC, highlighting both satisfaction and areas of unmet need. Patients expressed a sense of personal responsibility in ensuring that their symptoms were addressed, pointing to gaps in follow-up and communication. ePROMs emerged as a promising tool to enhance PCC by amplifying patient voices, enabling more holistic and responsive care, and potentially shifting some of the burden of symptom reporting from patients to HCPs.

Moreover, the findings of this study may have important implications for the design and implementation of eHealth interventions in cancer care. Integrating ePROMs into routine clinical practice could not only enhance the visibility and prioritization of symptom management but also contribute to more equitable care across diverse patient populations. In addition, ePROMs may foster a shared understanding between patients and HCPs regarding the importance of addressing symptoms proactively, thereby supporting a more collaborative and patient-centered approach to follow-up care.

Acknowledgments

The authors extend their profound gratitude to the 10 individuals living with cancer who willingly shared their time and insights regarding their experiences with them. The authors also wish to thank the oncologists who supported the study by distributing information sheets to potential participants, and the personnel at the 2 oncology departments for facilitating the interviews. This study would not have been possible without the contributions of all of you. This trial was supported by a grant from the Norwegian Cancer Society and the Norwegian Women's Public Health Association (Sanitetsforeningen). The authors acknowledge using Microsoft Copilot (GPT-4, August 2025 version) for text editing to improve the fluency of the English language in the preparation of this manuscript. The authors affirm that the original intent and meaning of the content remain unaltered during editing and that Copilot had no involvement in shaping the intellectual content of this work. The authors assume full responsibility for upholding the integrity of the content presented in this manuscript [61].

Data Availability

The datasets generated and analyzed during this study are not publicly available due to privacy concerns but are available from the corresponding author on reasonable request.

Authors' Contributions

TSS and MHM were responsible for data collection. TSS, MHM, TL, and JÅL were responsible for data analysis and drafting the manuscript. TSS had primary responsibility for data collection and for preparing the first version of the manuscript and took the lead in data analysis under the guidance and supervision of MHM, TL, and JÅL. SK, EDL, NdG, KRØ, and KVG made valuable and significant contributions to drafting the manuscript and to the review and editing process. SK, TL, EDL, MHM, and TSS made a significant contribution to the study design.

Abstract

Background: Breast cancer is prevalent among females in the United States. Nonmetastatic disease is treated by partial or complete mastectomy procedures. However, the rates of those procedures vary across practices. Generating real-world evidence on breast cancer surgery could lead to improved and consistent practices. We investigated the quality of data from the *All of Us* Research Program, which is a precision medicine initiative that collected real-world electronic health care data from different sites in the United States both retrospectively and prospectively to participant enrollment.

Objective: The paper aims to determine whether *All of Us* data are fit for use in generating real-world evidence on mastectomy procedures.

Methods: Our mastectomy phenotype consisted of adult female participants who had CPT4 (Current Procedural Terminology 4), *ICD-9* (*International Classification of Diseases, Ninth Revision*) procedure, or SNOMED (Systematized Nomenclature of Medicine) codes for a partial or complete mastectomy procedure that mapped to Observational Medical Outcomes Partnership Common Data Model concepts. We evaluated the phenotype with a data quality dimensions (DQD) framework that consisted of 5 elements: conformance, completeness, concordance, plausibility, and temporality. Also, we applied a previously developed DQD checklist to evaluate concept selection, internal verification, and external validation for each dimension. We compared the DQD of our cohort to a control group of adult women who did not have a mastectomy procedure. Our subgroup analysis compared partial to complete mastectomy procedure phenotypes.

Results: There were 4175 female participants aged 18 years or older in the partial or complete mastectomy cohort, and 168,226 participants in the control cohort. The geospatial distribution of our cohort varied across states. For example, our cohort consisted of 835 (20%) participants from Massachusetts, but multiple other states contributed fewer than 20 participants. We compared the sociodemographic characteristics of the partial (n=2607) and complete (n=1568) mastectomy subgroups. Those groups differed in the distribution of age at procedure (P<.001), education (P=.02), and income (P=.03) levels, as per χ^2 analysis. A total of 367 (9.9%) participants in our cohort had overlapping CPT4 and SNOMED codes for a mastectomy, and 63 (1.5%) had overlapping *ICD-9* procedure and SNOMED codes. The prevalence of breast cancer–related concepts was higher in our cohort compared to the control group (P<.001). In both the partial and complete mastectomy subgroups, the correlations among concepts were consistent with the clinical management of breast cancer. The median time between biopsy and mastectomy was 5.5 (IQR 3.5-11.2) weeks. Although we did not have external benchmark comparisons, we were able to evaluate concept selection and internal verification for all domains.

Conclusions: Our data quality framework was implemented successfully on a mastectomy phenotype. Our systematic approach identified data missingness. Moreover, the framework allowed us to differentiate breast-conserving therapy and complete mastectomy subgroups in the *All of Us* data.

Introduction

Breast cancer is one of the most common forms of cancer in females worldwide and has a lifetime prevalence of 13%. The incidence in the United States is estimated to be greater than 297,000 women annually and increases with patient age [1,2]. In addition to patient age, breast cancer risk factors include BMI, early age of menarche, late age of menopause, family history or genetic risk, and environmental exposures [3].

Nonmetastatic breast cancer is treated surgically, and approximately 30% of patients have a complete mastectomy. An alternative to a complete mastectomy is breast-conserving therapy (BCT), which consists of breast-conserving surgery and radiation therapy [4]. In multiple randomized controlled trials, BCT has been shown to have similar long-term disease-free survival to a complete mastectomy [5-8].

A recent systematic review found that patients' choice of surgical treatment was multifaceted. Some factors that were associated with patients choosing a mastectomy over BCT were related to tumor characteristics and pathology. Others were sociodemographic or individual belief factors, such as body image, aversion to radiation, and physician preference [9]. In a prospective study of 180 patients, surgeons' preference was the strongest predictor of surgical treatment [10]. Accordingly, there is a need to compare a complete mastectomy to a partial mastectomy, the surgical component of BCT that encompasses lumpectomy, quadrantectomy, and other BCT-related surgical interventions.

We believe that a robust characterization of partial and complete mastectomy patients with data from the *All of Us* Research Program could generate valuable real-world evidence regarding breast cancer treatment and be used to provide evidence towards best practices for patients with the disease. The *All of Us* Research Program has electronic health records (EHRs) on more than 287,000 patients from 50 health care organizations within the United States. The program does targeted enrollment of groups that are underrepresented in biomedical research. Because the *All of Us* Research Program is one of the most comprehensive and diverse observational health care databases worldwide, those findings would represent real-world data associated with partial or complete mastectomy procedures [11].

Accordingly, to date, we are unaware of a study assessing the fitness for the use of *All of Us* and focusing on mastectomy as a treatment modality. Accordingly, the primary objective of this study is to determine whether the *All of Us* data are fit for an analysis of women who had a mastectomy.

Methods

Observational Medical Outcomes Partnership Common Data Model

The Observational Medical Outcomes Partnership Common Data Model (OMOP CDM) is the data standard used by the *All of Us* Research Program. The OMOP CDM consists of standardized concepts and relationships, allowing for harmonizing data from different sources. OMOP CDM concepts use codes from structured medical terminologies as the source (eg, CPT4 [Current Procedural Terminology 4], *ICD-9* [*International Classification of Diseases, Ninth Revision*], and LOINC [Logical Observation Identifiers Names and Codes]). The schema consists of standardized concept relationships across data tables [12-14].

We created partial and complete mastectomy phenotypes by manual selection. First, we selected CPT4, *ICD-9* procedure, and SNOMED (Systematized Nomenclature of Medicine) codes for those procedures manually. We chose CPT4, *ICD-9* procedure, and SNOMED source codes because these are the standards that are used by the OMOP CDM. Then, we searched ATHENA for the corresponding OMOP CDM concepts [15]. The partial and complete mastectomy OMOP CDM concept sets were the basis for our phenotype queries. Additionally, we restricted the phenotype to the earliest occurrence of a procedure and to female participants who were at least 18 years or older at the time of the procedure.

Primary Outcomes and Variables

Overview

We developed a data quality dimensions (DQD) framework and evaluation matrix that was adapted from Kahn et al [16]. The framework comprises 5 mutually exclusive and parsimonious dimensions that can be operationalized and applied to a mastectomy cohort as primary outcome variables: conformance, completeness, concordance, plausibility, and temporality. A prior study applied these dimensions to a ductal carcinoma in situ cohort data quality analysis [17].

DQD Framework

Concomitantly, we evaluated the application of the DQD framework to a mastectomy cohort. Each framework element was evaluated with respect to concept selection, internal verification, and external validation. The overarching principles of assessing the DQD include internal characteristics, described by Kahn et al [16] as verification; comparing external benchmarks as validation; and applying descriptive, inferential, and agreement statistics and data visualization. In practice, a researcher would decide whether the data associated with their constructed cohort meets their expectations for fitness of use based on the rating matrix [18]. For the DQD analysis, we selected OMOP CDM concepts related to risk factors and the medical management of breast cancer. Specifically, we included concepts that included but were not limited to breast cancer diagnoses, breast biopsies, screening and diagnostic breast imaging, endocrine therapy, anti–human epidermal growth factor receptor 2 (anti-HER2) therapy, tyrosine kinase inhibitors, chemotherapy, radiation therapy, laboratory measurements, and genetic risk factors [19,20]. Many of our codes had been validated in a prior ductal carcinoma in situ study [17]. Furthermore, a surgical oncologist (SLG) reviewed those codes, confirmed their appropriateness, and recommended additional codes for our analysis. Representative codes are shown in the supplemental appendix (Tables S1-S8 in Multimedia Appendix 1).

XSL•FO
RenderX

Sociodemographic Characterization and Geospatial Analysis

We characterized the geospatial distribution of the mastectomy cohort participants based on state address at the time of enrollment. Also, we characterized the mastectomy cohort, the partial and complete mastectomy subgroups, and control cohort according to sex at birth, race or ethnicity, age group, education, and income.

Analysis

All of Us participants enrolled between May 6, 2017, and July 1, 2022, provided consent to participate and had the option to authorize sharing of their EHRs. Upon enrollment, participants were required to fill out a basic self-reported survey, which includes information on sociodemographic characteristics, and could also consent to have additional data submitted to the program, including data from biospecimens, genomic sequences, and wearable data. All analyses presented in this paper used the *All of Us* Controlled Tier Dataset v7, released on April 20, 2023. The source data were formatted to be compatible with OMOP CDM (version 5.3.1) [21]. Additionally, the data curation team modified some of the drug table schemas for optimal use with *All of Us* data. Accordingly, we modified our queries to maximize the capture of drug exposure data. Missing data were not included in the analysis and we did not make statistical adjustments for missingness.

All programming and statistical analyses were performed in Python (version 3.7.12) and were implemented in a Jupyter Notebook (version 6.5.4). We used chi-squared statistics to test for independent association, Spearman coefficients to measure bivariate correlations, and data visualization to explore the application of the DQD. The level of significant differences was set at $P<.05$.

Ethical Considerations

The *All of Us* Research Program complies with multiple ethical considerations. First, it has an institutional review board (IRB) that reviews the protocol, informed consent, and other participant-facing materials for the *All of Us* Research Program. The IRB follows the regulations and guidance of the Office for Human Research Protections for all studies [22]. The *All of Us* IRB determined that the data that were used in this analysis were considered non–human subjects' research. Second, participants are provided with information on how the program operates, reasonable expectations, and participants' rights. Participants who agree to enroll sign consent forms [23]. Third, *All of Us* participants' data are removed of identifiers and coded to protect their privacy before they are made available to researchers. Reidentification or recontacting of participants is prohibited, and governance mechanisms ensure protection against reidentification or recontact of participants [24]. Fourth, *All of Us* participants who give blood, saliva, or urine samples receive a one-time compensation of US $25 [25]. Otherwise, no direct compensation is provided. Fifth, this paper is not focused on imaging, and thus we have not included any images in the supplemental material. In addition, we censor counts that are less than or equal to 20 to comply with program requirements for minimizing disclosure risk. Data and code used in this study are available as a featured workspace to registered researchers of the *All of Us* Researcher Workbench [26].

Results

Sample

In the *All of Us* database, 249,565 participants consented to participate in the study, were at least 18 years old, and selected assigned as female at birth in the *All of Us* "Basics" self-reported questionnaire. Of those, 172,401 (69%) signed an authorization to share clinical data and had at least one data record in a participating EHR. We created a cohort of 4175 (2.4%) patients with mastectomy procedures and a control cohort of 168,226 (97.6%) female participants who did not have a mastectomy. Out of the 4175 female participants who had mastectomy procedures, 316 (7.6%) had both partial and complete mastectomy procedures. The first occurrence of the procedure code was used for subgroup assignment.

We plotted the mastectomy (partial or complete) cohort's geospatial distribution to assess whether our cohort was distributed equally across the United States (Figure 1). A total of 835 (20%) participants of our cohort had medical records from Massachusetts, 656 (15.7%) from Arizona, 547 (13.1%) from Wisconsin, 468 (11.2%) from California, 386 (9.3%) from New York, 369 (8.8%) from Illinois, 245 (5.9%) from Florida, and 197 (5.9%) from Michigan. Many states had mastectomy cases for fewer than 20 participants in our cohort and were not reported due to disclosure risk guidelines.

RenderX

Figure 1. Geospatial analysis of a mastectomy cohort (partial or complete). States with a white-gray fill color contributed no participants to the cohort. Data source: The *All of Us* research program.

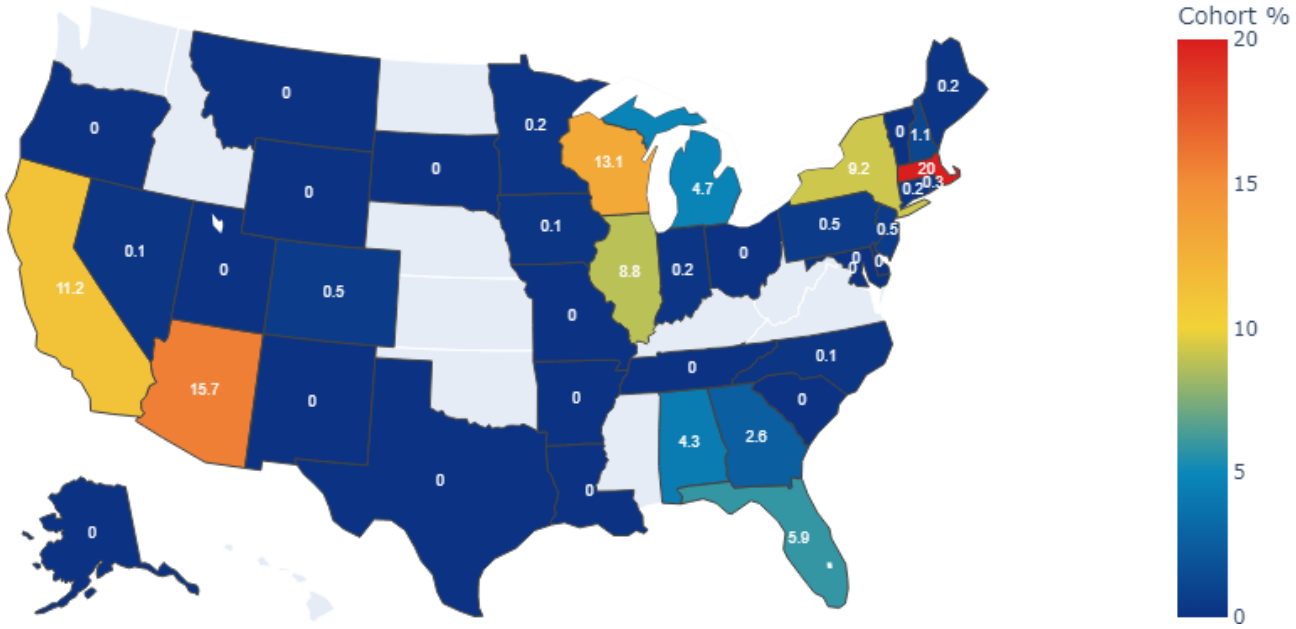

Table 1 provides a breakdown of the cohort by sex at birth, race or ethnicity, age group, education, and income by partial (n=2607) and complete (n=1568) mastectomy. Among the participants who underwent partial or complete mastectomy, the majority were white (66.9% and 70.4%, respectively), with procedures peaking between 40 and 79 years (89.5% and 82.6%, respectively), differ in achieving college or higher degree (52.2% and 58%, respectively), and household income greater or equal to 100k (27% and 32.3%, respectively). A similar sociodemographic comparison was performed for the mastectomy cohort and the control group (Table S8 in Multimedia Appendix 1).

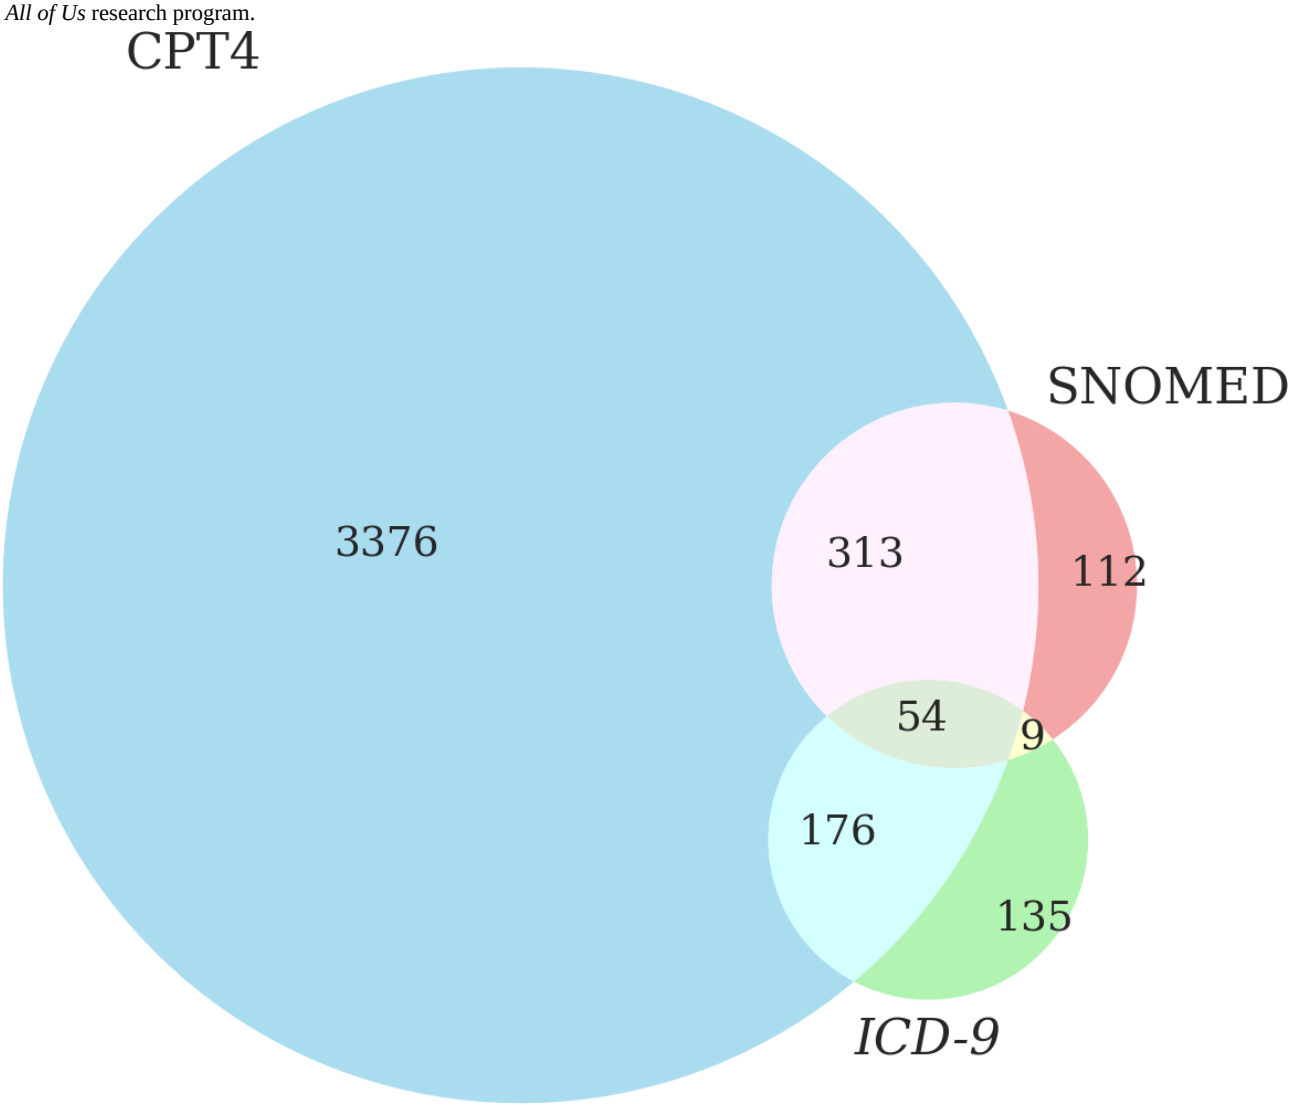
[b]More than one race or ethnicity category could have been selected.



[c]GED: General Educational Development.

Conformance

Data elements can be assessed according to standards. The *All of Us* Program uses SNOMED as a standard vocabulary. We created a butterfly plot to determine the overlap between CPT4, *ICD-9* procedure, and SNOMED procedure codes, as shown in Figure 2. Of the 4175 female participants in our cohort, 3376 (80.9%) had CPT4 codes only, 313 (7.5%) had both CPT4 and SNOMED codes, 176 (3.2%) had CPT4 and *ICD-9* procedure codes, and 63 (1.5%) had *ICD-9* procedure and SNOMED codes. A total of 54 (1.3%) female participants had overlapping CPT4, SNOMED, and *ICD-9* procedure codes (Figure 2). Thus, the overlap among standards was low.

To characterize the source data variance in the standards, we calculated the counts of the partial or complete mastectomy CPT4 codes in our cohort (Table 2). Of the 50 EHR-contributing *All of Us* sites, 24 reported mastectomy CPT4 codes. CPT4 code 19301 ("mastectomy, partial") was reported the most frequently by every site that contributed data to our cohort. The sets of distinct CPT4 codes that each site reported varied substantially, with the median site using 6 different CPT4 codes. We used data from within our cohort to verify conformance. However, we did not validate this dimension against an external benchmark because one was not available.

Figure 2. The butterfly plot of CPT4 (left), SNOMED (top right), and *ICD-9* (bottom right) mastectomy procedure codes. CPT4: Current Procedural Terminology 4; *ICD-9*: *International Classification of Diseases, Ninth Revision*; SNOMED: Systematized Nomenclature of Medicine. Data source: The *All of Us* research program.

Table . Mastectomy Current Procedural Terminology 4 (CPT4) counts by code. Codes with ≤10 counts were omitted. Data source: The *All of Us* research program.

CPT4 code	Count
19301[a]	2366
19303[b]	1304
19307[c]	358
19302[d]	160
19160[e]	126
19180[f]	53
19162[g]	48
19304[h]	44
19240[i]	35

[a]CPT4 code 19301=mastectomy, partial (eg, lumpectomy, tylectomy, quadrantectomy, and segmentectomy).

[b]CPT4 code 19303=mastectomy, simple, complete.

[c]CPT4 code 19307=mastectomy, modified radical, including axillary lymph nodes, with or without pectoralis minor muscle, but excluding pectoralis major muscle CPT4.

[d]CPT4 code 19302=mastectomy, partial (eg, lumpectomy, tylectomy, quadrantectomy, segmentectomy); with axillary lymphadenectomy.

[e]CPT4 code 19160=mastectomy, partial.

[f]CPT4 code 19180=mastectomy, simple, complete.

[g]CPT4 code 19162=mastectomy, partial, with axillary lymphadenectomy.

[h]CPT4 code 19304=mastectomy, subcutaneous.

[i]CPT4 code 19240=mastectomy, modified radical, including axillary lymph nodes, with or without pectoralis minor muscle, but excluding pectoralis major muscle.

Completeness

We used concept prevalence within our cohort to evaluate data completeness. Table 3 shows the counts and percentages of female participants who did and did not have partial or complete mastectomy procedures, for which each specific clinical measure and intervention was present in the *All of Us* EHR at least once. The participants in our partial or complete mastectomy cohort had a higher prevalence of breast cancer associated OMOP CDM concepts compared to female control cohort participants who did not have a partial or complete mastectomy code. Specifically, comparing females who had a partial or complete mastectomy to females who had neither showed increased prevalence of diagnostic mammography (70.7% vs 13.5%), biopsy (61.2% vs 3.3%), or endocrine therapy (51% vs 1.8%), or chemotherapy (25.1% vs 4.3%). A χ^2 test indicated that partial or complete mastectomy procedures were associated with clinical measures and interventions (P<.001).

XSL•FO
RenderX

Table . Clinical measures and interventions for female participants who had a mastectomy and who did not have a mastectomy. Data source: The *All of Us* research program.

Clinical measure	Mastectomy cohort, n (%)	Nonmastectomy cohort, n (%)	*P* value
Procedures			<.001
Breast biopsy	2554 (61.2)	5625 (3.3)	
Diagnostic mammography	2951 (70.7)	22,731 (13.5)	
Radiation therapy	1656 (39.7)	1644 (1.0)	
Screening mammography	2143 (51.3)	45,071 (26.8)	
Surgery	4175 (100.0)	0 (0)	
Medications			<.001
Anti-HER2[a]	221 (5.3)	151 (0.1)	
CDK[b] 4/6 inhibitors	60 (1.4)	138 (0.1)	
Chemotherapy	1046 (25.1)	7152 (4.3)	
Endocrine therapy	2130 (51.0)	3109 (1.8)	
Goserelin	106 (2.5)	91 (0.1)	
Olaparib	≤20	41 (<0.1)	
Pembrolizumab	≤20	162 (0.1)	
Tyrosine kinase inhibitor	50 (1.2)	277 (0.2)	
Conditions			<.001
Breast cancer gene mutation	435 (10.4)	903 (0.5)	
Estrogen receptor status	235 (5.7)	180 (0.1)	

[a]anti-HER2: anti–human epidermal growth factor receptor 2.

[b]CDK: cyclin-dependent kinase.

Table 4 shows the counts and percentages for the partial and complete mastectomy subgroups. Each specific clinical measure and intervention was in the *All of Us* EHR at least once. The partial mastectomy subgroup, compared to the complete mastectomy subgroup, had a greater proportion of radiation therapy (49.4% vs 23.5%), endocrine therapy (54.7% vs 44.9%), screening mammography (58.8% vs 39%), and diagnostic mammography (77.5% vs 59.3%). By contrast, the complete mastectomy group when compared to the partial mastectomy subgroup had a greater proportion of breast cancer gene (BRCA) mutations (18%vs 5.8%). A χ^2 test indicated that partial and complete mastectomy subgroup categories were associated with clinical measures and interventions (*P*<.001).

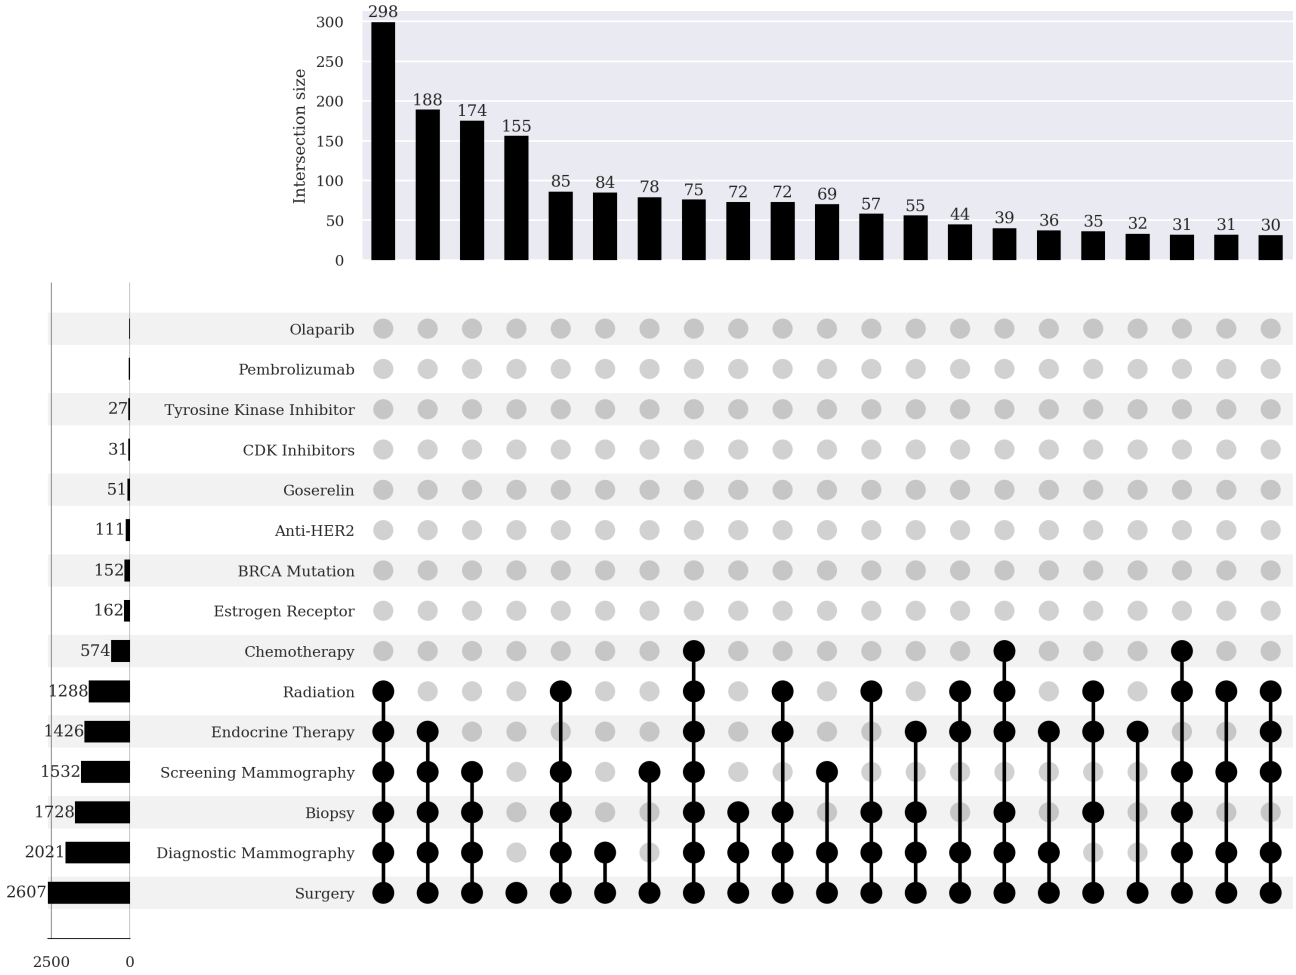
XSL•FO
RenderX

Table . Clinical measures and interventions for female participants who had a partial mastectomy and who had a complete mastectomy. Data source: The *All of Us* research program.

Clinical measure	Partial mastectomy, n (%)	Complete mastectomy, n (%)	*P* value
Procedures			<.001
Breast biopsy	1728 (66.3)	826 (52.7)	
Diagnostic mammography	2021 (77.5)	930 (59.3)	
Radiation therapy	1288 (49.4)	368 (23.5)	
Screening mammography	1532 (58.8)	611 (39.0)	
Surgery	2607 (100.0)	1568 (100.0)	
Medications			<.001
Anti-HER2[a]	111 (4.3)	110 (7.0)	
CDK[b] 4/6 inhibitors	31 (1.2)	29 (1.8)	
Chemotherapy	574 (22.0)	472 (30.1)	
Endocrine therapy	1426 (54.7)	704 (44.9)	
Goserelin	51 (2.0)	55 (3.5)	
Olaparib	≤20	≤20	
Pembrolizumab	≤20	≤20	
Tyrosine kinase inhibitor	27 (1.0)	23 (1.5)	
Conditions			<.001
Breast cancer gene mutation	152 (5.8)	283 (18.0)	
Estrogen receptor status	162 (6.2)	73 (4.7)	

[a]anti-HER2: anti–human epidermal growth factor receptor 2.

[b]CDK: cyclin-dependent kinase.



To further characterize completeness, we used UpSet plots (Figures 3 and 4) to assess which combinations of clinical measurements and interventions were prevalent among participants in the partial and complete mastectomy subgroups. The plots show the counts of the concept sets on the left-hand side, and the counts of concept set combinations at the top. The makeup of the combinations is indicated by the dotted lines below. The most frequent combinations in the partial mastectomy subgroup are presented in Textbox 1.

Textbox 1. The most frequent combinations in the partial mastectomy subgroup.

- Combination 1: Surgery, diagnostic mammography, biopsy, screening mammography, endocrine therapy, and radiation therapy (298 cases)
- Combination 2: Surgery, diagnostic mammography, biopsy, screening mammography, and endocrine therapy (188 cases)
- Combination 3: Surgery, diagnostic mammography, biopsy, and screening mammography (174 cases)

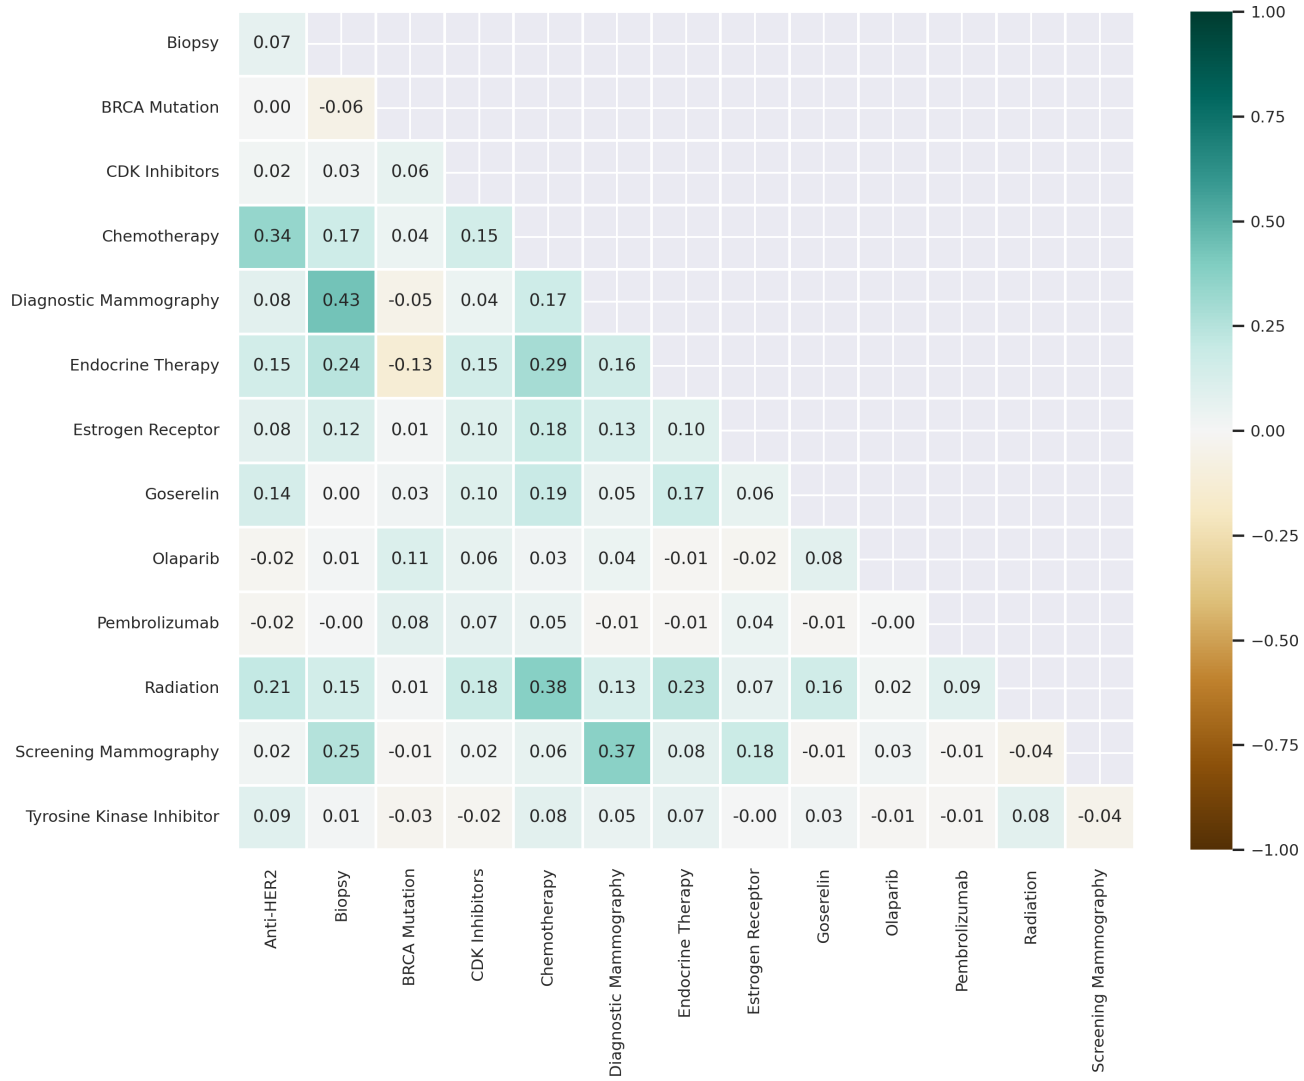
Concordance



We calculated the bivariate correlations between OMOP CDM concepts for clinical measures and interventions in the partial and complete mastectomy subgroups to measure concordance (Figures 5 and 6). The highest bivariate correlations for the partial mastectomy subgroup were between biopsy and diagnostic mammography (r=0.36) and chemotherapy and anti-HER2 therapy (r=0.36). We also calculated the bivariate correlations for the complete mastectomy subgroup; the highest bivariate correlations were between biopsy and diagnostic mammography (r=0.43), radiation therapy and chemotherapy (r=0.38), screening mammography and diagnostic mammography (r=0.37), and chemotherapy and anti-HER2 therapy (r=0.34).

Figure 5. Correlogram of medications, procedures, and genetic tests in the subgroup of partial mastectomy patients. Data source: The *All of Us* research program. anti-HER2: anti–human epidermal growth factor receptor 2; BRCA: breast cancer gene; CDK: cyclin-dependent kinase.

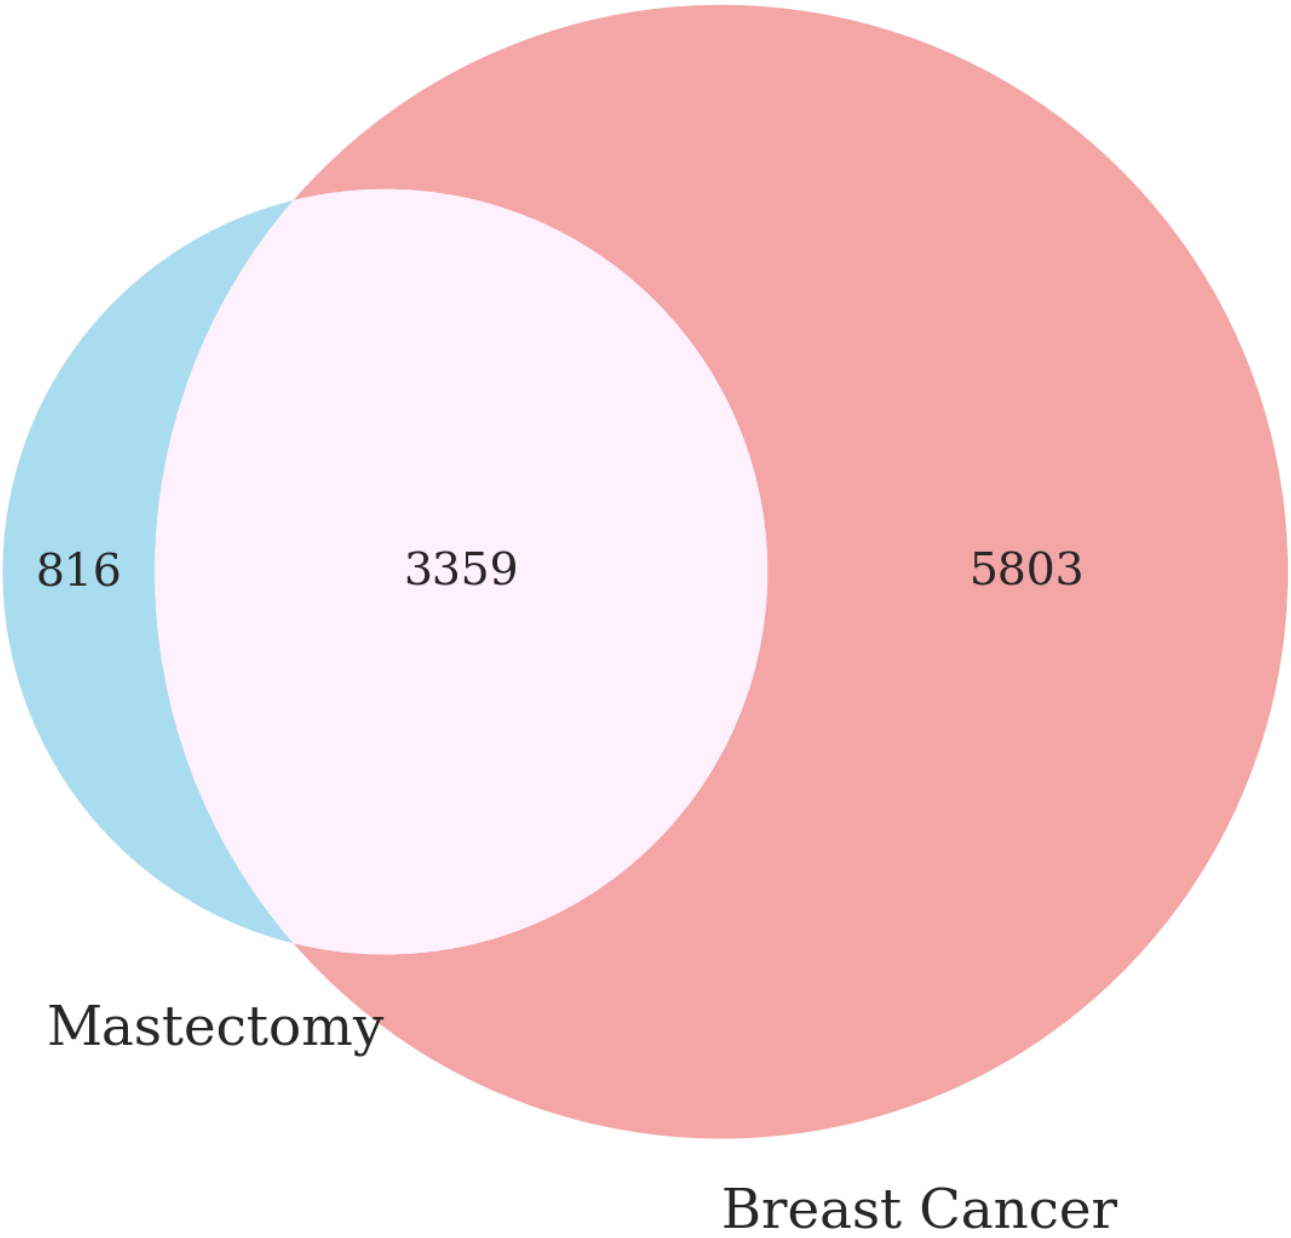
RenderX

Figure 6. Correlogram of medications, procedures, and genetic tests in the subgroup of complete mastectomy patients. Data source: The *All of Us* research program. anti-HER2: anti–human epidermal growth factor receptor 2; BRCA: breast cancer gene; CDK: cyclin-dependent kinase.



The overlap of patients who had a mastectomy procedure and breast cancer diagnosis (eg, SNOMED 254837009 “Malignant Neoplasm of Breast”) is shown in Figure 7. Of the 816 (19.5%) of female participants who had a mastectomy code only, 277 (33.9%) had diagnosis codes for physical or radiographic findings (eg, breast lump, mammographic calcification of breast), premalignant disease, or benign disease within 1 year before the procedure.

We did not validate concordance because external benchmarks were not available.

XSL•FO
RenderX

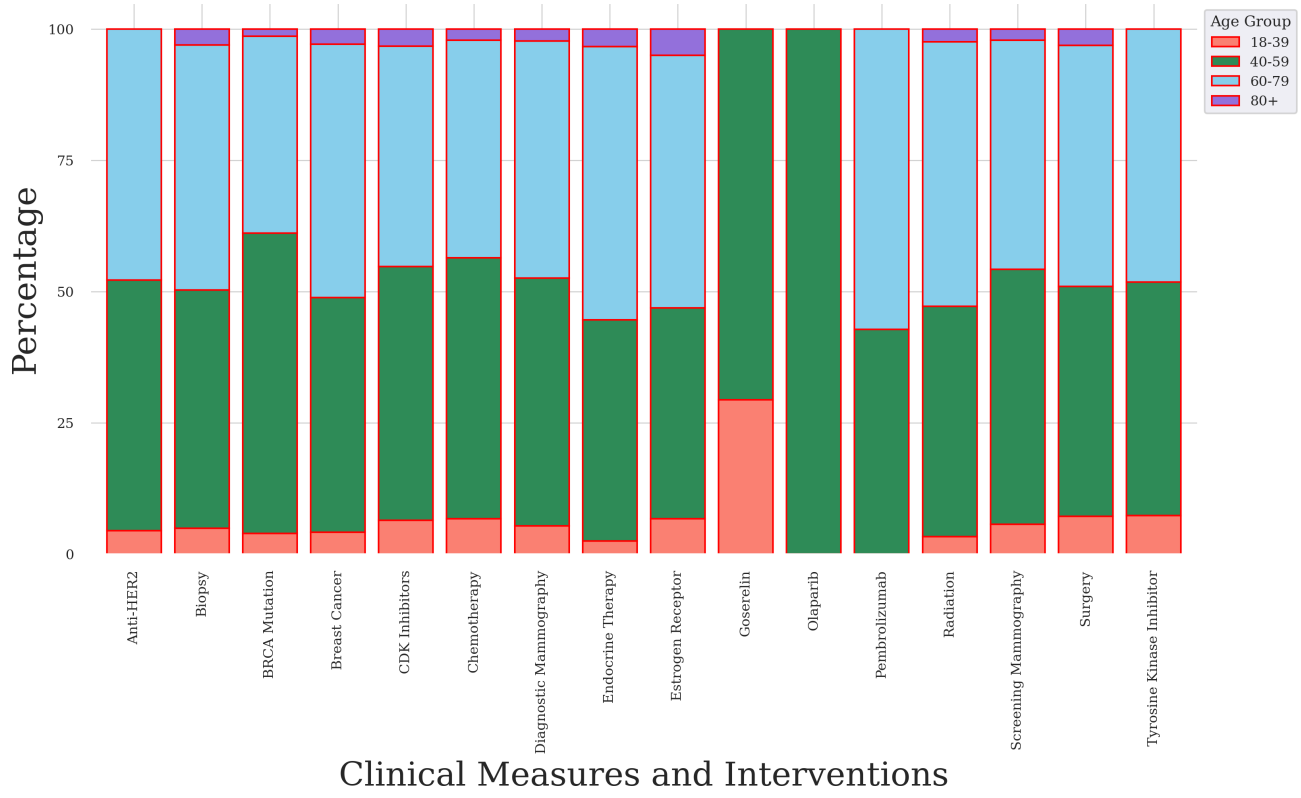
Figure 7. The butterfly plot of the mastectomy procedure (left) and the breast cancer diagnosis (right) codes. Data source: The *All of Us* research program.

Plausibility

We assessed plausibility by characterizing distributions of clinical measurement and intervention concepts by age group. We stratified the analysis by partial and complete mastectomy procedures (Figures 8 and 9). We used the age at which a participant's surgical procedure was recorded in EHR rather than other internal characteristics. Our data support a clear association between age patterns and the rate of mastectomy surgery (see Table 1) and the literature [3].

XSL•FO
RenderX

Figure 8. Bar chart of clinical measures and interventions for female participants who had a partial mastectomy. Data source: The *All of Us* research program. anti-HER2: anti–human epidermal growth factor receptor 2; BRCA: breast cancer gene; CDK: cyclin-dependent kinase.



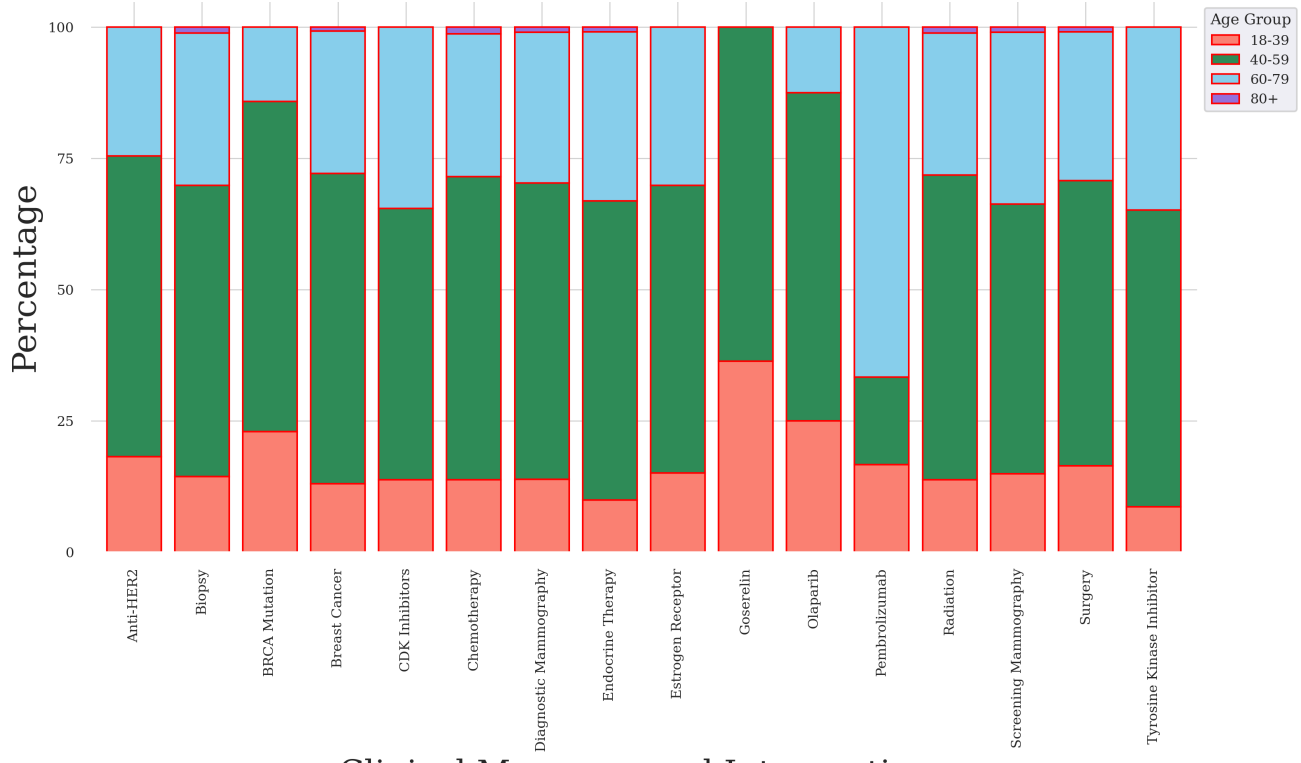


Figure 9. Bar chart of clinical measures and interventions for female participants who had a complete mastectomy. Data source: The *All of Us* research program. anti-HER2: anti–human epidermal growth factor receptor 2; BRCA: breast cancer gene; CDK: cyclin-dependent kinase.

For the partial mastectomy subgroup, clinical measures and interventions were most frequent in for adult female participants who were between 40 and 79 years of age (Figure 8). Specifically, BRCA mutation (57.2%) was most frequent in the 40 - to 59-year-old group. Biopsy (46.7%), radiation therapy (50.4%), surgery (45.9%), and endocrine therapy (52%) were most frequent in the 60 - to 79-year-old group. A χ^2 test indicated that age categories were associated with clinical measures and interventions (P<.001).

XSL•FO
RenderX

For the complete mastectomy subgroup, the frequencies of clinical measures and interventions were highest for adult female participants who were between 40 and 79 years of age (Figure 9). Specifically, BRCA mutation (62.9%), diagnostic mammography (56.5%), biopsy (55.4%), surgery (54.3%), endocrine therapy (56.9%), radiation therapy (58%), screening mammography (51.3%), and estrogen receptor status (54.8%) concepts were most frequent in the 40 - to 59-year-old age group. A χ^2 test indicated that age categories were associated with clinical measures and interventions (P<.001).

We did not validate plausibility because external benchmarks were not available.

Temporality

To assess temporality, we examined the time intervals between biopsy and mastectomy. A biopsy procedure was available for 2354 (56.4%) female participants in the partial or complete mastectomy cohort. There was a skewed time distribution from biopsy to surgery (right positive skew=9.9). Therefore, the median (5.5, IQR 3.5-11.2 weeks) better represents the distribution than the mean (18.4 weeks) for the time difference between biopsy and surgery.

We did not validate temporality because external benchmarks were not available.

Discussion

Principal Findings

The primary objective of this study is to determine whether the *All of Us* EHR data are fit for analyzing female participants who had a mastectomy. Indeed, this study provides valuable information to researchers on the quality of EHR data by operationalizing 5 DQD to the procedure-driven selection of the mastectomy cohort clinical measurements and interventions. We implemented concept selection and internal verification on all domains but were unable to validate them because external benchmarks were not available. Each domain provided unique information about data quality. In this study, our conformance analysis evaluated the overlap of procedure codes from different source vocabularies. The low overlap with SNOMED implies that there may be suboptimal linkage of procedure concepts with concepts from other domains because the standardized relationships may be underused. Furthermore, our method for evaluating conformance may be applicable to quantifying the amount of overlap between nonstandardized and standardized codes. The completeness DQD analysis can be used to identify disease-specific missingness in our data. The concordance analysis measures associations among concepts, which have implications for their relative missingness. The plausibility and temporality analyses are an effort to make the data quality issues transparent and comparable to existing clinical knowledge.

Despite the incompleteness of EHRs, breast cancer–related concepts were prevalent in our cohort. The correlations among those concepts were logical and consistent with the practice of treating breast cancer. For example, concepts for radiation therapy, which is an essential part of BCT, were more prevalent in the partial mastectomy subgroup. The completeness and correlations of our data allowed us to differentiate patients who had BCT from patients who had a complete mastectomy. Our cohort consisted of *All of Us* participants who had a mastectomy procedure at one of the participating sites. However, a greater number of participants may have had a mastectomy procedure at a site that was not part of our research network. Alternatively, diagnosis code-based phenotypes may have higher sensitivity and more false positives than procedure-based phenotypes.

This DQD paper is the first OMOP CDM study to evaluate the quality of partial or complete mastectomy procedure data with procedure-based phenotypes using *All of Us* EHR data. There are several distinct advantages to using a procedure-based phenotype over a diagnosis code-based phenotype. First, in the United States, procedure codes tend to be submitted by experts and can be subject to more rigorous quality checks than codes from other domains, which makes them more likely to be accurate. Second, a mastectomy is a disease-specific intervention for breast cancer. Therefore, a mastectomy phenotype should have a strong association with breast cancer. Third, procedure codes are well-defined and map to granular OMOP CDM concepts. Furthermore, the granularity of codes allows for differentiating partial from complete mastectomy procedures. Fourth, procedures are concrete events synchronizing a cohort to a point in the disease course. Synchronizing the cohort can be especially valuable for performing a treatment pathway analysis, a population-level estimation, or a patient-level prediction.

Comparisons to Prior Work

The relative proportions of the mastectomy cohort who had partial and complete mastectomy procedures were similar to the national averages [27]. However, we found that the frequencies of multiple concepts were lower than expected in our analysis. For example, 51% of our mastectomy cohort had endocrine therapy concepts, and only 5.6% had estrogen receptor status concepts.

Limitations

Our study had several limitations. First, the OMOP CDM breast cancer concepts had minimal information on the breast cancer stage, grade, pathology, laterality, and quadrant of a tumor. Consequently, adopting guidelines from other research networks, such as the National Comprehensive Cancer Network, was not feasible for our use because National Comprehensive Cancer Network guidelines are associated with specific tumor, node, and metastasis characteristics. Health Care Common Procedure Coding System and *International Classification of Diseases* procedure codes can help provide some information on mastectomy status; however, they are limited by their granularity and frequency in the dataset. Second, we wrote custom code to implement our phenotype and selected our concepts manually. Also, evaluating phenotypes with software packages such as CohortDiagnostics and Phevaluator is a possible future area of research. Third, our geospatial analysis was based on the participant's location at the time of enrollment. Some participants could have had surgical treatment in another state. Because our data does not identify the site, variation in practice patterns by institution or provider was unknown. These issues are potential sources of selection bias. Notwithstanding, we

XSL•FO
RenderX

recognize that institution and provider preferences can influence whether a patient undergoes a partial or complete mastectomy for breast cancer [9]. Future development with the *All of Us* Center for Linkage and Acquisition of Data may enable the effects of those preferences on patient procedure choice to be analyzed through the acquisition of health care claims data. Fourth, we restricted our analysis to female participants to reduce errors attributed to misclassification of participants' assigned sex at birth. A study that also includes males with breast cancer, who make up 1% of the breast cancer population, would be more generalizable [28]. Fifth, there was minimal data available for an external validation comparison.

Future Directions

Our study has shown that our data quality framework is systematic and comprehensive and can be implemented in a mastectomy use case. The results of our analysis could inform investigators about the feasibility of using *All of Us* data for follow-up studies. Furthermore, we encourage continued procedure-based phenotyping with our data. In summary, our methods can continue to assess data quality in the *All of Us* Research Program and they may lead to precision medicine studies applicable to diverse patient populations.

Conclusions

We successfully implemented a data quality framework to evaluate whether a mastectomy phenotype that uses *All of Us* data is fit for observational health care research. Our procedure-based phenotype overcame many EHR limitations. In a subgroup analysis, we achieved reasonable differentiation of BCT from complete mastectomy patients. We encourage the continued use of procedure-based phenotypes to evaluate data quality.

Acknowledgments

We gratefully acknowledge *All of Us* participants for their contributions, without whom this research would not have been possible. We also thank the National Institutes of Health's (NIH) *All of Us* Research Program for making available the participant data examined in this study. This study used data from the *All of Us* Research Program's Controlled Tier Dataset V7, available to authorized users on the Researcher Workbench. The implementation of the program is supported by awards through the NIH Office of the Director. We did not use large language models to produce this manuscript. We did not use generative AI to produce any part of this work.

Data Availability

Data and code used in this study are available as a featured workspace to registered researchers of the *All of Us* Researcher Workbench [26].

Abstract

Background: Early-stage breast cancer has the complex challenge of carrying a favorable prognosis with multiple treatment options, including breast-conserving surgery (BCS) or mastectomy. Social media is increasingly used as a source of information and as a decision tool for patients, and awareness of these conversations is important for patient counseling.

Objective: The goal of this study was to compare sentiments and associated emotions in social media discussions surrounding BCS and mastectomy using natural language processing (NLP).

Methods: Reddit posts and comments from the Reddit subreddit r/breastcancer and associated metadata were collected using pushshift.io. Overall, 105,231 paragraphs across 59,416 posts and comments from 2011 to 2021 were collected and analyzed. Paragraphs were processed through the Apache Clinical Text Analysis Knowledge Extraction System and identified as discussing BCS or mastectomy based on physician-defined Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) concepts. Paragraphs were analyzed with a VADER (Valence Aware Dictionary for Sentiment Reasoning) compound sentiment score (ranging from −1 to 1, corresponding to negativity or positivity) and GoEmotions scores (0 - 1) corresponding to the intensity of 27 different emotions and neutrality.

Results: Of the 105,231 paragraphs, there were 7306 (6.94% of those analyzed) paragraphs mentioning BCS and mastectomy (2729 and 5476, respectively). Discussion of both increased over time, with BCS outpacing mastectomy. The median sentiment score for all discussions analyzed in aggregate became more positive over time. In specific analyses by topic, positive sentiments for discussions with mastectomy mentions increased over time; however, discussions with BCS-specific mentions did not show a similar trend and remained overall neutral. Compared to BCS, conversations about mastectomy tended to have more positive sentiments. The most commonly identified emotions included neutrality, gratitude, caring, approval, and optimism. Anger, annoyance, disappointment, disgust, and joy increased for BCS over time.

Conclusions: Patients are increasingly participating in breast cancer therapy discussions with a web-based community. While discussions surrounding mastectomy became increasingly positive, BCS discussions did not show the same trend. This mirrors national clinical trends in the United States, with the increasing use of mastectomy over BCS in early-stage breast cancer. Recognizing sentiments and emotions surrounding the decision-making process can facilitate patient-centric and emotionally sensitive treatment recommendations.

Introduction

Early-stage breast cancer has the complex challenge of carrying a favorable prognosis with multiple treatment options, including breast-conserving surgery (BCS) or mastectomy. Treatment decisions are therefore driven by patient preferences, making information gathering and decision analysis critical. Multiple randomized trials have shown that locoregional recurrence and survival rates are similar with breast-conserving therapy (BCT) or mastectomy, with recent data even suggesting improved survival with BCT [1,2]. Nonetheless, trends indicate that women with early-stage, nonhereditary breast cancer are increasingly choosing mastectomy [3].

Many factors contribute to patient decision-making for cancer therapy, including the growing influence of social media. Several previous studies have investigated the use of online forums and social media by patients with breast cancer [4-8]. As many as 77% of patients with breast cancer cite the internet as their primary information source [9]. Additionally, patients who are frequent users of online communication and social media tools experience increased decision-satisfaction [10]. Additionally, large language models, including ChatGPT, are being increasingly used by patients for medical decision making. As social media data, including that from Reddit, are used to train these models, these discussions are relevant to the information that patients receive [11,12].

There are limited data characterizing social media conversations surrounding the decision regarding BCS or mastectomy, which is important to understand to gain insights into national trends in the United States and inform the counseling process. We applied sentiment and emotion analyses with natural language processing (NLP) approaches to a popular breast cancer online community to compare the sentiments and associated emotions around conversations of BCS and mastectomy.

Methods

Data Source

The moderated Reddit subreddit r/breastcancer was created on December 3, 2011, and is self-described as “a support and information group for people who have been diagnosed with breast cancer and for their caregivers and loved ones.” As of January 2023, it had 13,700 subscribed members. Out of all internet users, 8% of men and 4% of women used Reddit; of those, 11% were aged 18 - 29 years, 7% were aged 30 - 39 years, 2% were aged 50 - 64 years, and 2% were aged 65+ years [13]. We selected Reddit for social and technical reasons, as it is anonymous, public, open, and interaction-centric. Reddit text is also frequently used to train NLP algorithms, reducing concerns about model applicability.

All posts, comments, and metadata from r/breastcancer from 2011 to 2021 were collected using pushshift.io [14]. Pushshift.io is a public social media archiving platform with real-time Reddit data for social media research. As of March 20, 2024, it has 908 citations according to Google Scholar. Data from Pushshift.io were accessed on February 4, 2022.

Data Preprocessing and Topic Identification

These posts and comments were separated into paragraphs based on line breaks to separate topics for analysis. We applied the Apache cTAKES (Clinical Text Analysis Knowledge Extraction System) v. 4.0.0 default clinical pipeline to identify mentions of BCS- or mastectomy-related terms mapped to the Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT). cTAKES is an NLP software with multiple parts designed to process clinical free text. It had a sentence boundary detector, tokenizer, normalizer, part-of-speech tagger, shallow parser, and a named entity recognition annotator with negation. SNOMED keywords related to BCS or mastectomy were identified by a physician author (DYS). Examples of SNOMED words or phrases used in this analysis include *simple mastectomy*, *bilateral mastectomy*, and *modified radical mastectomy* as mastectomy keywords and *lumpectomy*, *excision biopsy*, and *segmental mastectomy* as BCS keywords. Analyses of paragraphs were based on references to BCS or mastectomy, nonexclusively. Paragraphs containing mentions of both were attributed to both treatments in the analysis.

Sentiment Analysis

Paragraphs (as a whole) were analyzed using VADER (Valence Aware Dictionary for Sentiment Reasoning) to generate compound sentiment scores from −1 to 1 (negative to positive). VADER is a popular sentiment analysis model trained on social media text, with performance comparable to more complex approaches and advantages of computational efficiency, explainability, and domain agnosticism or generalizability [12].

Emotion Classification

GoEmotions is the largest human-annotated dataset of fine-grained emotions, with 58,000 Reddit comments labeled for 27 emotions and neutrality [11]. We applied a publicly available BERT (Bidirectional Encoder Representations from Transformers) model from Google Research [15]. GoEmotions generates a score from 0 to 1 based on the intensity of the detected emotion. A paragraph was considered to express an emotion if its score was >0.5, as used in intensity annotations in the original GoEmotions benchmark studies [11].

Statistics were aggregated longitudinally for summary statistics per year. Years 2011 to 2014 had less than 100 posts discussing BCS or mastectomy; years 2011 - 2017 were pooled due to limited sample size. Sentiment scores were compared between BCS and mastectomy using a 2-tailed Student *t* test. Emotions across treatments were visualized using radar charts.

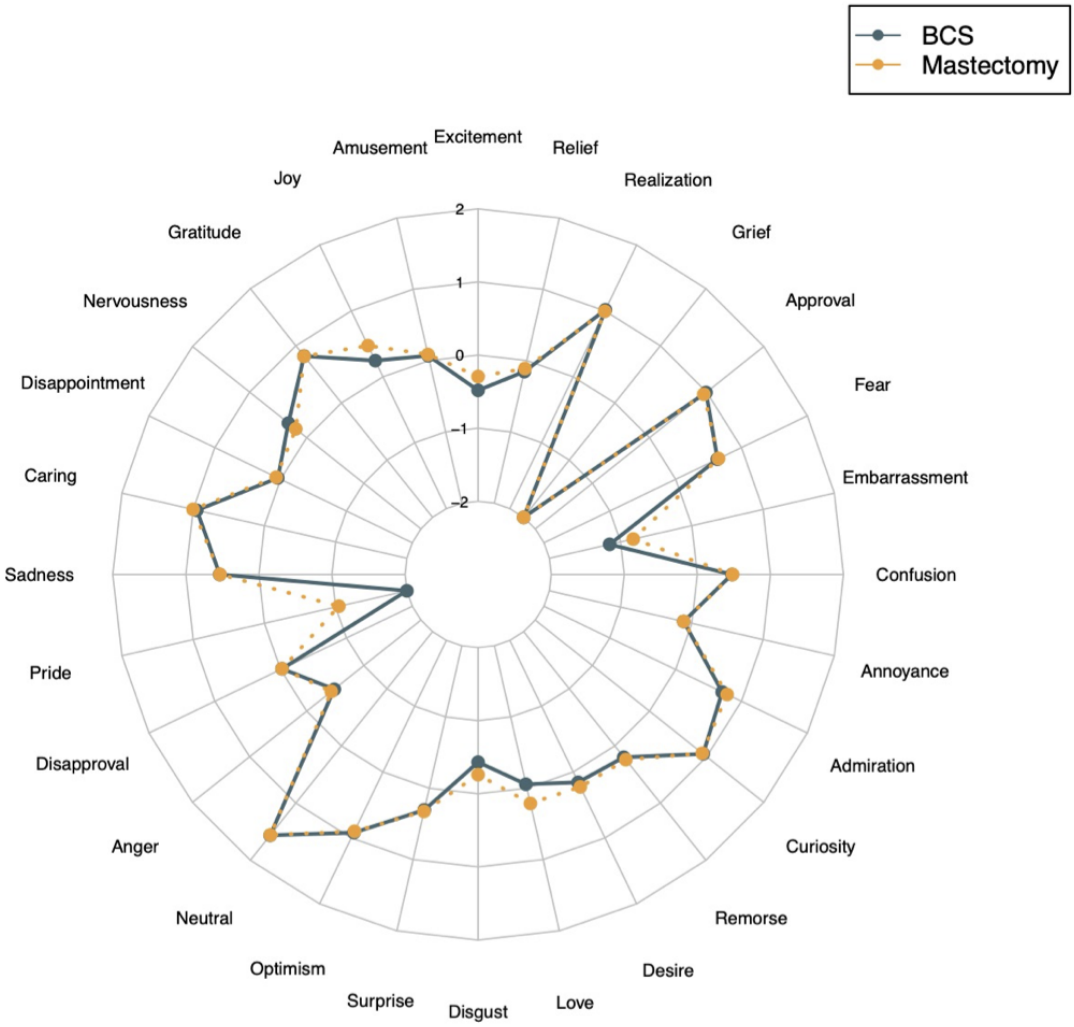
Ethical Considerations

The study data used in this analysis are anonymous, public, and open source. Therefore, there is minimal risk to performing these analyses. This study was approved by the University of San Francisco institutional review board, where the data collection and analyses were performed (IRB #21 - 35353).

Results

A total of 59,416 posts with 105,231 paragraphs on r/breastcancer, which were posted by 5845 users, were analyzed. There were 2729 mentions of BCS and 5476 mentions of

XSL•FO
RenderX



mastectomy, nonexclusively. Post volume increased over time (5282 in 2011 - 2017 to 44,235 in 2021). Words per paragraph had a slight increase over time, from a median of 28 (IQR 11 - 53) words per line in 2011 - 2017 to 26 (IQR 11 - 49) in 2018, 28 (IQR 12 - 50) in 2019, 30 (IQR 14 - 55) in 2020, and 30 (IQR 14 - 54) in 2021. The median number of comments per user was 2 (IQR 1 - 7).

Discussion of both BCS and mastectomy increased over time, but BCS outpaced mastectomy, with an increasing ratio of BCS to mastectomy mentions (0.312 in 2011 - 2017 to 0.583 in 2021). The median (IQR) sentiment score for all discussions became more positive annually: 0 (IQR –0.361 to 0.624) in 2011 - 2017 to 0.288 (–0.223 to 0.701) in 2021. Positive sentiments for mastectomy generally increased over time: median of 0 (IQR –0.599 to 0.726) in 2011 - 2017 to a median of 0.178 (IQR –0.511 to 0.73) in 2021. Similarly, the proportion of positive mastectomy-related discussions increased annually from 48.1% (151/314) in 2011 - 2017 to 53.3% (1107/2076) in 2021. Discussion of BCS remained neutral—median 0 (IQR –0.494 to 0.523) to median 0.039 (IQR –0.511 to 0.642)—and the proportion of positive BCS discussions did not show a similar trend year-to-year: 43.9% (43/98) in 2011-2017 to 52.3% (139/266) in 2019, and stable in 2021 to 50.7% (614/1211). Compared to BCS, conversations about mastectomy were more positive (P=.02), driven primarily by differences in 2021—median 0.178 (IQR –0.511 to 0.73) for mastectomy vs median 0.039 (IQR –0.511 to 0.642) for BCS, with P=.049.

The most common emotions across r/breastcancer were neutrality, gratitude, caring, approval, and optimism. The most common emotions for both BCS and mastectomy were similar: neutrality (BCS: 1001/2729, 36.68%; mastectomy: 1973/5476, 36.03%), caring (BCS: 242/2729, 8.87%; mastectomy: 547/5476, 9.99%), approval (BCS: 267/2729, 9.78%; mastectomy: 492/5476, 8.98%), realization (BCS: 284/2729, 10.41%; mastectomy: 542/5476, 9.9%), and curiosity (BCS: 237/2729, 8.68%; mastectomy: 459/5476, 8.38%) (Figure 1). Six emotions increased over time for all posts: approval (2011 - 2017: 354/5282, 6.7%; 2021: 4176/44,235, 9.44%), amusement (2011 - 2017: 34/5282, 0.64%; 2021: 677/44,235, 1.53%), desire (2011 - 2017: 37/5282, 0.7%; 2021: 552/44,235, 1.25%), disappointment (2011 - 2017: 64/5282, 1.21%; 2021: 787/44,235, 1.78%), excitement (2011 - 2017: 23/2729, 0.44%; 2021: 477/44,235, 1.08%), and realization (2011 - 2017: 259/5282, 4.9%; 2021: 2902/44,235, 6.56%). Fear (2011 - 2017: 203/5282, 3.84%; 2021: 1223/44,235, 2.76%) and neutrality (2011 - 2017: 2144/5282, 40.59%; 2021: 14,514/44,235, 32.81%) decreased over time (Table 1).

Emotion	All messages, n/N (%)	Breast conservation, n/N (%)	Mastectomy, n/N (%)
2021	2902/44,235 (6.56)	126/1211 (10.4)	208/2076 (10.02)

[a]Comparison of emotion trends overall and over time across all paragraphs and separated by breast conservation or mastectomy, nonexclusively, in r/breastcancer.

Five emotions became increasingly prevalent for BCS, although they were rare: anger (2011 - 2017: 0/98, 0%; 2021: 5/1211, 0.41%), annoyance (2011 - 2017: 0/98, 0%; 2021: 15/1211, 1.24%), disappointment (2011 - 2017: 0/98, 0%; 2021: 18/1211, 1.49%), disgust (2011 - 2017: 0/98, 0%; 2021: 5/1211, 0.41%), and joy (2011 - 2017: 0/98, 0%; 2021: 24/1211, 1.98%). No emotions showed a consistent trend for mastectomy-related posts (Table 1). Additionally, after 2017, realization and nervousness were more common for BCS than mastectomy annually. Realization, approval, and caring were the most strongly expressed emotions across both BCS (top decile scores: 0.52, 0.48, and 0.43, respectively) and mastectomy (top decile scores: 0.49, 0.41, and 0.5), with breast conservation being more associated with optimism (top decile score: 0.33).

Discussion

Principal Findings

Building upon past research in sentiment analysis of online discussions about breast cancer [4,5,16], NLP identified differences in social media discussions across BCS and mastectomy, reflecting trends reported clinically. Compared to previous studies [4,5,16] conducting sentiment analyses of online forums discussing cancer, our work focused specifically on surgical management options for patients with breast cancer. Our distinct NLP approaches identified that discussions surrounding mastectomy became increasingly positive over time, corresponding with concordant emotions. These findings are consistent with multiple studies that have found a growing trend of patients with early-stage breast cancer choosing mastectomy over BCS [3,17]. While it is not feasible to determine the reason for the observed increase in positive sentiments for mastectomy mentions based on the data available in this study, it does indicate a parallel with real-world patient decision-making.

Discussion in this breast cancer–specific forum increased substantially over time, confirming that patients are increasingly using social media as a resource. BCS and mastectomy-related posting increased, emphasizing trends in content-specific information. In a recent survey study, patients reported that their cancer diagnosis prompted them to join social media platforms, and over 80% of respondents reported using social media to gather information online [9]. The predominance of objectivity (neutrality emotion) and informative (realization and curiosity) emotions supports these findings.

Evidence surrounding treatment choice for early-stage breast cancer suggests the decision to pursue mastectomy over BCS is often driven by fear of recurrence and secondary cancers [18]. Our application of NLP identifies this in the online setting, with BCS posts more likely to express nervousness. Negative emotions such as anger, annoyance, disappointment, and disgust also became increasingly prevalent over time in BCS posts.

This study is limited by confounders. While VADER and GoEmotions are specifically developed for social media text and based on complementary approaches, they also may reflect inaccuracies and biases based on limitations in their training. Moreover, sentiments cannot be explicitly attributed to the topics themselves, but rather to the paragraphs associated with specific treatments. Nevertheless, these paragraphs likely reflect related discussions around each of these treatments or some aspect of related care.

These findings provide unique insight into patient decision-making. Social media reflects real-time discussions in a natural setting with less filtered discussion of patient concerns and experiences. Recognizing the sentiments and emotions expressed surrounding the treatment, the decision-making process can help clinicians create patient-centric recommendations.

Conclusion

As social media becomes more pervasive, patients are increasingly discussing options for breast cancer therapy online. NLP can characterize these candid online patient discussions at scale and help clinicians identify barriers to treatment decisions and strengthen counseling for patients. Additional studies will be required to see if ongoing social media sentiment trends continue to track patient decisions.

Abstract

Background: Breast cancer screening plays a pivotal role in early detection and subsequent effective management of the disease, impacting patient outcomes and survival rates.

Objective: This study aims to assess breast cancer screening rates nationwide in the United States and investigate the impact of social determinants of health on these screening rates.

Methods: Data on mammography screening at the census tract level for 2018 and 2020 were collected from the Behavioral Risk Factor Surveillance System. We developed a large-scale dataset of social determinants of health, comprising 13 variables for 72,337 census tracts. Spatial analysis employing Getis-Ord Gi statistics was used to identify clusters of high and low breast cancer screening rates. To evaluate the influence of these social determinants, we implemented a random forest model, with the aim of comparing its performance to linear regression and support vector machine models. The models were evaluated using R^2 and root mean squared error metrics. Shapley Additive Explanations values were subsequently used to assess the significance of variables and direction of their influence.

Results: Geospatial analysis revealed elevated screening rates in the eastern and northern United States, while central and midwestern regions exhibited lower rates. The random forest model demonstrated superior performance, with an R^2=64.53 and root mean squared error of 2.06, compared to linear regression and support vector machine models. Shapley Additive Explanations values indicated that the percentage of the Black population, the number of mammography facilities within a 10-mile radius, and the percentage of the population with at least a bachelor's degree were the most influential variables, all positively associated with mammography screening rates.

Conclusions: These findings underscore the significance of social determinants and the accessibility of mammography services in explaining the variability of breast cancer screening rates in the United States, emphasizing the need for targeted policy interventions in areas with relatively lower screening rates.

Introduction

In the United States, breast cancer ranks as the second most prevalent form of cancer among women, surpassed only by skin cancer [1]. Annually, approximately 240,000 cases of breast cancer are diagnosed in women, and tragically, approximately 42,000 women succumb to this disease each year in the United States. This makes breast cancer the second leading cause of cancer-related mortality among women in the country, following lung cancer [2]. Screening for breast cancer serves as a crucial secondary prevention measure, aimed at identifying the disease at an early stage, prior to clinical manifestation. Early detection of breast cancer enables the implementation of less intensive treatment strategies, contributing to improved survival rates.

XSL•FO
RenderX

Mammography-based screening detects lesions before they achieved clinical visibility [3]. Evidence shows that high-quality routine screening programs have led to a 25% to 31% reduction in breast cancer–related mortality among women aged 50 to 69 years [4].

The US Preventive Services Task Force recommends mammography every two years for women aged 40 to 74 years [5]. Despite these recommendations, current research indicates disparities in mammography screening across different parameters, including variations among women residing in different regions and belonging to different races, with varying levels of median household incomes, health insurance statuses, and access to mammography services [6]. The 2022 Cancer Trends Progress Report revealed that 76% of women aged 50 - 74 years underwent mammogram testing, with rates varying from 74% among Hispanic women to 82% among non-Hispanic Black women [7]. Additionally, 64% of women with less than a high school education, 67.5% of women with incomes below 200% of the federal poverty level, and 75% of those who were Medicare beneficiaries underwent a mammogram test [7]. The Healthy People 2030 [8] has set a target to increase the proportion of breast cancer screenings to 80% [9].

Geospatial and machine learning models have proven effective in identifying the impact of social, natural, and built environments on health outcomes [10-12]. This study seeks to explain the geographical disparities in breast cancer screening across the United States and to explore the area-level socioeconomic factors associated with the rates of breast cancer screening. By examining these disparities, we seek to provide insights that can guide targeted interventions and policies aimed at improving equitable access to breast cancer screening services.

Methods

This cross-sectional study investigates the spatial and socioeconomic factors influencing mammography screening rates among women aged 50 to 74 years in the United States. The methodology section outlines the steps, including data collection, variable selection, descriptive analysis, spatial analysis, machine learning model implementation, and model performance evaluation.

Data Collection

Dependent Variables

The data for mammography screening rates in this study were sourced from the Centers for Disease Control and Prevention's (CDC) PLACES Project for the years 2018 and 2020, which used responses collected through the Behavioral Risk Factors Surveillance System (BRFSS) survey [13]. This survey specifically targeted female respondents aged 50-74 years, categorizing them as women who reported having undergone mammogram screenings and those who did not (excluding unknowns and refusals). Our data extraction process comprised two main stages. First, we extracted age-adjusted mammography screening rates at the county level for spatial analysis, facilitating the visualization of patterns across the entire country. Second, we obtained the crude rates (raw percentages) of mammography screening at the census tract level, a small geographic unit used by the US Census Bureau for collecting and analyzing statistical data, explanatory analysis, and prediction model development by machine learning methods.

Independent Variables

Based on a preliminary literature review, we selected independent variables for the study from various sources. We incorporated socioeconomic data from the CDC, the 2013 - 2017 American Community Survey, the United States Department of Agriculture, and the Health Resources and Services Administration. The analyzed variables encompass a range of factors, including urban-rural location, population density, the rate of older women (aged 55 to 74 years), poverty rate, ethnicity (Black and Hispanic), educational attainment, uninsured rate, median home value, social vulnerability index, and primary care shortage area.

To assess accessibility, we used data from the US Food and Drug Administration's Mammography Facility Database, which included geocoding the locations of 8706 mammography centers. The geodesic distance from each census tract to the nearest facility and the number of facilities within a 10-mile radius were calculated. Table 1 provides a comprehensive overview of the dependent and independent variables used in this study, including their names, sources, and definitions.

XSL•FO

Table . Dependent and independent variables used in this study.

Variable name	Source	Unit	Definition
Dependent variables			
Mammography rate (2018)	CDC[a]	Percent	Crude percent of mammography use among women aged 50 - 74 years in 2018
Mammography rate (2020)	CDC	Percent	Crude percent of mammography use among women aged 50 - 74 years in 2020
Independent variables			
Urban-rural location	USDA[b]	Binary	Urban or rural tract as of 2019
Population density	2013 - 2017 ACS[c]	Per square mile	Number of people per square mile
Number of women aged ≥55 years	2013 - 2017 ACS	Percent	Estimated percent of the female population aged 55 or above
Poverty rate	Census ACS data	Percent	Estimated percent of all people that are living in poverty
Without health insurance	2013 - 2017 ACS	Percent	Estimated percent of the population without health insurance coverage
Higher education rate	2013 - 2017 ACS	Percent	Estimated percent of the population ≥25 years, with a bachelor's, graduate, or professional degree
Black population	2013 - 2017 ACS	Percent	Percent of the population that is Black or African American, by single census classification
Hispanic population	2013 - 2017 ACS	Percent	Percent of the population identified as Hispanic or Latino
Home value	2013 - 2017 ACS	Dollar	Estimated median value of an owner-occupied housing unit
Social vulnerability index	CDC	Index	Social vulnerability level as of 2020
Primary care shortage	HRSA[d]	Binary	Primary care health professional shortage area status as of 2020
Distance to nearest mammography facility	Calculated	Mile	Distance from the center of the census tract to the nearest accredited mammography facility
Number of mammography facilities	Calculated	Number	Number of mammography facilities within the 10-mile catchment of the census tract

Analysis

Preprocessing

The primary objective of preprocessing was to handle missing values of both dependent and independent variables within the dataset. Due to the complexity of accounting for both spatial and temporal correlations in imputing breast cancer screening rates, we opted to exclude any census tracts that lacked mammography screening data in the BRFSS dataset for the years 2018 and 2020. Missing independent variables were imputed using the mean values for numerical data and the mode for binary data from the 20 closest neighboring records.

Thematic Mapping and Spatial Clustering

The age-adjusted rates for breast cancer screening were integrated into a shapefile of ArcGIS containing 3143 counties across all 50 states and the District of Columbia. Subsequently, the data was visualized using the natural break method [14] to enhance clarity. Using the Getis-Ord Gi statistic [15], we identified hotspots indicating areas with either high or low mammography screening rates. This spatial analysis allowed us to discern localized patterns and trends of breast cancer screening behavior.

XSL•FO
RenderX

Machine Learning Analysis

While constructing the predictive model, the response variable was the mean value of mammography screening rates in 2018 and 2020 for each census tract. The dataset was randomly split into two parts: 75% was used for training the model, and the remaining 25% was reserved for testing. This division allowed us to develop the model using the training data and then assess its predictive performance on the unseen testing data.

In this study, an ensemble learning algorithm known as random forest (RF) was employed to model the relationship between geospatial factors and breast cancer screening rates. Ensemble learning combines multiple models to improve the overall prediction accuracy and robustness, which is the rationale for choosing RF [16].

To enhance the efficacy of the RF model, we conducted a systematic hyperparameter search, where a predefined grid of values for the number of trees and the number of variables sampled at each split were explored to identify the optimal configuration [17]. We defined a grid of values for the number of trees and the number of variables sampled at each split.

We utilized the 5-fold cross-validation to evaluate the RF model's performance across different combinations of hyperparameters. In a 5-fold cross-validation, the dataset is split into 5 subsets, with each subset serving as the validation set once, while the other 4 subsets are used for training. This process helps in assessing the model's generalization ability. The model's performance was fine-tuned by selecting the combination of hyperparameters that minimized the root mean squared error (RMSE), a metric indicating the average difference between observed and predicted values. The RMSE is critical as it directly relates to the model's prediction accuracy, with lower values indicating better performance [18].

To benchmark the performance of the RF model, we also implemented the linear regression (LR) and support vector machine (SVM) models. The LR provides a straightforward baseline, while SVM is known for its effectiveness in high-dimensional spaces. The inclusion of these three algorithms was motivated by their complementary strengths in handling different data characteristics, allowing for a comprehensive comparison of predictive accuracy.

The models were implemented using the Scikit-learn package in Python, a widely used library for machine learning that provides efficient tools for model training, evaluation, and hyperparameter optimization [19].

Following the training process, predictions of breast cancer screening rates were made on a separate testing set. Model accuracy was evaluated using metrics such as R^2 and RMSE. R^2 represents the proportion of variance in the dependent variable explained by the model, serving as an indicator of goodness-of-fit. RMSE, as previously mentioned, measures the average difference between predicted and observed values, providing insight into the model's prediction error [18].

To interpret the model's predictions, we calculated Shapley Additive Explanations (SHAP) values for each feature. SHAP values provide a detailed understanding of how each feature contributes to the model's predictions [20]. By examining the mean SHAP values, the most influential variables in predicting breast cancer screening rates were identified. For variables with average SHAP values exceeding 0.3, scatterplots were created to explore the direction and magnitude of their effects on screening rates [21].

Ethical Considerations

The Institutional Review Board at the University of Tennessee Health Science Center determined that this study (24 - 10240-NHSR) qualifies for Not Human Subjects Research status as it does not involve human subjects as defined by 45 CFR 46.102. The data used in this study were obtained from the publicly available BRFSS dataset provided by the CDC. All study data were aggregated at the census tract level, and no individual-level data were accessed or analyzed, ensuring participant anonymity and compliance with ethical standards.

Results

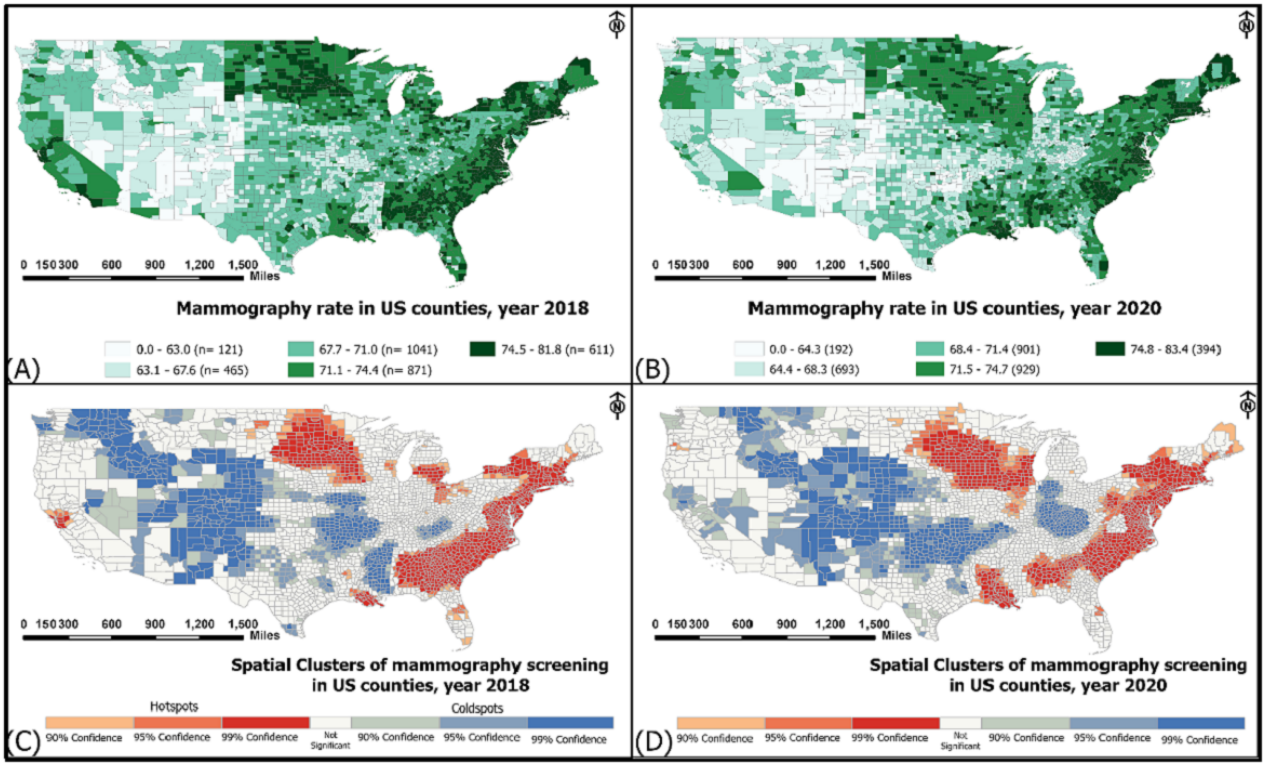
Summary Statistics About Data

Of the 72,337 census tracts nationwide, 49,118 were eligible for inclusion in our analysis, as they had available mammography screening data. The mean mammography screening rate within these census tracts was 77% (SD 3.62) in 2018 and 76.51% (SD 3.71) in 2020. Table 2 provides a detailed overview of summary statistics for all variables considered in our analysis, encompassing the 49,118 included census tracts.

XSL•FO
RenderX

Table . Summary statistics for all dependent and independent variables for 49,118 census tracts included in the analysis.

Variables	Missing values, n	Census tracts (N=49,118)
Mammography rate (2018) (%), mean (SD)	0	77 (3.6)
Mammography rate (2020) (%), mean (SD)	0	76.5 (3.7)
Location n (%)		
Rural	0	12,284 (25)
Urban	0	36,834 (75)
Population density (per square mile), mean (SD)	0	5,547.38 (13,334.53)
Women aged ≥55 years (%), mean (SD)	0	7.9 (4.0)
Poverty rate (%), mean (SD)	49	16.3 (12.5)
Without health insurance (%), mean (SD)	35	11.47 (7.83)
Higher education rate (%), mean (SD)	4	28.4 (18.6)
Black population (%), mean (SD)	1	15.2 (23.6)
Hispanic population (%), mean (SD)	1	12.7 (18.5)
Home value (US $), mean (SD)	727	203,834 (170,438)
Social vulnerability index, mean (SD)	82	0.59 (0.28)
Primary care shortage, n (%)		
Yes	0	28,031 (57.1)
No	0	21,087 (42.9)
Distance to nearest mammography (miles), mean (SD)	0	1.8 (3.2)
Number of mammography facilities, mean (SD)	0	18.1 (28.6)



Thematic Mapping and Spatial Clustering

Figures 1A and B illustrate the distribution of breast cancer screening rates across the 3143 US counties for the years 2018 and 2020, respectively. Regions in the eastern and northern parts of the country exhibited higher rates of breast cancer screening (>71%), while counties in the central, midwestern, and southern areas displayed comparatively lower rates (<63%). While these visual representations provide valuable insights, further confidence in the findings is derived from statistical and spatial analyses.

Figures 1C and D present the outcomes of Getis-Ord Gi statistics for the clustering of breast cancer screening rates across the United States in 2018 and 2020, respectively. The red areas (hotspots) on these maps represent spatial clusters characterized by high mammography rates, indicating that the screening rates and their neighboring values significantly surpass those in other regions. Conversely, the blue areas denote coldspots, representing spatial clusters with lower screening rates. The similarity in patterns between the two time points underscores the reliability of the observations and strengthens the robustness of the identified spatial clusters. The map also reveals certain disparities. For instance, counties along the western borders, such as California, experienced a decline in mammography rates from 2018 to 2020. Similarly, regions in Indiana, Texas, and Arkansas saw decreased rates of breast cancer screening during this period. Conversely, parts of Illinois and Louisiana showed reported mammography rates from 2018 to 2020.

XSL•FO
RenderX

Figure 1. Age-adjusted rates of breast cancer screening in US counties for (A) 2018 and (B) 2020. Spatial clusters in (C) 2018 and (D) 2020.

Machine Learning Analysis

Evaluation of the final RF model, along with the LR and SVM models, based on R^2 and RMSE of the testing dataset is presented in Figure 2. The results indicate that the RF model, with an optimal number of trees set to 500 and the number of nodes (m) set to 4, outperforms both LR and SVM. Specifically, the RF model achieved a higher R^2 value and a lower RMSE, indicating its superior ability to capture and predict the underlying patterns in the data. This performance underscores the suitability of the RF model for this analysis.

Figure 3 depicts the relative importance of each factor, as determined by SHAP values, at the census tract level in predicting the rate of breast cancer screening across the United States. The mean of SHAP values provides a measure of the overall contribution of each variable to the model's predictions. As evident from Figure 3, the proportion of the Black population is the most important factor, followed by the number of mammography facilities within a 10-mile distance and the higher education rate. For the subsequent analysis, we refined our focus to variables with SHAP values exceeding 0.3 (the top 6 variables) to assess the direction and magnitude of influence that each variable exerts on the prediction of breast cancer screening rates as the variables vary in value.

While assessing variable importance using mean SHAP values offers crucial insights into the most influential factors in predicting breast cancer screening rates, it does not elucidate the direction of their effects on the outcome variable across different variable values. To address this, we generated scatterplots of individual SHAP values for the selected six variables to examine the detailed changes in SHAP values across varying values of these variables. Figure 4 shows that higher proportions of the Black population, higher education levels, an increased number of mammography facilities, and a higher median home value exhibit positive associations with breast cancer screening rates. Conversely, a higher proportion of Hispanic ethnicity and a lack of health insurance demonstrate negative impacts on the screening rates.

Discussion

Our research employed a combination of spatial analysis, statistical methods, and machine learning techniques to elucidate the disparities in breast cancer screening across the United States. Spatial patterns revealed clusters of low screening rates, particularly in central, midwestern, and southern regions, contrasted with hotspots of mammography rates, particularly evident along the east coast and in the northern parts of the United States. A predictive model for breast cancer screening rates was developed using the RF algorithm. Meanwhile, key influencing factors for predicting breast cancer screening rates were identified based on the mean SHAP values, including the proportion of the Black population, availability of mammography facilities, and higher education rates.

Spatial clustering identified through Getis-Ord Gi statistics reinforces the observed patterns and underscores their persistence across two distinct time points (2018 and 2020). The consistency of these spatial clusters suggests enduring factors influencing breast cancer screening behavior in specific areas, providing valuable information for policy makers and health care professionals seeking to implement targeted interventions.

It is crucial to acknowledge that the onset of the COVID-19 pandemic has significantly impacted various aspects of human life, including breast cancer screening [21]. The pandemic may have played a role in the decreased mean breast cancer screening rate of breast cancer from 77% in 2018 to 76.51% in 2020. The disruption of routine health care services and the challenges associated with social distancing could have affected mammography screening rates, particularly in urban areas with denser populations. However, it is important to consider that the BRFSS survey focuses on individuals who have undergone breast cancer screening in the last two years. Consequently, women who underwent mammography screening in the year prior to the COVID-19 pandemic could still respond affirmatively. The influence of COVID-19 on the average rate and pattern of breast cancer screening may vary significantly in 2022 and 2023, particularly in cities with higher disease prevalence. Additional investigations are warranted to understand the influence of COVID-19 on changes in breast cancer screening rates across the United States and globally.

Our machine learning analysis that uses an RF model contributes toward understanding the complex interplay of various factors influencing breast cancer screening rates. The RF model with optimal hyperparameters outperformed the LR and SVM models. The ability of RF to capture complex nonlinear relationships and interactions among influencing factors aligns with findings from other population-level studies, highlighting its superiority in predicting population health outcomes [22,23], which confirms our choice of RF as the primary model for our analysis.

While the RF model demonstrated superior performance in predicting breast cancer screening rates, there is a potential risk of overfitting, inherent to ensemble methods [24]. To mitigate this, we implemented cross-validation during the hyperparameter tuning process and evaluated the model's performance on a separate testing dataset to ensure that the RF model maintained its predictive accuracy on unseen data.

It is particularly noteworthy that a higher proportion of the Black population within a census tract was positively associated with increased mammography screening rates. This finding aligns with a 2022 cancer trends progress report, which revealed that 82% of Black women underwent mammography screening, while the screening rate was as low as 74% among other ethnic groups [1]. Possible explanations for this positive association

XSL•FO
RenderX

may include the effectiveness of targeted public health interventions and community-based outreach programs specifically designed to increase awareness and accessibility of breast cancer screening in these communities. Additionally, it may reflect a growing awareness and proactive behavior regarding breast cancer prevention among Black women, possibly influenced by public health campaigns and community support networks. Some studies also suggested that when access to health care is equitable, racial and ethnic minorities who are often more aware of their heightened risk, may be more likely to use preventive services like mammography [25]. However, despite the relatively higher mammography screening rates in areas with a larger Black population, it is crucial to underscore that Black women are 40% more likely to die from breast cancer compared to White women [26]. This disparity could be attributed to delays in diagnosis and treatment, particularly when a breast tissue abnormality is identified by mammography [27,28]

Our findings highlighted the importance of the number of available mammography facilities within a 10-mile radius, despite the relatively low SHAP value assigned to the distance to the nearest facility. A plausible explanation is that proximity to a facility may not always be a decisive factor, as various considerations such as affordability and type of insurance can significantly impact facility selection. Moreover, our research revealed that the education rate plays a pivotal role in determining breast cancer screening rates. This finding aligns with prior studies indicating that American women with lower educational attainment are less likely to undergo screening [29]. Educational attainment is closely linked to health literacy [27]; women with lower health literacy have a reduced likelihood of accessing health services, including breast cancer screening [28]. Moreover, women with lower educational attainment might face limited employment opportunities and a lack of jobs that offer access to employee health insurance, leading to a lower likelihood of consulting physicians who recommend mammography.

The variables of home value, rate of the Hispanic population, and rate of the uninsured population exhibited relatively similar and high SHAP values. Areas with higher home values and lower uninsured populations tend to have fewer financial barriers to accessing preventive services. According to existing literature, Hispanic women exhibit lower rates of breast cancer and mortality compared to non-Hispanic Black women and non-Hispanic White women [30]. This disparity could explain the lower screening rate in census tracts with higher proportions of Hispanic population.

Variables analyzed in this study are based on estimates from the CDC PLACES project, which uses a multilevel regression and poststratification approach. This method combines individual-level BRFSS data with demographic data from the US Census to produce reliable estimates at small geographic levels, including census tracts. The multilevel regression and poststratification method has been validated against direct survey data, ensuring that the aggregated rates at the census tract level are both stable and accurate for our analysis [31].

Our study has several limitations. The use of cross-sectional data restricts our capacity to establish causality, underscoring the importance of future research examining temporal changes in breast cancer screening rates. Moreover, as is inherent in all self-reported sample surveys, the BRFSS data may be susceptible to systematic errors stemming from noncoverage, nonresponse, or measurement bias. It is imperative to note that our study was conducted at an aggregate level; therefore, prudence is advised when extrapolating individual-level conclusions. The ecological fallacy, a key concern in population studies, underscores the necessity of avoiding assumptions about individual behaviors based solely on group-level observations.

This study provides a comprehensive analysis of breast cancer screening disparities in the United States, combining spatial, statistical, and machine learning approaches. The spatial patterns and influential factors identified in this study offer valuable insights for policy makers, health care professionals, and researchers striving to implement targeted interventions to reduce breast cancer screening disparities and improve overall public health outcomes. Ongoing research and targeted interventions are vital for achieving equitable access to breast cancer screening services and ultimately reducing the impact of this significant health issue.

Abstract

Background: Breast cancer is a major health concern in various countries. Routine mammography screening has been shown to reduce breast cancer mortality, and Japan has set national targets to improve screening participation and increase public attention. However, collecting nationwide data on public attention and activity is not easy. Google Trends can reveal changes in societal interest, yet there are no reports on the relationship between internet search volume and nationwide participation rates in Japan.

Objective: This study aims to reveal and discuss the relationship between public awareness and actual behavior in breast cancer screening by examining trends in internet search volume for the keyword “breast cancer screening” and participation rates over a decade-long period.

Methods: This time-series study evaluated the association between internet search volume and breast cancer screening participation behavior among women aged 60‐69 years in Japan from 2009 to 2019. Relative search volume (RSV) data for the search term “breast cancer screening (nyuugan-kenshin)” were extracted from Google Trends as internet search volume. Breast cancer screening and further assessment participation rates were based on government municipal screening data. Joinpoint regression analyses were conducted with weighted BIC to evaluate the time trends. An ethics review was not required because all data were open.

Results: The RSV for “breast cancer screening (nyuugan-kenshin)” peaked in June 2017 (100) and showed clear spikes in June 2016 (94), September (69), and October (77) 2015. No RSVs above 60 were observed except around these three specific periods, and the average RSV for the entire period was 30.7 (SD 16.2). Two statistically significant joinpoints were detected, rising in December 2013 and falling in June 2017. Screening participation rates showed a temporary increase in 2015 in a slowly decreasing trend, and no joinpoints were detected. Further assessment participation rates showed a temporary spike in 2015 in the middle of an increasing trend, with a statistically significant point of slowing increase detected in 2015. Post hoc manual searches revealed that Japanese celebrities’ breast cancer diagnoses were announced on the relevant dates, and many Japanese media reports were found.

Conclusions: This study found a notable association between internet search activity and celebrity cancer media reports and a temporal association with screening participation in breast cancer screening in Japan. Celebrity cancer media reports triggered internet searches for cancer screening, but this did not lead to long-term changes in screening participation behavior. This finding suggests what information needs to be provided to citizens to encourage participation in screening.

KEYWORDS

breast cancer; cancer screening; internet use; mass media; public health surveillance; health belief model; mammography; awareness; Japanese; Google

Introduction

Breast cancer is a major health concern that affects large numbers of women in various countries. It is the most common cancer in women, with approximately 2.3 million new cases diagnosed and 680,000 deaths reported in 2020 [1,2]. The disease burden of breast cancer is also high in Japan. The age-adjusted incidence rate of breast cancer continues to increase every year, and it has been reported that breast cancer accounts for about 20% of all cancers in women in Japan [3,4]. As Japan’s

XSL•FO
RenderX

population ages, the burden of breast cancer is predicted to increase [5].

Several studies have indicated the efficacy of mammography screening for breast cancer in reducing the burden of breast cancer. Routine mammography screening has been shown to reduce breast cancer mortality by 25% - 31% [6,7]. The long-term effects of mammography have also been shown in a 30-year follow-up study [8]. In Japan, national policy recommends biennial mammography for breast cancer screening in women older than 40 years [9]. Therefore, screening is a practical approach to reducing the long-term burden of breast cancer, and its importance is increasing in Japan.

Cancer screening programs in Japan are divided into two main types: municipal screening and workplace screening. Municipalities conduct screenings, and information is collected by the Ministry of Health, Labor, and Welfare and made available to the public. This is the only data on cancer screening for all regions in Japan for which the government reports actual statistics annually. This report includes data on screening and further assessment participation. The participation rate is the proportion of the target population that receives the primary screening test, which in the case of breast cancer screening is mammography. The further assessment participation rate is the proportion of women who, after a positive screening test result, receive the following test to confirm the diagnosis: fine needle aspiration cytology or core needle biopsy in breast cancer screening. Even if a person participates in screening, the effectiveness of cancer screening will not be fully realized unless the screening-positive person receives a further assessment. The further assessment participation rate is an important indicator, as is the screening participation rate. Japan has set national targets to improve screening participation, further assessment participation, and increase public attention to the importance of cancer screening [10]. Understanding the public's attention and behavior around cancer screening is critical to improving screening participation rates. However, it is not easy to collect nationwide data on public attention and activity to assess the association with screening participation.

Internet search volume has recently become one of the most valuable tools for exploring human interests and behavior. Google Trends is a popular open web-based tool that quantifies changes in internet search volume for a given term based on actual Google search history [11,12]. Google Trends is used for academic research in fields as diverse as social science, economics, language, and medicine and can also reveal changes in societal interest in public health issues [13]. Google Trends initially focused on detecting infectious disease outbreaks, and past studies have reported early detection of influenza outbreaks [14].

Google Trends is now expected to be used in noncommunicable disease areas such as mental health and preventive behaviors and is a potential source of information for understanding the public's interest in and behaviors around cancer screening [15]. Malaysia reported a significant correlation between Google Trends search patterns and Pink Ribbon Month, a breast cancer awareness campaign [16]. Among several internet search engines, Google was also shown to have the best search validity (regarding whether a web page could be opened) for breast cancer screening information [17]. In contrast, a previous Japanese study analyzed trends in cervical cancer and reported no change in public interest during the cervical cancer awareness month [18].

Therefore, there is considerable interest in the relationship between internet search activity and cancer screening. In Japan, it would be valuable to determine the relationship between public attention to cancer screening and participation rates at the national level to understand public awareness and behavior. However, there are no reports on the relationship between changes in internet search volume and long-term trends in nationwide participation rates in Japan.

This study examined the relationship between public awareness and actual behavior in breast cancer screening at the national level. This study is the first report in Japan to reveal and discuss the background of the relationship between trends in internet search volume for the keyword "breast cancer screening" and participation rates over a decade-long period. As an example of the application of epidemiologic research using internet search volume, this approach could provide knowledge for promoting cancer screening and providing appropriate information.

Methods

Study Design

This time-series study uses internet search volume and national cancer screening statistics. Internet search volume targets those who conducted searches in Japanese using Google in Japan. Cancer screening data targets municipal screening in Japan. Both data are openly available on the web.

Data Sources (Internet Search Volume)

Google Trends is a data tool that publishes the volume of keyword searches worldwide in Google Search, an internet search engine, since 2004. This tool allows users to access the relative search volume (RSV) but not the absolute number of searches. RSV is calculated on a scale of 0 to 100 based on the volume with the most searches per unit of time in the defined region, period, category, and search term. For example, RSV=30 means 30% of the highest search volume observed within a given condition. RSVs can assess changes in interest in a particular term by showing the relative value of search volume trends over time.

The search term was "nyuugan-kenshin," which means "breast cancer screening" in Japanese. Monthly RSV data from the Google Trends platform were retrieved on September 17, 2023. Since the Japanese term "nyuugan-kenshin" is written as one continuous word without any spaces, we did not enclose it in quotes when using it in Google Trends. Because Google Trends does not provide a "Topic" option for the Japanese term "nyuugan-kenshin," we used the "Search Term" option instead. It was set to Japan as the target region and 2009 - 2019 as the target period. To ensure that all possible contexts in which the term might appear were captured, we set "All categories" as the "Category" and "Web Search" as the "Search Type."

XSL•FO
RenderX

If a significant trend increase was observed, a post hoc manual search was conducted using the "Related Keywords" feature of Google Trends to see if any socially essential media reports might be related to the increase.

Data Sources (Cancer Screening)

For cancer screening, this study included screening participation rates and further assessment participation rates in municipal screening for breast cancer in Japan from 2009 to 2019. Municipal screening does not include individuals who participate in workplace screening. Consequently, when calculating screening participation rates for ages 40 years and older using the population as the denominator, workplace screening participants are excluded from the numerator. This omission can lead to fluctuations in time-series data, for example, if there is a change over time in the proportion of working individuals. Furthermore, when participation rates differ by age group, they are also affected by changes in the age distribution over time. To eliminate this effect as much as possible and to improve the time-series analysis's validity, the calculation of participation rates was restricted to women aged 60 - 69, who are mainly retired. The number of participants in screening, positive cases in screening, and further assessment participants were obtained from the "Report on Regional Public Health Services and Health Promotion Services" by the Ministry of Health, Labor, and Welfare [19]. Population data were obtained from the Statistics Bureau of the Ministry of Internal Affairs and Communications [20]. Screening participation rates were calculated by dividing the number of screening participants by the population of women in the target age group. The further assessment participation rates were calculated by dividing the number of further assessment participants by the number of positive screening cases. The recommended interval for breast cancer screening in Japan is once every two years, and the original "screening participation rates" are calculated by considering the number of participants screened for two years. However, this calculation method equalizes two years of information and may not detect sensitive value changes. As this study aimed to detect changes over time rather than absolute assessments, "screening participation rates" were defined as calculated values per one-year period and used in the analyses.

Statistical Analysis

Joinpoint regression analyses were performed to assess RSV trends quantitatively. This analysis is an appropriate way to examine data over time and statistically detect points of change in gradient [21]. The software used was the Joinpoint Regression Program (version 5.0.2, Statistical Research and Applications Branch, National Cancer Institute) [22]. The statistical method used for joinpoint detection was weighted BIC, a standard method in Program version 5.0 and later. Weighted BIC is the most flexible and adaptable method for various situations in this software. Joinpoint regression analysis requires many computing resources, and the calculation time depends on the maximum number of detectable joinpoints set before the calculation. This analysis's maximum number of joinpoints was set to 3 due to calculation time. Changing the maximum number of joinpoints can alter the significance level for individual tests and potentially change the number of joinpoints in the optimal model [22]. When no joinpoints were detected in the initial analysis, we conducted additional analyses with the maximum number set to two and one. The statistical significance level for joinpoint detection was set to 0.05.

Ethical Considerations

This study was conducted per the principles of the Declaration of Helsinki. An ethics review was not required because all data used in this study were open. For this type of study, formal consent is not required.

Results

Internet Search Volume

Figure 1 shows the trend of RSVs for the search term "breast cancer screening (nyuugan-kenshin)" from 2009 to 2019. The RSV peaked in June 2017 (100) and showed clear spikes in June 2016 (94), September 2015 (69), and October 2015 (77). No RSVs above 60 were observed except around these three specific periods. The average RSV for the entire period was 30.7 (SD 16.2). Figure 2 shows the results of the joinpoint regression analysis for RSVs. Two statistically significant joinpoints were detected, rising in December 2013 and falling in June 2017.

Cancer Screening Participation

Figure 3 shows the trend of breast cancer screening participation rates from 2009 to 2019. Visual observation shows a temporary increase in 2015 in the slowly decreasing trend. Figure 4 shows the results of the joinpoint analysis for screening participation rates. No joinpoints were detected. Even in additional analyses with the maximum number set to two or one, no joinpoints were detected.

Figure 3. Annual breast cancer screening participation rates (mammography) among Japanese women aged 60 - 69 years from 2009 to 2019, based on municipal screening data. The rate is the proportion of screening participants in the target population.

XSL•FO
RenderX

Figure 4. Joinpoint regression analysis of the annual breast cancer screening participation rates (mammography) among Japanese women aged 60 - 69 years from 2009 to 2019. No joinpoints were detected.

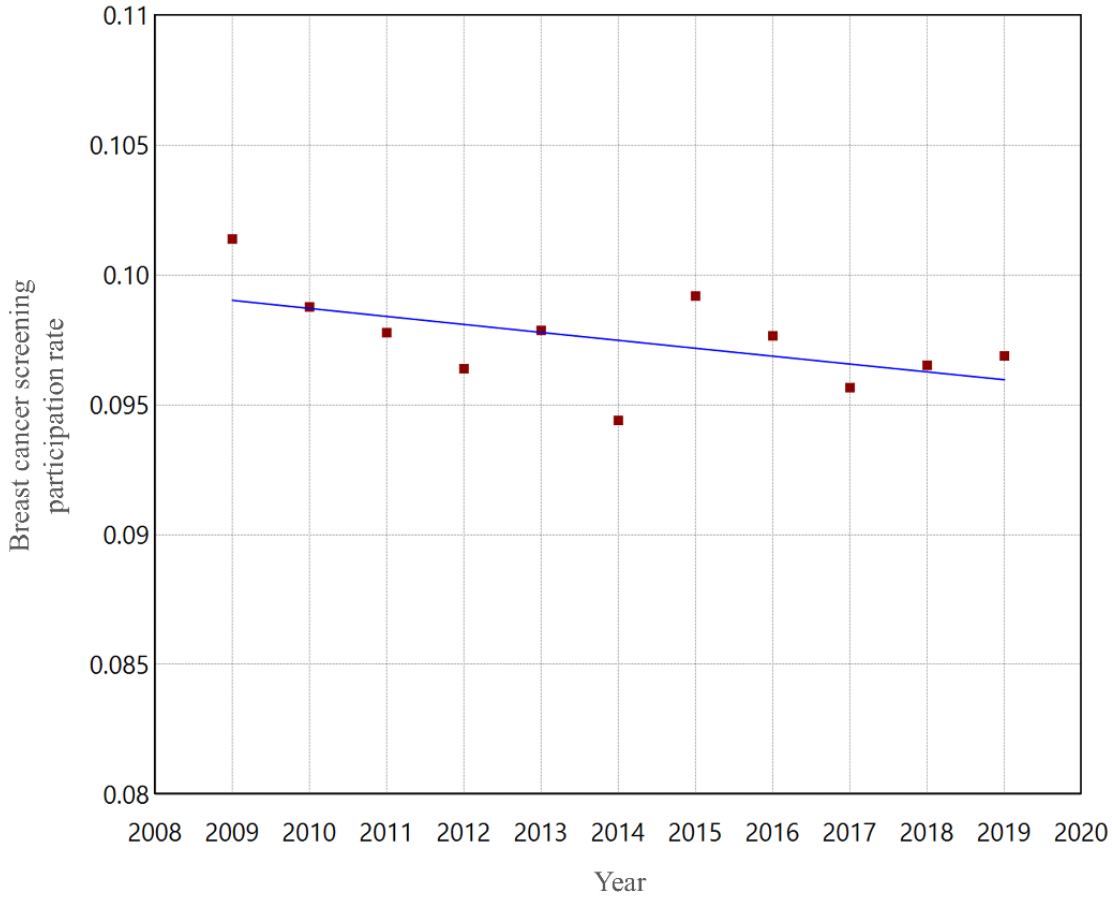

Figure 5 shows the trend of further assessment participation rates for breast cancer screening from 2009 to 2019. Visual observation shows a temporary spike in 2015 in the middle of an increasing trend. Figure 6 shows the result of the joinpoint analysis for further assessment participation rates. While the trend has been increasing for the entire period, a statistically significant point of slowing increase was detected in 2015. The year 2015 was the maximum for screening and further assessment participation rates, except for 2009 and 2019, the two ends of the period covered.

Post Hoc Manual Search

When RSV spiked in 2015, 2016, and 2017, three periods were explored post hoc. A detailed review of the RSV data downloaded from Google Trends, restricting the period specified, revealed a notable spike on September 23 and 24, 2015, June 9, 2016, and June 23, 2017. The day's news and Google Trends "Related Keywords" were manually searched for these three periods. For the term "nyuugan-kenshin," only general keywords such as "examination," "cost," "mammography," "breastfeeding," and "symptoms" were suggested on each of the relevant dates. In contrast, as "Related Keywords" for "nyuugan (breast cancer)" on September 23 and 24, 2015, a Japanese celebrity, AH, was suggested as a nonmedical term. A Google search limited to the same period revealed that her breast cancer incidence was announced on September 23, 2015, and many Japanese media reports were found. In the same way, the Japanese celebrity MK's breast cancer incidence was announced on June 9, 2016, and her passing on June 23, 2017, confirmed many media reports.

Discussion

General Interpretation of the Results

We conducted a time-series study for 2009 - 2019 on Japanese internet search volume and breast cancer screening data for 60 - 69-year-olds. Internet search RSVs for "breast cancer screening" spiked notably in three specific periods in September 2015, June 2016, and June 2017. The joinpoint analysis for RSVs revealed two joinpoints in December 2013 and June 2017, showing an increase over the period, including the spikes mentioned above. The 10-year trend in internet searches for breast cancer screening was dynamically changing, down, up, and down. The joinpoint of screening data was not detected for screening participation rates but was detected in 2015 for further assessment. Upon examination of Figure 5, it might be reasonable to interpret this as a temporary increase in 2015 and a return to the original trend from 2016 onwards. Indeed, the screening and further assessment participation rates reached their maximum in 2015, except for 2009 and 2019, the two ends of the period covered. A post hoc search for the timing of the three RSV spikes from 2015 to 2017 was consistent with the dates of media reports of breast cancer incidences and the passing of Japanese celebrities.

It is worth noting that 2015 marked the timing of the first media reports on celebrities, the first notable increase in RSVs, and the short-term maximum in the screening and further assessment participation rates. In particular, the consistency of the three dates between celebrity media reports and search trends is evident. RSV provided by Google Trends is not an absolute number of searches but a relative measure of the maximum number of searches scaled to 100 within a defined period. Therefore, if there is even one moment of drastic increase in search, RSV for the rest of the period will be relatively low. The fact that the average volume for the entire period in this analysis was 30.7 (SD 16.2) highlights the magnitude of the three spikes. Many individuals became interested in breast cancer screening when AH and MK were featured in the media, which probably triggered internet search behavior. Additionally, screening and further assessment participation rates increased temporarily in 2015, suggesting some individuals may have engaged in screening participation behaviors. Celebrity media reports may have influenced individuals, leading to search and screening participation behavior. This contrasts with a previous Japanese study that showed no association between cervical cancer awareness months and RSVs for "cervical cancer" [18].

However, screening and further assessment participation rates showed only a temporary spike in 2015 and did not increase the long-term trend. RSVs also declined after the 2017 joinpoint. These findings provide insight into the mechanisms necessary for citizens to be concerned about, act on, and maintain their health. To interpret this study's results, referring to the findings of established behavioral models and previous studies would be appropriate.

Interpretation Based on the Health Belief Model

Participation behavior in cancer screening has been a critical subject of study in the Health Belief Model (HBM). HBM is a theoretical model in the behavioral sciences that aims to explain, predict, and promote individual health behaviors. This model was developed in the 1950s to understand the factors determining participation in immunization and screening [23-25]. HBM considers that individual health behaviors are determined by the interaction of six factors: "perceived susceptibility," "perceived severity," "perceived benefits," "perceived barriers," "self-efficacy," and "cues to action." The model is widely used to design education and promotion programs for health activities. In cancer screening, the model has been primarily used to improve participation in colorectal cancer screening and has been validated in several randomized controlled trials [26,27]. Recently, there has been much research on breast cancer screening [28-33].

It would be meaningful to interpret the results of this study based on HBM. In the media reports, AH was 48 years old, and MK was 32 when they were diagnosed. Consecutive media reports of breast cancer in young celebrities may have caused "perceived susceptibility" among the public. MK passed away about a year after her diagnosis was announced. The sad outcome of the celebrity, which had been worrying through media reports, would have caused "perceived severity" for the public. Indeed, the RSV peaked on June 23, 2017, when MK's passing was announced. MK's weblog about her fight against breast cancer has attracted attention in Japan and around the world, and she was named one of the BBC's 100 Women of the Year in 2016 [34,35]. Citizen exposure to a series of media reports may have fulfilled these elements in the HBM. Additionally, for those who were already aware of "susceptibility" and "severity," media reports on the cancer of celebrities may have become "cues to action" to help them take action.

There have been several reports on the impact of celebrity cancer media reports on the behavior of citizens [36,37]. In Australia, mammography screening appointments increased by 40% in the two weeks following media reports of singer Kylie Minogue's breast cancer diagnosis [38]. In the United States, Angelina Jolie's decision to share her experience with the increased risk of breast and ovarian cancer due to BRCA1 gene

XSL•FO
RenderX

mutations has improved public awareness of the disease and increased genetic testing and breast cancer screening. In particular, Angelina Jolie's influence was reported to be related to "perceived susceptibility" and "cues to action," which are elements of HBM [39,40].

These reports illustrate the appropriateness of interpreting the impact of personal cancer experiences and narratives on people's emotions and behaviors based on the HBM. The findings on these effects support the validity of the interpretation that the two celebrities' media reports were elements of "perceived susceptibility," "perceived susceptibility," and "cues to action" in the HBM.

Importance of Removing Barriers

Conversely, information that provides "perceived benefits" or "self-efficacy" for screening or removes "perceived barriers" is not directly included in the celebrity cancer media reports. In contrast to the case of Angelina Jolie, where there is a direct link between her actions and the benefits of preventive behavior, there is a gap in logic between media reports of celebrity breast cancer and the benefits of screening participation. For internet users, there are few barriers to search action. However, there are significant barriers to screening participation on an entirely different level than internet searches. To participate in screening, citizens must confirm the possible dates, times, locations, and costs, make an appointment, and go to mass screening sites or hospitals. Media reports and internet search activity showed a direct relationship, while screening participation behavior showed a limited response. This suggests that information from media reports and internet searches did not remove barriers to screening participation. Some citizens who participated in screenings triggered by the media reports may not have continued to behave because they were unaware of the benefits. This finding of limited participation versus notable search activity highlights the importance of removing "perceived barriers" in the HBM component. This study's post hoc manual search was limited to breast cancer information for 10 years. In today's Japan, where approximately half of the population will be diagnosed with some form of cancer in their lifetime, media reports on celebrities provide citizens with many opportunities to perceive the susceptibility and severity of cancer. Nonetheless, information to remove barriers does not occur unless someone intends it. The importance of "perceived barriers" in HBM elements has long been recognized [41]. A meta-analysis of 18 communication campaigns shows that "perceived benefits" and "perceived barriers" were consistently the most robust predictors [42]. This study supports the idea that removing barriers is an essential public action to encourage healthy behaviors.

Limitations and Strengths of This Study

There are several limitations to this study. First, there is a restriction due to the time-series analysis design. It is unknown whether specific individuals were exposed to media reports, performed search actions, or participated in screening because this is a comparison through time for the whole population. It is important to note that the results indicate only an association, and do not necessarily imply a causal relationship among celebrity news, search spikes, and screening uptake. Various real-world factors, such as concurrent public health campaigns or medical policies, could have influenced the keyword search volume, the screening participation rate, or both. Even if there is a match between exposure and outcome for an individual, it does not prove causation because confounding by unknown factors cannot be ruled out. Given this study's data sources and design, directly evaluating causality is complex and remains an issue for future research.

Second, there is a lack of data on workplace screening. Japan's cancer screening programs are divided into municipal screening and workplace screening. Due to incomplete legislation on workplace screening, data have not been collected and published for the entire country, and it was necessary to use only municipal screening data. In this study, to remove the effect of the lack of workplace screening data as much as possible, the age range for calculating participation rates was restricted to 60 - 69 years so that retirees would represent most of the population. Due to this restriction, the generalizability of the screening data is limited. In the future, once workplace screening data becomes available, it will be necessary to include those data in the analysis to more accurately evaluate trends in screening participation rates among the working population.

Third, the coverage of Google Trends data. Given that the RSV is based on Google search data, it does not reflect the interests of populations that do not use Google or internet search. The percentage of Japanese aged 60 - 69 years using the internet increased from 71.6% (60-64) and 58% (65-69) in 2009 to 90.5% (60-69) in 2019 [43]. This percentage and time change may have affected the results. Even if internet use was high enough in the age group 60s, RSV is an indicator that includes all ages and does not necessarily reflect search activity in the 60s. Furthermore, even if they use internet search, they may use a search engine other than Google. As of 2019, Google accounted for 92% of the global market share for internet search engines, 93% in Europe and 89% in North America, whereas in Japan, it was 75% [44]. While there is no doubt that Google holds the top market share in Japan, unlike Baidu in China or Yandex in Russia, its relatively lower share compared to Western regions could influence the validity of Google Trends data [45]. Further, an absolute assessment is impossible since RSV is a relative measure for a given period and search term.

Fourth, some of the methods and interpretations of this study were post hoc. In the analysis phase of this study, we found a marked increase in the RSV data for the keyword "breast cancer screening" in three specific periods. To explore background information, we performed a post hoc manual search and found that the media reports of the celebrity matched the RSV spikes. This manual search was not planned at the time the study was designed. Because these manual searches and discussions involve the arbitrariness of the researcher, careful attention should be paid to the validity of the interpretation of the results.

Furthermore, one possible reason that no joinpoints were detected for screening participation rates is that the limited number of data points may not have provided sufficient statistical power. To analyze one or more joinpoints, at least seven data points need to be observed [22]. Although this study had 11 data points for both screening and further assessment

XSL•FO
RenderX

participation rates, exceeding seven, the number of data points may still have been insufficient for detecting any joinpoints.

Despite these limitations, there are strengths to this study. Google Trends, an internet search volume, is a limited source of information that directly reflects changes in the preferences and interests of the entire population over time. Media reports related to changes in internet search volume will be revealed after data analysis. Therefore, the type of study that follows participants prospectively cannot discuss what this study did. Retrospective studies that question about past exposures may cause recall or information bias due to the validity of the questionnaire. Internet search volume has none of these biases and selection biases for study enrollment, so it directly reflects citizens' actual preferences. The screening data also have no self-reporting bias because they are actual values reported to the government by municipalities. This study design is conducive to exploring what influences public interest in cancer screening and leads to participation behavior.

Practical Considerations and Future Implications

We found that internet search volume for "breast cancer screening" was notably associated with media reports of the celebrity's cancer and was temporally associated with participation in screening. Although caution is needed in interpreting causal relationships, it is worth noting that the three periods in which the spike in internet search volume occurred match the media reports of the celebrities. It is reasonable to assume that media reports clearly impacted search activity. The results also showed barriers to screening participation and limitations to explaining behavior only by internet search volume. Established "model" and "effect" in behavioral medicine could describe these associations and limitations. Importantly, pragmatic data without educational intervention or questionnaire surveys supported these effects. This finding suggests that internet search volume is valuable for deciphering individuals' behavior. Internet search volume can also help verify the effectiveness of efficacy findings confirmed by exploratory methods, such as intervention trials, with real-world data. Although it is essential to evaluate various potential biases in internet search volume, with an understanding of its limitations, using it for epidemiologic studies will continue to be beneficial and may suggest improvements in public health policy and risk communication.

Conclusions

The public impact of celebrity cancer media reports found in this study will lead to the development of information and awareness methods to improve and sustain participation in cancer screening. A colorectal cancer awareness campaign conducted on television by Katie Couric, a well-known American television anchor, was associated with an increase in colonoscopy use [46]. The results of this study support the potential for such celebrity publicity for preventive health programs to be temporarily effective in Japan. If doing so, information on removing barriers should be included to maximize and sustain the effect.

Abstract

Background: Patients with breast cancer frequently experience significant uncertainty, prompting them to seek detailed, personalized, and reliable medical information to enhance adherence to prescribed treatments, medications, and recommended lifestyle adjustments. Although high-quality information exists within oncology guidelines and patient-oriented resources, the provision of tailored responses to individual patient queries remains challenging, especially for non–English-speaking populations.

Objective: This study aims to evaluate the potential of an artificial intelligence–driven chatbot, specifically leveraging ChatGPT (GPT-4; OpenAI) combined with retrieval-augmented generation, to deliver personalized answers to complex breast cancer-related patient questions in German.

Methods: We collaborated with one of Germany's largest breast cancer Patient Representation Groups to collect authentic patient inquiries, receiving a total of 118 questions. After initial screening, we selected 104 medical questions, organized into 7 distinct categories: aftercare, bone health, ductal carcinoma in situ, diagnostics, nutrition and supplements, complementary medicine, and therapy. A customized version of GPT-4 was configured with specific system prompts emphasizing empathetic, evidence-based responses and integrated with a comprehensive database comprising guidelines, recommendations, and patient information materials published by recognized German medical societies. To assess chatbot responses, we used 4 evaluation criteria: comprehensibility (clarity from a patient perspective), correctness (accuracy per current medical guidelines), completeness (inclusion of all relevant aspects), and potential harm (risk of undue patient harm or misinformation). Ratings were conducted using a 5-point Likert scale by a breast cancer expert (correctness, completeness, and potential harm) and patient representatives (comprehensibility).

Results: The chatbot provided high-quality responses across multiple dimensions. Of the 499 responses evaluated for comprehensibility, 427 (85.6%) were rated as comprehensible. Among the 104 responses assessed for the remaining dimensions, 91 (87.5%) were rated as correct, 72 (69.2%) as complete, and 93 (89.4%) as nonharmful. Reasons for incomplete answers included omission of reimbursement details, updates from recent therapeutic guidelines, or nuanced recommendations regarding endocrine therapy and aftercare schedules. In addition, 6 (5.8%) of the answers were rated as potentially harmful due to outdated or contextually inappropriate recommendations. The chatbot also performed well in the nutrition and bone health categories despite occasionally incomplete document retrieval.

Conclusions: Our findings demonstrate that an artificial intelligence–powered chatbot with GPT-4 and retrieval augmentation can effectively provide personalized, linguistically accessible, and largely accurate information to German-speaking patients with breast cancer. This approach holds considerable promise for improving patient-centered communication, empowering patients to make informed decisions. Nonetheless, observed limitations regarding response completeness and potential harm underscore the critical need for ongoing human oversight. Future research and development should prioritize regularly updated databases, advanced retrieval methods to handle complex document structures, multimodal capabilities, and clearly articulated disclaimers emphasizing the necessity of professional medical consultation. Our evaluation, along with the provided set of realistic patient questions, establishes a benchmark for future development and validation of German-language oncology chatbots.

KEYWORDS

breast cancer; chatbot; patient information; Generative artificial intelligence; Gen AI; Retrieval-augmented generation; RAG

Introduction

Breast cancer (BC) is the most frequent form of cancer in women [1,2] and a global health concern. Patients with BC have a substantial need for information on their disease at all stages of the patient journey, prefer information tailored to their individual circumstances [3-5], and it is well-known that information on disease and treatments is an important factor for medication adherence and persistence [6-9]. While health care professionals (HCPs) aim to provide comprehensive answers, time constraints and resource limitations can lead to a mismatch in information provision.

Many patients routinely use the internet as a source for information about their condition [5,10], which increases their risk of exposure to misinformation [11,12]. It is expected that patients increasingly turn to artificial intelligence (AI)–based solutions, such as chatbots, which can help to assess the credibility of information. Chatbots can play a significant role in informing patients about their situation and treatment options [13-16]. A substantial benefit of digital information sources is the easy 24-hour access to information and that these sources may answer questions that were left out during consultation by the HCPs. This may help patients have a more informed consultation with their HCP and supports shared decision-making.

Chatbot apps based on large language models (LLMs) are promising as interactive assistants to tailor medical information for patients' specific needs [17-20]. Most existing chatbots are primarily trained on English language data, creating a language barrier for non–English-speaking patients [21,22]. LLM-based chatbots can generate conversational and personalized answers that include context. In general, medical practice differs significantly between different countries due to differences in reimbursements, regulatory frameworks, and cultural attitudes, among other factors [23,24]. While English-speaking LLM-based chatbots are developed for other cancer entities [25], there are, to the best of our knowledge, no existing publications about LLM-powered chatbot solutions for German-speaking patients with BC.

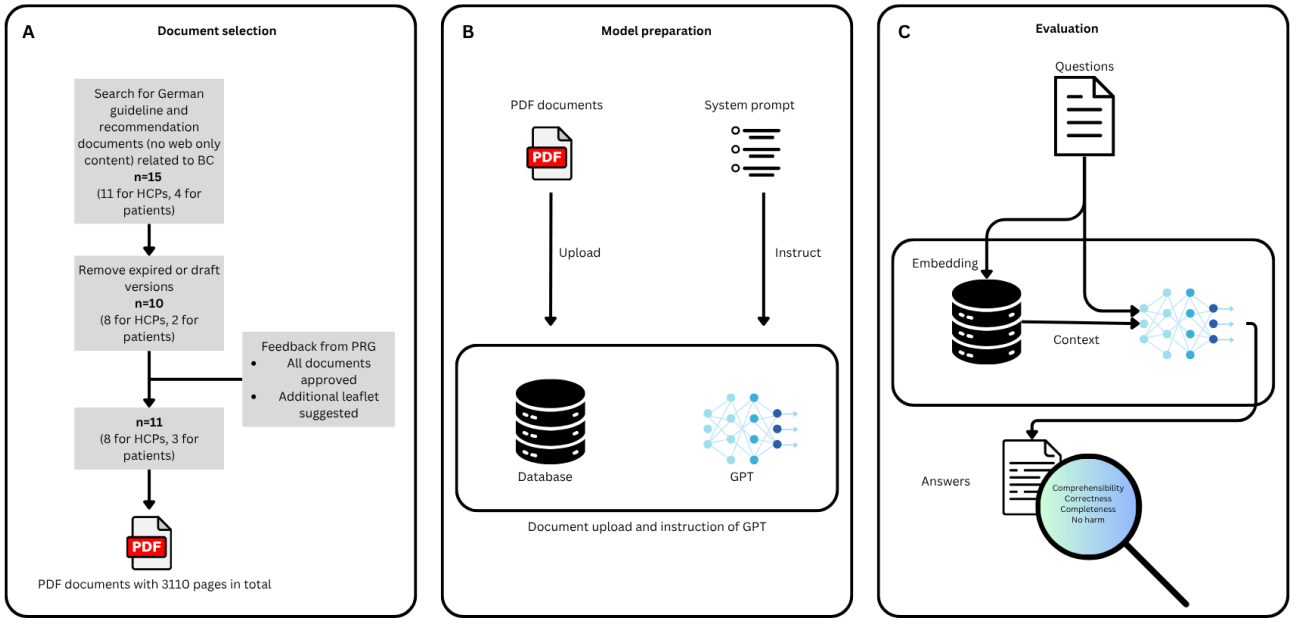
The major disadvantage of LLMs is that they can confidently generate various types of false answers (eg, hallucinations, confabulations, misrepresentations, and omissions among others). A taxonomy of false output and mitigation strategies is a topic of current research [26,27]. A mitigation strategy is to map user questions by classifying their intent to predefined answers. Solutions with predefined answers exist for lung cancer in Japanese [28] and prostate cancer in German [29]. While this approach is generally more reliable, since answers are preselected and quality controlled, it lacks flexibility and personalization of the answers.

Another emerging strategy to mitigate the risk of false information is retrieval-augmented generation (RAG) [30-32] where a trained LLM, such as a generative pretrained transformer (GPT), has access to additional information sources (eg, a database with oncology guidelines and other quality-controlled documents). This additional information can provide up-to-date and quality-controlled context for an LLM to a given query [33].

Ultimately, as AI technologies continue to evolve, health care institutions and organizations may increasingly explore the development of their own LLM-based apps to support more inclusive and patient-centered care. For such efforts to be effective and responsible, they must be grounded in language- and context-specific considerations that reflect patients' real-world concerns.

The aim of this paper is to explore the potential of a retrieval-augmented German-language chatbot based on ChatGPT to address typical information needs of breast cancer patients using real patient questions.

Methods



Overview

This study was conducted in Germany as a collaborative project between researchers from industry and academic experts in digital health, oncology, and AI. An essential partner in this initiative was one of the country's largest breast cancer Patient Representation Groups, comprising individuals with lived experience of breast cancer and deep engagement in patient advocacy. The Patient Representation Group contributed real-world patient questions and helped shape the evaluation criteria, enabling the assessment of the chatbot in a way that reflects the practical needs and concerns of breast cancer patients in the German health care context. This study was performed in accordance with the TRIPOD+LLM (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis+Large Language Model) guidelines (the TRIPOD+LLM checklist is provided in Checklist 1).

The initial phase of the work, including chatbot refinement, question selection, and response evaluation, was completed in April 2024 (see Figure 1).

XSL•FO
RenderX

Figure 1. Overview of the document selection process, chatbot preparation, and evaluation. BC: Breast cancer; HCP: health care professional; PRG: Patient Representation Group.

Document Selection

We selected documents with the purpose of providing the chatbot with up-to-date, evidence-based guidelines and recommendations, ensuring that its responses are grounded in the current standard of care for BC in Germany.

Oncology guidelines and recommendations provided by professional societies are reliable, high-quality sources of information on the diagnosis and treatment of BC. The guidelines are based on expert consensus and compile evidence-based information with a comprehensive coverage and regular updates [34,35]. Guidelines are designed for clinicians to develop tailored diagnosis and treatment plans to the patients' individual tumor biology [36].

Some societies (the German Cancer Society [DKG e.V.], the Arbeitsgemeinschaft Gynäkologische Onkologie e.V. [AGO e.V.], and the Commission Breast of the German Society of Gynecology and Obstetrics) additionally provide information sources directly for patients.

The authors screened and reviewed guidelines and information documents from prominent German medical societies, BC working groups, and nonprofit organizations providing material for HCPs and patients. The entities were selected based on their established role and recognition within the German BC clinical and patient support landscape. A consensus from all authors was reached through discussion and feedback from the Patient Representation Group solicited.

We considered documents from well-known entities (see Textbox 1).

Textbox 1. Medical entities considered for document selection.

We considered documents from the following well-known entities:

- Arbeitsgemeinschaft der Wissenschaftlichen Medizinischen Fachgesellschaften e.V. (AWMF).
- Deutsche Krebsgesellschaft e.V. (DKG).
- Deutschen Krebshilfe e.V. (DKH).
- Deutsche Gesellschaft für Gynäkologie und Geburtshilfe e.V. (DGGG).
- PRIO (Prävention und Integrative Onkologie, eine Arbeitsgemeinschaft der DKG).
- Deutsche Gesellschaft für Hämatologie und Medizinische Onkologie e.V. (DGHO).
- Deutschen Gesellschaft für Ernährungsmedizin e.V. (DGEM).
- Arbeitsgemeinschaft, Supportive Maßnahmen in der Onkologie, Rehabilitation und Sozialmedizin der Deutschen Krebsgesellschaft (ASORS).
- Österreichische Arbeitsgemeinschaft für klinische Ernährung (AKE).
- Dachverband der Deutschsprachigen Wissenschaftlichen Osteologischen Gesellschaften e.V. (DVO).
- Arbeitsgemeinschaft Gynäkologische Onkologie e.V. (AGO).
- Arbeitsgemeinschaft für Psychoonkologie in der Deutschen Krebsgesellschaft (PSO).

XSL•FO
RenderX

And selected all documents addressing HCPs or patients that cover diagnosis, treatment, and aftercare of breast cancer; complementary medicine for oncological patients; nutrition in clinical oncology; osteoporosis and psycho-oncological diagnosis, consultation, and treatment.

Each document was manually reviewed, and we excluded documents that are either expired or not yet consented (ie, draft versions and versions for discussion only) from our selection. Draft, discussion, or expired marks (as assigned by the Arbeitsgemeinschaft der Wissenschaftlichen Medizinischen Fachgesellschaften e.V.) were verified by 2 authors (SDB and UM). The selection was internally reviewed and discussed with representatives from the BC Patient Representation Group as well as the senior BC expert. All suggestions by one of the authors or the Patient Representation Group made it into the final selection. In total, we included 13 documents comprising 3110 pages (Figure 1A). The documents are available through the respective entities' website, and the compendium can be used by other researchers.

The included documents are shown in Table 1.

A list of excluded documents can be found in Multimedia Appendix 1.

Table . Included documents.

Document title	Type of document	Primary target audience	Publisher or leading Medical Societies
Interdisziplinäre S3-Leitlinie für die Früherkennung, Diagnostik, Therapie und Nachsorge des Mammakarzinoms. Langversion 4.4, June 2021, Register 032-045OL	S3 Guideline	HCPs	AWMF, DKG, DKH, DGGG, and DKG.
S3-Leitlinie Komplementärmedizin in der Behandlung von onkologischen PatientInnen Langversion 1.1, September 2021, Register 032/055OL	S3 Guideline	HCPs	AWMF, DKG, DKH, DKG, PRIO, DGGG, and DGHO.
Klinische Ernährung in der Onkologie. 2015, Register 073/006. (DOI 10.1055/s-0035-1552741).	S3 Guideline	HCPs	DGEM with DGHO, ASORS, and AKE.
Prophylaxe, Diagnostik und Therapie der OSTEOPOROSE. Langfassung, September 2023, Register 183/001	S3 Guideline	HCPs	DVO.
Diagnostik und Therapie früher und fortgeschrittener Mammakarzinome 2023.1	Recommendations	HCPs	AGO Breast Commission (of DGGG) and DKG.

Voiß P. (2018) Möglichkeiten und Grenzen der Komplementärmedizin.	Information leaflet	Patients	Brustkrebs Deutschland e.V.

Model Preparation

We used OpenAI's feature to build custom GPTs, based on GPT-4, with user-defined instructions and access to a document database for RAG [37,38]. The retrieval mechanism can find relevant information from the uploaded documents and pass it along with the original question to the GPT. For our experiments, it was sufficient to upload the documents one by one. All technical details (eg, splitting documents into chunks, embedding chunks to obtain a vector index, question embedding, and similarity-based matching) are handled by OpenAI. The RAG mechanism is used as is, since parameters that affect

XSL•FO
RenderX

retrieval (eg, threshold values for similarity measures or number of retrieved documents) are not exposed. A detailed explanation of the RAG technology can be found elsewhere [33,39,40].

We experimented with different instructions in the system prompt using a set of 5 short questions (included in Multimedia Appendix 1) that the authors formulated before receiving test questions from the Patient Representation Group. Based on the initial experiments, we agreed on using the following five instructions: (1) search for relevant information in the documents uploaded; (2) clearly advise against therapies that are not evidence-based; (3) ask clarifying questions, if necessary; (4) formulate empathetic answers; and (5) not to mention severe complications unless they are clearly indicated by the patient; implemented through the system prompt (Figure 1B). Since our goal is to evaluate the answering capability in the German language, we used the instructions in German (also included in Multimedia Appendix 2). All evaluations took place on or before April 19, 2024.

Test Questions

We asked one of Germany's largest BC Patient Representation Groups to share a set of commonly asked questions. We indicated that we have a focus on medical questions only and made no further recommendations as to topic, number, difficulty, or length of the question. Questions were submitted to the Patient Representation Group in person at regional or national meetings, via phone, email, or various online social network platforms that the BC Patient Representation Group is active on. The Patient Representation Group selected the questions based on their judgment of their importance and frequency of occurrence in real-world patient interactions. They grouped the questions into 7 categories (Aftercare, Bone health, DCIS [ductal carcinoma in situ], Diagnostics, Diet and nutritional supplements, Complementary medicine, and Therapy). Answers were not provided.

We performed an initial screening of each received question to determine whether its nature is medical and excluding legal and reimbursement questions. Exclusion decisions are based on consensus between 2 reviewers (SB and UM). All questions (included and excluded) are included in the Multimedia Appendix 1.

Most remaining questions are used in the evaluation "as-is," even if the question is complex or with a high potential of misinterpretation. We edited some questions by writing out abbreviations or adding the category at the start of the question. The edits are detailed in Table 2.

Table . Edits on the original questions before using them to evaluate our chatbot.

Original	Modification	Translation	Affected questions
AI[a]	Aromatase-inhibitor	Aromatase inhibitor	17, 34, 37, 38, 41, 78, and 104.
Empty	Category placed in front of the question for context (eg, Brustkrebs, hormoneller Brustkrebs, Ernährung und Nahrungsergänzungsmittel, Hitzewallungen und Schweißausbrüche (vasomotorische Symptome))	Breast cancer, hormonal breast cancer, nutrition and dietary supplements, excessive sweating (vasomotor symptoms)	74, 75, 76, 77, 89, 96, and 98.
NEM	Nahrungsergänzungsmittel	Dietary supplements	76, 80, 82, 88, and 102.

[a]AI: aromatase inhibitor.

Evaluation

Evaluating the output of LLMs in medical question-answering systems is a topic of current debate, with consortia developing standards [41]. To date, a standardized evaluation framework is missing. Typically, evaluation criteria are defined at the outset of the study and evaluated on a Likert scale [42-45].

We consented to 4 criteria on which to evaluate the chatbot after feedback from the Patient Representation Group. It was agreed that the Patient Representation Group rate the comprehensibility of the answers ("The answer is clear to me."), a senior BC expert (ML), who is represented in several German guideline commissions and on the board of the German Society for Senology, rated correctness ("The answer presents scientifically correct information."), completeness ("The answer includes all important aspects.") and whether the answer has potential to cause undue harm ("The answer does not cause undue harm."; Figure 1C). For the Patient Representation Group, 5 raters were recruited by the spokesperson during an in-person event of regional leaders. Each rater independently completed the evaluation using the 5-point Likert scale and a "don't know / can't answer" option. Only aggregate response counts per item were collected; no individual-level data were recorded. Direct interaction with individual patient raters was not pursued due to legal and ethical considerations.

The 104 questions are posed to the LLM once. To rate an answer, the raters evaluated each statement on a 5-point Likert scale (5=Strongly agree, 4=Agree, 3=Neutral, 2=Disagree, and 1=Strongly disagree). For each of the given criteria, we present individual ratings per category divided by the total number of ratings for the given category.

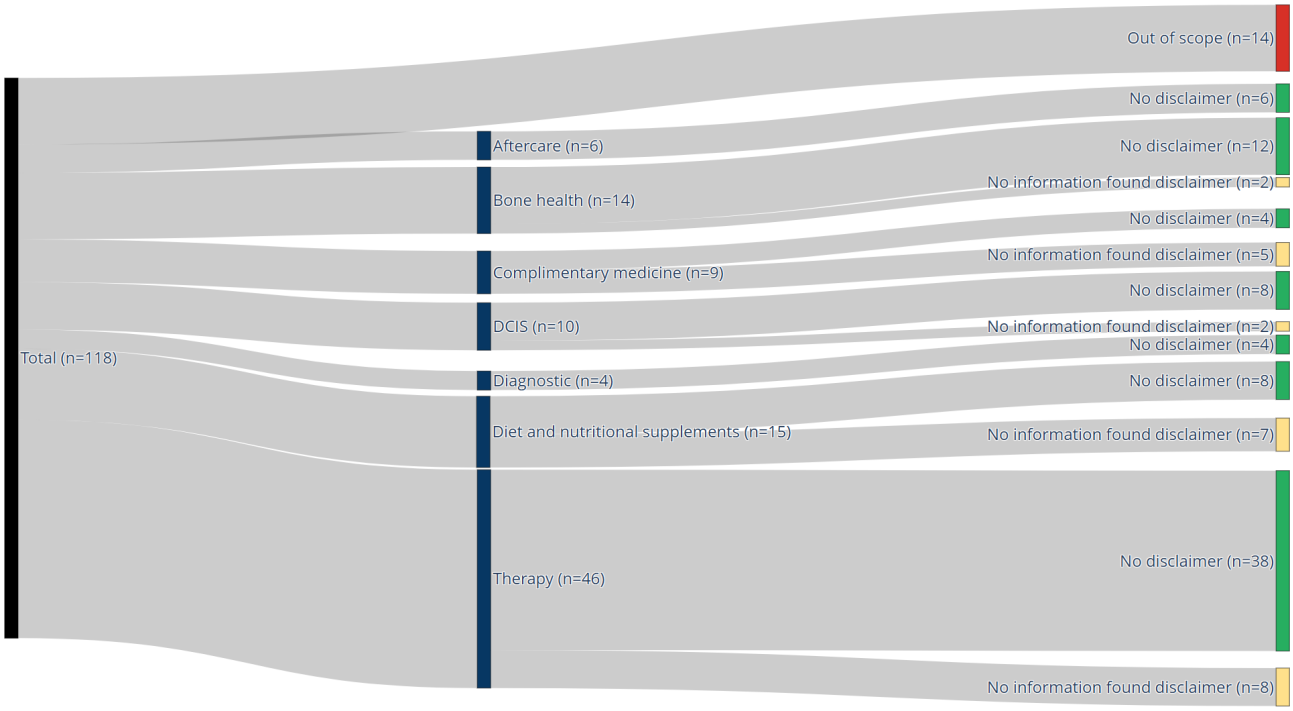
Ethics Statement

According to §15 of the Professional Code of the Berlin Medical Association, research based solely on anonymized data is exempt from the requirement for formal ethical approval. In line with this provision, we did not obtain ethics committee approval for this study, as only aggregated, deidentified data were used. However, we recognize that the Ethics Committee's guidance encourages researchers to seek consultation even when data are

XSL•FO
RenderX

deidentified or aggregated. Prospective consultation with the ethics committee was not sought.

Participants were invited to complete a paper-based form, and there was no direct interaction between the research team and patients. All communication and data collection were managed by a spokesperson from the Patient Representation Group, who aggregated and anonymized the responses before sharing them with the research team. All data were handled in accordance with applicable data protection regulations and shared in anonymized, aggregated form only.



No direct compensation was provided to individual participants. A modest compensation was provided to the Patient Representation Group for their coordination efforts and data aggregation in accordance with the FSA Code for Collaboration with Patient Organizations specified in the EFPIA Code of Practice (2008). All financial contributions and contracts with Patient Representation Groups are publicly disclosed in the "Transparenzkodex" annually.

Results

Questions

We received a total of 118 questions and a corresponding category for each question. A total of 14 questions are excluded because they were related to nonmedical aspects (eg, insurance coverage, reimbursements, and legal aspects). The questions are grouped into 7 categories (Aftercare, Bone health, DCIS, Diagnostics, Diet and nutritional supplements, Complementary medicine, and Therapy). Figure 2 shows the breakdown of the number of questions per category. Many questions were asked on managing side effects, particularly for endocrine and endocrine-based therapy, with a specific emphasis on complementary and alternative medicine, as well as dietary supplements.

Figure 2. In total, we received 118 questions (black). Human review determined that 14 questions are out of scope (red). The remaining questions are grouped into different categories (blue). Color codes green and yellow indicate whether the model retrieves relevant information from the documents. DCIS: Ductal carcinoma in situ.

For some questions, the LLM reported that no relevant information was found in the documents included. This means that the retriever mechanism was not able to match a query to information stored in the adjacent database. In several cases, the RAG-based model returned no relevant documents from the retrieval component. As internet search was not enabled in our experimental setup, the LLM proceeded to generate responses based solely on its pretrained and fine-tuned knowledge. These instances are reported as part of the results, reflecting the system's behavior when retrieval fails. The model reported for 24 questions that no relevant information was found (see Figure 2).

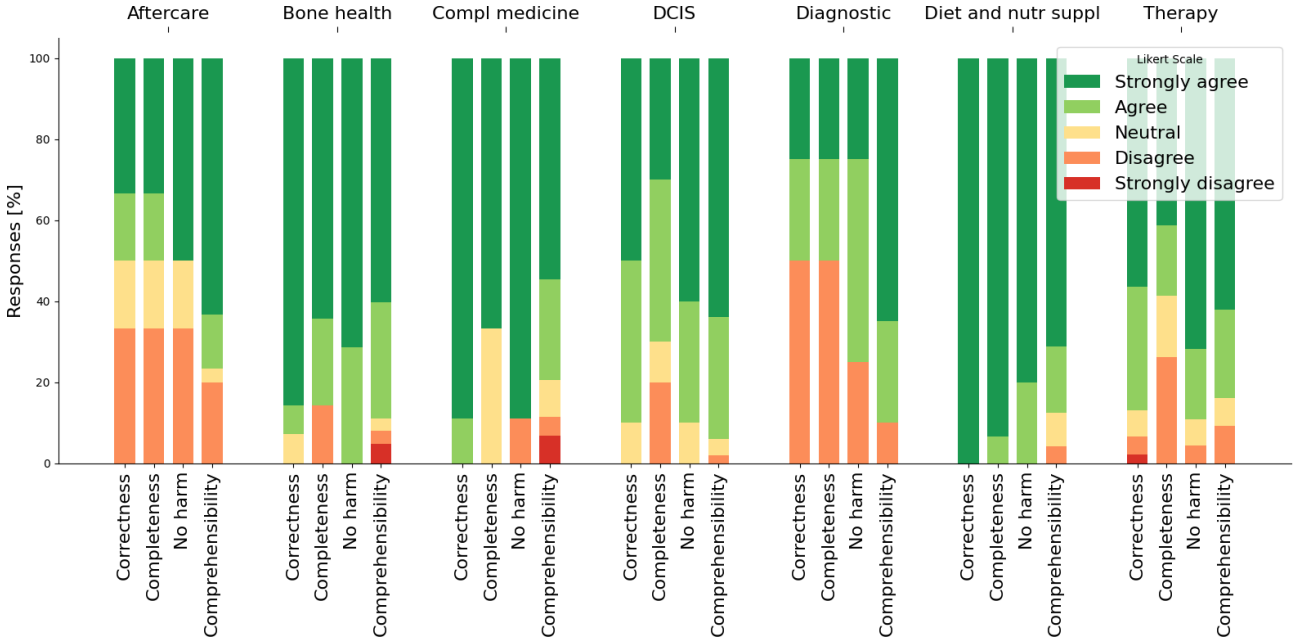
Chatbot Answers and Evaluation

The answers were evaluated using the four criteria (1) correctness, (2) completeness, (3) no harm, and (4) comprehensibility, either by a senior BC expert (criteria 1 - 3) or the Patient Representation Group (criteria 4). For each criterion, we formulated a statement (see the Methods section) and evaluated the statement along a 5-point Likert scale. By combining "Strongly Agree" with "Agree" and "Disagree" with "Strongly Disagree," we see that:

- In total, 427 out of 499 (85.6%) ratings of the answers are rated as comprehensible and 42 (8.4%) as incomprehensible.
- A total of 91 out of 104 (87.5%) answers are rated as correct and 7 (6.7%) incorrect.

XSL•FO
RenderX

- In addition, 72 out of 104 (69.2%) answers are rated as including all relevant information, and 20 (19.2%) have some missing information.
- Furthermore, 93 out of 104 (89.4%) answers are rated as not harmful, and 6 (5.7%) may cause potential harm.



The "Neutral" ratings account for the remaining percentages up to 100. Note that comprehensibility was rated by multiple raters, hence the number of ratings exceeds the number of questions.

A total of 6 answers are considered potentially harmful. One answer related to gene expression testing was classified as potentially harmful due to an incorrect statement on reimbursement. In addition, 2 answers on the use of abemaciclib did not provide information on its use in premenopausal women or failed to mention the absence of data regarding the initiation of abemaciclib therapy 2 - 3 years after starting endocrine therapy. Furthermore, 2 answers were deemed potentially harmful because they provided individualized recommendations for the duration of aftercare, including breast sonography. Finally, the chatbot mentioned hormone replacement therapy as a treatment for vasomotor symptoms but failed to mention nondrug therapies.

A total of 2 answers were deemed incomplete due to missing reimbursement information. In addition, some answers failed to mention new therapeutic treatment regimens, lacked comprehensive details on aftercare or testing, or omitted aspects related to endocrine therapy, osteo-oncology, or hormonal testing for menopause status.

We analyze the answers for each category separately (see Figure 3 and Table 3). We observe that the chatbot performs well across all criteria for Bone health (14 questions) and diet and nutritional supplements (15 questions). For the latter category, the chatbot reported no relevant information found in the documents for 7 out of 15 questions (see Figure 2). The worst-performing categories (Aftercare and Diagnostics) also have the fewest number of questions (6 and 4, respectively). Some answers (20 out of 104) omit important information, except for the Diet and nutritional supplement category. A total of 6 responses were identified as potentially harmful by expert judgment, typically for omitting important caveats about medication use or not mentioning alternative (nondrug-based) therapies. One answer on abemaciclib therapy did not include information on its use in premenopausal women. Another answer failed to mention the absence of data regarding the initiation of abemaciclib therapy 2 - 3 years after starting endocrine therapy. Furthermore, 2 answers were deemed potentially harmful because they provided individualized recommendations for the duration and type of aftercare.

Figure 3. Evaluation of the 4 criteria (Comprehensibility, Correctness, Completeness, and No harm) using a 5-point Likert scale for each question category. Compl: Complimentary; DCIS: Ductal carcinoma in situ; Nutr suppl: nutrition supplement.

XSL•FO
RenderX

Table . Individual ratings per category along the 4 dimensions.

Category	Questions	No information found	Dimension	Ratings, n				
				5	4	3	2	1
Aftercare	6	0	Correctness	2	1	1	2	0
			Completeness	2	1	1	2	0
			No harm	3	0	1	2	0
			Comprehensibility	19	4	1	6	0
Bone health	14	2	Correctness	12	1	1	0	0
			Completeness	9	3	0	2	0
			No harm	10	4	0	0	0
			Comprehensibility	38	18	2	2	3
Complementary medicine	9	5	Correctness	8	1	0	0	0
			Completeness	6	0	3	0	0
			No Harm	8	0	0	1	0
			Comprehensibility	24	11	4	2	3
Ductal carcinoma in situ	10	2	Correctness	5	4	1	0	0
			Completeness	3	4	1	2	0
			No harm	6	3	1	0	0
			Comprehensibility	32	15	2	1	0
Diagnostic	4	0	Correctness	1	1	0	2	0
			Completeness	1	1	0	2	0
			No harm	1	2	0	2	0
			Comprehensibility	13	5	0	2	0
Diet and nutritional supplements	15	7	Correctness	15	0	0	0	0
			Completeness	14	1	0	0	0
			No harm	12	3	0	0	0
			Comprehensibility	52	12	6	3	0
Therapy	46	8	Correctness	26	14	3	2	1
			Completeness	19	8	7	12	0
			No harm	33	8	3	2	0
			Comprehensibility	136	48	15	20	0

Finally, the chatbot mentioned hormone replacement therapy as a treatment for vasomotor symptoms (as side effects of endocrine therapy). However, hormone replacement therapy is a contraindication for breast cancer patients in this specific therapeutic situation (Table 3).

Discussion

Principal Findings

One of the largest German BC Patient Representation Group shared a set of typical questions (without identifiable information) that commonly arise. These questions highlight

XSL•FO
RenderX

significant and specific information needs of patients—specially regarding endocrine or endocrine-based therapy and the prevention or management of side effects—that go beyond the scope of general health literacy support. Unlike other AI or chatbot or patient vignette studies, this BC Patient Representation Group provided relatively complex medical questions in German, not easily answered through a simple Google search or by referring to patient versions of guidelines.

In response, we evaluated whether a RAG and LLM-based chatbot solution could provide high-quality, tailored information in German. The database included authoritative German-language guidelines and patient information materials that are valid for Germany. Overall, the answers to 104 BC questions were evaluated on 4 criteria (comprehensibility, correctness, completeness, and potential harm) using a 5-point Likert scale. Despite an overall high quality of responses, 20 out of 104 answers were incomplete, and 6 were potentially harmful.

In summary, the chatbot was tested on 104 frequently asked breast cancer–related questions and produced answers that were mostly rated positively across 4 criteria (comprehensibility, correctness, completeness, and harm potential). Specifically, 85.6% (427 out of 499 ratings) of responses were deemed comprehensible, 87.5% (91/104) correct, and 89.4% (93/104) free of undue harm; however, only 69.2% (72/104) of answers were judged complete. Shortcomings primarily involved incomplete details on reimbursement or newer treatment regimens and omissions regarding aftercare or endocrine therapy.

Potentially harmful guidance stemmed mainly from two issues: (1) outdated or ambiguous source material (eg, reimbursement rules that had changed, guidance on hormone replacement therapy lacking caveats about medication use, or not mentioning alternatives) and (2) retrieval gaps that prevented the model from grounding its answer in the most relevant passages. When the necessary nuance was scattered across tables, figures, or inconsistent terminology (“aftercare,” “follow-up,” and “screening”), the retrieval component sometimes surfaced a partial context, prompting the LLM to fill the vacuum with general knowledge that did not fit the oncological edge cases.

For example, the answer related to gene expression testing was classified as potentially harmful due to an outdated statement on reimbursement found in the source document [46]. In addition, no context was provided for the use of abemaciclib on premenopausal women, likely because the 2018 and 2021 guidelines [47,48] did not provide data on its use in early breast cancer.

The chatbot may have been misled for the recommendation of individualized recommendations for the duration and type of aftercare by the varying terminologies used in the documents (“aftercare,” “follow-up,” and “screening”), different design formats, tables, and inconsistent time formats (months, years; in numbers or text). In addition, considerations for specific situations such as DCIS, breast scarring after surgery, or the statement that aftercare can be adapted to the symptoms may have contributed to the “confusion.” While potentially harmful answers were identified through expert review, actual harm to patients remains unlikely due to clinical safeguards.

Notably, the chatbot performed better than expected in the areas of bone health and nutrition, even when relevant documents were not retrieved, suggesting that its base training data sufficed to answer many diet-related questions. Overall, the system demonstrated promising accuracy and clarity but showed room for improvement in providing comprehensive and fully risk-aware medical guidance.

Several questions encompassed multiple aspects and included subquestions that required broad answers to cover all points (see Multimedia Appendix 1). Incomplete answers were primarily due to the absence of reimbursement details, newer therapeutic regimens not yet documented in guidelines, and retrieval limitations affecting tabular and graphical data representation. In 3 cases, there was a lack of clinical data to address the specific question. For 16 other cases, there was an absence of information in the source documents. Specifically, in 2 of these cases, information on new therapeutic treatment regimens was not yet included in any guidelines. In another case, outdated guideline information led to an inaccurate and incomplete answer. In addition, in 2 cases, the topic of reimbursement was inappropriately covered, despite it typically being out of scope for the source documents. Furthermore, in 8 instances, the available information was not retrieved, probably because it was presented in tables, figures, or listings with ratings (such as on level of evidence and on the grade of recommendation) rather than text, making it accessible only to medical experts who could interpret it, a task beyond the capability of the current retrieval mechanism. The inconsistent terminologies and varying design and time formats across and within the source documents might have also contributed to the nonretrieval of information.

The curation of up-to-date and machine-accessible information in the database improves results. We hypothesize that a textual representation of information from tables, figures, or listings improves results with the given RAG technology. Alternatively, digitized and annotated versions of relevant documents [49] or multimodal RAGs [50] likely improve retrieval.

To mitigate the risk of potentially harmful or incomplete answers, it is important to provide a disclaimer that the chatbot is not able to replace consultation with medical professionals and encourage patients to seek consultation. We strongly suggest that continuous monitoring in the form of transcript reviews and human oversight by medical professionals is implemented, as others have pointed out as well [44]. Furthermore, it is clear that chatbots are classified as medical devices [31] and need substantial safety measures before being used at scale.

Comparison With Previous Work

In agreement with our results, it has been observed that ChatGPT scores high on correctness and often significantly lower on completeness for cancer-related question-answer pairs in an English-language setup [51,52]. A growing body of literature demonstrates that the RAG mechanism helps to ground LLMs in factual information for medical use cases [53,54]. To the best of our knowledge, there is no similar study evaluating

XSL•FO
RenderX

LLM-based chatbots on German question-answer pairs for any cancer entity. The training on English-language data may introduce subtle biases from the respective health care systems. Our results show that ChatGPT, together with authoritative documents, can answer BC questions in German with similar performance.

Our realistic set of real-world patient questions can be used by other researchers to develop German BC chatbots. Many questions raised by the BC Patient Representation Group pertain to endocrine and endocrine-based therapy, particularly related to the prevention or management of side effects. Providing active patient support for this therapy is crucial to ensure adherence and prevent early termination, as discontinuation of endocrine or endocrine-based therapy is associated with worse outcomes, including reduced overall survival [55].

A further topic of interest among patients is food supplements and alternative medicine. Evidence-based recommendations on complementary and alternative medicine can help patients avoid negative interactions with cancer treatment, prevent harmful or ineffective therapies, and potentially contribute to treatment success [56]. The chatbot might provide substantial support for patients, especially when based on evidence-based information such as from the German S3 guidelines on complementary medicine in oncology.

This evaluation of a chatbot prototype in German language provides a strong baseline for evaluating German BC chatbot apps. We observe that ChatGPT, together with appropriate documents in the vector store, provides a strong performance even for a German medical question answering task.

Limitations

First, we pose each question to the chatbot only once. Thus, we do not assess whether the retrieval mechanism consistently retrieves the same result or if the LLM's answers are consistent across repeated queries.

Second, the evaluation criteria—correctness, completeness, and potential for undue harm—are only evaluated by a single expert, introducing subjective judgment and potential bias representing a subjective evaluation.

Third, it is possible that the Patient Representation Group introduces a bias in the question selection.

Fourth, our study does not simulate real-world interactions, where patients typically ask follow-up questions and discuss outcomes directly with their treating physicians. A comprehensive real-world evaluation would require extended and interactive dialogues between patients and the chatbot.

Fifth, although we share test questions, source documents and prompts, reproducibility is only partially achievable because our study relies on closed-source algorithms for information retrieval and output generation by the LLM, whose parameters and implementations may change over time.

Future Directions

Since we observe that some questions are not directly addressed in the included documents, a future model can be improved by including relevant journal articles or guidelines and recommendations from other countries. It is well-known that the prompting strategy can influence model performance [57]; therefore, improved prompting (eg, chain-of-thought [58], multiround iterative questioning [59], or self-reasoning [60]) may significantly improve results. In addition, specific fine-tuning on a BC question answering task can be expected to improve performance [61].

A total of 14 questions revolved around insurance coverage, reimbursement, and legal aspects of social law, which underscores the need for specific support in these areas. For our study, we consider these topics out of scope, since an interdisciplinary collaboration between legal and social service experts would be required and a different set of authoritative documents. However, it is crucial to address these issues, as a cancer diagnosis poses a high risk of financial problems for patients [55]. An enhanced chatbot or a chatbot specifically designed to address patient questions in these areas would increase.

Conclusion

A cancer diagnosis is a major turning point in life for most, as it is potentially life-threatening and life-changing. We evaluate an AI-based chatbot in answering realistic and challenging patient questions in the German language. The BC chatbot prototype provides largely accurate, comprehensible, and safe answers for German-speaking patients with BC, but incomplete information remains a limitation, particularly concerning reimbursement and newer treatments. The technology may provide real value today, as it can always be used easily and might help to meet patients' needs for information. Further development, testing, and evaluation of chatbots for patients is a multidisciplinary endeavor that should involve patients actively in this process. In addition, the inclusion of guardrails and prominent disclaimers that technology cannot replace professional consultation and human oversight is important for apps.

Acknowledgments

We would like to thank mamazone–Frauen und Forschung gegen Brustkrebs e. V. for their invaluable support that made this project possible. In addition, we would like to thank Christina Claußen and her Patient Advocacy Team of Pfizer Germany for their many contributions.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Abstract

Background: An increasing number of early-stage breast cancer (EBC) survivors and limited health care resources have raised interest in developing digital methods for communication between patients and health care personnel. In 2015, Helsinki University Hospital (HUS) Comprehensive Cancer Center (CCC) launched a digital solution called Noona (Helsinki University Hospital; Noona Healthcare) for patients with cancer, which allows patients to report their symptoms or side effects and ask questions with a computer or smart mobile device.

Objective: In this study, we compare the cost and contacts of surveillance of EBC by 2 follow-up methods: digital solution and phone calls during their first year of follow-up outside preplanned visits.

Methods: This was a prospective, open-label, randomized crossover study. After postoperative radiotherapy, patients with EBC were randomized to surveillance with either a digital solution or phone calls in addition to routine follow-up visits. After 6 months, the patient switched to the alternative follow-up method. All patients were thus exposed to both follow-up methods, and the order was determined by randomization. Hospital contacts and the costs of specialized health care were extracted from the Ecomed database of the Helsinki and Uusimaa Hospital District. The Ecomed database records all hospital costs. The costs of follow-up visits and diagnostics at the HUS CCC were analyzed in a repeated measurements general linear model analysis.

Results: The study extended from July 2015 to January 2017. Of 765 patients, 734 were included in the final analyses. For the digital solution group, the mean number of contacts per patient was 1.06 (SD 1.57) during the first 6-month period and 1.22 (SD 1.04) in the second period, with associated costs of €269 (US $313.21) and €311 (US $362.11). Similarly, in the phone call group, the mean number of contacts increased from 0.95 (SD 1.39) to 1.24 (SD 1.14) with the costs of €236 (US $274.78) and €344 (US $400.53), respectively. There were no statistically significant differences in the number of outpatient contacts (P=.46 and P=.35) or total costs (P=.80 and P=.12) between the 2 follow-up methods or randomization groups.

Conclusions: We did not find any statistically significant differences in the total cost of follow-up of EBC by digital solution or phone calls. The number of visits and costs were higher during the latter follow-up period, probably due to the scheduled routine 1-year visit. There were more visits and higher costs in the digital solution group during the first 6 months, but these were higher in the phone call group during the latter 6-month period. This shows that the digital solution may enable faster access to outpatient services than conventional follow-up.

Introduction

Breast cancer is the most common cancer among women. Due to early detection of disease and effective treatments, breast cancer mortality has declined. The 5-year relative overall survival after breast cancer treatment is approximately 90% in Western countries [1,2]. However, breast cancer is still the leading cause of cancer death for women worldwide [3-6].

All breast cancer treatments (chemotherapy, radiotherapy, and endocrine therapy) may cause short- and long-term adverse events. The main aims of breast cancer follow-up are to detect recurrences, give advice, treat long-term side effects, and provide psychological support [5,7-9]. The follow-up protocol must be balanced with regard to the workload on health care, patients' needs, and costs of follow-up [5,10].

In 2000, Helsinki University Hospital (HUS) Comprehensive Cancer Center (CCC) started a breast cancer nurse practitioner telephone service in addition to regular mammograms and appointments with an oncologist.

Due to the increasing number of breast cancer survivors and limited health care resources, there was a need to develop web-based systems for communication between patients and professionals. In 2015, a web-based patient report app Noona (Helsinki University Hospital; Noona Healthcare) was developed at the HUS CCC in collaboration with a Finnish start-up company. Noona app enabled patients to contact specialist breast cancer nurses between visits. It allows patients to report their cancer- and treatment-related symptoms and health outcomes to the hospital, and to ask questions and deliver messages remotely via a computer, smartphone, or tablet [11].

This prospective controlled randomized crossover study (ClinicalTrials.gov ID NCT04980989) was set up to test the digital solution during the first year of follow-up of early-stage breast cancer (EBC) outside preplanned visits. A total of 765 patients were randomized into sequential digital and conventional phone call follow-up during the first follow-up year, 734 of which were included in this analysis. The order of the 2 follow-up methods was determined by randomization. The results on the primary end point, patient preference, have been previously reported [12]. There was no statistically significant difference in patient preference for the 2 follow-up methods among 142 patients who had experience with both follow-up methods. A total of 40% (56/142) preferred the phone call service and 30% (43/142) the digital solution, while 30% considered both modalities equally good.

The purpose of this study was to analyze whether the cost of follow-up of EBC by a digital solution or phone call differs during the first year outside preplanned visits.

Methods

Participants and Follow-Up

Patients with EBC who received radiotherapy after breast cancer surgery were eligible for the study. Inclusion criteria allowed chemotherapy and endocrine therapy if indicated. Patients had to have histologically verified breast cancer or ductal carcinoma in situ, be aged ≥18 years old, and understand Finnish or Swedish. Patients and their tumors' characteristics were collected from the patient records. Routine follow-up consisted of 3 preplanned appointments at 1, 3, and 5 years after primary diagnosis. Mammography was performed yearly. In addition, patients were requested to contact an educated breast cancer nurse practitioner for symptoms that might be related to breast cancer or its treatment according to a written patient information. Patients were asked to participate in the study on their last appointment with the oncologist at the end of adjuvant radiotherapy. Eligible patients who signed a written consent were included in the study.

The participants were randomized to contact the breast cancer nurse in 2 alternative ways: via the digital solution or the phone call service. After 6 months, the patients switched surveillance methods. The total follow-up time in this study protocol was 1 year. Thus, all patients were exposed to both follow-up methods. When using the digital solution, patients were also allowed to contact the nurse by phone. However, during the phone call follow-up period, patients were not able to use the digital solution.

The purpose of randomization was to ensure that all patients used both monitoring methods and were able to compare them. In addition, we ensured that the differences between the follow-up methods were not due to the order of the 2 methods.

Costs

The costs of specialized medical care were obtained from the Ecomed database of the Helsinki and Uusimaa Hospital District. Ecomed records contain all hospital resource use and costs including information about the exact day on which the hospital contact started and ended, diagnosis and procedure code, type of contact, and patient-level costs, including overheads, equipment, hospitalization, and drugs for inpatient use. Hospital contacts included hospitalization periods, emergency visits, doctor or nurse appointments, phone calls, letters, and rehabilitation. Contacts to the Department of Oncology of the CCC were classified as contacts due to breast cancer.

Costs of outpatient contacts included outpatient appointments with a doctor or nurse, rehabilitation, medical aids (eg, compression sleeves), letters, and phone calls from hospital personnel to the patient.

The costs of phone calls to the nurse and use of the digital "Noona" solution were free of charge and thus not included in the costs in the analysis. The definition of a letter and phone call is a prearranged individual letter or phone call about the diagnostics and treatment of the patient's illness, which can replace a visit.

Costs of diagnostics included laboratory tests, pathology reports, and imaging.

Statistical Analyses

All analyses were carried out using SPSS, version 25 (IBM Corp.). The significance levels were set at $P<.05$.

The effect of the follow-up method was analyzed in repeated measurements general linear model analysis with the follow-up

XSL•FO
RenderX

method as a repeated measurement variable and randomization group as a between-patients variable. This design allows testing the effect of both follow-up methods and the effect of timing (first or second 6-month period) on the number of visits and costs. Dependent variables were the number of visits, the costs of diagnostics and visits, and total costs.

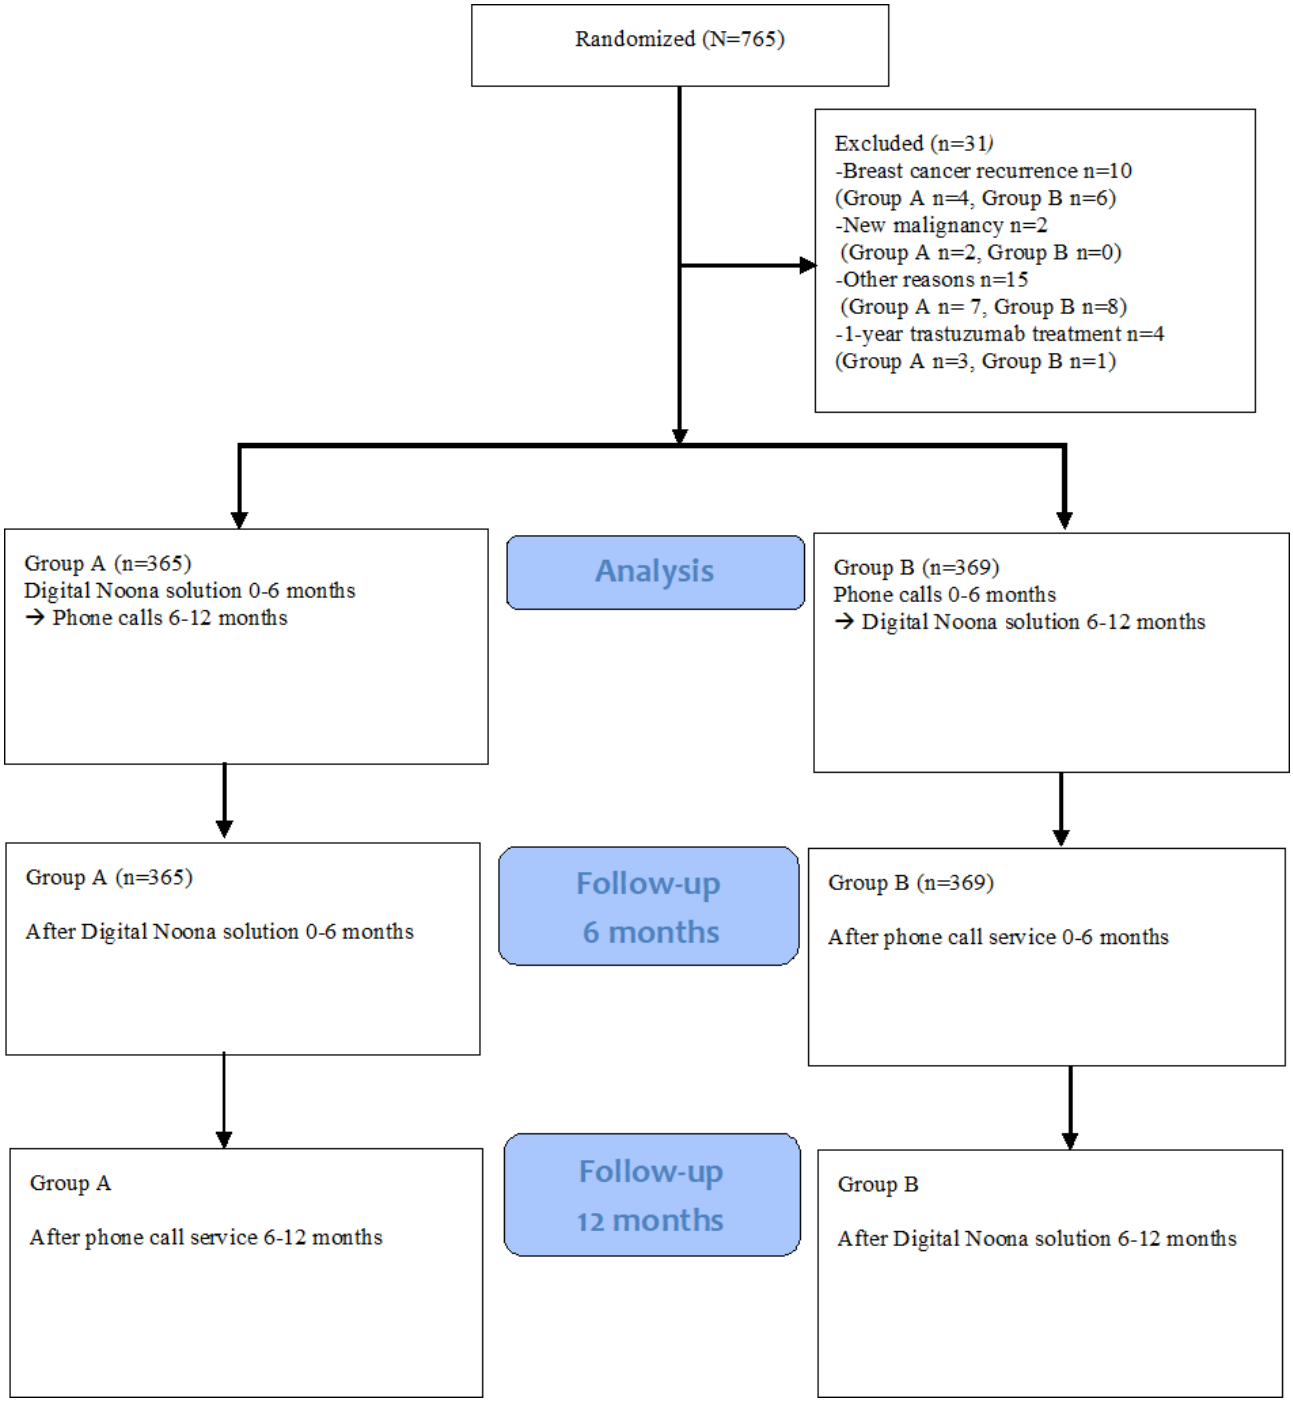
Descriptive statistics were calculated for the digital solution and the phone call solution at baseline, at 6 months, and at 12 months.

Ethical Considerations

This prospective, open-label, and randomized crossover study was registered at the HUS CCC in Finland (ClinicalTrials.gov ID NCT049809899). Written informed consent was obtained from each eligible patient before participation in the trial. The study complied with local ethical and legal requirements. The informed consent and study protocol were approved by the Institutional Ethics Committee of HUS, Finland (trial number Dnro 112/13/03/2015).

Results

From July 2015 to January 2017, 765 patients with EBC were randomized to this study at the HUS CCC in Finland.



A total of 734 patients were included in the final analyses. Two individuals were excluded from the study due to a new malignancy, 10 due to recurrence of breast cancer, and 15 discontinued the study. In addition, 4 patients receiving adjuvant trastuzumab treatment every 3 weeks during the study period were excluded from the analyses, since the costs of follow-up could not be separated from treatment costs in the Ecomed database (Figure 1).

Patient characteristics (n=734) are shown in Table 1. The median age was 61 (range 28 - 83) years. Most patients, 630 out of 734, had estrogen receptor–positive breast cancer (85.8%). Two patients out of 734 were male (0.3%).

Hospital contacts during the two 6-month study periods are shown in Table 2. During the 12-month follow-up period, the mean number of hospital contacts was 4.50 (SD 5.14). The mean number of hospital contacts due to breast cancer was 2.23 (SD 1.84). A total of 49% (360/734) of the patients had only one contact, while 29% (213/734) of the patients had 3 or more contacts. There were no hospitalization periods or emergency visits due to breast cancer.

Rehabilitation	3 (0)	2 (0)	3 (0)	4 (1)	12 (0)
All contacts per patient					
Mean (SD)	1.06 (1.56)	0.95 (1.39)	1.22 (1.04)	1.24 (1.14)	2.23 (1.84)
Median (IQR)	0 (0 - 2)	0 (0 - 2)	1 (1-2)	1 (1-2)	2 (1-3)

The analyses of outpatient contacts and costs by follow-up method and period are shown in Table 3. There were no significant differences between the 2 follow-up methods or randomization arms. However, there was a statistically significant interaction between follow-up method and randomization arm in outpatient contacts, outpatient costs, diagnostics costs, and total costs (*P* values for time: *P*=.001, *P*<.001, *P*=.002, *P*<.001, respectively).

The number of contacts and costs were lower in the first follow-up period compared to the second period. For the digital solution, the mean number of contacts was 1.06 (SD 1.57) in the first period versus 1.22 (SD 1.04) in the second, with costs of €269 (US $313.21) compared to €311 (US $362.11). For the phone call solution, the mean number of contacts increased from 0.95 (SD 1.39) in the first period to 1.24 (SD 1.14) in the second, while costs increased from €236 (US $274.78) to €334 (US $388.89).

In addition, in the first follow-up period, the number of contacts and costs associated with the digital solution were higher than those associated with phone calls, with 1.06 contacts and costs of €269 (US $313.21) for digital versus 0.95 contacts and €236 (US $274.78) for phone calls. However, in the latter period, the costs and contacts using phone calls exceeded those using the digital solution, recording 1.24 contacts and costs of €334 (US $388.89) for phone calls compared to 1.22 contacts and €311 (US $362.11) for the digital solution.

In Table 3, the first *P* value for the follow-up method indicates whether there is an overall difference between the 2 follow-up methods (digital solution or phone calls). The second *P* value for the time period indicates whether the measurement time point (6 or 12 months) affects the difference between the methods. The third *P* value for arm indicates whether the mean score of Group A at 6 and 12 months differs from the mean score of Group B, assessing the difference between the randomization groups (digital solution from baseline to 6 months and phone calls between 6 and 12 months or vice versa).

Discussion

Principal Findings

The main finding of this study was that the number of hospital contacts and costs during the first follow-up year of patients with EBC with the digital Noona solution did not differ from those of a traditional phone call service. During both surveillance methods, the number of contacts and costs were higher during the latter 6 months of follow-up. This is probably explained by the preplanned routine 1-year visit scheduled approximately 1 year after surgery, which for most patients occurred during the latter study period.

The mean number of hospital contacts at the Department of Oncology was 2.23 (SD 1.84), and the mean number of contacts was 4.50 (SD 5.14), when hospital contacts in specialties other than oncology were included. Thus, breast cancer survivors need frequent medical care both due to cancer and for other reasons during the early part of follow-up. The patients had, for example, gynecological or traumatological visits due to other diseases or accidents.

Comparison to Prior Work

The average costs of 6 months of surveillance were similar in both groups, that is, €290 (US $337.66) in the digital solution group and €285 (331.84) in the phone call group. Thus, the costs of EBC follow-up were relatively low and in line with previous studies [13,14]. During the first year of follow-up, breast cancer recurrence is rare. Kokko et al [13] showed that the total costs of EBC follow-up over 4.2 years ranged from €1050 (US $1222.55) to €2269 (US $2641.87) per patient (6 months mean €125 [US $145.54] to €270 [US $314.37]), depending on the follow-up method in patients whose disease had not recurred. Another Finnish study also obtained similar results; the mean outpatient cost of EBC follow-up for 6 months was €192 (US $223.55)[14].

Perhaps the most clinically intriguing finding in our study was that diagnostics and costs tended to occur earlier during the follow-up with the digital solution. A possible explanation for this could be that the digital solution provided faster access to the hospital than the phone call service. Results from several previous studies support this interpretation [15,16]. In a previous report of this study on patient preference and satisfaction, satisfaction of patients with EBC was equally high during the digital solution and traditional phone call service. However, patients graded the timeliness of response higher during the digital solution period [12].

Previous studies in metastatic cancer may also support this interpretation. Denis et al [17] randomized 133 patients with metastatic lung cancer (Stage III-IV) after primary treatment to conventional surveillance with scheduled imaging or to use the digital electronic patient-reported outcomes (ePRO) app (Noona Healthcare Oy) once a week. In the ePRO arm, recurrence was detected earlier, fewer computer tomographies were needed, quality of life was better, and median overall survival was 7 months longer [17]. Cost-effectiveness was a secondary end point of the study, and annual cost in the ePRO arm was €362 (US $421.49) lower per patient than in the conventional arm [18].

To our knowledge, this is the first health economy study comparing ePRO and conventional follow-up in EBC. The strengths of our study are the large sample size and the high compliance rate. The characteristics of the patients were well representative and similar to previous studies in patients with EBC [5,19]. The costs of the follow-up were obtained directly from the hospital Ecomed database.

XSL•FO
RenderX

Limitations

We are aware of the limitations of the study. First, the study included a short follow-up time of 12 months, so long-term results could not be evaluated. Second, patients with relapsed disease were excluded from the study because of the crossover study design. Third, it is not possible to report the proportion of additional phone contacts during the digital solution period. Fourth, the data were collected from July 2015 to January 2017, and costs may have changed. Since the COVID-19 pandemic, the need for remote oncology services has expanded, and the acceptability of using digital solutions may have increased. As the costs were the same, this should not have had an impact on our results.

Future Directions

In summary, we did not find any statistically significant differences in the total cost of follow-up of EBC by digital solution or phone calls. More diagnostic tests and visits occurred during the first half of the follow-up period in the digital solution group, indicating that digital follow-up may enable faster access to outpatient services than conventional follow-up. There is a need to develop digital services for the follow-up of breast cancer.

Conclusions

We did not find any statistically significant differences in the total cost of follow-up of EBC by digital solution or phone calls. The number of visits and costs were higher during the latter follow-up period, probably due to the scheduled routine 1-year visit. There were more visits, and costs were higher in the digital solution group during the first 6 months, but higher in the phone call group during the latter 6-month period. This shows that the digital solution may enable a faster access to outpatient services than conventional follow-up.

Acknowledgments

We thank the patients who made this study possible. We also thank study nurses Satu Forsström, Kaisa-Liisa Heikkilä, and Riitta Mustonen for their assistance in collecting the data.

Data Availability

All data generated or analyzed during this study are included in this published article.

Authors' Contributions

JM and CB designed and supervised the study. CB, MP, and NF analyzed the data. MP wrote the original draft. All authors interpreted the results, reviewed, commented, and approved the final version of the article.

Conflicts of Interest

This study was partially supported by the Helsinki University Hospital (HUS) and Noona Healthcare Oy. The Noona digital solution was developed in collaboration with Noona Healthcare Oy/Varian Medical Systems Finland; however, the authors have no economic interest in the company. The authors confirm that the funder had no influence over the study design, analyses of data, content of the article or decision to submit the article to this journal.

Abstract

Background: Germline genetic variants are important for prostate cancer (PCa) management and hereditary cancer risk assessment, but testing is underused. Furthermore, patients are often unaware of the genetic connections to PCa. Social media is increasingly serving as a source of awareness for health information and a method to gather data from a large population.

Objective: There were three objectives: to (1) create and test social media messages related to PCa genetics and genetic testing, (2) determine which social media message was most engaging, and (3) assess knowledge of and attitudes toward PCa genetic testing through an online survey using the most engaging social media message.

Methods: A paid social media campaign was developed to disseminate targeted messages about PCa and genetics. We tested combinations of 8 images and 8 messages that were created or selected by the research team and reviewed by a study-specific advisory board. We targeted men and women older than 35 years living in the United States. The campaign was launched on Facebook for 6 days (June 3-8, 2023). We tracked the reach and impressions of each post. The survey, administered directly after someone viewed a post, assessed knowledge about PCa and cancer genetics as well as beliefs about cancer risk and genetic testing. Descriptive and multivariable analyses were used to analyze survey data.

Results: Most posts were viewed by women (13,675/16,224, 84.3% of impressions) and people over the age of 55 years (19,997/22,906, 87.3% of impressions). The 2 most engaging images were a group of men of different races and ethnicities (reach: 28,151 people; impressions: 33,727 views), followed by a Hispanic family (reach: 16,026 people; impressions: 20,113 views). The following message had the most engagement: “Breast cancer and prostate cancer may be related because they can arise from the same gene mutation in a family” (reach: 58,980 people; impressions: 74,834 views). A total of 875 people (n=796, 91% male; mean age 43.42, SD 14.1 years; n=224, 25.6% Black or African American individuals; n=255, 29.1% Hispanic individuals) completed the survey. In total, 75.2% (658/875) strongly or somewhat agreed that genetics play a role in the development of PCa, and 84% (735/875) would want to know if they had a genetic predisposition to PCa.

Conclusions: It is feasible to use social media platforms to test and disseminate messages that raise awareness about PCa genetics and the connection with other cancers (eg, breast cancer), as well as to deploy surveys that reach a wide audience.

Introduction

Prostate Cancer Genetics

The American Cancer Society estimated that more than 299,010 men would be diagnosed with prostate cancer (PCa) and more than 35,000 would die of PCa in 2024 [1]. Approximately 11% to 17% of patients with metastatic PCa have been reported to have germline mutations in key hereditary cancer genes, including *BRCA2*, *ATM*, *CHEK2*, *BRCA1*, *RAD51D*, or *PALB2* [2-4], which represents a substantial population burden. Patients with early-stage disease have rates of germline mutations reported at 5% to 7% [4,5]. Clinical genetic testing for PCa has rapidly expanded due to the implications for precision therapy in the metastatic setting and PCa screening [4,6-8]. Many of the genes recommended for testing confer hereditary cancer risk for individuals and their families, such as for hereditary breast and ovarian cancer or Lynch syndrome [4,6-8]. Many genes of moderate penetrance that are increasingly being tested in PCa multigene panels can provide information for targeted therapy eligibility and have additional associated cancer risks impacting patients and their families, such as *CHEK2* (breast and colorectal cancer risk), *PALB2* (breast and pancreatic cancer risk), and *ATM* (breast and pancreatic cancer risk) [4,6,7]. Therefore, the impact of genetic testing for PCa has significantly increased for patients with PCa and at risk of PCa and has expanded impact based on hereditary cancer risk for patients and their families.

Low Understanding of PCa Genetics

Multiple factors, including feeling susceptible to PCa and understanding that PCa early detection is important, have been linked to intentions to undergo PCa genetic testing [9]. Previous research has reported low levels of knowledge among men about PCa, risk factors, screening, and genetic testing options [10,11]. Similarly, negative beliefs about the importance of cancer screening or genetic testing, as well as the efficacy of such tests, have hampered efforts to increase screening and testing for PCa among eligible men [12,13]. Disparities are most pronounced among male African American individuals, those with less formal education, and those living in rural areas [14,15].

Social Media Can Raise Awareness of PCa Genetics

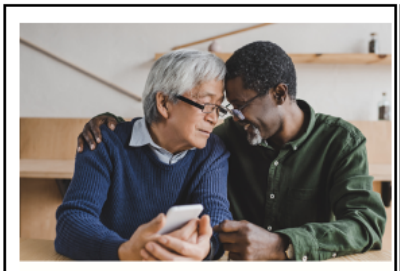
The use and role of social media in PCa continues to expand, providing a potential platform through which to promote greater knowledge and awareness [16]. With respect to PCa genetics, our group previously examined activity related to *BRCA* and genetic testing on Facebook, YouTube, and Twitter (subsequently rebranded X) [17]. Overall, we found substantially less social media activity on these topics for PCa compared to breast cancer. In a follow-up study using data from the National Cancer Institute's Health Information National Trends Survey, we examined differences in awareness and uptake of genetic testing among participants with a history of breast or ovarian cancer versus PCa [18]. Significantly fewer patients with PCa were aware of or had used cancer genetic testing than participants with a history of breast or ovarian cancer. Interestingly, patients with PCa reported that the internet was the most common source of information about genetic testing, suggesting that this is a promising avenue to increase knowledge and awareness of this topic.

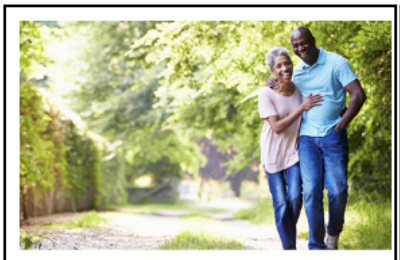
Study Purpose

Recognizing the low awareness of PCa genetics among the public and the promise of social media as a platform for education, we developed and implemented a social media-sponsored advertising campaign with two goals: (1) to determine the images and messages about PCa genetics that resonated the most with a targeted social media audience and (2) to understand current knowledge of and attitudes toward PCa genetics among a diverse sample of respondents.

Methods

Study Team





This research was guided by a multidisciplinary team consisting of a medical oncologist specializing in cancer genetics, a urologist specializing in PCa, a population science researcher with training in health communication, a staff member at the Prostate Cancer Foundation, a research coordinator, a data analyst, and a biostatistician. In addition, the team was supported by a 12-member advisory board consisting of 9 clinicians who specialize in various aspects of treating PCa, a genetic counselor, a chief social media officer for a large health system, and a program director who runs a patient support group for men with PCa.

Creating the Social Media Posts

The research team identified 8 different types of images that were related to PCa genetic testing: men (in general), male-female relationships, doctor-patient relationships, individuals that identify as belonging to sexual and gender minority groups, Hispanic individuals, Asian individuals, a strand of DNA, and a teal ribbon for PCa advocacy (Figure 1). Images were gathered from Shutterstock (Shutterstock, Inc). Next, the team created 8 short messages that included information about PCa statistics, its link to breast cancer, and the genetic aspect of the connection (Figure 2). All images and messages were reviewed and approved by the research team and the advisory board, which was assembled specifically for this study.

Figure 2. Message testing and engagement results.

Advertisement Placement and Targeted Audience

We used Facebook Ads Manager's (Meta Platforms) manual advertisement placement feature to place advertisements throughout Facebook. The date and time when advertisements were shown on Facebook were determined by an algorithm that maximized viewership, although each advertisement received the same amount of placement time. We limited the viewing to male and women aged 35 years or older who resided in the United States. Although the advertisements were about PCa, we included women in our targeted audience as they often make health care decisions for spouses and family members [19].

Metrics

To determine which image and message had the greatest engagement, we tracked metrics for each post through Facebook analytics: reach (the number of unique individuals who viewed an advertisement), impressions (the total number of people who viewed an advertisement), and total and unique number of clicks. We used the survey service platform Qualtrics (Qualtrics International Inc) to track the number of participants

XSL•FO
RenderX

who clicked a link in the post that was unique to each of the 8 post combinations (Qualtrics link clicks).

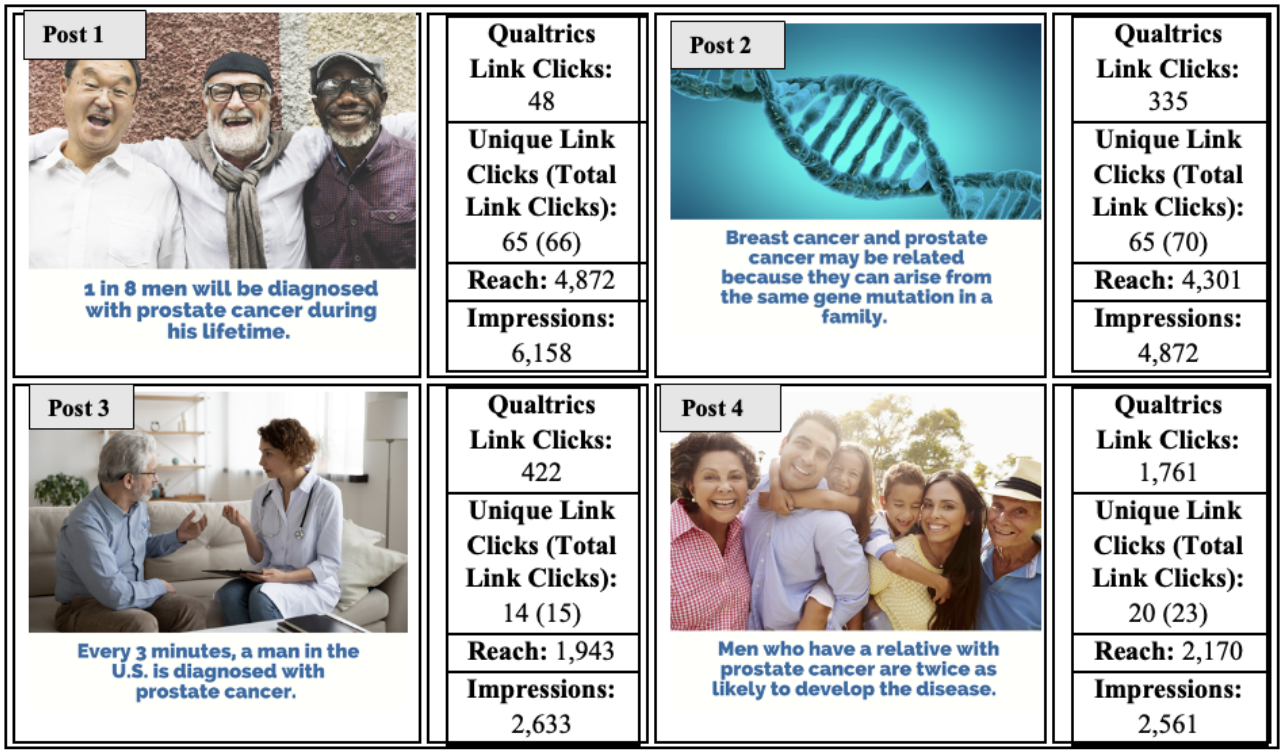

Image and Message Testing

The image and message testing phases took place over 10 days on Facebook. For the image testing, we chose the most generic message to test with each of the images ("Know your family history. Prostate cancer can be genetic"). The image with the most Qualtrics link clicks, reach, and impressions was then used to test each of the 8 messages.

Final Campaign

The final 4 posts were created using the 4 best-performing images and messages (Figure 3). The combination of images and messages was randomly generated to create the 4 final posts. The posts depicted men of different ethnic backgrounds paired with the message "1 in 8 men will be diagnosed with prostate cancer during his lifetime" (post 1), an image of a DNA helix paired with the message "Breast cancer and prostate cancer may be related because they can arise from the same gene mutation in a family" (post 2), an image of a patient with a health care provider paired with the message "Every 3 minutes, a man in the U.S. is diagnosed with prostate cancer" (post 3), and a Hispanic family paired with the message "Men who have a relative with prostate cancer are twice as likely to develop the disease" (post 4). Each of the 4 posts included a link to the short survey about PCa genetics.

Figure 3. Final campaign: combination of best-performing images and messages.

Survey Development

We created a survey that covered the following topics: 4 questions about general knowledge of PCa and 6 questions about knowledge of PCa genetics [20], 4 questions about attitudes toward and beliefs about PCa and PCa genetic testing [21], 5 questions about family and personal history of PCa and genetic testing and demographic characteristics (sex, age, race, ethnicity, marital status, and educational attainment). The 23-item survey, with 3 additional questions if a participant indicated a PCa diagnosis, was completed, on average, in 7 (SD 1.21) minutes. Participants were required to answer each question. The survey was hosted on the Qualtrics platform. The survey is available in Multimedia Appendix 1.

Recruitment

We launched the posts in collaboration with the Prostate Cancer Foundation and used their Facebook platform to distribute the posts over the course of 6 days (June 3-8, 2023). We paid to have the posts displayed to users whose profiles identified them as a man or woman who was over the age of 35 years and lived in the United States. These were the same criteria we used for survey eligibility. Participants clicked on a link in the social media post to verify their eligibility and take the online survey.

Data Cleaning and Analysis

We accepted the first survey completed from each unique IP address to limit responses from spammers and bots and duplicate responses. The survey data were tallied using descriptive statistics. Mean scores with corresponding SDs were reported for the scores of correct responses for the sections on general PCa knowledge, genetics of PCa, and cancer and genetic testing beliefs. Frequencies and percentages were also reported for the number of correct responses about general PCa knowledge and genetics of PCa, and for participants' PCa or genetic testing history and general demographic information. Multiple linear regression modeling was used to compare the mean scores between the different demographic and cancer history groups. The models were adjusted for potential confounding from age,

XSL•FO
RenderX

sex, race, ethnicity, and educational level. All statistical analyses were conducted using SAS (version 9.4; SAS Institute). A nominal significance level of α=.05 was used in these analyses.

Ethical Considerations

This study was approved by the institutional review board at Thomas Jefferson University (20G.013). Participants provided consent before completing the online survey, which consisted of reading a statement about the study and its risks and benefits and checking a box stating that they agreed to participate. All study data were anonymous and separated from the personal information required to receive US $10 compensation in the form of an e-gift card for survey completion.

Results

Image Testing

The 4 images with the most engagement on social media were those of men of different ethnic backgrounds, the Hispanic family, the Asian family, and the DNA helix. Each reached more than 11,000 individuals and had more than 14,000 impressions, twice as high or more than the other images. Men engaged with the posts more than women, as did those over the age of 65 years compared to younger viewers (data not shown).

Message Testing

The following messages had the most engagement: “Breast cancer and prostate cancer may be related because they can arise from the same gene mutation in a family,” “Every 3 minutes, a man in the U.S. is diagnosed with prostate cancer,” “1 in 9 men will be diagnosed with prostate cancer during his lifetime,” and “Men who have a relative with prostate cancer are twice as likely to develop the disease.” The metrics and corresponding data can be found in Figure 2. Women were more likely to respond to the messages in the posts, as were those aged 65 years and older compared to younger viewers (data not shown).

Final Campaign

The post with the greatest reach was the image of the men of different ethnic backgrounds accompanied by the message “1 in 8 men will be diagnosed with prostate cancer during his lifetime,” followed by an image of a DNA strand and the message “Breast cancer and prostate cancer may be related because they can arise from the same gene mutation in a family.” The doctor-patient image with the message “Every 3 minutes, a man in the U.S. is diagnosed with prostate cancer” was the third most engaging, while the fourth most engaging post was the Hispanic family with the message “Men who have a relative with prostate cancer are twice as likely to develop the disease.” Data from all 4 final posts can be found in Figure 3. The advertisements were viewed the most by women (13,675/16,224, 84.3% of impressions) and people over the age of 55 years (19,997/22,906, 87.3% of impressions; data not shown).

Survey Participants

Of the 875 survey participants, most were male (n=796, 91%) and married or living with someone (n=701, 80.1%). The mean age of the respondents was 43.42 (SD 14.1) years; one-quarter (n=224, 25.6%) self-identified as Black or African American individuals, and almost one-third (n=255, 29.1%) self-identified as Hispanic individuals. One-third (n=302, 34.5%) had a history of PCa; of those, more than half (171/302, 56.6%) had undergone genetic testing. Of the 124 respondents who did not undergo genetic testing, 69 (55.6%) said that it was not offered to them. The characteristics of the participants are shown in Table 1.

Missing	7 (2.3)

Survey Findings

Respondents had varying knowledge about the prostate, PCa, and PCa genetics (Table 2). Most (699/875, 79.9%) correctly answered that the prostate was located under the bladder, but 75% (656/875) of men agreed with the statement that "more men die from prostate cancer in the U.S. than from any other cancer," which is untrue. At least 70.1% (613/875) of respondents answered each of the PCa genetics questions correctly except for 1 question about the number of genes that can increase the risk of PCa (254/875, 29%). Three-quarters of the respondents (658/875, 75.2%) strongly or somewhat agreed that genetics play a role in the development of PCa (mean score 3.21, SD 0.76), and 84% (735/875) would want to know if they had a genetic predisposition to PCa (mean score 3.13, SD 0.80). More than half (534/875, 61%) agreed that genetic testing is risky due to privacy concerns (mean score 2.99, SD 0.97). When survey results were stratified by personal history of PCa, the results were inconclusive (Table S1 in Multimedia Appendix 2).

XSL•FO
RenderX

Table 2. Knowledge and beliefs about prostate cancer and prostate cancer genetics (N=875).

Statement	Values
Knowledge about prostate cancer	
"Both men and women have a prostate gland," n (%)	411 (47)
"The prostate gland is located under the bladder," n (%)	699 (79.9)
"Black men are more likely to get prostate cancer than White men," n (%)	584 (66.7)
"More men die from prostate cancer in the U.S. than from any other cancer," n (%)	219 (25)
Score (number correct), mean (SD)	2.19 (0.87)
Knowledge about prostate cancer genetics	
"People get half of their genetic makeup from their mother and half from their father," n (%)	646 (73.8)
"There is only one gene that can increase the risk of prostate cancer," n (%)	254 (29)
"A mutation in a gene can lead to an increased risk of cancer," n (%)	667 (76.2)
"If a woman has a breast cancer gene mutation (such as BRCA2), she can pass that mutation to her son," n (%)	649 (74.2)
"The breast cancer gene BRCA2 can increase the risk for prostate cancer," n (%)	625 (71.4)
"Breast cancer and prostate cancer may be related because they can arise from the same gene mutation in a family," n (%)	655 (74.9)
Score (number correct), mean (SD)	4.00 (1.38)
Beliefs about prostate cancer (score of 1-4), mean (SD)	
"How much do you think genetics, that is characteristics passed from one generation to the next, determine whether or not a person will develop prostate cancer?"[a]	3.21 (0.8)
"I would want to know if I have a genetic risk for prostate cancer"[b]	3.13 (0.8)
"Getting genetic testing is risky because you cannot guarantee the privacy of the results"[b]	2.99 (1.0)

[a]Response options: 4="a lot," 3="somewhat," 2="a little," and 1="not at all."

[b]Response options: 4="strongly agree," 3="agree," 2="disagree," and 1="strongly disagree."

Multiple linear regression modeling suggested that there were notable differences in PCa and PCa genetics knowledge and beliefs that depended on the demographic characteristics of the respondents (Table 3). Lower mean scores on knowledge of PCa were associated with those reporting the oldest ages compared to those under the age of 40 years (for those aged ≥60 years: β=−.20; *P*=.024), although higher scores were associated with reporting Asian, Pacific Islander, or Alaska Native race compared to White race (β=.22; *P*=.046) or Hispanic or Latino ethnicity (β=.23; *P*=.001). Higher mean scores on knowledge of PCa genetics were associated with those reporting older ages compared to those under the age of 40 years (for those aged 40-49 years=: β.41 and *P*=.001; for those aged 50-59 years: β=.539 and *P*<.001; for those aged ≥60 years: β=.65 and *P*<.001), Black or African American race compared to White race (β=.36; *P*=.001), or higher educational attainment compared to those without a college degree (for those with an associate's or bachelor's degree: β=.47 and *P*<.001; for those with a master's or doctoral degree: β=.69 and *P*<.001).

Regression modeling for additional survey items, as well as modeling for participants with and without a personal history of PCa, is shown in Tables S2-S6 in Multimedia Appendix 2. Stronger agreement with the statement "Getting genetic testing is risky because you cannot guarantee the privacy of the results" was associated with those reporting older ages compared to those under the age of 40 years (for those aged 50-59 years: β=.19 and *P*=.03; for those aged ≥60 years: β=.37 and *P*<.001), Hispanic or Latino ethnicity (β=.20; *P*=.007), or higher educational attainment (for those with an associate's or bachelor's degree: β=.25 and *P*=.01; for those with a master's or doctoral degree: β=.54 and *P*<.001), although agreement was weaker for female than for men (β=−.38; *P*=.001). Stronger agreement with "How much do you think genetics, that is characteristics passed from one generation to the next, determine whether or not a person will develop prostate cancer?" was associated with those reporting older ages compared to those under the age of 40 years (for those aged 40-49 years: β=.14 and *P*=.04; for those aged 50-59 years: β=.38 and *P*<.001; for those aged ≥60 years: β=.58 and *P*<.001) or the highest educational attainment compared to lower than an associate's degree (for those with a master's or doctoral degree: β=.34; *P*<.001), although agreement was weaker for those reporting Hispanic or Latino ethnicity (β=−.13; *P*=.03). No direct associations in modeling by personal history of PCa were observed.

Discussion

Principal Findings

This study combined a social media advertising campaign about PCa genetics to determine the images and message text that resonated the most with an at-risk audience with a brief survey to understand knowledge and beliefs about PCa and PCa genetics. Through a series of image and message tests for engagement on social media, we created 4 posts for Facebook and linked those posts to a brief survey. Three of the 4 high-engagement images had families in them, and 3 of the 4 messages had the word "male" or "man" in them. A total of 875 people who saw a post completed the survey, leading to results that showed that knowledge about PCa and PCa genetics, as well as beliefs about PCa genetics, vary significantly by the characteristics and experiences of the individual. Results from the social media portion of this study can be used to inform future PCa genetics awareness campaigns; in fact, a recent roundtable of experts endorsed social media as an effective channel to reach patients with credible messages [22].

Comparison With Prior Work

The image testing revealed that a variety of images—from groups of men to patients and providers to families to images of DNA—resonated with the audience. Interestingly, while the image of the Asian family had high engagement, it did not result in many completed surveys. This may be due to the reluctance of people who are of Asian descent to participate in research [23]. For all advertisements, the most engagement and interactions came from participants aged 65 years and older, consistent with data that show that 6 out 10 men are aged 65 years or older when they are diagnosed with PCa, and therefore, this age group is most likely to be looking for this information [24].

While 3 of the 4 messages with the highest engagement included the word "men" or "man," the message with the highest engagement linked both breast cancer and PCa. It may be that this information about the connection between breast cancer and PCa is new and piqued people's curiosity. In an environment such as social media where the volume of information and messages is infinite, new information may stand out from the noise. Notably, in the survey data, more than 7.1% (613/875) of the respondents answered 2 questions correctly about the genetic link between breast cancer and PCa, possibly correctly recalling what they had just viewed in the post. Women were more likely to engage with messages than men. The most engagement from women was with more broad, general messages. Similar to the image testing, all messages had more engagement among those aged 65 years or older. Our experience and results indicate that, when creating public information campaigns, it is important to pretest images and messages to

XSL•FO
RenderX

determine which have the most salience for different audiences [25].

From the survey data, there was strong understanding that genetics can play a role in PCa development, and there was high interest in knowing one's own risk of PCa, but there was also concern that genetic testing carries some risk with respect to data privacy. There is a substantial evidence base about the public's understanding of PCa and the disparities in knowledge among subpopulations, but less is known about the public's understanding of the role of genetics in the disease. While data protection and privacy is a dynamic field, there is a sense that patients are concerned about sharing their genetic data [26]. Increasing uptake of genetic testing across all populations will require continued educational campaigns coupled with information to alleviate concerns about data privacy.

Limitations

There were numerous strengths and limitations to this study. Strengths of this study included the novel use of social media posts for an awareness campaign about PCa genetics and to conduct a survey on educational gaps in this area. Limitations of this study included that the results of a survey conducted through social media may not be generalizable to people who do not use social media platforms. It is also possible that bots may have affected the results, although checks were in place to reduce this risk. In addition, a single social media platform was used to post the advertisements, and results may differ on other platforms with different audiences.

Conclusions

Our results show that it is feasible to use social media platforms to create effective public awareness campaigns and increase awareness of the link between PCa and genetics. Given the lack of awareness of this link and the implications for medical surveillance and the early detection of cancer, campaigns such as this one are warranted. To be effective and attention getting, messages should be tailored to different viewers, as indicated by our results. Further studies are needed to assess calls to action based on social media campaigns to increase engagement for PCa genetic testing across populations.

Acknowledgments

Funding was provided by the Prostate Cancer Foundation Valor Challenge Award (19CHAL05).

The authors would like to acknowledge the contribution of the following advisory board members who helped in the selection of images and messages for the social media campaign: Daniel Becker, MD (New York University Langone Health); Austin Chiang, MD (Thomas Jefferson University); Atreya Dash, MD (University of Washington); Adam Dicker, MD (Thomas Jefferson University); Leonard Gomella, MD (Thomas Jefferson University); Matthew Katz, MD (Radiation Oncology Associates, Pennsylvania); Nina Lamble, MD (University of Washington); Terri Likowski (ZERO Prostate Cancer); Christopher Pieczonka, MD (Associated Medical Professionals of New York); Abhishek Solanki, MD (Loyola University Chicago); Brittany Szymaniak, PhD (Northwestern University); and David Wise, MD (New York University Langone Health). No artificial intelligence technologies were used in any aspect of this research or manuscript preparation.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on request.

Authors' Contributions

AEL and VNG conceptualized the study, received the funding, and provided research oversight. PS was responsible for project administration. SL was an investigator on the research team. AH provided resources from the Prostate Cancer Foundation. RH and SWK conducted the formal analysis of the data. AEL drafted the manuscript, and all authors reviewed and approved the final version.

Abstract

Background: Several guidelines recommend posttreatment surveillance for non–small cell lung cancer (NSCLC). However, studies evaluating surveillance patterns often cannot distinguish between imaging ordered for surveillance versus for symptoms suggestive of recurrence. Moreover, early recurrences and other competing events hamper efforts to determine true surveillance rates because of wide variability in reported guideline adherence in clinical practice. Leveraging comprehensive Veterans Health Administration data, we developed a novel competing risks framework to describe the patterns and predictors of NSCLC imaging surveillance.

Objective: This study aims to examine posttreatment surveillance to estimate the true surveillance rates and predictors of guideline-concordant care in patients with early-stage NSCLC.

Methods: The study cohort comprised veterans who were treated for stage 1 to 3 NSCLC between 2008 and 2016 and who survived for ≥6 months. Clinical documents and radiology reports were abstracted for image indication and clinical information. We estimated the cumulative probability of receiving guideline-concordant surveillance, defined as chest computed tomography imaging within 4 to 9 months after treatment, accounting for competing risks and censoring. Multivariable cause-specific Cox regression was used to estimate associations between patient factors and guideline-concordant surveillance, with adjustments made for multiple comparisons.

Results: The cohort consisted of 1888 patients. The mean age of the analysis cohort was 66.4 (SD 7.9) years; 95.9% (1811/1888) of the patients were male, 71.1% (1342/1888) of the patients were White, and 43.1% (814/1888) were married. Of the 1888 patients, 57% (n=1076) presented with stage 1 disease, and the most common treatment modality was surgery alone (n=1068, 56.6%). The most common type of imaging performed during the initial 120- to 270-day window was chest computed tomography (1460/3278, 44.5%). Chest X-rays accounted for 36.3% (1190/3278) of all imaging performed, while the remaining 11.8% (386/3278) and 7.4% (242/3278) were positron emission tomography scans or other imaging modalities, respectively. Compared to the years 2008 to 2010, patients treated for NSCLC from 2014 to 2016 had a significantly higher likelihood of receiving guideline-concordant surveillance (hazard ratio 1.42, P<.001).

Conclusions: In this unique application of a competing risks framework, the rate of guideline-concordant surveillance in this national cohort was lower than that reported in many previous studies. This finding highlights a potentially substantial gap in surveillance among eligible, asymptomatic lung cancer survivors. More strategies are needed to measure the true rate of guideline-concordant surveillance, along with education and advocacy to ensure guideline-concordant care.

Introduction

Lung cancer is one of the most common cancers worldwide and remains the leading cause of cancer mortality [1]. Following treatment for lung cancer, patients remain at risk both for recurrence and the development of second primary lung cancer (SPLC). Surgery remains the mainstay of curative-intent therapy in early-stage disease. However, patients can have recurrence rates ranging from 30% to 68% despite complete resection [2,3]. As a result, several expert bodies have issued guidelines recommending routine surveillance following treatment completion to detect recurrence and SPLC [4-6]. Nearly all these guidelines recommend imaging surveillance within 6 months following treatment completion.

Despite these recommendations for posttreatment surveillance, there is wide variability in guideline adherence in clinical practice. Previous studies have evaluated adherence to these recommendations for posttreatment surveillance, with reported rates ranging from 25% to 71% [7-10]. The cause of this variability remains unknown and is likely multifactorial, although differences in patient populations, demographics, ongoing access to specialized cancer care, and health care professional practice are likely factors [11]. In addition, the VA population faces unique stressors that may negatively influence health management behaviors, making them more vulnerable to stressors [12].

We contend that incomplete data on imaging indications are a potential contributing factor to the observed variability in guideline adherence. Imaging after definitive treatment can occur for multiple reasons, including nonsurveillance indications such as a chest computed tomography (CT) ordered for a traumatic injury. Previous studies that have included information on imaging indications have been limited to single-center experiences with a relatively small patient sample and are likely influenced by these population differences and varying institutional practices [8,13]. Large population-based studies that assess guideline-concordant surveillance across health care professional and patient characteristics have lacked information on imaging indications by relying on administrative claims–based data [7,9,10,14]. Patients may have imaging procedures captured in claims data despite competing events (ie, early recurrence) that exclude them from undergoing true surveillance, thereby leading to inaccurate estimates of posttreatment surveillance rates. Each of these limitations has hampered efforts to evaluate true surveillance rates and the effectiveness of surveillance programs more broadly.

Herein, this study examines posttreatment surveillance using detailed national Veterans Health Administration (VHA) data to estimate the true rate of adherent surveillance and predictors of guideline-concordant care in patients with early-stage non–small cell lung cancer (NSCLC). We used a novel annotation methodology to abstract imaging indications from national data at scale. Information on imaging indications and clinical documentation allowed us to use a competing risk analysis for estimating the cumulative probability of surveillance. In contrast to previously published reports, this form of time-to-event analysis offers the opportunity to account for events and describe the factors that affect posttreatment surveillance [15,16]. We expect that this analysis will provide a more accurate estimate of the rates and predictors of guideline-concordant posttreatment surveillance.

Methods

Cohort and Definitions

Using the VHA electronic health record databases, we identified 20,532 patients treated with curative intent for nonmetastatic primary NSCLC who were diagnosed between January 1, 2008, and April 30, 2016. We used the *International Classification of Diseases, 9th/10th Edition* (*ICD-9/10*) diagnosis codes (Table S1 in Multimedia Appendix 1). We also retrieved demographic, clinical, and vital status information for these patients. For inclusion, patients must have had either ≥1 inpatient or ≥2 outpatient NSCLC diagnosis codes, and the date of diagnosis must be the date of the earliest code demonstrating connectedness to care [17]. Curative-intent treatment was classified based on the *ICD-9/10* procedure codes and Current Procedural Terminology (CPT) codes (Table S2 in Multimedia Appendix 1) within 6 months of diagnosis. The NSCLC stage was classified according to the American Joint Committee on Cancer TNM (tumor, nodes, and metastasis) staging system (seventh edition in effect during the observation period). We excluded patients who did not receive curative-intent therapy, received chemotherapy only, died within 6 months of initiating therapy, had stage 4 cancer, had a non–skin cancer diagnosis (except melanoma and cervical cancer) within 5 years before the NSCLC diagnosis, or had any diagnosis of lung cancer before 2008. Participant follow-up ended on December 31, 2016.

The study cohort included a random subset of 1890 eligible patients with completely abstracted radiology reports and clinical notes from a 9238-sample cohort. An additional 369 patients from the sample cohort had no radiology reports directly relevant to NSCLC surveillance. To avoid overrepresentation of patients without abstractable radiology reports in our analysis, we weighted these patients so that their proportion in the study cohort was the same as their proportion among all eligible patients in the sample cohort—bringing the final analysis sample to 1888.

Radiology Abstraction

We abstracted image indications (surveillance, symptoms, abnormality follow-up, other, and unknown) and modalities (positron emission tomography [PET]; chest X-ray [CXR]; chest CT; and other [magnetic resonance imaging, non–chest CT, and bone scan]) from radiology reports. Imaging indications were identified in the report text and recorded as documented.

We used the previously published semiautomated chart abstraction protocol by our group for obtaining detailed radiology data [18]. A searchable radiology index was created, which included full-text radiology reports that were then queried using SQL (structured query language) to identify all radiology-related text documents to be indexed. VISA, an open-source full-text search engine written in Java, was used to search the radiology reports for text relevant to the user query.

XSL•FO
RenderX

Upon searching, VISA returned the user-defined full-text radiology reports with highlighted relevant text snippets, which were then manually reviewed, annotated, and coded by an abstractor.

Clinical Abstraction

Clinical notes from patient charts were used to abstract any missing data on disease stage, smoking status, NSCLC recurrence or an SPLC, and tumor histology. Final pathologic staging took precedence during chart abstraction. Smoking at the time of diagnosis or initial presentation was considered "current." The presence of recurrent NSCLC or SPLC was determined based on documentation by a treating clinician. Histologic subtypes were identified directly from pathologic reports when available or collected from other clinical note types (eg, progress notes). Patients who had small cell histology, had recurrence or SPLC outside the lungs within 120 days after treatment, or did not undergo curative-intent treatment were also excluded.

Outcomes of Interest

The primary outcome was receipt of guideline-concordant surveillance imaging. The National Comprehensive Cancer Network (NCCN) recommendations for posttreatment surveillance imaging at the time of diagnosis were used as a base set of guidelines [19]. Although the published guidelines are updated, they have consistently recommended routine posttreatment surveillance with chest CT imaging approximately every 6 months during this study period. We defined guideline-concordant surveillance as performing chest CT imaging for surveillance purposes (as documented by the image indications) within 120 to 270 days following the first day of treatment or first day of last treatment with multimodality therapy. Imaging performed explicitly for surveillance purposes via other imaging modalities (eg, PET) was considered nonconcordant surveillance. The 120- to 270-day (4‐9 mo) posttreatment interval was adopted to represent the first surveillance window, with the intent of creating a more liberal window with a 2- to 3-month buffer on either end of the published 6-month guideline (Multimedia Appendix 1).

Ethical Considerations

This study was approved by the institutional review boards of Stanford University and the Department of Veterans Affairs (IRB-46841). The study data used were deidentified. Informed consent was waived as per institutional review board review.

Statistical Methods

To estimate the cumulative probability of patients receiving guideline-concordant surveillance imaging within the initial 120- to 270-day surveillance window after curative-intent therapy, we used a competing risks framework to account for competing events. This can help provide unbiased estimates of patients experiencing the event of interest, given that competing events materially alter their probability or preclude them entirely. For example, receiving a diagnosis of recurrent NSCLC before scheduled surveillance precludes guideline-concordant surveillance, as imaging after recurrence can no longer be considered surveillance. Recurrences discovered during surveillance imaging were coded as surveillance events. An example schematic of the time-to-event analysis helps visualize a few of these relatively common clinical scenarios (Figure S1 in Multimedia Appendix 1).
