Abstract

Background: Digital health solutions that incorporate electronic patient-reported outcomes (ePROs) hold promise for enhancing communication and patient engagement in pediatric oncology and palliative care. While ePROs are increasingly used in adult populations, their use in children, especially when combined with gamification, remains underexplored.

Objective: This MyPal4Kids study aimed to assess the feasibility, acceptability, and user engagement of a digital health platform that integrates ePROs and a serious game, designed for pediatric oncology patients aged 6 - 17 years and their caregivers.

Methods: A multicenter observational feasibility study was conducted between December 2020 and September 2022 at 3 clinical sites in Germany and the Czech Republic. A total of 83 children and adolescents with cancer, their parent or legal guardian, as well as 10 health care professionals (HCPs) participated. Primary outcomes included platform acceptability and engagement, assessed through recruitment, participation, and attrition rates, adherence, and usability ratings. Secondary outcomes focused on the feasibility of ePRO-based data capture and the perceived impact on HCP workflows and communication. A mixed methods design was used, combining in-app data and surveys with qualitative insights from focus groups.

Results: The recruitment rate was 55%, with an attrition rate of 18%. Usability was rated positively, with most users finding the platform intuitive. Sustained engagement declined over time, particularly among older children who found the serious game insufficiently engaging. Adherence varied by age group and HCP involvement. Participants reported increased motivation when symptom reports were acknowledged by HCPs, although the impact on communication was perceived inconsistently.

Conclusions: The developed platform shows potential for use in clinical care and research. However, maintaining long-term engagement remains a challenge. Tailoring content to different age groups and strengthening feedback mechanisms from HCPs are critical for improving the user experience. Successful implementation in routine clinical practice will require integration into existing workflows and digital infrastructure, along with ongoing user-driven development.

Introduction

The illness trajectory of children and adolescents with cancer presents a heavy burden for patients and their families, marked by diagnosis, the difficult treatment process, and fear of relapse or death. Physical and psychological challenges affect patients, relatives, and peers [1-3]. This underscores the need for comprehensive support, including palliative care, which should begin at diagnosis, not just at the end of life [4].

Recognizing this, pediatric oncology has shifted toward investigating patient-reported outcomes, typically collected via standardized questionnaires. Electronic patient-reported outcomes (ePROs) are digital versions, often available through mobile apps [5-7]. This patient-centered approach allows young patients with cancer to self-report experiences, preferences, concerns, and symptoms in real time [8], without relying on health care professionals (HCPs) [9]. Such patient-centered approaches aim to improve self-efficacy and health-related quality of life (QoL) for young patients with cancer and their relatives [9,10]. They also aim to improve communication among all stakeholders [11], addressing time constraints during appointments and providing continuous, nuanced information on patients' well-being [12].

While ePROs have demonstrated utility as outcome measures in clinical trials involving childhood cancer and palliative care [6,13-17], their implementation in daily clinical practice remains limited and underexplored [13,18-22]. Expert guidance also highlights the need for carefully designed development and implementation processes for pediatric ePRO systems to ensure usability, clinical relevance, and successful integration into routine care [23-25].

Approaches such as serious games [26] and gamification [27-29] have gained increasing attention as strategies to enhance engagement with digital health interventions, particularly in younger populations [30-33]. Gamification elements (eg, rewards, narratives, or interactive tasks) may foster motivation, adherence, and sustained use of health apps, thereby potentially improving data completeness and the overall effectiveness of ePRO systems in supporting coping, communication, and self-expression. However, the use of gamification to engage young patients is still poorly understood [18,34-40].

At the same time, the application of digital health tools in pediatric oncology requires careful consideration of the heterogeneity of the target population. Children and adolescents differ widely in terms of cognitive development, emotional needs, and digital literacy, and their experiences of cancer vary depending on diagnosis, treatment intensity, and prognosis [1-3]. Moreover, the involvement of parents or caregivers plays a central role in treatment-related decision-making, distinguishing pediatric settings from adult care, while also being associated with increased levels of distress among caregivers [41,42]. These factors highlight the importance of designing flexible, developmentally appropriate platforms that can accommodate both self-reporting by patients and proxy reporting by caregivers, while remaining sensitive to the diverse clinical and psychosocial contexts within pediatric oncology.

The European Union-funded MyPal project (grant 825872 [43]) addressed these challenges by developing and evaluating a novel digital health platform under real-world conditions. The MyPal digital health platform and its components were developed by the MyPal project partners Foundation for Research and Technology-Hellas and Promotion Software GmbH. It encompassed two clinical studies: MyPal Adults (adult patients with cancer) [44] and MyPal4Kids (children and adolescents with cancer) [45]. MyPal4Kids aimed to evaluate the acceptability, appropriateness, and impact of an ePRO-based platform for pediatric oncology and palliative care, as perceived by children and adolescents with cancer, parents, and HCPs. The study also sought to identify barriers and facilitators relevant to the platform's integration into routine care. An interdisciplinary team, including experts from pediatric oncology, palliative care, psychology, IT, and software development, oversaw all stages from design to implementation and evaluation.

Previous publications from the MyPal consortium have addressed key feasibility aspects [46], including a systematic review on ePRO interventions in palliative care [47], ethical and legal considerations [48], implementation frameworks [49], technical development [50], psycho-oncological aspects [51], and policy implications [52]. This paper presents the core findings of the MyPal4Kids clinical study, combining quantitative and qualitative data to evaluate whether integrating ePROs via a digital platform can support more personalized and sustainable care in pediatric oncology and palliative care.

Methods

Overview

The multicenter observational feasibility study, MyPal4Kids, was conducted from December 2020 to September 2022 at Saarland University (USAAR), Hannover Medical School (MHH; Germany), and University Hospital Brno (FNBRNO; Czech Republic). Recruitment closed on March 31, 2022 (last patient, first visit).

Study Design

An observational study design was chosen to evaluate the feasibility of the platform in a real-world setting without randomization, enabling a naturalistic assessment of acceptability and engagement.

Setting and Participants

The study took place in pediatric oncology units at all 3 participating hospitals, which provide inpatient and outpatient care to about 290 new pediatric oncology patients annually, supported by multidisciplinary teams. Eligible participants were children and adolescents with cancer aged 6-17 years diagnosed

XSL•FO
RenderX

with solid tumors or leukemia and treated at one of the sites within the previous 12 months.

Recruitment

Trained clinical staff recruited participants. Eligible patients and at least 1 parent or legal guardian were invited to participate in the 6-month study during an informational session. Written informed consent was obtained from patients and their parents. Study staff created user accounts, provided leaflets with QR codes for app installation and baseline questionnaires, and offered support as needed. Details of recruitment and eligibility are available in the protocol [45].

Intervention: The MyPal Digital Health Platform

In addition to standard care, participants used the ePRO-based platform during their 6-month study participation. The platform had 3 components (Table 1) [50], which were available in German and Czech with a "read-aloud" functionality for younger users. A video demonstrating the MyPal platform and its apps is available online [53]. The platform was implemented through these 3 components and was offered for use within clinical workflows across user-selected devices. Participation was voluntary, and no mandatory actions or response pathways were established for HCPs. Data were securely transmitted and made available to HCPs to support clinical decision-making.

Table . A description of the 3 components of the MyPal digital health platform evaluated in MyPal4Kids.

Component	Description
MyPal-Child App	A mobile video game designed for young patients with cancer that integrates ePRO[a]-based symptom self-reporting and diary entries into the serious game "AquaScouts." [50] The game immerses players in an underwater adventure in which infected areas are progressively restored through the gameplay. Players collect tokens while responding to prioritized symptom-related questions presented both inside and outside the game environment. Diary entries could be optionally shared with treating HCPs[b] through the App. Gamification elements included obstacle avoidance mechanics associated with point deductions, selectable movement speeds, token-based rewards (eg, artifacts), daily high-score lists among study participants, and avatar customization intended to support motivation and engagement.
MyPal-Carer App	Enables parents to proxy-report their child's symptoms and access relevant web links. Both this and the MyPal-Child App could be installed on mobile devices and were also used to complete study questionnaires.
Browser-based HCP interface	A web-accessible tool (via smartphone, tablet, or desktop) that allows real-time review of reported symptoms and diary entries through interactive visualizations. HCPs could add treatment protocols, symptoms, and reactions based on observed data. The study protocol did not prescribe specific HCP responses. The interface was used on a discretionary basis.

[a]ePRO: electronic patient-reported outcome.

[b]HCP: health care professional.

Participatory Design

A participatory design approach guided the development of the platform with the aim to enhance its relevance, utility, and usability for the target population. This process included a literature review, prestudy focus groups [54], and structured discussions with patients, parents, and HCPs to identify needs, preferences, potential barriers, and desired functionalities. These activities served as a prestudy assessment to inform key design decisions and ensure that the platform was aligned with user requirements prior to implementation. Development followed an iterative feedback loop and included a 2-week pilot phase with children prior to study initiation to further refine the platform, identify technical issues, evaluate the local technical infrastructure, and obtain initial insights before the feasibility study commenced [50].

Outcomes Measures

Participants were invited to use the platform and its apps for 6 months. Table 2 summarizes the study end points, outcome measures, and time points adapted from the published study protocol [45]. In addition to optional symptom reporting, patients and parents completed ePRO-based secondary end point measures via the apps. The questionnaires were selected based on validity, dissemination, digital availability, and author agreement (refer to Table 2 for end points and the assessment schedule and S5 in Multimedia Appendix 1 for questionnaire dimensions, rating scales, and scoring information).

XSL•FO
RenderX

Table . The study end points and outcome measures in MyPal4Kids.

Outcome measures and ePROs[a]	Time point of measure
Primary end points	
Acceptability of and engagement with the MyPal Platform	
Recruitment rate, participation rate, attrition rate, and adherence to the different components of the MyPal platform	M1-M6[b] continuously
System Usability (validated System Usability Scale [SUS] [55]) and a self-adapted version for children (S1 in Multimedia Appendix 1, child-adapted SUS version)	Once after M6
Focus groups with children and their parents	Once after M6
Secondary end points	
Demonstrating the feasibility of measuring	
Children's symptom burden (digital adaptation of the validated Mini-SSPedi[c] [56] and SSPedi [57]): higher ratings indicate higher burden	M1-M6 optional anytime
Children's QoL[d] (validated PedsQL[e] 3.0 Cancer Module [58,59]): higher scores indicate fewer problems and better QoL	Monthly (Baseline, M1-M6)
Parents' satisfaction with cancer care (validated EORTC PATSAT-C33[f] [60,61], adapted to assess parent's satisfaction with children's cancer care): higher scores indicate greater satisfaction with care	Monthly (Baseline, M1-M6)
Impact of pediatric illness on the family (validated IOFS[g] [62,63]): higher scores indicate greater negative impact on family	Monthly (Baseline, M1-M6)
Parents' QoL (EuroQol EQ-5D-3L [64]): higher visual analog scale scores indicate better perceived health	Monthly (Baseline, M1-M6)
Focus groups with children and their parents	Once after M6
Impact on HCPs[h] due to the integration of ePROs in care	
Web-based follow-up questionnaire (S2 in Multimedia Appendix 1, questionnaire for HCPs)	Once after M6
Focus groups with project-internal and external HCPs involved in the study	Once after M6

[a]ePRO: electronic patient-reported outcome.

[b]M[X]: Month X of study participation.

[c]SSPedi: Symptom Screening in Pediatrics.

[d]QoL: quality of life.

[e]PedsQL: Pediatric Quality of Life Inventory.

[f]EORTC PATSAT-C33: European Organisation for Research and Treatment of Cancer Satisfaction with Cancer Care Core Questionnaire.

[g]IOFS: Impact on Family Scale.

[h]HCP: health care professional.

Per protocol, the recruitment rate was defined as the proportion of recruited patients among eligible patients. The participation rate referred to recruited participants completing at least 70% of the 28 monthly questionnaires (before imputation). The attrition rate included patients who did not complete the 6-month study due to withdrawal or death. Reasons for missed assessments (multiple-choice and free-text responses) were documented when available.

Adherence was assessed by user group. For patients, adherence included the number of optional monthly symptom reports, diary entries, and in-game personalization activities. For parents, adherence included the number of monthly optional proxy symptom reports. For HCPs, adherence included the number of monthly treatment plans, reaction protocols, and proxy symptom reports. Engagement was defined as the frequency and consistency of platform use over time. Adherence referred to the completion of scheduled questionnaires, while participation described overall involvement in study activities.

Scoring and missing data handling followed the respective questionnaire guidelines (refer to Table 2). Additional details, including the full questionnaires, interview guides, coding schemes, paraphrased statements, and extended statistical outputs, are provided in Multimedia Appendix 1.

Follow-Up Focus Groups

Focus groups were conducted at all three sites with (1) children and adolescents with cancer, their parents and (2) HCPs to obtain

XSL•FO
RenderX

qualitative feedback on the platform (eg, experiences, challenges, barriers, and facilitators).

Semistructured interview guides, based on the mHealth App Usability Questionnaire [65], included prioritized, neutral, open-ended, unambiguous questions (refer to S3 in Multimedia Appendix 1 for patient and parent focus groups and S4 in Multimedia Appendix 1 for focus groups with HCPs). Patients and parents were approached post study. HCPs were divided into two subgroups: (1) project-internal HCPs who provided feedback during the platform's development and (2) project-external HCPs who were involved only in the study.

Written informed consent was obtained before interviews (conducted in person or online and in the local language). Sessions lasted 45 - 60 minutes and were moderated by trained local researchers. Audio recordings were transcribed verbatim, pseudonymized, and translated into English for analysis.

Data and Statistical Analysis

Statistical analyses were conducted in R (version 4.3.2, R Core Team, R Foundation for Statistical Computing) [66]. Descriptive statistics summarized recruitment and baseline characteristics (frequency, mean [SD], or median [IQR], as appropriate). Tests were chosen based on variable distribution. Two-sided *P* values <.05 were considered significant.

Missing data were imputed according to questionnaire guidelines. For symptom reports, the highest monthly symptom burden per patient was considered. Missing responses (≤2 per measure) were replaced by the nearest previous value. The target sample size was 100 participants [45]. To accommodate missing data and the small sample size, repeated measures (baseline and M1-M6) were grouped into 4 time points (baseline, M1-M2, M3-M4, and M5-M6), ensuring no significant differences between merged time points via the two 1-sided tests, with odds ratios calculated as effect sizes.

The aligned rank transformation (ARTool; developed by Kay et al. [67]) enabled a nonparametric 2-factor repeated measures ANOVA for the factors of time, group, and their interaction effects [68]. Participants were grouped by (1) birth sex (female or male), (2) age (6-9, 10-13, and 14-17 years), (3) diagnosis (leukemia or solid tumor), and (4) Karnofsky Performance Status (KPS) [69,70] scale (below or above the cohort median). Partial eta squared (η_p^2) was classified as small ($\eta_p^2 \geq 0.01$), medium ($\eta_p^2 \geq 0.06$), and large effect size ($\eta_p^2 \geq 0.16$). Post hoc comparisons used Wilcoxon signed-rank tests (time points) and Mann-Whitney *U* tests (group comparisons), both with Holm-Bonferroni correction. For significant interactions, rank-transformed time-point differences between groups were compared using Mann-Whitney *U* tests with Holm-Bonferroni correction.

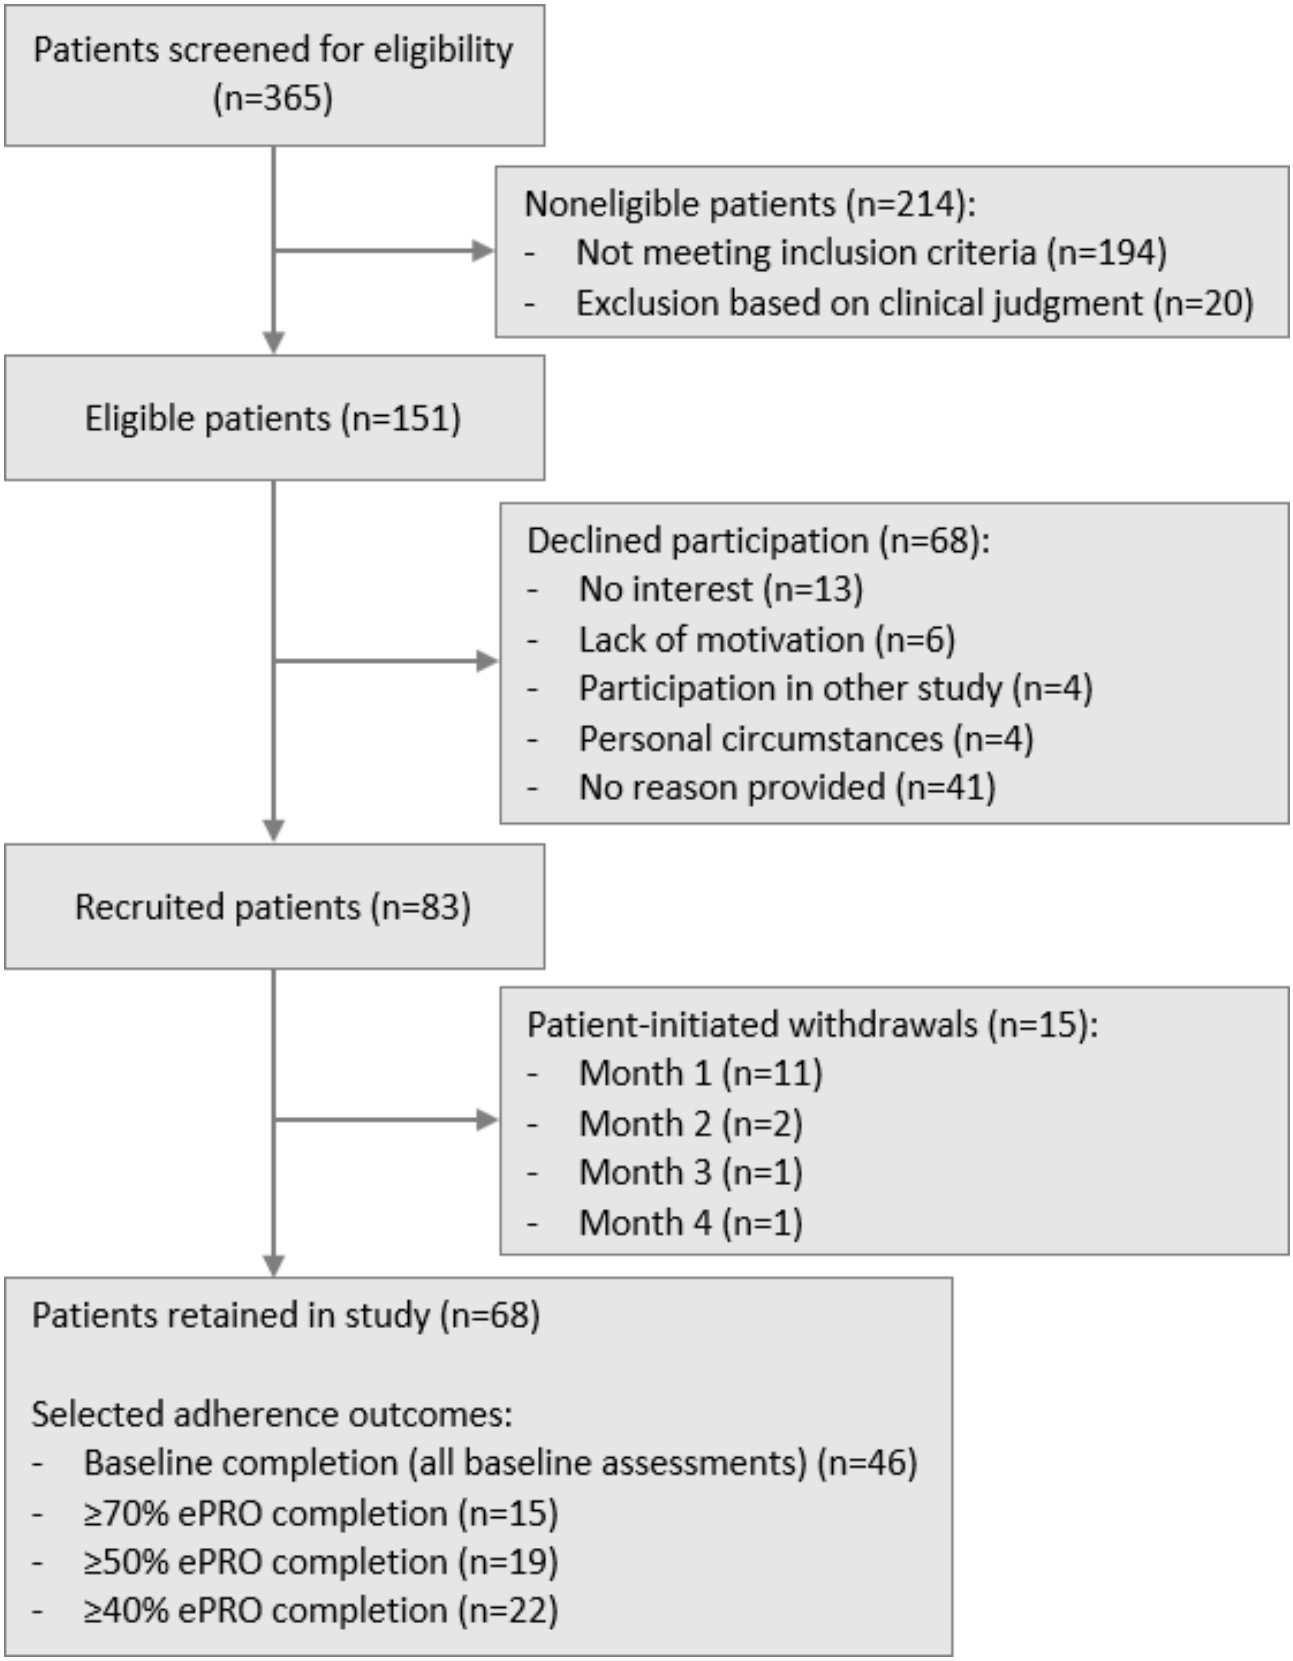
Spearman rank correlation (ρ) assessed monotonic associations between patient self-reports and parent proxy reports of symptom burden per month (no imputation). Effect sizes were classified as weak ($|\rho| \geq 0.1$), moderate ($|\rho| \geq 0.3$), and strong ($|\rho| \geq 0.5$).

Qualitative focus group data were analyzed in MAXQDA 2022 (VERBI Software) using deductive and inductive approaches [71]. Two researchers independently reviewed transcripts and developed a consensus coding system for thematic analysis. Statements were cross-coded when applicable (eg, positive, neutral, and negative) and paraphrased after joint review.

Missing data handling, subgroup analyses, and model specifications were performed as described in this section. No formal adjustment for site-level differences was performed because of the limited sample size at each site.

Ethical Considerations

The MyPal4Kids study protocol has obtained ethical approval from the ethics committee competent for the Saarland University (Ärztekammer des Saarlandes; reference: Ha 23/20; March 16, 2020), the ethics committee of the Hannover Medical School (reference: 9095_BO_K_2020; February 12, 2020), and the ethics committee of the University of Brno (reference: 01 - 1 20 220/EK; May 11, 2020). This study was performed in line with the principles of the Declaration of Helsinki. Ethical and General Data Protection Regulation (GDPR) compliance considerations ensured data safety for this vulnerable participant group [48], as reflected in the protocol through age-appropriate information sheets and informed consent forms [45]. Informed consent was obtained from all participants and from parents or legal guardians of children or adolescents.



Results

Recruitment

Recruitment took place over 15 months (December 2020-March 2022), including a 6-month COVID-19 extension. A total of 83 participants were enrolled (refer to Figure 1).

XSL•FO
RenderX

Figure 1. Flow diagram on screening, eligibility, and recruitment in MyPal4Kids. ePRO: electronic patient-reported outcome.

Enrollment Characteristics

Table 3 summarizes the characteristics of the enrolled patients. Birth sex distribution and treatment status were nearly balanced. Almost half of the patients were aged 14 - 17 years. Solid tumors accounted for nearly half of the cases, with brain tumors listed separately due to their potential neurological effects [72]. Most patients were newly diagnosed (70/83, 84%) and 16% (13/83) of patients had relapsed.

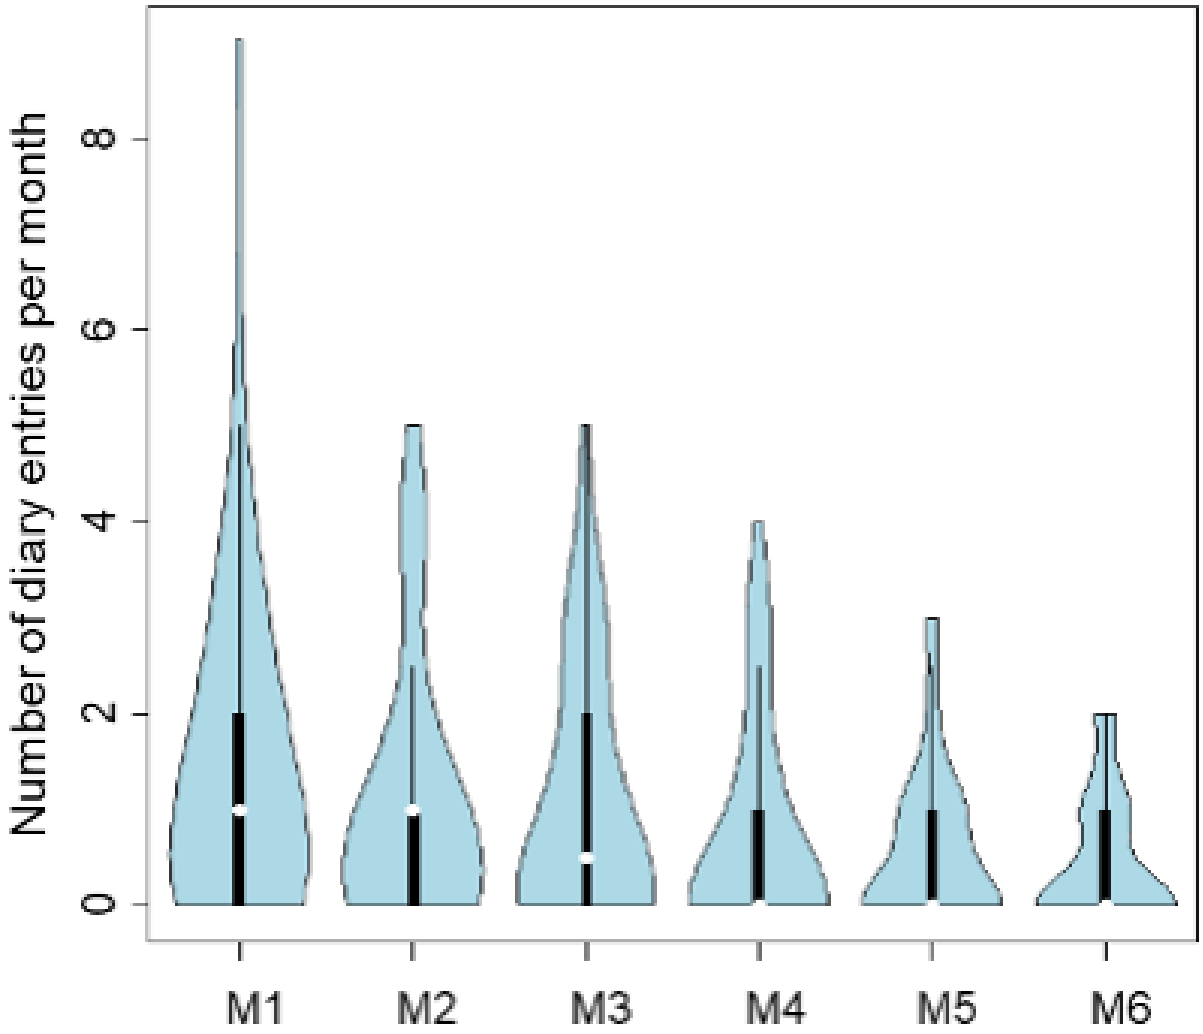
[c]Range (min-max): 50-100.

[d]Nonmandatory information.

Acceptability and Engagement With the MyPal Platform

Attrition, Participation, and Adherence Patterns



The attrition rate was 18% (15/83), with 73% of withdrawals at participants' request (11/15) occurring in the first month (M1). Withdrawn participants included 8 male and 7 female participants; 8 had solid tumors, 6 had leukemia, and 1 had a brain tumor. The age distribution among those who discontinued participation was 10 aged 14 - 17 years, 4 aged 10 - 13 years, and 1 aged 6 - 9 years. Most were newly diagnosed (n=14) and receiving treatment (n=9). Reasons for withdrawal (documented in 7 cases; multiple choice) included disease progression (n=4) and/or patient reluctance (n=6). No deaths occurred during participation.

Per protocol, 15 of 83 (18%) participants completed ≥70% of all monthly questionnaires, 19 (23%) completed ≥50%, and 22 (27%) completed ≥40%. Overall, 46 (55%) participants completed all baseline assessments (refer to Figure 1). Because these adherence thresholds were cumulative, the categories were not mutually exclusive. HCPs documented reasons for missed assessments in 32 cases (39%): patient reluctance (n=17) and disease progression (n=15).

Of 83 participants, 62 (75%) patients assessed each symptom at least once. Assessment frequency declined over time. Overall, 42 (51%) patients created at least one diary entry, with the frequency declining over time (refer to Figure 2). In total, 64 (77%) patients customized their game avatar.

XSL•FO
RenderX

Figure 2. Violin plot depicting monthly frequencies of diary entries created by patients with at least one diary entry (n=42, 51%). In all violin plots, the width of the violin reflects the frequency of the respective measure, with white dots representing the median values, thick black bars indicating the IQR, and thin black bars indicating 1.5 x the IQR for each measure. Each violin represents the distribution across the entire study cohort for the respective month.

Regarding proxy reports on symptom burden, at least 53 (64%) parents assessed each symptom at least once. HCPs created overall 98 treatment plans for 29 (35%) patients, ranging from 1 to 8 plans per patient. HCPs documented symptoms through the HCP interface 15 times for 13 (16%) patients. HCPs added reactions to reported symptoms 24 times for 15 (18%) patients.

Usability of the MyPal Platform

Sixty of 83 patients and parents (72%) completed the respective version of the System Usability Scale (SUS). Among responding patients, 30% (18/60) were younger than 10 years, whereas 70% (42/60) were 10 years or older. Younger children largely found the game enjoyable and easy, whereas older patients reported more variable ratings (refer to Table 4). A significant association with a small effect size was found between age group and game enjoyment (Q1; χ^2_1=4.4; *P*=.04; ϕ=−0.27).

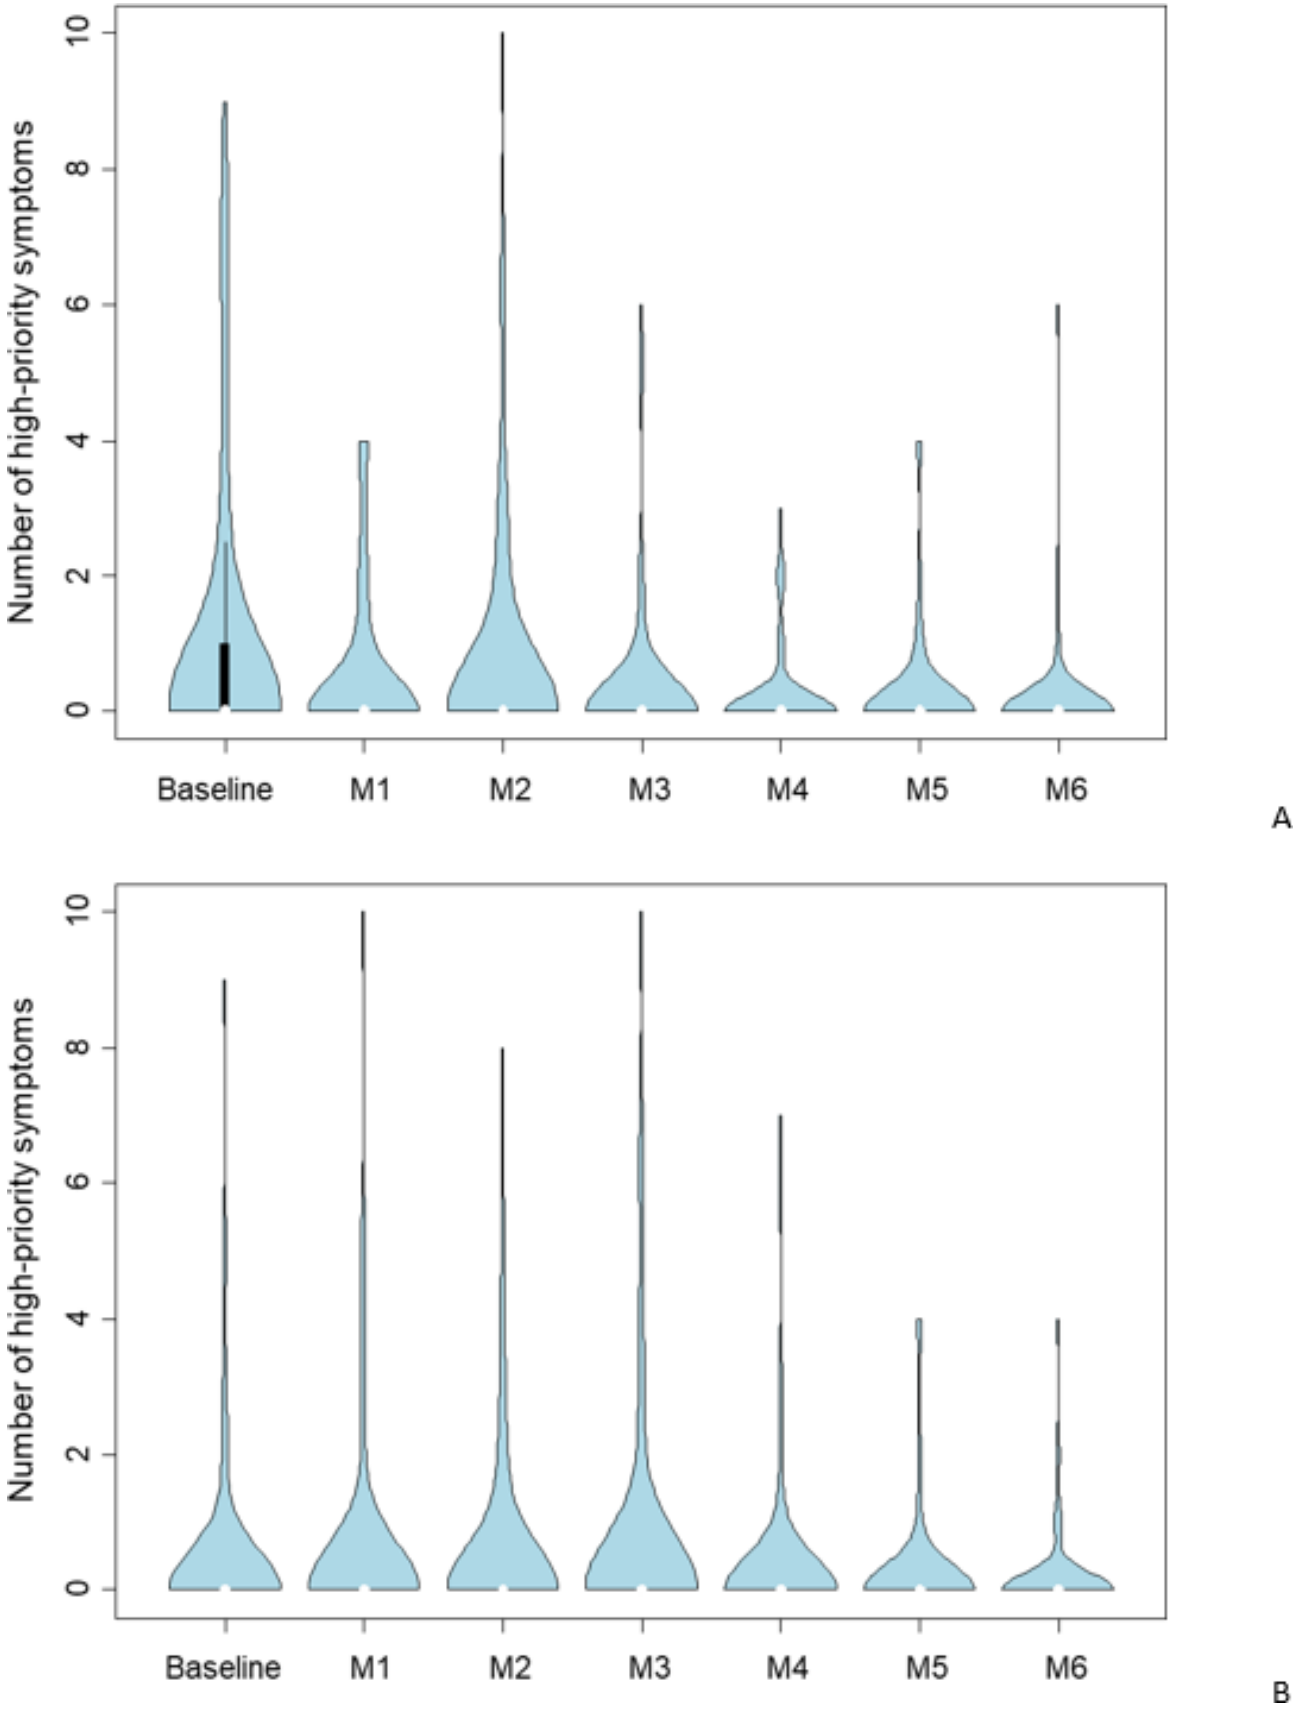
XSL•FO
RenderX

Table . Answers to the adapted SUS[a] evaluating the usability of the MyPal-Child app were received from 60 of 83 patients.

Questionnaire items	Yes, n (%)	No, n (%)	Indecisive, n (%)
Adapted SUS[a] for children <10 years (n=18)			
Q1: Did you like the game?	15 (83)	3 (17)	0 (0)
Q2: Was the game easy to play?	15 (83)	2 (11)	1 (6)
Q3: Did you like to answer questions in the game?	10 (56)	8 (44)	0 (0)
Adapted SUS for children≥10 years (n=42)			
Q1: Did you like the game?	23 (55)	19 (45)	0 (0)
Q2: Was the game easy to play?	39 (93)	2 (5)	1 (2)
Q3: Did you like to answer questions in the game?	21 (50)	21 (50)	0 (0)
Q4: Were the questions asked to you relevant at the time?	25 (60)	15 (36)	2 (5)
Q5: Was the frequency of the reminders to answer questions appropriate?	24 (57)	18 (43)	0 (0)

[a]SUS: System Usability Scale.

Free-text comments from 34 (57%) patients mentioned avatar customization, points collection, and graphics as enjoyable features. Some found the game too simple and repetitive and suggested increased difficulty, customization options, and additional achievements. Parents rated the MyPal-Carer app highly for usability (mean SUS 76.8, SD 15.9; median 82.5, IQR 63.1 - 90), indicating good to excellent usability [55].



Feasibility of ePRO-Based Measures

Patient and Proxy-Reported Symptom Burden

Overall, 42 of 83 (51%) participants reported at least one symptom with the highest burden (rating 4=extremely bothered) during the 6-month period (Figure 3A). The most frequent symptoms were tiredness (29 reports), pain (other than headache; 26 reports), mouth sores (23 reports), and changes of appetite (23 reports). Less than 50% of patients reported at least one symptom with the highest burden per month.

XSL•FO
RenderX

Figure 3. Frequency distribution of monthly symptom reports with high priority (ie, the highest burden) via Symptom Screening in Pediatrics or Mini Symptom Screening in Pediatrics during study participation. Each violin represents the distribution across the entire study cohort for the respective month. (**A**) Self-reports by children and (**B**) proxy reports by parents for their children.

Overall, 34 of 83 (41%) parents submitted proxy reports (refer to Figure 3B), citing feeling disappointed or sad (24 reports), perceived changes in appearance (23 reports), and changes in appetite (23 reports) with the highest burden. Thus, some overlap existed between child and parent reports.

XSL•FO
RenderX

Spearman rank correlation across 15 symptoms over 7 time points revealed significant correlations for 8 symptoms at up to 3 time points each (refer to Table 5), ranging from ρ=0.39 to ρ=1.0 (moderate to strong), but inconsistently across time.

Subgroup and Longitudinal Differences in Symptom Burden and QoL

Table 6 summarizes results from the aligned rank transformation analysis, excluding symptoms without significant findings. KPS-based subgroups were categorized as above or below the median score of 90 (IQR 80 - 90). For example, a significant main effect of time was found for changes in taste (Figure 4A), with symptom burden decreasing from M1-M2 to M5-M6 regardless of group according to post hoc comparisons (birth sex: P=.003, η_p^2=0.151; age: P=.01, η_p^2=0.124; diagnosis: P=.007, η_p^2=0.118; KPS: P=.02, η_p^2=0.128). Regarding problems with thinking, a significant main effect of group was found, with symptom burden being higher among females than among males, regardless of time (Figure 4B).

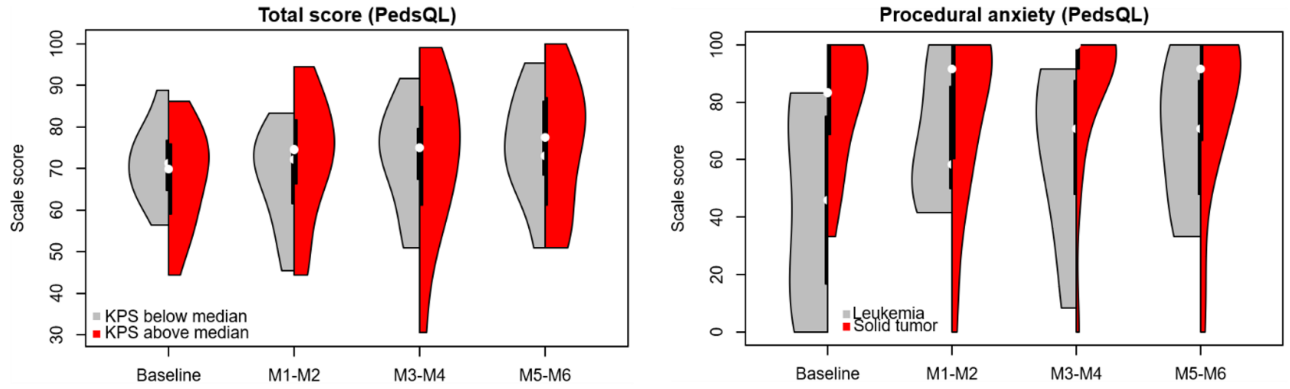

Figure 4. Violin plots depicting the distribution of maximum burden (ranging from 0=not at all bothered to 4=extremely bothered) for 2 Symptom Screening in Pediatrics or Mini Symptom Screening in Pediatrics symptoms across 4 timepoints from baseline until the final 2 months of study participation (M5-M6).

A B

Similarly, time, group, and interaction effects emerged for the other ePRO measures. For example, there was a significant main effect of time for the children's QoL total score regardless of group. Post hoc tests revealed a significant increase from baseline to M5-M6 (P=.02; η_p^2=0.126; Figure 5A). A significant main effect of group (Figure 5B) was found for procedural anxiety, regardless of time: problems with procedural anxiety were more prevalent in patients with leukemia and in the youngest age group compared with patients with solid tumors and the oldest age group (P=.009; η_p^2=0.285). Full statistical results for these ePRO measures (Pediatric Quality of Life Inventory [PedsQL], European Organisation for Research and Treatment of Cancer Satisfaction with Cancer Care Core Questionnaire [PATSAT-C33], and Impact on Family Scale [IOFS]), including subgroup analyses, are provided in S6 in Multimedia Appendix 1.

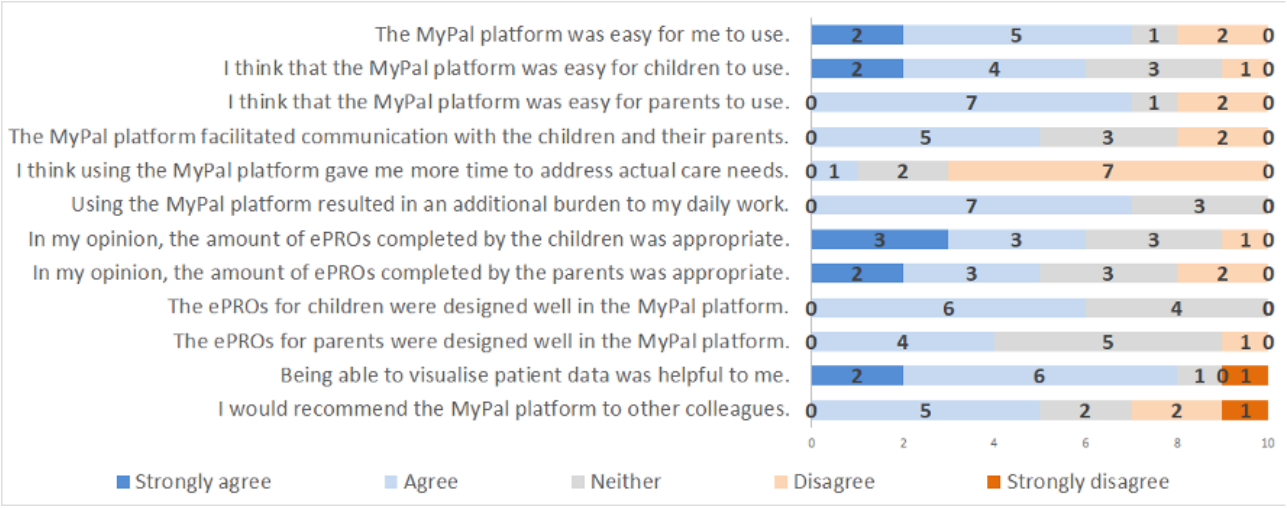
Focus Groups With Children and Their Parents

Ten parent-child pairs participated: 3 at USAAR, 4 at MHH, and 3 at FNBRNO, across all age groups: 2 aged 6 - 9 years, 2 aged 10 - 13 years, and 6 aged 14 - 17 years. The coding system linking 18 categories to statements and their frequencies is shown in S7 in Multimedia Appendix 1. Most comments concerned the categories "Recommendations," followed by "Game Design" and "ePROs." Key findings are provided in Table 7, while the full coding scheme, category frequencies, and paraphrased statements are provided in S7 in Multimedia Appendix 1.

Table . Key findings from the focus groups with children and their parents.

Code category	Summary
Game Design	Children frequently mentioned enjoying the customization features and underwater theme. Comments on gameplay included perceptions of repetitiveness and limited challenge.
ePROs[a]	Parents appreciated symptom reporting but noted some children underreported, often due to fatigue. Both parents and children found the questions understandable, but some described the questions as repetitive or less relevant during symptom-free periods.
Consequences of App Usage	The app felt most beneficial at the treatment's onset. However, engagement decreased over time. It was useful for self-reflection and documenting symptoms, particularly when direct communication with HCPs[b] was limited.
Communication	The app was not commonly perceived as improving communication but was reported as enabling some children to express feelings outside face-to-face interactions. However, infrequent feedback from HCPs in response to symptom reports led to frustration.
Recommendations	Participants suggested expanding gameplay variety, customization options, tailoring the App for different age groups, and adding multiplayer modes and peer support as social interaction features, as well as improving HCP feedback to enhance engagement.

[a]ePRO: electronic patient-reported outcome.



[b]HCP: health care professional.

Impact on HCPs Due to the Integration of ePROs in Care

Follow-Up Questionnaire for HCPs

Ten HCPs (5 project-internal and 5 project-external) completed the follow-up questionnaire (refer to Figure 6). No significant group differences were found. Half added free-text comments, praising online communication when in-person appointments were not possible. They valued ePROs and the idea of the platform but stressed the importance of personal contact. Concerns included missing data from disengaged participants. Recommendations included better integration with existing clinical systems, enhanced data visualization, and improved game design.

Figure 6. Distribution of the absolute frequencies of the health care professionals' responses to the items of the web-based follow-up questionnaire (n=10). ePRO: electronic patient-reported outcome.

XSL•FO
RenderX

Focus Groups With HCPs

Nine HCPs joined focus groups: 4 physicians (2 from MHH, 1 from FNBRNO, and 1 from USAAR), 1 nurse (MHH), and 1 psychologist (MHH) as project-internal, along with 1 physician (MHH), 1 psychologist (MHH), and 1 physician (FNBRNO) as project-external. The coding mirrored parent-child pair focus groups, but "Game Design" and "ePROs" were addressed less, while "Influences on Motivation," "HCP-Patient Communication," and "Compliance" had higher coverage. Compared to internal HCPs, external HCPs provided fewer statements coded as negative during focus group discussions and discussed user experiences and suggestions more than internal HCPs. Tables 8 and 9 summarize the internal and external HCP focus groups, respectively. The full coding schemes, category frequencies, and paraphrased statements are provided in S7 in Multimedia Appendix 1.

Table . Key findings from the focus groups with project-internal HCPs[a].

Code category	Summary
Game Design	HCPs[a] observed that older children were less engaged, mentioning limited variety and a perceived lack of competitiveness in the game.
Expectations	Initial expectations ranged from mixed curiosity to skepticism regarding the platform's ability to sustain engagement and seamlessly integrate into clinical workflows.
Consequences of App Usage	HCPs noted that some patients seemed to avoid the app as it reminded them of their illness, leading to disengagement, especially at home.
Communication	The app served as an additional communication channel, particularly for teenagers who preferred expressing themselves digitally. However, its impact on team communication seemed to highly depend on the strength of existing communication between HCPs, patients, and families. In cases of weaker communication, digital tools were seen as helpful for capturing and preserving important information.
Influences on Motivation	Initial curiosity waned due to limited feedback. HCPs reported more consistent use among girls and follow-up patients compared to boys or those in acute care.
Recommendations	HCPs recommended incorporating automated data collection (eg, wearables) and enhancing the HCP interface for better notification management. However, they also highlighted the need to address data protection and institutional barriers in general before effective implementation is possible.

[a]HCPs: health care professionals.

XSL•FO
RenderX

Table . Key findings from the focus groups with project-external HCPs[a].

Code category	Summary
Game Design	External HCPs[a] found the game's long-term engagement insufficient, citing competition with highly stimulating commercial games as a major hurdle.
Expectations	Initially, HCPs were optimistic about the app providing a constructive, meaningful alternative to passive media consumption for children.
Consequences of App Usage	HCPs described limited changes in daily workflows, although some noted occasional use for symptom tracking. Families sometimes used it to recall symptoms during appointments, but it did not seem to substantially alter HCP working routines.
Communication	The app aided communication for children more comfortable with digital tools, though HCPs emphasized that digital reporting should complement, not replace, in-person interactions.
Influences on Motivation	HCPs observed reduced engagement over time, particularly as patients' health improved. Parents of younger children were more engaged in symptom tracking, while older children primarily used the diary function for information sharing. Participants described engagement as influenced by usage habits, perceived utility, and occasional technical challenges (eg, login issues).
Impression of eHealth[b] Solutions	HCPs were generally optimistic about the growing role of eHealth but stressed that digital tools must complement traditional care. Challenges included administrative barriers and insufficient digital infrastructure.
Recommendations	External HCPs suggested additional personalized game features to increase long-term engagement and enhance the app interface for HCPs, including a priority system to highlight urgent issues.

[a]HCPs: health care professionals.

[b]eHealth: electronic health solution.

Discussion

Principal Findings

MyPal4Kids assessed the feasibility and acceptability of an ePRO-based platform in pediatric oncology and palliative care. Patient engagement was strongly influenced by perceived system utility, linked to HCP feedback frequency and the game's ability to sustain motivation. The core hypothesis that gamification would make self-reporting more engaging for young patients was partially supported: initial interest was high, but long-term engagement declined. These findings align with research emphasizing bidirectional communication in digital health [73-75], while also highlighting implementation challenges.

A key challenge was a disengagement cycle: fewer patient reports led to fewer platform reviews by HCPs, reducing feedback and further discouraging engagement. Similar patterns have been observed in other studies [76], likely amplified by the emotional burden on young patients with cancer and their families, along with competing HCP priorities. Usability did not limit patient engagement in our study but was more relevant for HCP adoption. These findings suggest that all groups may require additional support, such as proactive feedback loops and tighter integration into clinical workflows and systems, to maintain engagement. Engagement decreased over time, which represents an important finding of this study. This pattern was analyzed using descriptive longitudinal summaries rather than formal subgroup modeling. Engagement reflects a behavioral usage process characterized by heterogeneous exposure durations, irregular participation intervals, and varying initiation and discontinuation points across participants. This differs from structured repeated-measures clinical outcome assessments collected at predefined time points, which are more suitable for subgroup comparisons within the feasibility framework. To complement the quantitative description, we also further provide stratified descriptive observations (eg, age-related differences in usability and engagement patterns) alongside qualitative findings that help contextualize these trends, including differences in motivation, disease status, and HCP feedback.

Potential explanations for the observed decline include limited novelty effects, insufficient personalization of gamification elements, and varying needs across age groups. Additionally, the degree of feedback from HCPs may have influenced sustained use. These findings highlight the need for adaptive and user-centered design strategies to maintain long-term engagement. In addition to the COVID-19 pandemic, institutional factors such as varying levels of digital infrastructure, staffing resources, and staff engagement may have influenced implementation processes and platform use across study sites.

Similar engagement trajectories have been reported in pediatric digital health and ePRO-based interventions, where engagement is typically high at initiation but declines over time despite generally acceptable usability. Prior pediatric ePRO studies have similarly described decreases in reporting frequency in longitudinal implementations [77-79], as well as in broader mHealth and game-based interventions [80,81]. These findings

XSL•FO
RenderX

are consistent with evidence that gamification strategies often produce short-term engagement effects but are insufficient to sustain long-term use [30]. In addition, the effectiveness of social or competitive design elements may depend on a sufficiently large and continuously active user base, which is often lacking in pediatric feasibility settings [82]. Together, these observations suggest that sustained engagement requires more than initial usability and gamification and depends on continued perceived relevance, feedback mechanisms, and integration into clinical workflows.

Platform Utility for Clinical Care and Research

Importantly, this study was designed as a feasibility study and was not intended to evaluate the effectiveness of the intervention. Therefore, any observed changes in ePROs should be interpreted descriptively and not as evidence of causal effects. The platform proved feasible for tracking individual symptom burden over time, contingent on patient engagement in reporting symptoms. Clinicians could benefit from reviewing individual symptom trajectories. Statistical analyses showed significant main and interaction effects of time and group. Larger datasets could enable more nuanced comparisons, enhancing the platform's potential for research applications, such as comparing treatments in terms of effectiveness or side effects. This dual capability, supporting individualized patient care while generating population-level insights, underscores the platform's potential for both clinical practice and research. While symptom burden was the primary focus, secondary measures like children's QoL also showed improvement from baseline until the end of the study. Interpretation of these findings should remain cautious, as broader pandemic-related disruptions may have influenced reporting behaviors, engagement patterns, and ePROs during the study period [83-85].

Contextual Factors Influencing Implementation

Underlying factors may include age, digital literacy, emotional strain, and institutional support for digital health tools. Assessed symptoms largely reflected expected chemotherapy side effects, about which patients and parents had prior information. Consequently, HCPs sometimes gave limited direct feedback. Still, reports of symptoms such as tingling or numbness in the extremities are clinically relevant, potentially guiding treatment adjustments of medication doses. Our findings reinforce concerns that insufficiently integrated digital health tools can increase rather than reduce workload for HCPs, particularly when clear integration pathways into routine clinical workflows and responsibilities are lacking [75,86,87]. In the present study, the platform was deliberately not embedded into mandatory clinical workflows, which may have contributed to this effect. Existing commercial clinical systems offer limited interoperability with digital health platforms, including electronic health record integration, application programming interfaces and authentication infrastructures (eg, different user accounts and password systems). This complicates seamless integration into routine clinical workflows and requires the use of parallel systems. Dedicated staff to review digital health data could alleviate this burden, an approach supported in the literature [12]. Timely symptom data are crucial for responsive care, particularly between infrequent visits [88]. The observed decline in symptom reporting mirrors similar studies, possibly due to symptom relief or engagement fatigue. While gamification sparked initial interest, it alone was insufficient to sustain engagement, especially in older children. The game's design was constrained by requirements for nonviolence, gender neutrality, and broad age group appeal. While these specifications ensured accessibility, they may have resulted in an overly cautious design. Concerns about overuse did not materialize. Established gamification elements such as rewards and competitive features were less effective without a critical mass of simultaneous active users. Perspective differences between internal and external HCPs should be considered. Internal HCPs, involved in platform development, focused on long-term potential, while external HCPs emphasized practical challenges like workflow integration. Both groups agreed that technology should complement, not replace, direct care [89].

Strengths and Limitations

Interdisciplinary collaboration and testing across multiple clinical sites strengthened the study. Patient, parent, and HCP involvement in the design and evaluation enhanced the relevance of the findings. Ethical considerations were central to platform development and study implementation. Integration of ePROs into a gamified mobile app for young patients with cancer was innovative, aligning with evidence that children prefer visually engaging digital measures with short recall periods [90]. A strength of the presented platform is its flexibility for various ePROs and gamification strategies, enabling implementation across varied contexts.

The study period overlapped with the COVID-19 pandemic, which likely affected recruitment, clinical workflows, and sustained platform engagement. Reduced face-to-face interactions, restrictions during clinical visits, and increased reliance on digital communication may have influenced onboarding, participant retention, and reporting behavior. Prolonged exposure to digital communication and online platforms during the pandemic may also have contributed to digital fatigue and declining engagement over time. Similar pandemic-related disruptions affecting recruitment, ePRO-based research, and health-related QoL assessments have been described in pediatric and digital health research [83,85,91].

Further limitations include discrepancies between child and parent symptom reports, possibly due to recall issues or differing perceptions. While proxy reports can increase data completeness, they may introduce bias, highlighting the importance of careful interpretation and, where possible, cross-checking [92]. Some parents may have prioritized immediate care over proxy reports. Dual reporting was optional, limiting analyses to overlapping cases. Still, at certain time points, some symptoms demonstrated strong parent-child correlations, supporting limited proxy validity. MyPal was not designed as an emergency tool, as stated in the consent. Legal and ethical concerns, such as liability for missed reports, implicated that HCPs were not expected to monitor reports constantly. This limited the platform's immediate clinical utility but matched its intended use as a supplemental communication channel. The small sample size limits the robustness and generalizability of the findings. Given the limited sample size and reduced numbers in subgroup

XSL•FO
RenderX

analyses, these findings should be interpreted with caution. The results are exploratory and intended to inform future studies rather than provide definitive conclusions. The 6-month study period may not reflect long-term patterns. Given the drop in engagement, longer studies may require design refinements. The sample was limited in terms of diversity (eg, age and disease types). Selection bias is possible, as families with higher digital literacy or strong clinical engagement may have been more likely to participate. The overrepresentation of adolescents (aged 14 - 17 years) does not reflect the general pediatric cancer population [93]. Younger children younger than 4 years have the highest cancer incidence but were excluded due to literacy barriers. Treatment plan creation in the platform was optional for HCPs, limiting analysis of symptom-treatment correlations. Recruitment and HCP availability were likely affected by the pandemic, though the impacts are hard to quantify. Emotional burden during early illness phases also influenced recruitment. Subjective feedback from participants within the clinical setting may have shaped both recruitment and engagement. Measures such as flexible baseline and monthly assessment windows, as well as offline functionality, were implemented to support compliance, though their success was limited. Secondary end point measures (eg, patients' and parents' QoL, care satisfaction, and family impact) were not available to HCPs during the study. Access to these data could increase HCP engagement.

Taken together, these factors may limit the generalizability of the findings beyond European pediatric oncology settings, particularly in contexts with different health care infrastructures, cultural expectations, and levels of digital literacy.

Implications and Future Directions

Although more digital health solutions are emerging for specific illness phases, creating comprehensive platforms that address diverse individual needs remains challenging. Concerns persist about using research-oriented ePRO measures in clinical decision-making [8]. Pediatric-specific clinical ePRO guidelines are lacking [94], underscoring the need for evidence to support standardization and broader clinical adoption. Future versions should consider structured HCP training and targeted family support. Embedding ePROs into standard care rather than offering them as optional tools may help sustain use. Refinements should reflect user feedback and improve age-specific adaptability to enable scalability across clinical settings. Hybrid models, combining automated feedback with periodic HCP review, may boost engagement and long-term utility. Digital health solutions may not suit all patients; tailoring them to specific populations is key. Longitudinal randomized controlled trials are needed to assess effectiveness. Future research should explore the use of the platform in different patient populations, such as long-term survivors, who may demonstrate different supportive care needs and engagement patterns. In addition, studies conducted in postpandemic settings may help clarify the extent to which engagement patterns, recruitment dynamics, and sustained platform use were influenced by pandemic-related contextual factors. Evaluating the platform in larger cohorts and in more controlled study settings will be important next steps.

In conclusion, integrating digital health tools into pediatric oncology and palliative care requires both technological innovation and thoughtful workflow integration. Sustaining participation and utility demands consistent HCP engagement and compelling gamification. Large-scale implementation will require dedicated resources, including staff time for data monitoring, integration into existing hospital IT infrastructures and application programming interfaces, authentication systems, and sustainable allocation of clinical responsibility for digital symptom review. Our findings highlight key areas for refinement to improve ePRO-based approaches before clinical use is feasible.

Acknowledgments

MyPal was coordinated by Kostas Stamatopoulos of the Centre for Research and Technology Hellas, Greece. Other partners were Fraunhofer Institute for Biomedical Engineering, Germany; Foundation for Research and Technology Hellas, Greece; International Observatory on End of Life Care, Lancaster University, United Kingdom; Central European Institute of Technology, Masaryk University, Czech Republic; Karolinska Institute, Sweden; Vita-Salute San Raffaele University, Italy; University Hospital of Heraklion, Greece; Hannover Medical School, Germany; University Hospital Brno, Czech Republic; Saarland University, Germany; Promotion Software GMBH, Germany; Atlantis Healthcare, United Kingdom; European Association for Palliative Care; International Children's Palliative Care Network; National School of Public Health, Greece. The authors are grateful to the clinicians at the clinical study sites who were essential to this study through patient recruitment, symptom assessment and management, and data collection. This work is dedicated to Vassilis Koutkias.

Funding

MyPal: Fostering Palliative Care of Adults and Children with Cancer Through Advanced Patient-Reported Outcome Systems was funded by the European Union's Horizon 2020 Framework Programme under grant 825872. The funder had no role in the study design, data collection, data analysis, data interpretation, or writing of this paper.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available due to the sensitive nature of pediatric patient data and restrictions imposed by ethical approval and data protection regulations. However, anonymized data may be available

XSL•FO

Abstract

Background: Randomized controlled trials (RCTs) are the gold standard for evaluating interventions in oncology, but reporting can be subject to "spin"—presenting results in ways that mislead readers about true efficacy.

Objective: This study aimed to investigate whether large language models (LLMs) could provide a standardized approach to detect spin, particularly in the conclusions, where it most commonly occurs.

Methods: We randomly sampled 250 two-arm, single–primary end point oncology RCTs from 7 major medical journals published between 2005 and 2023. Two authors independently annotated trials as positive or negative based on whether they met their primary end point. Three commercial LLMs (GPT-3.5 Turbo, GPT-4o, and GPT-o1) were tasked with classifying trials as positive or negative when provided with (1) conclusions only; (2) methods and conclusions; (3) methods, results, and conclusions; or (4) title and full abstract. LLM performance was evaluated against human annotations. Afterward, trials incorrectly classified as positive when the model was provided only with the conclusions but correctly classified as negative when provided with the whole abstract were analyzed for patterns that may indicate the presence of spin. Model performance was assessed using accuracy, precision, recall, and F_1-score calculated from confusion matrices.

Results: Of the 250 trials, 146 (58.4%) were positive, and 104 (41.6%) were negative. The GPT-o1 model demonstrated the highest performance across all conditions, with F_1-scores of 0.932 (conclusions only; 95% CI 0.90-0.96), 0.96 (methods and conclusions; 95% CI 0.93-0.98), 0.98 (methods, results, and conclusions; 95% CI 0.96-0.99), and 0.97 (title and abstract; 95% CI 0.95-0.99). Analysis of trials incorrectly classified as positive when the model was provided only with the conclusions revealed shared patterns, including absence of primary end point results, emphasis on subgroup improvements, or unclear distinction between primary and secondary end points. These patterns were almost never found in trials correctly classified as negative.

Conclusions: LLMs can effectively detect potential spin in oncology RCT reporting by identifying discrepancies between how trials are presented in the conclusions vs the full abstracts. This approach could serve as a supplementary tool for improving transparency in scientific reporting, although further development is needed to address more complex trial designs beyond those examined in this feasibility study.

Introduction

Randomized controlled trials (RCTs) represent the gold standard for evaluating interventions in oncology [1]. However, the reporting and interpretation of trial results can be subject to inconsistency and "spin"—the presentation of results in a way that may mislead readers about the true efficacy of interventions [2]. This can, for example, be accomplished by emphasizing secondary end points or subgroup analyses when primary end points are not met. While most research that has looked at the topic has found a substantial prevalence of spin, the exact number varies as it is not always straightforward to differentiate between what constitutes a balanced and comprehensive presentation of the results and what may be an attempt to mislead the reader [3].

The presence of spin has important implications. Clinicians, policymakers, and even patients often rely heavily on abstracts and conclusions when interpreting trial findings, as full-text

XSL•FO
RenderX

analyses are time-consuming and not always accessible. Therefore, misrepresentation of results might contribute to overly optimistic perceptions of treatment benefits, potentially influencing clinical decision-making, guideline development, and even the allocation of research funding. Given the increasing complexity of cancer care and the rapidly expanding volume of clinical trials, ensuring clarity and accuracy in scientific reporting is crucial to avoid bias in evidence synthesis and translation into practice.

The growing capabilities of large language models (LLMs) could constitute a standardized way to determine the presence of spin. If an abstract is clearly written, a state-of-the-art LLM should be able to determine whether its primary end point was met. As multiple studies have identified the conclusions as the most frequent source of spin [4,5], we hypothesized that trials which are correctly classified as negative—defined as trials that did not meet their primary end point—by an LLM when provided with the title and abstract, but incorrectly classified as positive when provided with only the conclusions, would be likely to contain some form of spin. Therefore, the aim of this study was to evaluate whether LLMs can reliably classify oncology RCTs as positive or negative and whether discrepancies between conclusion-only and full-abstract classifications can help identify patterns consistent with spin.

Methods

Overview

Randomized controlled oncology trials from 7 major medical journals (*British Medical Journal*, *Journal of the American Medical Association*, *Journal of the American Medical Association Oncology*, *Journal of Clinical Oncology*, *The Lancet*, *The Lancet Oncology*, and *The New England Journal of Medicine*) published between 2005 and 2023 were randomly sampled by downloading the available abstracts for the time frame via PubMed in a text file and parsing the abstracts using regular expressions. These 7 journals were selected because they publish a large and consistent volume of oncology RCTs and are widely regarded as leading general or oncology-specific medical journals. The 2005 to 2023 range was chosen to capture contemporary trial reporting practices while ensuring sufficient volume across all selected journals. To avoid edge cases for this feasibility study, it was decided to limit the eligible trials to designs with exactly 2 arms and 1 primary end point.

We aimed to sample 250 trials as this number ensured a sufficiently large dataset for the feasibility analysis while remaining feasible for manual dual annotation. Trials were sampled by creating a randomized list of all retrieved abstracts. Two authors (CK and PW) then started the annotation from the top of the random list and stopped after 250 two-arm, single–primary end point oncology trials had been annotated. No journal-level quotas were applied.

The purpose of the annotation was to establish the ground-truth classification—whether the trial met its primary end point—against which model predictions could be evaluated. The annotation was conducted in a 2-step process. After annotating the first 20 trials, all samples were discussed to recognize potential differences in the annotation criteria. The remaining trials were annotated separately, and discrepancies were discussed after all trials had been annotated. A third author (DRZ) would have been responsible for judging disagreements that persisted after discussion. However, this was not necessary. The annotation was performed using the Prodigy tool (version 1.13.1; Explosion), which only showed the extracted abstract as text without any additional information such as authors or institutions. Only in cases in which the abstract did not clearly state the primary end point and its results did we refer to the full publication or protocol. Three commercially available LLMs, namely, GPT-3.5 Turbo, GPT-4o, and GPT-o1 (OpenAI), were then tasked with classifying the trials as positive or negative. The 3 models were chosen to investigate whether the inherent capabilities of the models would impact their suitability for the classification task (eg, simpler models requiring more explicit language to correctly identify trials) and, thus, their performance when trying to leverage differences in classification accuracy to detect unclear writing and spin. The decision to use OpenAI models was based on the prevalent use of these models at the time as well as the convenience of application programming interface access and lack of privacy concerns regarding the study data. The respective model snapshots were gpt-3.5-turbo-0125, gpt-4o-2024-11-20, and o1-2024-12-17. The LLMs were called via the application programming interface, with the temperature parameter set to 1. We refrained from performing multiple classification runs as a previous study from the same research group had shown very consistent performance by LLMs for both classification and named-entity recognition tasks, as long as the temperature was kept at or below 1.50 [6].

Each model was evaluated in 4 different rounds. In round 1, the models were only provided with the conclusions of the abstract. In round 2, the models were provided with the methods and conclusions of the abstract. In round 3, the models were provided with the methods, results, and conclusions of the abstract. In round 4, the models were provided with the title and the full abstract.

The following system prompt (ie, the fixed instruction provided to the model to define its task) was used: “You will be provided with the {section} of a randomized controlled oncology trial. Your task will be to classify if the trial was positive, i.e. if it met its primary endpoint, or negative, i.e. if it did not meet its primary endpoint. Your response should be either the word POSITIVE (in all caps) or NEGATIVE (in all caps).”

The “{section}” part was replaced with either “conclusion,” “methods and conclusion,” “methods, results, and conclusion,” or “title and abstract.” The user prompt (ie, the specific input text) was the corresponding title, abstract, or sections of the abstract.

The prompts were designed to be as explicit as possible regarding the definition of a positive trial to minimize ambiguity and ensure consistent model behavior across conditions. However, we did not conduct a systematic comparison of different prompts.

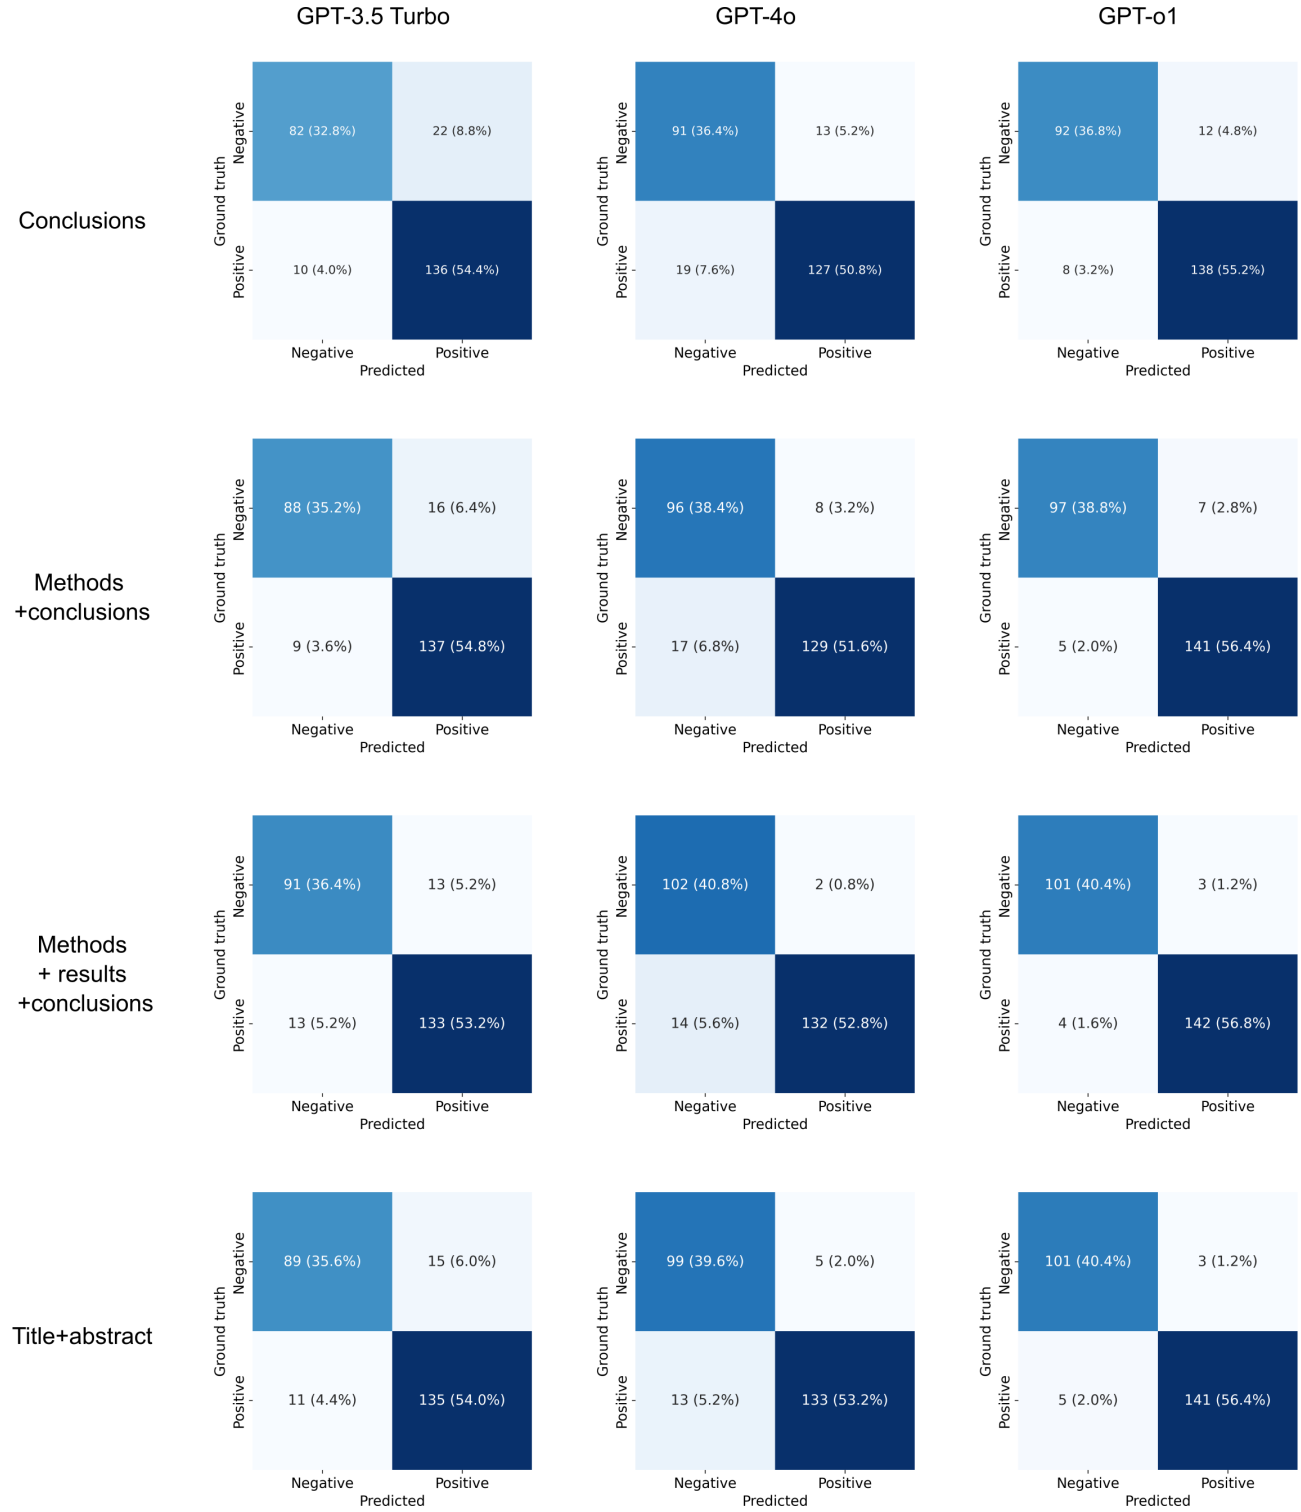
Statistical Analysis

Interannotator agreement was calculated as the percentage of agreement divided by the total number of annotated trials.

The results were evaluated against the ground truth (ie, the human-annotated classification of whether the trial met its primary end point) by creating confusion matrices and computing several performance metrics to obtain a holistic picture of model performance. These included accuracy (the proportion of correctly classified trials among all trials), precision (the proportion of predicted positive trials that were truly positive; equivalent to positive predictive value), recall (the proportion of truly positive trials that were correctly predicted as positive; equivalent to sensitivity), and F_1-score (the harmonic mean of precision and recall). For completeness, specificity (true negative rate), and negative predictive value can also be derived from the confusion matrix but were not separately reported. The 95% CIs were estimated using normal approximation intervals. For the best-performing model, we further analyzed and categorized the trials that were incorrectly predicted as positive when provided with the conclusions but were correctly predicted as negative when provided with the title and abstract. For these trials, a single author (PW) reviewed the full conclusions and abstracts to categorize the patterns leading to incorrect classification (eg, omission of primary end point, emphasis on subgroup findings, or unclear distinction between end points). To contextualize these findings, we additionally selected 10 randomly chosen trials correctly classified as negative by GPT-o1 and performed the same qualitative assessment. All programming was performed in Python (Python Software Foundation; version 3.13.2) using, among others, the *pandas* (version 2.2.3) and *openai* (version 1.67.0) packages.

Ethical Considerations

This study used publicly available abstracts from published clinical trials. All data were deidentified and contained no patient-level information; therefore, ethics approval was not required.



Results

Interannotator agreement was 97.2% (243/250). All of the disagreements were caused by simple mistakes and could be easily resolved during the discussion. Ultimately, 58.4% (146/250) of the trials were annotated as positive, and 41.6% (104/250) were annotated as negative.

The performances of the models when provided with different sections of the abstract are shown in Figure 1 and Table 1. GPT-o1 exhibited the best performance in each round, with F_1-scores of 0.932 (conclusions only), 0.96 (methods and conclusions), 0.98 (methods, results, and conclusions), and 0.97 (title and abstract). GPT-4o's F_1-scores across the 4 rounds were 0.89, 0.91, 0.94, and 0.94, respectively. GPT-3.5 Turbo exhibited F_1-scores of 0.89, 0.92, 0.91, and 0.91, respectively.

We further analyzed trials that were incorrectly predicted as positive by GPT-o1 when the model was only provided with the conclusions but predicted correctly when provided with the title and abstract. Of these 10 trials, 6 (60%) did not mention the primary end point in the conclusions [7-12]. One mentioned an improvement in the primary end point in a subgroup [13]. One mentioned both improved secondary end points and the unimproved primary end point without specifying which was which [14]. The remaining 2 trials mentioned that one arm was superior to the other one without specifying that it was the control arm that showed improved results [15,16]. The list of trials is provided in Table 2.

XSL•FO
RenderX

Table . Trials that were incorrectly predicted as positive by GPT-o1 when the model was only provided with the conclusions but predicted correctly when provided with the title and abstract.

Title	Conclusions reported on primary end point	Possible reason for incorrect prediction
"Total Body Irradiation or Chemotherapy Conditioning in Childhood ALL: A Multinational, Randomized, Noninferiority Phase III Study" [15]	Yes	Conclusions mentioned that TBI[a] plus etoposide showed improved overall survival. Therefore, the model likely thought that TBI plus etoposide was the intervention that was tested, whereas it was actually the control.
"Volasertib Versus Chemotherapy in Platinum-Resistant or -Refractory Ovarian Cancer: A Randomized Phase II Groupe des Investigateurs Nationaux pour l'Etude des Cancers de l'Ovaire Study" [7]	No	Primary end point was not discussed in the conclusions.
"High-Dose Therapy and Autologous Blood Stem-Cell Transplantation Compared With Conventional Treatment in Myeloma Patients Aged 55 to 65 Years: Long-Term Results of a Randomized Control Trial From the Group Myelome-Autogreffe" [14]	Yes	Conclusions mentioned both improved secondary end points and the unimproved primary end point without specifying which was which.
"Results of a Randomized Trial of Chlorambucil Versus Fludarabine for Patients With Untreated Waldenström Macroglobulinemia, Marginal Zone Lymphoma, or Lymphoplasmacytic Lymphoma" [8]	No	Primary end point was not mentioned in the conclusions.
"Bortezomib-Dexamethasone, Rituximab, and Cyclophosphamide as First-Line Treatment for Waldenström's Macroglobulinemia: A Prospectively Randomized Trial of the European Consortium for Waldenström's Macroglobulinemia" [9]	No	Primary end point was not mentioned in the conclusions.
"Adjuvant tamoxifen and exemestane in early breast cancer (TEAM): a randomised phase 3 trial" [12]	No	Primary end point was not mentioned in the conclusions.
"Addition of Bevacizumab to Bolus Fluorouracil and Leucovorin in First-Line Metastatic Colorectal Cancer: Results of a Randomized Phase II Trial" [10]	No	Primary end point was not mentioned in the conclusions.
"Oral ibandronic acid versus intravenous zoledronic acid in treatment of bone metastases from breast cancer: a randomised, open label, non-inferiority phase 3 trial" [16]	Yes	Conclusions mentioned the superiority of zoledronic acid. Therefore, the model likely thought that zoledronic acid was the intervention, whereas it was the comparator in this noninferiority study.
"Bcl-2 Antisense (oblimersen sodium) Plus Dacarbazine in Patients With Advanced Melanoma: The Oblimersen Melanoma Study Group" [13]	Yes	Improvement in the primary end point in a subgroup was mentioned.
"Efficacy and Safety of Trabectedin or Dacarbazine for Metastatic Liposarcoma or Leiomyosarcoma After Failure of Conventional Chemotherapy: Results of a Phase III Randomized Multicenter Clinical Trial" [11]	No	Primary end point was not mentioned in the conclusions.

[a]TBI: total body irradiation.

To confirm that those writing patterns were not equally frequent in trials correctly classified as negative, we also analyzed 10 random trials predicted correctly as negative by GPT-o1 and have provided the analysis in Multimedia Appendix 1. Of these trials, only 10% (1/10) did not mention the primary end point for the whole trial population in its conclusions but, instead, reported the results of the primary end point in a positive subgroup [17]. In total, 70% (7/10) of the trials explicitly mentioned that the primary end point failed to meet statistical significance or that the trial as a whole was negative or only mentioned the negative primary end point in their conclusions [18-24]. A total of 20% (2/10) of the trials mentioned both the primary end point and secondary end points or subgroups [25,26].

Discussion

Principal Findings

In this study, we evaluated the ability of 3 commercial LLMs to classify oncology RCTs as positive or negative based on different sections of trial abstracts. Our findings demonstrate that modern LLMs, particularly more advanced models, can achieve high classification accuracy even when provided with limited information. Our findings also support the hypothesis that trials that are correctly classified as negative by an LLM when provided with the title and abstract but incorrectly classified as positive when provided with only the conclusions are likely to contain patterns that may be interpreted as spin. While there is no ground truth of what constitutes spin, not mentioning the results for the primary end point at all in the conclusions, mentioning an improvement in the primary end point that only occurred in a subgroup, or mixed reporting of primary and secondary end points without clear distinction would be at least considered questionable by many readers [27]. Our findings also highlight that the LLM-based approach is not perfectly specific. In total, 20% (2/10) of the studies for which o1 was misled to believe they were positive when provided only with the conclusions had conclusions that clearly mentioned which arm had better outcomes. However, the LLM did not know which arm was the intervention and which arm was the control, so it assumed that the superior arm was the intervention arm. While this way of phrasing a conclusion may not be optimal for readability, it is certainly not an attempt at misleading the reader, who will still know which treatment yielded better results.

Therefore, our approach is likely not suitable as a fully automated solution. However, it demonstrated its potential to inform editors, reviewers, and authors alike of potential spin or unclear writing. The question of “Are the results for the primary endpoint clearly recognizable in the conclusion?” might serve as an alternative litmus test. Even though reviewers and journal editors are generally capable of recognizing questionable conclusions, we do believe that automated tools have value considering the ever-increasing list of items that have to be considered when conducting a careful review as they may, if implemented carefully, point toward parts of the manuscript that need increased attention. Another group of people who might benefit from a higher degree of automation are physicians who do not routinely read RCTs or have to do it in a situation in which they do not have time to fully digest all aspects of the research, such as in between patient consultations.

Comparison to Prior Work

While research on LLMs and spin is still in its infancy, Yun et al [28] evaluated 22 LLMs and found that they are actually more susceptible to spin than humans. As LLMs are being used increasingly for screening and synthesizing scientific literature, this highlights the importance of improved detection of spin, preferably at the prepublication stage. However, the approach demonstrated in this study could also be leveraged as part of a screening pipeline to detect spin when trying to systematically analyze the literature in an automated fashion.

Strengths and Limitations

This study has several strengths. The human annotation process was systematic, with independent dual review and consensus resolution, resulting in a reliable ground-truth dataset. Evaluating 3 LLMs of differing capability provided insights into how model complexity affects performance and sensitivity to unclear reporting. In addition, the structured comparison across 4 abstract conditions enabled us to isolate how specific sections of reporting contribute to misclassification.

This study has several limitations. First, the analysis was restricted to RCTs with 2 arms and a single primary end point. This constraint reduced complexity and helped ensure consistent interpretation but limits the applicability of our findings to trials with more complex designs, such as those involving multiple or co–primary end points. As noted in this paper, such designs introduce additional analytic considerations, for example, prespecified alpha splitting, that would have increased methodological heterogeneity and potentially confounded the evaluation [29]. Therefore, the restriction was deliberate, but it reduced generalizability.

Second, we did not include trials using analytical frameworks other than standard hypothesis testing, such as Bayesian designs [30]. Because these studies report results differently and may emphasize posterior probabilities rather than traditional statistical significance, the performance of LLMs in such contexts remains unknown. This limitation reflects the scope of the feasibility study rather than an inherent barrier of the method.

Third, it is uncertain whether the models had previously encountered some of the included abstracts during training. If so, prior exposure could have artificially increased performance, particularly when models were presented with only part of an abstract. Although this possibility cannot be fully eliminated for proprietary language models, our key analyses focused on discrepancies between conclusion-only and full-abstract predictions. These discrepancies are less susceptible to prior knowledge because recognizing internal inconsistencies requires examining the relationship between sections rather than retrieving memorized text. Nonetheless, this limitation may have influenced overall performance metrics.

Fourth, this study used a single, clearly defined prompt that specified what should be considered a positive or negative trial. While this approach ensured consistent instructions across models and conditions, it remains possible that different prompting strategies would yield different results. The choice of a single explicit prompt was intended to minimize variability, but it may limit insight into how models behave under alternative or less directive task formulations.

Future Directions

Future work could extend this approach to more complex trial designs, including studies with multiple or co–primary end points, adaptive designs, or Bayesian frameworks, to determine whether LLM-based assessments remain reliable under conditions in which end point interpretation is less straightforward. Evaluating models from different vendors and open-source architectures may also help clarify how

XSL•FO
RenderX

generalizable these findings are beyond the commercial systems examined in this study. In addition, refining prompting strategies or incorporating structured domain knowledge could improve model understanding of trial context, particularly in situations in which the distinction between intervention and control is not explicitly stated. Prospective integration of LLM-based screening tools into editorial workflows may help assess their practical utility in real-time manuscript evaluation. Finally, future studies may investigate whether LLMs can assist in promoting clearer reporting practices by providing automated feedback to authors during manuscript preparation.

Conclusions

In conclusion, this study demonstrates that LLMs can highlight potential spin in oncology trial reporting by identifying inconsistencies between conclusions and full abstracts. These findings suggest a possible role for LLMs as supportive tools that draw attention to areas in which reporting may be unclear or incomplete. While not a substitute for expert review, such tools may help promote clearer communication of trial results. Further evaluation in more complex trial settings will be needed to determine how broadly this approach can be applied.

Abstract

Background: There is a growing interest in characterizing the relationship between long-term physical activity (PA) habits and cancer-related outcomes such as treatment-related toxicities, recurrence, and complications. Wearable devices can provide critical information to achieve this goal; however, inferences are significantly influenced by device wear adherence.

Objective: This study aimed to assess the feasibility of using wearable devices to monitor short- and long-term PA in adolescent and young adult (AYA) patients with sarcoma during and after chemotherapy in a free-living environment and evaluate the ability to accurately capture changes in PA over 3 years.

Methods: A total of 63 AYA patients with sarcoma were provided with a Fitbit Charge 3 to track daily steps, sedentary time, and heart rate for up to 3 years.

Results: On average, during the first 30 days of follow-up, 57.1% (36/63) of patients wore their device at least 10 hours per day, and only 23.8% (15/63) of patients wore their devices thereafter. Patients spent a mean of 80% (SD 11%) of their day in a sedentary state. Despite low adherence, daily step count trends increased over time.

Conclusions: This study highlights the adherence challenges met with longitudinal PA monitoring in AYA patients with sarcoma. Wearer discomfort, lost devices, and lack of data uploading compliance contributed to data missingness and attrition. Caution is warranted when relying on wearable activity trackers to inform program decisions, accurately assess PA outcomes, and monitor program adherence longitudinally without consideration of wearer bias. Alternative methods that would be more broadly accepted by AYA patients for effective long-term monitoring should be considered.

KEYWORDS

sarcoma; adolescents and young adults; physical activity tracking; wearable device; chemotherapy

Introduction

Adolescent and young adult (AYA) patients who receive high doses of anthracycline treatment such as doxorubicin are at high risk of long-term cardiac morbidity and mortality [1]. Physical activity (PA) has been previously demonstrated to protect against and mitigate doxorubicin-induced cardiotoxicity [2-4]. As a result, exercise is often proposed as a nonpharmacological early prevention intervention to combat cardiovascular side effects of cancer therapy. There is a growing interest in characterizing the relationship between long-term PA habits and cancer-related outcomes such as treatment-related toxicities, recurrence, and complications. Furthermore, there is interest in understanding how PA interventions may modify these crucial outcomes. Wearable devices are widely used for quantification of PA [5]. Among the demographic of AYA patients with sarcoma who receive high-dose anthracyclines, little is known regarding the feasibility of using wearable devices to monitor PA longitudinally for associations with late cancer-related outcomes.

In addition to wearable devices being capable of providing long-term activity data [6-8], it has been well established that PA monitoring can inform exercise prescription decisions and

XSL•FO
RenderX

quantify exercise intervention participation [9-11]. Information gathered from PA monitoring devices aids in designing tailored interventions for specific patient populations of interest. Exercise intervention programming and resultant prevention success hinge on the current behaviors, interest, and activity levels of a given cohort of individuals [12]. On the basis of the target population, exercise prescription in terms of frequency, intensity, time, and type can be highly variable. Among AYA patients with cancer, there is a lack of consensus on frequency, intensity, time, and type parameters to be used in patients receiving therapy [13]. Information gathered from regular activity levels may indicate optimal timing as well as intensity for a practical PA intervention. Therefore, recording PA in AYA patients undergoing chemotherapy is essential for the design of a feasible exercise regimen to improve adherence probability in a randomized trial.

The lack of participant willingness to wear and interact with PA tracking devices longitudinally can present a significant challenge for creating exercise interventions, monitoring program adherence, conducting unbiased data interpretation, and deducing critical scientific conclusions for determining the impact of exercise interventions on cancer-related toxicities. Researchers have called for investigations that evaluate the long-term adherence to and sustainability of activity-monitoring interventions using wearables [14-16]. Therefore, the purpose of this study was to evaluate the feasibility of assessing short- and long-term PA during and after chemotherapy using a wearable device in AYA patients with sarcoma in a free-living environment and determine whether such data can accurately describe the evolution of PA levels of AYA patients over the span of 3 years.

Methods

Patient Recruitment

PA was assessed as a component of a primary cardiotoxicity investigation. Patients between the ages of 15 and 39 years at the time of study entry were recruited at MD Anderson Cancer Center. The study follow-up period for the primary cardiotoxicity end points was 2 years after recruitment. Cardiotoxicity end points and sample size calculations were based on evidence that demonstrated significant cardiac remodeling 2 years after diagnosis [17]. However, patients were informed that the Fitbit study monitoring period would last up to 3 years from enrollment, wherein data would be collected passively without intervention to maximize the information gained from the wearable device and gaining new information from it.

Inclusion criteria were patients with a histologically confirmed diagnosis of sarcoma (including either soft tissue or bone sarcoma) and anticipated total doxorubicin dose of 300 mg/m^2 or higher or other anthracycline with doxorubicin equivalence of 300 mg/m^2 or higher as determined by the treating physician. Moreover, individuals included in the study must indicate that they were willing to wear and upload data from the PA wearable device throughout the study period. Patients were excluded if there was any condition that compromised the ability of the patient or their legally recognized representative to give written informed consent and/or comply with the study. Patients with a history of cardiac morbidity were also excluded from study participation.

Ethical Considerations

Informed consent was obtained from all participants included in the study. The study was approved by the MD Anderson Cancer Center institutional review board (PA18-0462). All study procedures were conducted in accordance with the ethical standards of the Declaration of Helsinki. The privacy and confidentiality of the research participants' data and identity were maintained. Patients were allowed to keep the Fitbit Charge 3 (Google) device after study conclusion or discontinuation. No other patient incentive was provided for participation.

PA Tracking

PA was assessed using an electronic wearable activity-monitoring device (Fitbit Charge 3 provided by the Department of Pediatrics of MD Anderson Cancer Center). Fitbit devices are widely used and well known for their commercial popularity, high wear compliance, and strong correlation with research-grade monitoring devices [15,18]. The Fitbit Charge 3 was selected based on the resources available for device purchase and implementation [19], as well as for its demonstrated significant correlation with research-grade PA monitoring devices such as the ActiGraph wGT3X-BT [18]. After consent, patients were given a Fitbit device and went through an educational introduction to the device whereby a study coordinator explained how to wear it and charge it and aided in downloading the Fitbit app to the participants' mobile devices or tablets for device data synchronization. Patients were asked to wear the device for a minimum of 6 months and were instructed to wear it at all times unless they were charging it. Participants were additionally informed that the study monitoring period would last a maximum of 3 years. No PA-specific instructions were given in order to to assess changes in PA without an intervention during and after chemotherapy. The Fitbit device was used to track aerobic PA, which included minute-level measures of steps; heart rate (HR); and a classification of activity as sedentary, light, moderate, or active. The device was linked to Fitabase (Small Steps Labs LLC), a database that stores activity data on a secure online website. Data storage on the Fitabase platform was participant dependent via app synchronization. Therefore, data were reviewed routinely throughout the study period. Study coordinators attempted to contact participants who did not upload data for 10 of the previous 14 days for participant retention. There were no device-integrated automatic or proactive reminders to participants to wear or synchronize their devices.

Device Wear Time Parameters

Whether the device was being worn in at a given minute was determined based on (1) whether the patient's device logged any data during the given day and (2) applying the algorithm developed by Choi et al [20] to consider the device worn during minutes for which there was an HR measurement or during minutes of spurious missing HR. PA was summarized between the hours of 8 AM and 8 PM, with daily summaries calculated

XSL•FO
RenderX

only for "valid days," defined as days during which the device was worn for at least 10 hours between 8 AM and 8 PM per best practice consensus for waking day sampling [19]. The 8 AM to 8 PM time window has been previously used and defined as a standard waking or daytime period used to monitor PA [21-23].

Statistical Analysis

Study device wear patterns were summarized by calculating the proportion of participants enrolled on a given follow-up day who wore the Fitbit device for at least 10 hours between 8 AM and 8 PM (a "valid day"). Daily PA summaries for each patient were calculated as the total number of steps, average daily HR, and proportion of time classified as sedentary activity among valid days of device wear. Means are reported with the SD, and medians are reported with the IQR. To evaluate changes in PA over time, a mixed-effects linear regression model with normally distributed random intercepts and slopes was fit to model trends in daily step count. This model specified patient-specific time trends, various patient characteristics (sex, tumor location, BMI, and age), and treatment status (during or after chemotherapy treatment) and adjusted for day of the week variability. The follow-up day was calculated as the day from primary cardiotoxicity study enrollment.

Results

Overview

A total of 75 patients were eligible, recruited, consented for participation, and enrolled in the study. In total, 84% (63/75) of these patients (33/63, 52.4% male and 30/63, 47.6% female) had valid Fitbit data that were included in the analysis (Table 1). The reasons for 16% (12/75) of the individuals not logging Fitbit data were variable; however, most related to inability or unwillingness to use the Fitbit device and/or its supporting app or study withdrawal before setting up the Fitbit device. The mean age and BMI of the cohort were 24 (SD 7.4) years and 27.7 (SD 10.0) kg/m^2, respectively. The most common types of sarcoma diagnosis were osteosarcoma (18/63, 28.6%) and synovial sarcoma (13/63, 20.6%), and the most common locations of the primary tumor were the trunk (33/62, 53.2%) and lower limb (21/62, 33.9%; Table 1). Patients were enrolled in the primary study for a median of 730 (IQR 622-730) days. The median number of days that a patient logged Fitbit data was 205 (IQR 58-352).

Over the study duration, 11.1% (7/63) of the wearable devices were lost, and 3.2% (2/63) were broken. All were replaced by the study team. Among the 63 patients, there were 5 (7.9%) reports of wearer discomfort due to skin sensitivity wherein patients subsequently stopped wearing the activity tracker. In several instances, wearers forgot to synchronize the device for data transfer, making consistent data collection a recurrent challenge for the study team.

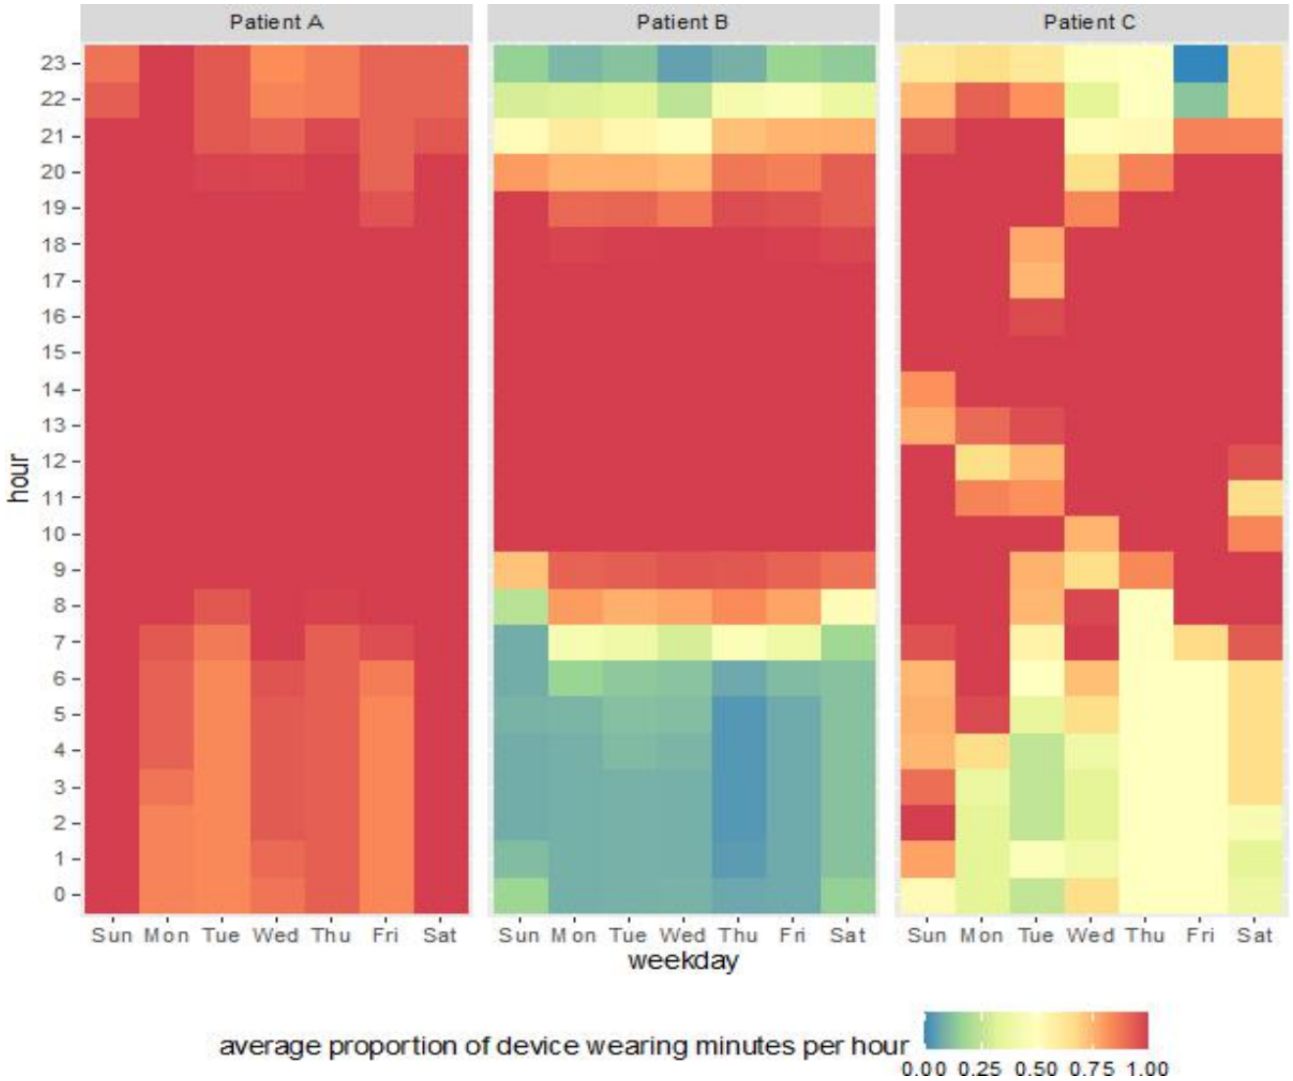
Device Wear Summary

The highest proportion of device wear occurred on day 9 of follow-up, when 66.7% (42/63) of study participants exhibited valid wear of at least 10 hours between 8 AM and 8 PM. All other study days saw fewer patients with valid device wear, which decreased as the study progressed. Allowing for a 7-day lag to set up the Fitbit app, the average proportion of patients exhibiting valid daily wear was 57% during follow-up days 8 to 30, with the proportion of valid wear averaging 24% during days 31 to 365 and 6% from day 366 to the primary cardiotoxicity study end point of 2 years. Device wear during the study period is summarized in Figure 1. Moreover, patients demonstrated intervariability for daily patterns of device wear. Figure 2 shows key examples of the heterogeneity of wear patterns across different hours of the day and days of the week for 3 anonymized patients.



XSL•FO
RenderX

Figure 1. Number of patients enrolled (red) and number of patients exhibiting at least 10 hours of Fitbit wear time between 8 AM and 8 PM ("valid day"; blue) across their days in the study. Given that physical activity was assessed as a component of a primary cardiotoxicity investigation, the primary cardiotoxicity study end point has been indicated in the figure (black dotted line). Patients were informed that the Fitbit study monitoring period would last up to 3 years from enrollment, wherein data would be collected passively without intervention.

XSL•FO
RenderX

Figure 2. Proportion of device wear time during specific hours of days of the week across 3 anonymized patients.

PA During Device Wear

Table 2 summarizes the overall daily HR, step count, and proportion of time between 8 AM and 8 PM spent in the sedentary activity category among available valid days of device wear. The cohort was found to have a mean daily HR of 91 (SD 8.6) beats per minute and a mean daily step count of 2970 (SD 1902) steps. Moreover, patients spent a mean of 80% (SD 11%) of their day in a sedentary activity state. Figure 3A summarizes observed heterogeneity in PA across patients in terms of daily steps and HR during valid days for the entire study sample and for each patient individually. Table 3 describes Fitbit PA measures during patients' chemotherapy treatment period and after completion of chemotherapy. On average, and as expected, patients exhibited slightly less steps during chemotherapy (mean 2714, SD 1747 vs 3676, SD 2743 after), with comparable average HR and proportion of time spent sedentary. Importantly, we additionally found that 98.4% (62/63) of the patients had valid Fitbit wear during chemotherapy, whereas postchemotherapy summaries are based on only 68.3% (43/63) of the patients, who had valid Fitbit wear after completion of chemotherapy.

Figure 3B depicts the distribution of average daily step count across all participants exhibiting valid daily wear on each day of study follow-up, showing that the average daily step count among device wearers tended to increase over the course of the study. To further evaluate changes in daily step count over time, a mixed-effects regression model was fit with patient-specific random intercepts and slopes for follow-up time and adjustment for day of the week, patient sex, BMI, and tumor location, as well as whether the steps were recorded during or after chemotherapy treatment. Regression coefficient estimates from this model are reported in Table 4. This model indicated that, on average, across all patients, there was no significant trend in daily step counts as patients remained in the study for longer (P=.85), although there was substantial heterogeneity in patient-specific daily step trends—evidenced by a high variance of the patient-level random intercepts. The model also estimated that daily step count was 487 steps lower on average during chemotherapy treatment than after completion of chemotherapy (P<.001). With the exception of patient age, there was no evidence that any other patient characteristic or variable was significantly associated with daily step counts after accounting for chemotherapy, day of the week, and patient-specific time trends.

Table . Estimated regression coefficients from the linear mixed-effects model of daily steps during the study period[a].

Variable	Estimate (SE)	*P* value
Intercept	636.628 (1535.538)	.68
Days in the study	−0.345 (563.422)	.85
During chemotherapy	−487.326 (115.124)	<.001
Sex: male	625.104 (498.854)	.22
Age	77.911 (34.891)	.03
BMI	15.181 (25.771)	.56
Tumor location: lower limb	−184.588 (923.439)	.84
Tumor location: trunk	−286.307 (895.38)	.75
Tumor location: upper limb	1549.331 (1363.375)	.26

[a]Estimates represent the average difference in daily steps associated with a 1-unit increase in each individual feature controlling for all other variables presented in the model table, patient-specific trends in daily steps, and day of the week. The sex coefficient is the difference between male and female patients. Tumor location estimates are compared to "other" locations.

Discussion

Principal Findings

Given the popular desire by investigators to quantify longitudinal PA levels and changes in PA among AYA patients with cancer for the evaluation of the relationship between PA and cancer-related clinical outcomes, we investigated the practicality of assessing longitudinal PA using a wearable device in AYA patients with sarcoma who received high-dose doxorubicin in a free-living environment.

We found that, although participants were enrolled in the study for an average period of 630 (SD 208; median 730, IQR 622-730) days, PA wearable device data were logged for less than half of that time (mean 245, SD 226; median 205, IQR 58-352 days). Devices were worn and tolerated by an average of 57% of AYA patients for PA monitoring and data logging for at least 10 hours from 8 AM to 8 PM up to day 30 of study enrollment. Device wear declined drastically to 24% of patients on average after follow-up day 30. On the basis of AYA patient device wear patterns from this study, we identified that 30 days may be the upper limit for study duration in investigations that aim to use wearable devices such as Fitbit in similar cohorts, particularly without more active efforts to encourage device wear. We do not believe that these findings are exclusive to Fitbit device monitoring. Importantly, there is significant heterogeneity in the devices used in the field of PA monitoring [15]. We expect that our findings in AYA patients with sarcoma likely extend to the vast majority of devices. This study did not provide proactive reminders to participants to wear or synchronize the devices. Due to this passive monitoring modality, patients lacked routine motivational encouragement to wear their devices. Previous studies have demonstrated a significant positive impact of using SMS text message–, app-, and device-based reminders, notifications, and encouragement on PA-related behaviors, self-management, and adherence [24-26]. Therefore, motivational tactics should be considered for future investigations to modify behavioral patterns that augment device wear.

The practicality of using wearable devices in AYA patients with sarcoma appears to be greatly challenged by attrition and wearer difficulties. During the study period, qualitative reports of wearer and user challenges such as wearer discomfort, lost devices, and lack of data uploading compliance were identified as primary contributors to data missingness and participant attrition. Considering the high use of technology and mobile devices among AYA individuals [27,28], future studies that aim to monitor PA for longer periods should consider individual PA monitoring preferences and the use of digital health and mobile app alternatives rather than wearable devices to leverage current technology routinely used by this population [28]. Moreover, future studies should consider individual and treatment-related barriers such as side effects (eg, drug-induced skin sensitivity), psychological motivation, time availability, and technological challenges and preferences that AYA patients may face during monitoring periods that may largely impact adherence [14-16].

Our secondary longitudinal outcome evaluated what happened to the PA levels of AYA patients with sarcoma during and after exposure to high-dose chemotherapy. We found that, on average, across the subset of patients who persistently wore their devices both during and after chemotherapy, AYA patients performed 487 fewer steps during chemotherapy compared to after chemotherapy. These findings of reduced PA during chemotherapy are in agreement with those of several previous studies in the field [13,29,30]. After chemotherapy, the activity levels were observed to increase longitudinally over time (measured via step counts). However, such an inference is limited to the subset of patients who persistently wore their devices during and after chemotherapy. This key finding highlights the potential risk for self-selection or wearer bias and subsequent incorrect study conclusions. Individuals who are more physically active may be more likely to wear an activity-tracking device, which may result in inflation or overestimation of average PA. Future investigators should be wary of this inference limitation when collecting PA data using wearable devices.

XSL•FO
RenderX

Overall, individuals within the cohort demonstrated variable patterns of wear (length of time and days of the week) and heterogeneity in activity level. On average, the patients spent 80% (SD 11%) of their day sedentary. Interestingly, this cohort of AYA patients with sarcoma was found to have substantially lower PA levels (steps) than comparative reports. Previous studies have found that AYA patients with bone, soft tissue, and additional mixed cancer diagnoses undergoing variable therapies and procedures recorded an average of 5699 to 6434 steps per day and a notable range of patient variability [13]. In contrast, this cohort spent 80% (SD 11%) of their activity time between 8 AM and 8 PM sedentary and recorded an average of 2714 (SD 1747) steps during chemotherapy and 3676 (SD 2743) steps after chemotherapy completion. This difference in PA level may be explained by lifestyle behaviors, cancer location, surgery, radiation, and/or high anthracycline chemotherapy dosages. In total, 33.9% (21/62) of the patient population in our study had lower-extremity tumors, which may cause reduced lower body function and PA. Additionally, anthracycline chemotherapy has been observed to cause significant skeletal muscle weakness and fatigue [31]. Similar deleterious effects on skeletal muscle function and reduced PA are commonly reported after both radiation therapy and significantly reported after surgery.

Several limitations of this study should be considered, such as device selection, confounding factors, patient education and incentives, and potential biases. This study used the Fitbit Charge 3 device to quantify PA. While the Fitbit Charge 3 is known to be significantly correlated with research-grade devices such as the ActiGraph wGT3X-BT, it has been previously demonstrated that Fitbit may comparably overestimate PA [18]. The sedentary PA level among the cohort may be in part due to a combination of cancer location and fatigue. This study was not designed to determine the *impact* of either of these potentially confounding factors but, rather, report on PA tracker wear patterns and the resultant activity data and assess the usefulness of a PA monitoring device for future studies investigating the impact of PA on cancer-related clinical outcomes such as cardiac morbidity and fatigue. Moreover, this study was designed as an observational feasibility study. Our study was not designed with the intention to parse or investigate the cancer-related psychosocial or behavioral motivations that may impact the use of wearables. The psychological impact of cancer diagnoses and care should be considered in future wearable device research. Although device familiarization and patient education were provided for the use of wearable devices in this study, future studies should consider continuing education as a necessary component to ensure consistent use and study validity. This study did not offer patient incentives beyond allowing participants to keep the wearable device. Monetary or other incentives should be considered to increase adherence past 30 days and encourage PA throughout the study [32]. When interpreting patterns from wearable devices, it is essential to consider the possibility that device wear is related to PA, meaning that individuals who consistently adhere to wearing devices may differ systematically in their activity levels, potentially skewing data toward either higher or lower levels of PA. We restricted PA measurement to “valid days” of greater than or equal to 10 hours of wear during waking hours (8 AM-8 PM) to ensure that PA summaries actually represented daily behavior. Nonetheless, patients wore their devices for variable lengths of time throughout the study follow-up, implying that cross-sectional summaries at different study time points (eg, Table 3 and Figure 3B) cannot distinguish between behavior *changes* among persistent device wearers and behavioral *differences* between persistent wearers and patients who stopped wearing their devices. The mixed-effects regression model used in this study was designed to measure individual patient behavior changes over the time when the device was worn. The lack of significant trend in daily steps from this model suggests that individual patients did not tend to change their behavior over time. The apparent increase in daily steps among all patients with valid wear on a given follow-up day depicted in Figure 3B suggests that patients who wore their devices longer into the study were those who were more physically active.

Conclusions

This study demonstrated the need to identify alternative methods to a wearable device that would be more acceptable to AYA patients with cancer for monitoring PA longitudinally. On the basis of AYA patient device wear patterns from this study, we identified 30 days as a potential upper limit for study duration when using wearable devices such as Fitbit to accurately represent free-living environment PA without increased risk of biases. This study additionally confirmed poor PA levels among AYA patients with sarcoma. Importantly, future studies should consider AYA patient preferences for PA quantification and reporting, as well as study designs that implement continued patient education, regular participant notifications and reminders, and adherence incentives to ensure optimal longitudinal data collection and study success.

Abstract

Background: Cancer survivors face significant challenges in maintaining adequate physical activity levels, which are essential for overall health and quality of life. Telehealth-based interventions offer promising opportunities to provide accessible support and promote healthier lifestyles throughout the cancer survivorship continuum. HealthScore is a telehealth coaching program designed to optimize the health of cancer survivors.

Objective: This study assessed the effectiveness of HealthScore in improving physical activity metrics among cancer survivors compared to controls. We also evaluated participants' qualitative experiences with the program to understand its impact on motivation, accountability, and overall health-related quality of life.

Methods: We performed a secondary analysis of a randomized controlled study of cancer survivors who participated in a comprehensive health coaching intervention called HealthScore. Participants in control and intervention groups received a Fitbit activity tracker that collected heart rate, step counts, active minutes, and calories burned. These metrics were analyzed using statistical methods to compare overall averages and temporal trends between intervention and control groups. Eleven exit interviews were conducted with intervention arm participants to ascertain their experiences with HealthScore. Inductive thematic analysis was performed to identify emerging themes. Data were collected between May 2020 and March 2022.

Results: Of the 32 participants enrolled, 20 (62%) were in the intervention group. Compared to the control group, intervention participants had significantly higher average daily steps (mean 3660, SD 3344; 95% CI 3557-3764 vs mean 3408, SD 3288; 95% CI 3299-3518; P=.001) and more moving average daily steps (mean 4813, SD 1723; 95% CI 4680-4946 vs mean 4581, SD 1224; 95% CI 4494-4669; P=.003). Moving average daily step counts in the intervention arm showed an increasing trend, which was significantly higher than that of the control group (regression slope=5.89 vs 2.80; P<.001). Compared to the control group, the intervention participants had significantly higher average daily walking distance (mean 2.6, SD 2.5; 95% CI 2.5-2.7 vs mean 2.4, SD 2.3; 95% CI 2.3-2.5; P<.001) and more moving average daily walking distance (mean 3.5, SD 1.3; 95% CI 3.4-3.6 vs mean 3.2, SD 0.8; 95% CI 3.1-3.3; P<.001). Moving average daily walking distances among intervention participants increased, which was also significantly higher than that of the control group (regression slope=0.0046 vs 0.0017; P<.001). Participants in the intervention group reported a growing sense of accountability and motivation. One barrier was completing weekly monitoring

XSL•FO
RenderX

of patient-reported outcome surveys, which focused on symptoms and physical function and did not always align with participants' goals.

Conclusions: The HealthScore telehealth coaching program improved physical activity levels among cancer survivors and enhanced motivation and accountability. These findings support the integration of telehealth-based health coaching into posttreatment care, promoting healthier lifestyles and improved quality of life for cancer survivors.

Trial Registration: ClinicalTrials.gov NCT04923997; https://clinicaltrials.gov/study/NCT04923997

Introduction

Maintaining adequate physical activity levels poses a significant challenge for cancer survivors [1]. The toxicity associated with cancer treatments often results in fatigue, pain, and decreased physical function, which can discourage individuals from participating in regular exercise [2,3]. Additionally, psychological symptoms, such as anxiety and depression, further impede motivation and adherence to physical activity regimens [4]. The lack of tailored programs for cancer survivors increases these challenges, making it harder for individuals to incorporate physical activity consistently into their routines [5].

Low physical activity levels among cancer survivors can have detrimental effects on their overall well-being and health care outcomes [1,6]. Inactivity has been associated with reduced health-related quality of life (HRQOL), increased fatigue, and higher anxiety and depression scores [7]. Additionally, a sedentary lifestyle is linked to higher risks of comorbidities, complicating the health status of cancer survivors [8]. Conversely, regular physical activity can alleviate treatment-related adverse effects, reduce cancer-specific and overall mortality, and improve HRQOL [9]. Furthermore, studies have demonstrated that telehealth exercise-based interventions can significantly enhance cardiorespiratory fitness, quality of life (QOL), and physical activity levels in cancer survivors [10,11]. Home-based physical activity interventions have been shown to be safe, with very low adverse event rates [12]. Finally, exercise has been recommended to cancer survivors since 2019 [13]. Therefore, promoting and maintaining adequate physical activity is essential for improving overall health among cancer survivors.

Research has shown that health coaching can be an effective method to promote physical activity among cancer survivors [14-16]. By definition, health coaching involves participant-led personalized support and guidance to help individuals set and achieve health-related goals [7]. In general, health coaching can lead to significant improvements in the frequency and intensity of physical activity, thereby improving overall physical activity levels [17,18]. However, to date, many health coaching programs have not shown improvements in physical activity among those with cancer, largely due to lower intervention intensity or low quality of coaching [19,20].

Telehealth-based health coaching has emerged as a promising solution to address these challenges by providing ongoing, personalized support with remote convenience. Telehealth allows for higher accessibility for individuals who may not have access to in-person services [21]. Telehealth coaching combined with remote symptom monitoring can effectively increase patients' physical activity levels, improve biomarkers associated with diabetes, and reduce body weight [4,22]. Health coaching is distinct among behavioral interventions for cancer survivors for a number of reasons: (1) its emphasis on improving patient activation and motivation, (2) its ability to be delivered by trained and supervised lay health coaches, and (3) the extent to which participants drive the direction. Coaching is less scripted than other behavioral interventions in general, given the focus on encouraging participants to take ownership of their health. HealthScore places emphasis on improving motivation, mood, mindfulness, and movement (the 4M model) [23]. However, the effect of telehealth coaching on the physical activity levels of cancer survivors is unknown.

HealthScore is a telehealth coaching program that focuses on optimizing the overall health of cancer survivors (ie, from diagnosis through end-of-life) through (1) weekly, structured coaching sessions and (2) physiologically based patient-generated health data (PGHD) capture to enable comprehensive support to promote health. Preliminary work has demonstrated high levels of acceptability and feasibility of the HealthScore intervention [24]. The purpose of this study was to assess HealthScore's potential for improving physical activity and report on the experiences of intervention participants.

Methods

Overview

We conducted a secondary analysis of a randomized controlled pilot study [24] of cancer survivors who participated in a comprehensive health coaching intervention called HealthScore, using an explanatory sequential mixed methods approach [25]. This study was a registered clinical trial (NCT04923997). The pilot study assessed the feasibility and acceptability of the HealthScore program by measuring changes in physical function from baseline, evaluations conducted at 3 and 6 months, and patient-reported outcomes (PROs) as secondary outcomes. This secondary analysis assesses HealthScore's potential for improving physical activity by examining daily step count and walking distance, coupled with thematic analysis of participant exit interviews. For this study, we adopted the National Cancer

Institute (NCI) definition of cancer survivor: "An individual is considered a cancer survivor from the time of diagnosis through the balance of life" [26]. Data were collected between May 2020 and March 2022.

HealthScore's key components consist of weekly meetings with coaches to develop and clarify goals, the collection of PGHD from Fitbit activity tracking, and weekly participant-completed surveys centered on physical function, HRQOL, and symptom burden. Participants in the intervention group completed weekly sessions with a trained health coach who guided them in creating individualized SMART (Specific, Measurable, Achievable, Relevant, and Time-Bound) goals, reviewed their survey responses, including a graphic display of their self-reported physical function metrics over time (labeled their Health Score), and, when needed, connected them to additional supportive care resources [27]. Health coaches were a combination of 2 full-time cancer center staff and 12 volunteer health coaches. All coaches received training in motivational interviewing strategies, common symptoms affecting cancer survivors, and goal setting to facilitate focused, goal-oriented sessions. Coaches had participated in a series of didactic presentations surrounding the transtheoretical model of behavior change, coaching foundations, cancer center resources, and other health-related topics, including exercise, nutrition, and sleep. Training videos and manuals were developed by a board-certified health coach and maintained for reference [24].

The team was formally trained in conducting interviews and comprised of medical professionals and 12 interdisciplinary volunteer coaches. The majority of coaches were recruited through the National Board of Health and Wellness Coaches job board, had already completed an accredited program, and were planning to pursue the National Board examination for health and wellness coaching. Coaches were asked to complete a HealthScore-specific training, which included human participants protections, 5 hour-long HealthScore coaching trainings and associated assessments, and practice coaching sessions with the same board-certified staff coach. Having a singular coach trainer provided consistency across the multiple volunteer health coaches. Coaches were not permitted to work with patients who participated in HealthScore until the study team and the volunteer coach were confident that the volunteer had sufficient coaching skills and understanding of cancer center resources. Coaches were required to attend monthly team meetings to ensure they were up to date with study progress and to have a shared space where they could brainstorm participant-specific coaching challenges together. All volunteer coaches were supervised by a board-certified health coach.

The intervention group completed semistructured exit interviews after the intervention ended at 6 months. Exit interviews lasted 30-45 minutes and elicited participants' perspectives about the impact of the HealthScore intervention on their health goals and outcomes. The objective of the current analysis was to report findings from both the objective Fitbit physical activity data and intervention participant exit interview themes and to provide insight into HealthScore's mechanisms of action and refine the intervention for a future fully powered efficacy trial.

Study Design

To promote the autonomy and self-efficacy of participants and improve their long-term QOL, the HealthScore program is grounded on self-determination theory [28]. Additionally, the principles and the transtheoretical model of behavior change were supplemented by motivational interview techniques [29,30].

Patients were either referred to our program by clinical oncology teams, identified through screening of clinical visits, or self-referred to our program in response to the University of North Carolina (UNC) Research For Me listing. Patients across a variety of cancer types with advanced cancer staging were recruited. Once patients were identified, they were screened to ensure they met the inclusion criteria. Information, such as cancer type and treatment status, was collected; however, this information was used for evaluation of study eligibility and not used as exclusion criteria based on type and treatment status. If eligible, a study team member contacted them via phone to gauge interest, provide more information about the study. Once consented, patients completed the PROMIS (Patient-Reported Outcomes Measurement Information System) Physical Function 8b, [31] which evaluates limitations in physical activities (eg, mobility and extremity function). Responses were stratified into high or low physical function and then randomized into either the intervention or a waitlist control arm to study the impact of the intervention on the participants' physical function, HRQOL, and physical activities as measured by weekly averages of daily step counts. Participants were randomized by the research team and stratified at the median of baseline PROMIS physical function scores of (45+ and <45). The final number of participants included 20 in the intervention group and 12 in the control group, totaling 32 participants for the entire cohort. While there were 46 total participants in the parent trial, 14 participants were excluded from this secondary analysis due to missing or abnormal data. The TIDieR (Template for Intervention Description and Replication) and the CONSORT (Consolidated Standards of Reporting Trials) checklists were referenced to describe this study (Multimedia Appendices 1 and 2, respectively). Qualitative methods were guided and reported in compliance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) reporting guideline [32].

Measures

Quantitative Data Collection

Participants in control and intervention groups received a Fitbit activity tracker that collected metrics, such as heart rate, step counts, active minutes, and calories burned. The study team provided training and troubleshooting for participants, if needed. Data from each device were automatically sent via an intermediary application programming interface to the UNC Connected Health for Applications & Interventions (CHAI) Core, a UNC-developed secure data collection system used by the study team. CHAI Core created a HealthScore platform for coaches and participants to provide participant monitoring, generate reports, visualize data capture (including the PROMIS Physical Function measure, referred to as the HealthScore), and serve as a platform for collaborative goal setting. Survey

XSL•FO
RenderX

responses were collected and aggregated through another internal platform called PRO-Core.

Qualitative Data Collection

A semistructured interview guide (Multimedia Appendix 3) designed to synthesize themes of participants' perspectives of the HealthScore program was collaboratively developed by the study team and pilot tested during earlier phases of HealthScore. This guide structured questions around patients' perceived facilitators and barriers to participation, their interactions with their health coach, thoughts on the program's metrics, and caregiver involvement. Intervention group participants were asked about their perceptions after completing the one-time 6-month HealthScore program and its components, such as the Fitbit tracker, short- and long-term benefits, and recommendations for changes to HealthScore.

Study team members conducted interviews using web-based videoconferencing platforms or telephonically. The 30-minute interviews were audio recorded and transcribed, and representative quotes were identified. Field notes were captured during the sessions to amplify recordings. Transcripts were not shown or returned to participants for comment or correction.

Outcomes

This paper's analytical outcomes were (1) physical activity (daily step count and daily walking distance over the week) and (2) perceptions of participants in the intervention group elicited from exit interviews with intervention participants.

Data Analysis

Quantitative Analysis

Frequencies and means describing participant characteristics in both arms were calculated. A pragmatic methodological approach was undertaken for this mixed methods study [25].

For assessment of physical activity, we used the records of each participant's daily step count captured from participant-worn Fitbits. We calculated moving averages of daily step count for each participant using a window size of 7 days, as we inferred that the data collected from the participants tended to change over the course of the week, and this interval matched the frequency of weekly coach calls. The missing data and abnormal data (negative step counts) were removed (18%). The moving average of daily step count between participants in the intervention and control arms was compared, and *t* test was applied to detect the difference between them. Then, with the time change as the independent variable and the moving averages per participant as the dependent variable, linear regression models were fit to further analyze the trend of step counts per participant during this experimental phase, helping to understand how participants' adherence and motivation for physical activity changed over time. The same procedures were also applied to the analysis of walking distance. A *P* value less than .05 was considered significant.

Qualitative Analysis

For the participant perspectives of the intervention, an inductive qualitative research approach was used for analysis, with each unique participant serving as the unit of analysis [33]. The qualitative sample was limited to those participants for whom full interviews were available, totaling 11 participants overall. The interview sessions were automatically transcribed and then analyzed using Dedoose, a qualitative management web-based tool [34]. The research team followed a phased approach to ensure rigor and reproducibility in our analysis. Two coders (JG and KM) developed a codebook of 25 unique codes based on the initial readings of transcripts reviewed and standardized to code the interview transcripts [35]. Codes were focused on facilitators, barriers, and suggestions for improvement. We then reviewed codes to identify broader themes and refined them to ensure no key aspects of the data were overlooked. Finally, we captured direct quotes to provide meaningful insights that are aligned with our study's aim. Participants did not provide feedback on our findings.

Mixed Methods Integration

Following the explanatory sequential mixed methods design, quantitative and qualitative findings were integrated during the interpretation phase to provide a comprehensive understanding of HealthScore's intervention effectiveness. Integration involved comparing quantitative physical activity outcomes (eg, step counts) with qualitative themes. This integration aimed to explain how and why the intervention achieved its quantitative outcomes by examining participants' perspectives on program components, such as accountability and measurement tools. This integrated analysis facilitated a richer interpretation of the findings and leveraged the GRAMMS (Good Reporting of a Mixed Methods Study) checklist (Multimedia Appendix 4).

Ethical Considerations

The IRB (Institutional Review Board) of the UNC at Chapel Hill approved the study and its use of electronic consent (IRB number 20-0051). Consents were emailed and signed via UNC REDCap (Research Electronic Data Capture; Vanderbilt University). All study data complied with institutional guidelines and were deidentified. Participants provided written informed consent and received a US $20 gift card as compensation for returning questionnaires at each study milestone.

Results

Overview

There were 163 patients approached to participate in the HealthScore program (Figure 1). Of those, 53 consented, and 46 ultimately enrolled. Participants were randomized and stratified at the median of baseline PROMIS physical function scores of (45+ and <45). The final number of participants included 20 participants in the intervention group and 12 participants in the control group for a total of 32 participants (Figure 1). No adverse events related to exercise were noted.

XSL•FO

Figure 1. CONSORT (Consolidated Criteria for Reporting Qualitative Research) flow diagram.

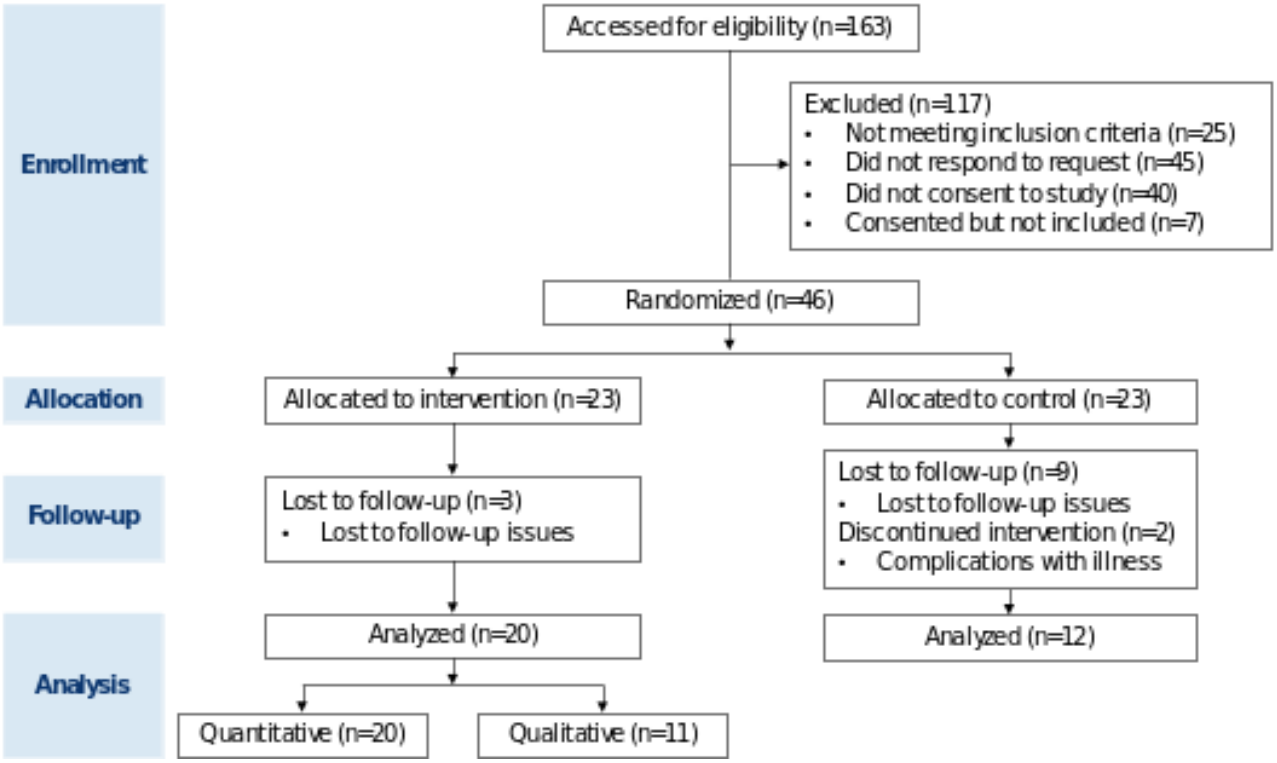

Table 1 provides participant demographics (N=32). Of the 20 intervention participants, 13 (65%) were female, 17 (85%) were Non-Hispanic White, and 11 (55%) were between 60 and 79 years old. Of 12 participants in the control group, 9 (75%) were female, 6 (50%) were White, 4 (33%) were between 40 and 59 years old, and 4 (33%) were between 60 and 79 years old. Baseline demographic data did not significantly differ between intervention and control participants (Table 1). Furthermore, within the intervention group, the participant demographics of the 11 interviewees were not significantly different from those of the other 9 intervention group participants. Multimedia Appendix 5 includes a demographics table specifically for the 11 interviewees.

Quantitative Results: Physical Activity

Participants in the intervention group had an overall average number of 3660 (SD 3344; 95% CI 3557-3764) daily steps, which was significantly more than participants in the control group, who had an overall average number of 3408 (SD 3288; 95% CI 3299-3518; t_{7476}=3.3; *P*=.001) daily steps. The comparison of weekly moving averages showed similar results. The weekly moving average step count of participants in the intervention group was 4813 (SD 1723; 95% CI 4680-4946), which was significantly more than that of the control group 4581 (SD 1224; 95% CI 4494-4669; t_{1400}=2.9; *P*=.003). Weekly moving average step counts in the intervention arm showed an increasing trend as the study progressed, with a regression slope parameter of 5.89 (*P*<.001). In contrast, the control weekly average step counts increased with a regression slope parameter of 2.80 (*P*<.001) but at a lower rate than the intervention arm. The slope of the line of best fit of the intervention group is steeper than that of the control group (Figure 2).

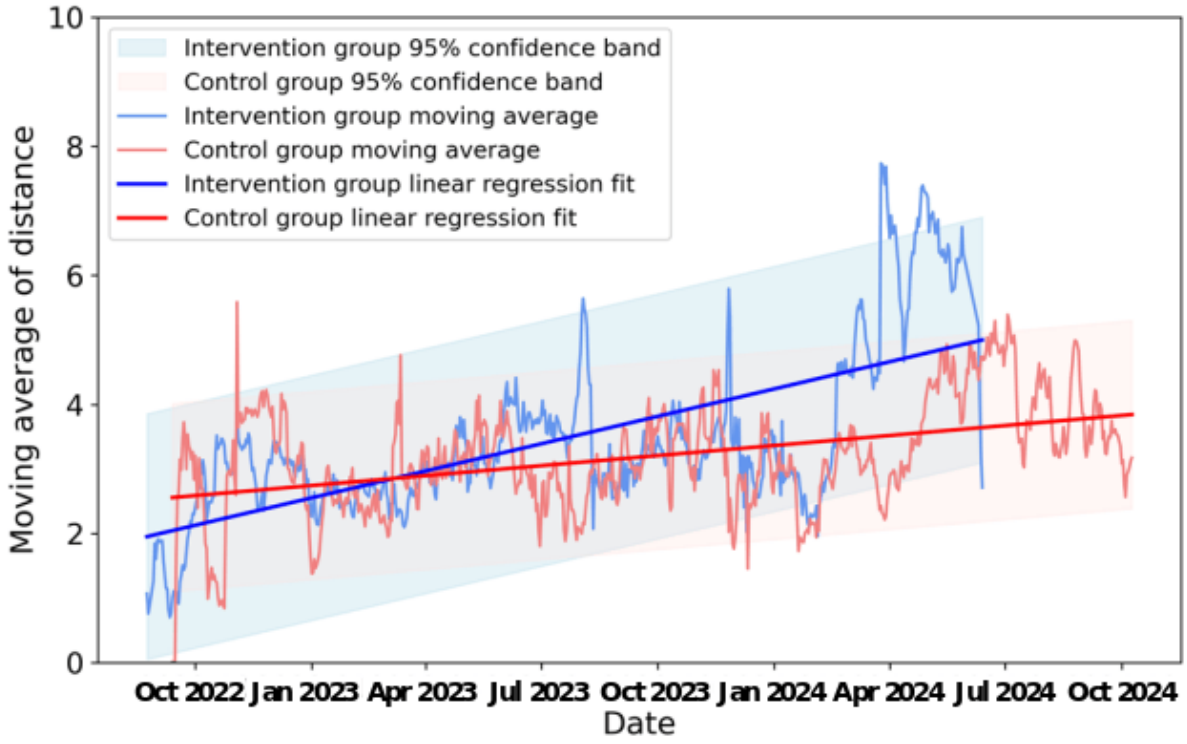

Figure 2. Linear regression of the weekly moving average steps over date per participant.

For the daily walking distance, intervention participants had an overall average daily walking distance of 2.6 (SD 2.5*;* 95% CI 2.5-2.7) miles, which was significantly more than control participants, who had a weekly average of daily walking distance of 2.4 (SD 2.3; 95% CI 2.3-2.5; t_{7476}=3.8; *P*<.001) miles. The comparison of the weekly moving average showed similar results. The weekly moving average walking distance of intervention participants was 3.5 (SD 1.3; 95% CI 3.4-3.6) miles, which was significantly more than that of control participants, 3.2 (SD 0.8; 95% CI 3.1-3.3; t_{1400}=4.6; *P*<.001) miles. Weekly moving average walking distances among intervention participants increased, with a regression slope parameter equal to 0.0046 (*P*<.001). In contrast, though the weekly average of daily walking distances also increased for controls, the regression slope parameter was smaller than that of the intervention group, less than half of that, at 0.0017 (*P*<.001). The slope of the line of best fit of the intervention group is steeper than that of the control group (Figure 3). Thus, walking distances of the intervention participants showed greater increases than those of the controls.

XSL•FO
RenderX

Figure 3. Linear regression of the weekly moving average of walking distance over date per participant.

Qualitative Results

Participant Perspectives of the HealthScore Intervention

The inductive coding and analysis of 11 intervention participant interviews revealed 3 major thematic areas, including facilitators and barriers to participant engagement and program improvement. Each theme and subtheme was supported by multiple participant quotes, and thematic saturation was achieved after coding 6 interviews, as no new codes emerged in subsequent interviews (Table 2).

XSL•FO
RenderX

Table 2. Qualitative excerpts about the facilitators, barriers, and areas for improvement of the HealthScore from participants in the intervention group.

Major theme and subtheme	Representative quote
Facilitators	
Relationship with coach	• "[The health coach] and I talked a lot about my goals each week: what went well, what didn't go as well. And she would help me reflect on how I was doing which was really helpful. She helped me move forward." (F[a], 50-64)
Accountability via weekly calls	• "It's hard to feel motivated when you are sick, so having someone to talk to every week was really beneficial." (F, 50-64)
Increased physical function	• "It really helped me increase it. It was an inspiration to move, to get to the gym, to exercise. It definitely helped." (F, 65+)
Improved self-efficacy or QoL[b]	• "The more exercise you get, the more positive your attitude is, the more positive your attitude is the more chance you have to live longer." (F, 50-64) • "The cancer might get me, but at least I will die healthy!" (F, 65+)
Barriers	
Ineffective survey tool	• "Questions are always the same on the survey, which might not be great, and they are vague. 'In the last 7 days..' was hard to remember. Run 3 miles question is never going to happen." (M[c], 65+)
Lack of caregiver involvement	• "For them to learn to meet you where you are and to understand that more. Having caregivers learn how to release their expectations of what you need to do and not to push their own desires onto your experience." (F, 65+)
HealthScore metrics are not comprehensive	• "My symptoms were not addressed by the program- I talked to Bri (Health Coach) about my symptoms." (F, 50-64)
More attention on topics outside of physical activity	• "Diet- especially for diet with a compromised immune system. Being coached on nutrition- what is/isn't the best foods to eat, what helps your system regain immunity and strength." (F, 65+)
Areas for improvement	
Survey improvement	• "Some of the questions were redundant. The redundancy made me question my answers. Some of those questions could be removed." (F, 50-64) • "Let us tell you how we're feeling and what would help us, especially if we don't have a counselor. More of a mental component to the program might be helpful for some people who are struggling more with their cancer." (F, 50-64)
Caregiver support	• ".. husband could have used some mental support. Some caregivers might need physical and mental support. They will have different needs. Meet the caregiver where they are at and be able to answer questions for the caregiver because they are going to have a lot of questions..." (F, 50-64)
HealthScore metrics	• "Disappointed that I used the bike a lot and it didn't pick up a lot of steps." (M, 65+)

[a]F: female.

[b]QoL: quality of life.

[c]M: Male.

Facilitators

Patients reported that maintaining a strong positive relationship with the coaches and the weekly coaching calls were key facilitators that enabled them to establish accountability. Many patients expressed their appreciation for the encouragement and empathy they received from the coaches, which facilitated the patient-coach connections and openness. The rapport established enabled the coaches to guide participants to achieve success by reframing setbacks, shifting mindsets, and achieving SMART goals. Personal connection and trust enhanced patients' engagement more during the weekly check-ins, fostering accountability and contributing to overall success.

Patients voiced that Fitbit tracking and goal setting facilitated consistency of participation and adherence to health goals. Patients reported increased levels of physical activity, often making progress toward pretreatment levels and improved QOL. Many patients expressed eagerness to continue goal setting, exercise, and FitBit tracking beyond the conclusion of the study

XSL•FO
RenderX

period. This sustained interest reflects an improvement in their confidence to manage their own health and well-being without their coaches, indicating an improvement in self-efficacy.

Additionally, patients reported improved communication with their care teams, which enabled them to be more proactive in managing their symptoms. They felt more confident in expressing their concerns clearly and seeking help early.

Barriers

Some patients expressed that the survey tool, which primarily focused on symptoms and physical function, was ineffective in capturing the progress they observed through their Fitbits. Many participants reported frustration at having to complete weekly surveys, which they felt were tedious and repetitive. Some patients felt that specific survey questions provided led to the setting of unrealistic goals and feelings of discouragement. Completing the survey at the end of each week also posed a challenge, as some struggled to recall their weekly progress accurately. Since the surveys directly impacted the HealthScore metrics, patients felt that regularly displaying the HealthScore (physical function measure) during the study could have negatively affected their motivation. Additionally, participants expressed a preference for coaching with a focus on their personal needs, such as mental health, nutrition, and weight management.

One idea that some patients noted was that involving a family or friend caregiver in the coaching sessions could be an additional component to the program, with additional implications. Some noted that the program could be adapted to allow for shared goal-setting across patients and caregivers, which may benefit both members. Others expressed concern about placing an additional burden on their caregivers.

Areas for Improvement

Patients identified scope for improvement in the weekly surveys, HealthScore metrics, caregiver involvement, and customized coaching topics. They felt that the surveys needed to be revisited and adapted to better capture the progress they were making. They suggested the incorporation of the Fitbit data (step count, heart rate, and sleeping pattern) into the HealthScore Metric to provide a more accurate and comprehensive reflection of their progress.

Most patients perceived that there is a significant potential for this program to improve caregiver support by offering tailored resources, information, and services that address their caregiver responsibilities as well as their own physical and emotional well-being. Some patients believe that by providing the resources, tools, and services that alleviate caregiver burden, the program has the potential to improve caregiver HRQOL and ultimately the support they can provide to patients. Additionally, participants also perceived that caregiver support can be improved through the program by supporting the physical and mental well-being of their caregivers.

Some patients also identified ideas for personalizing the program by including additional health coaching topics, such as nutrition, sleep, weight management, and mental health. The program could also be improved by enhancing the referral process to other community-based resources and services.

Integrated Mixed Methods Findings

The integration of quantitative physical activity data with qualitative interview themes revealed explanatory insights into the findings of the intervention group. Quantitatively, the findings demonstrated that intervention participants achieved significantly higher average daily step counts and daily walking distances compared to the control group, with steeper increases over time. Our qualitative analysis explained these improvements through specific program facilitators (eg, weekly coaching calls or growth in self-efficacy). However, this analysis also revealed a disparity in quantitative outcomes and participant experiences. While physical activity metrics improved overall, participants expressed frustration with the weekly PRO surveys, as they felt they were not aligned with their Fitbit-captured progress. Moreover, participants desired additional coaching in areas outside physical activity (eg, nutrition and sleep), topics not captured quantitatively but perceived as integral to their overall recovery and well-being.

Discussion

Principal Findings

We conducted a secondary analysis of a randomized controlled pilot study of cancer survivors who participated in a novel telehealth-based coaching program called HealthScore [24]. We found that participants in the intervention group had significantly higher physical activity than participants in the control group. Average daily step counts and average daily walking distance in the intervention participants were both significantly more than those of control participants and increased over the course of the 6-month intervention more than twice that of control participants. The integration of quantitative and qualitative findings revealed that these improvements were driven by enhanced accountability through weekly coaching relationships and increased self-efficacy, although the measurement tools themselves presented barriers that may have affected some participants' motivation. Our findings underscore the potential effectiveness of the HealthScore coaching program in enhancing physical activity levels among cancer survivors.

The combination of personalized coaching and physiologically based PGHD positions HealthScore as a robust approach to overcoming barriers associated with physical inactivity among cancer survivors. Our findings demonstrate patterns resonant with those in similarly designed health coaching interventions tested in cancer survivors [19,20], align with existing literature on the benefits of structured health coaching, and affirm that tailored interventions can significantly impact exercise adherence [36,37]. However, the sustained engagement via weekly sessions allowed participants to set realistic SMART goals and receive ongoing support, fostering an environment conducive to behavior change, which was praised by participants as an effective design for the coaching program. Moreover, the inclusion of motivational interviewing techniques proved beneficial in empowering participants, fostering autonomy, and addressing intrinsic barriers, such as anxiety and depression.

XSL•FO
RenderX

Qualitatively, participants indicated a growing sense of accountability and motivation throughout the program duration. Many expressed that the regular weekly check-ins with their health coaches provided essential encouragement and instilled a sense of connection, which is critical for cancer survivors who often experience feelings of isolation [38,39]. Participants recognized improvements in their physical capabilities and reported enhanced emotional well-being, highlighting the multifaceted benefits of the HealthScore program.

Key barriers identified by participants included aspects of the weekly monitoring PRO surveys, which were focused on symptoms and physical function. Participants felt that the surveys did not accurately capture their progress, which led to frustration with the tedious and repetitive nature of these assessments. This finding is congruent with prior literature showing survey fatigue as a common pain point in cancer health services research [1,40]. Additionally, challenges in recalling weekly progress and the potential negative impact of the displayed HealthScore on motivation were noted. Prior research reported similar findings that using self-monitoring tools can negatively impact participants' motivation [41,42]. Potential solutions include motivational messages accompanied by positive statistics showing improvement over time or comparing the participant's activity to the overall performance of participants.

The mixed methods integration illuminated meaningful insights. For example, participants attributed their increased activity to enhanced accountability through weekly coaching calls and the relationships they had built. Additionally, participants experienced growth in self-efficacy as they internalized goal-setting practices and saw tangible progress via their Fitbit devices. However, identified barriers, such as survey fatigue, may help explain the variability in quantitative outcomes. The participants' frustration with repetitive surveys that failed to capture their perceived progress suggests that while objective metrics improved overall, the measurement tools themselves may have dampened motivation for some. Therefore, it is important to align measurement approaches that optimize participant engagement throughout a sustained trial, such as HealthScore. Our convergence of quantitative improvements with qualitative insights strengthens the findings and can inform recommendations for refinement of similar programs.

Future iterations of HealthScore, or other similar programs, will integrate feedback from participants to further streamline the program for improved user experience. As identified by participants, the number and length of monitoring surveys should be reduced to avoid survey fatigue by considering biweekly or monthly surveys. In addition, incorporating Fitbit data into HealthScore metrics and providing personalized, evidence-based guidelines around nutrition, sleep, and mental health could improve the intervention. Emerging technologies, including artificial intelligence, have the power to collect, analyze, and synthesize PGHD and to provide real-time information from trusted sources.

Comparison to Prior Work

Prior research underscores the importance of high-quality, standardized coaching programs, as previous studies have shown that intervention intensity and participant engagement are critical for effective behavior change [43-45]. These limitations can be mitigated by implementing user-centered design principles through design thinking methods, expanding and incorporating objective measures alongside self-reports, and ensuring consistent training for all health coaches, all of which could enhance the effectiveness of future health interventions for cancer survivors.

This study contributes to prior literature by exploring the effectiveness of a telehealth-based coaching program, HealthScore, specifically designed to enhance physical activity among cancer survivors. It integrates PGHD from Fitbit devices for objective assessments, uses a mixed methods approach to combine quantitative and qualitative insights, and emphasizes the importance of structured, personalized coaching sessions aligned with SMART goals. The rigorous training of health coaches in motivational interviewing further distinguishes this study, highlighting the importance of interpersonal support in behavioral change, thereby offering a comprehensive and modern perspective on improving health outcomes in cancer survivors.

Limitations and Future Directions

Some limitations are worth noting. First, the sample size, while adequate for preliminary analysis, may not fully represent the diversity of the patients with cancer and cancer survivors. Future studies should consider larger, more diverse cohorts to better understand the generalizability of HealthScore's findings across the cancer continuum. Second, longer follow-up periods could help ascertain the sustainability of physical activity levels beyond the intervention, as well as the long-term effects on overall health outcomes. Third, there was a significant attrition imbalance between the control and intervention groups. While this is likely attributed to the fact that the intervention group entailed more time demand, there may also have been reluctance to the increased accountability of having a health coach. Importantly, the imbalance may have influenced both the qualitative and quantitative findings. Fourth, there are some limitations inherent in secondary data analysis. The original trial was not powered to detect the specific outcomes examined here, and the relatively small, demographically homogeneous sample, coupled with reliance on volunteer coaches, constrains both generalizability and scalability. Fifth, we acknowledge the potential for selection bias given that participation relied on self-referral and that a substantial number of individuals were lost between screening and analysis. As a result, those who remained in the study may represent a more motivated or otherwise distinct subset of the broader population, which may limit the generalizability of our findings. Future research should examine the long-term effects and applicability across diverse cancer populations and equally sized groups.

Conclusion

The HealthScore telehealth coaching program shows promise in enhancing physical activity and QOL for cancer survivors. Personalized coaching and PGHD foster sustained engagement in exercise, overcoming common barriers. Participants reported increased motivation and adherence to regimens, highlighting the importance of tailored support for psychological and physical

XSL•FO
RenderX

challenges. Qualitative feedback indicated that the program's holistic approach improved participants' confidence in managing their health after treatment. Integrating telehealth coaching into standard care for cancer survivors might be possible once these findings are replicated in larger and more diverse cohorts to promote active lifestyles and better health outcomes.

Abstract

Background: Cognitive impairments, a prevalent quality-of-life concern in breast cancer (BC), are particularly pronounced in women having undergone adjuvant chemotherapy. These impairments—affecting executive function, attention, and processing speed—are often underdiagnosed, with no established treatments. Exercise is a potential intervention to mitigate cancer-related cognitive impairment (CRCI). Since virtual care delivery is feasible, remotely delivered exercise interventions for CRCI management in patients with BC may be explored.

Objective: We examined the feasibility of an 8-week remotely delivered combined exercise program (aerobic+resistance training) compared to a stretching and toning active control in postchemotherapy patients with BC.

Methods: Patients with BC who completed adjuvant chemotherapy within 48 months were recruited across Canada from February to July 2023. The combined exercise group engaged in unsupervised aerobic exercise (30 minutes, thrice per week), supervised group-based resistance training (30 minutes, twice per week via Zoom [Zoom Communications, Inc]), and one recorded class weekly, supplemented with 4 biweekly behavioral counseling sessions. The active control group participated in low-intensity balance and flexibility classes (30 minutes, twice per week live, once per week recorded). Feasibility was assessed via enrollment, adherence, attrition, measurement completion, adverse events, and participant satisfaction; cognitive function, using the National Institutes of Health Toolbox Cognition Battery Remote Administration (V2) at baseline and post intervention.

Results: Twenty-one participants (mean age 51.6, SD 7.2 years; 11.8, SD 12.9 months since treatment) were randomized to the combined exercise (n=10) or the active control (n=11) group. Final analyses included 18 participants (mean age 51.9, SD 7.4 years; mean months since treatment 12.6, SD 13.5) with 9 participants in each group (51.2% enrollment rate; 14.3% attrition; no adverse events). Measurement completion rates were 85.7% and participants reported high satisfaction with the intervention, indicating minimal burden. Adherence rates for exercise classes were 70.8% in both groups. Adherence to behavioral counseling sessions was 77.5% (combined exercise group only). There were no significant differences in objectively measured cognitive function, but small-to-medium effect size improvements were observed in objectively measured episodic memory (mean difference 5.33, 95% CI –12.5 to 23.2; ηp^2=0.03), working memory (mean difference 8.17, 95% CI –4.2 to 20.6; ηp^2=0.12), executive function updating (mean difference –394.35, 95% CI –1035.67 to 246.96 ms; ηp^2=0.07), and immediate memory and verbal learning (mean difference +3.22, 95% CI –2.0 to 8.5; ηp^2=0.12), trending toward the multicomponent exercise group vs the active

XSL•FO
RenderX

control group. In contrast, small-to-medium effect size improvements were observed in the Oral Reading Recognition Test (mean difference –9.65, 95% CI –22.9 to 3.5; *P*=.14; ηp^2=0.14) and Picture Vocabulary Test (mean difference –2.48, 95% CI –5.2 to 0.3, *P*=.07; ηp^2=0.20), trending toward the active control group.

Conclusions: A remotely delivered combined exercise intervention is feasible and may improve CRCI in patients with BC. Larger randomized controlled trials are warranted to confirm its efficacy in enhancing cognitive function and quality of life in this population.

KEYWORDS

cancer-related cognitive impairment; breast cancer; quality of life; exercise, feasibility study

Introduction

An increasing number of patients with breast cancer (BC) are experiencing chronic symptoms due to rising cancer incidence and improving survival rates [1]. Treatments, such as chemotherapy, radiation therapy, and hormone therapy, while effective at reducing mortality, are associated with many adverse side effects, including cognitive decline known as cancer-related cognitive impairment (CRCI) [2]. CRCI has been reported in up to 85% of patients with BC, lasting for months, years, and not uncommonly indefinitely following treatment completion [3]. CRCI manifests as problems with attention, processing speed, memory, and executive function and is most commonly reported following chemotherapy [4-6]. Chemotherapeutic drugs may have neurotoxic effects, leading to structural and functional changes in the brain [4,7-9]. Other chemotherapy-related side effects, such as fatigue, anxiety, depression, stress, and sleep dysfunction, may further degrade cognition in patients with BC [10,11]. These cognitive problems can significantly impair work performance, social relationships, and daily functioning, ultimately reducing quality of life (QoL) [12,13]. Despite the prevalence and significance of this problem, no established treatment has yet been identified to mitigate the adverse effects of CRCI on patients with BC [14].

Although the majority of evidence for CRCI in patients with BC is attributed to chemotherapy, one confounding aspect is the impact of aging and changes in menopausal status that result from chemotherapy-induced menopause and lowered levels of estradiol [15-17]. Case studies in patients with BC show that CRCI may vary in those who received the same course of chemotherapy, potentially due to differences in menopausal status [18]. Schilder et al [19] demonstrated that after one year of adjuvant therapy, tamoxifen use was associated with statistically significant lower functioning in verbal memory and executive functioning, whereas exemestane use was not associated with statistically significant lower cognitive functioning in postmenopausal patients with BC. Klemp et al [20] conducted a longitudinal study examining both subjective and objective measures of cognitive function and QoL in pre- and perimenopausal patients with BC receiving chemotherapy. Assessments were conducted prior to chemotherapy, after cycle 3, within 2-3 weeks of completing adjuvant chemotherapy, and more than 8+ years later. Neither age nor estradiol levels were associated with cognitive complaints. Vega et al [21] compared a group of primarily postmenopausal women with persistent CRCI to 2 groups of postmenopausal women: women who endorse menopause - associated subjective cognitive decline (maSCD+) and women who do not (maSCD−) to explore the potential role of menopause in CRCI. Women with persistent CRCI reported more severe subjective symptoms of cognitive decline, along with measurable differences in objective performance, compared to women who experienced natural menopause. In addition, women with persistent CRCI reported greater menopausal symptoms compared with the maSCD- group, but not the maSCD+ group. These findings were unrelated to menopausal status prior to chemotherapy or current endocrine therapy use. Although menopausal symptoms may contribute to some CRCI experienced by patients with BC, they do not fully account for CRCI. Future research is needed to determine the specific predictors and causal mechanisms for CRCI.

Implementing combined (aerobic+resistance training) exercise interventions could be a promising strategy to improve cognitive outcomes and reduce the impact of CRCI. Studies with older adults have demonstrated that combined exercise improves memory more than aerobic exercise alone by producing changes in brain structure, brain function, and brain connectivity [22,23]. Recent reviews indicate that exercise interventions, such as aerobic and combined aerobic-resistance training, may help improve cognitive function in patients with BC [3,24]. Across interventions, programs delivered 2-5 times per week for 10-60 minutes, or aerobic training combined with whole-body resistance, most consistently improved short-term self-reported cognition [3,24]. Another scoping review of 97 studies on physical activity (PA) and cognition among cancer survivors, primarily patients with BC, found that 32% of studies reported positive associations, 66% had inconclusive results, and only 2% showed negative associations, with cognition assessed using both objective and subjective measures [25]. While the review encompassed various study designs, including observational and interventional research, most interventions were delivered after, rather than during, chemotherapy. Complementing these findings, the recent ACTIVATE (Aerobic exercise and CogniTIVe functioning in women with breAsT cancEr) trial specifically examined the effects of aerobic exercise during chemotherapy, demonstrating significant improvements in self-reported cognitive function and QoL in women with BC, despite no significant effects on objective cognitive outcomes [26].

XSL•FO
RenderX

Despite growing interest in this area, findings remain preliminary with limited evidence derived from high-quality, adequately powered randomized controlled trials (RCTs) in patients with BC [3,24]. For example, a 3-arm RCT compared 16 weeks of concurrent aerobic-resistance exercise, continuous moderate-intensity aerobic exercise, and high-intensity interval training to usual care in 206 patients with BC following chemotherapy [27]. Immediately post intervention, the aerobic-resistance training group had no changes in self-reported cognitive function [27]. However, lower levels of cognitive cancer-related fatigue were noted at the 2-year follow-up in this group [28]. Nevertheless, the lack of data on the specific type and frequency of exercise during the follow-up period makes it challenging to attribute these improvements solely to the initial aerobic-resistance exercise intervention.

Meanwhile, many trials are limited to subjective measures of cognitive function and do not prioritize objective cognitive function as a primary outcome. While self-reported CRCI is correlated with mood and fatigue, the gold standard for measuring cognitive function, as developed by the International Cognition and Cancer Task Force (ICCTF), is objective tests of processing speed, memory, and executive function [6]. In practice, objective batteries are often relegated to secondary end points, and when included, they tend to show smaller or inconsistent effects compared with perceived cognition. For example, the recent ACTIVATE trial found improvements in self-reported cognitive function and QoL without parallel benefits on objective tests [26]. Similarly, Galiano-Castillo et al [29] conducted an RCT to test the effects of an 8-week remotely delivered combined exercise program on cognitive function for patients with BC. Following this program, improvements were found in short-term memory, measured by the recall of auditory consonant trigrams, but not mental flexibility, measured by Trail Making Test performance. While this study highlights the potential benefits of a remotely delivered combined exercise program on cognitive function, its primary focus was on physical functional capacity, with cognitive function evaluated as a secondary outcome [29]. Koevoets et al [30] examined the effects of a 6-month supervised combined exercise intervention on cognitive function for patients with BC exposed to chemotherapy. Beneficial intervention effects were found for secondary outcomes of self-reported cognitive function, fatigue, QoL, and depression, but not for the primary outcome of total recall measured by the Hopkins Verbal Learning Test-Revised, or other objective measures of cognitive function measured by the Amsterdam Cognition Scan [30].

Overall, key gaps were noted in the literature regarding exercise interventions, including limited understanding of the exercise dose needed to elicit cognitive benefits, insufficient attention to behavior change support required for maintaining long-term exercise engagement and reducing long-term CRCI [3,25,31,32], and a lack of remotely delivered exercise interventions. Moreover, inconsistent inclusion of patients with BC with self-reported CRCI following chemotherapy, absence of active comparators, and considerable heterogeneity in cognitive function measures are also notable gaps in the literature. Attention-matched or active comparators (eg, stretching and toning) are needed to isolate exercise effects and minimize bias [33-35]. Active control groups (receiving intervention during or after the intervention period) have lower contamination (ie, increasing exercise) and maintains participant engagement regardless of group assignment. This noncompliance may lead to decreased power to detect a significant intervention effect [34]. As such, the available evidence is insufficient for expert consensus to guide exercise recommendations for CRCI management and additional research is warranted.

Previous studies were conducted in person under supervised conditions, and little is known about remotely delivered combined exercise interventions. Patients with BC commonly report issues with transportation to fitness centers, weather constraints, and lack of accessibility as barriers to in person exercise [36]. Remotely delivered combined exercise programs have the potential to reduce these barriers and enhance reach and accessibility to patients with BC [29,37]. Preliminary evidence suggests that 10- to 16-week [28,38] supervised or 8-week [29] home-based combined exercise can improve self-reported cognitive function in patients with BC. Systematic reviews have also shown the effectiveness of remotely delivered exercise interventions in improving physical outcomes [39,40], with high adherence and satisfaction rates among patients with BC [41]. Therefore, there is a clear need for more rigorous neuropsychological testing to examine the effects of combined exercise on cognitive function in patients with BC, especially given the promising preliminary evidence supporting its benefits and the limited knowledge of remotely delivered interventions [28,29,38].

The primary purpose of this study was to assess the feasibility of an 8-week, remotely delivered, combined exercise intervention (aerobic+resistance training) on cognitive function in patients with BC following chemotherapy. Feasibility indicators included enrollment rates, adherence (defined as maintaining an exercise rate of ≥70%), attrition rates (<30%), adverse events, participant satisfaction, and feedback. It was hypothesized that the trial would meet the following a priori feasibility indicators, including an adherence rate 70%, an attrition rate <30% [42-44], and that no adverse events or major injuries would occur as a result of the combined exercise intervention. We also predicted that the combined exercise group would result in significantly greater improvements in objective measures of attention, executive function, and memory (secondary outcomes) compared to the active control group at post intervention (8 weeks), with sustained exercise.

Methods

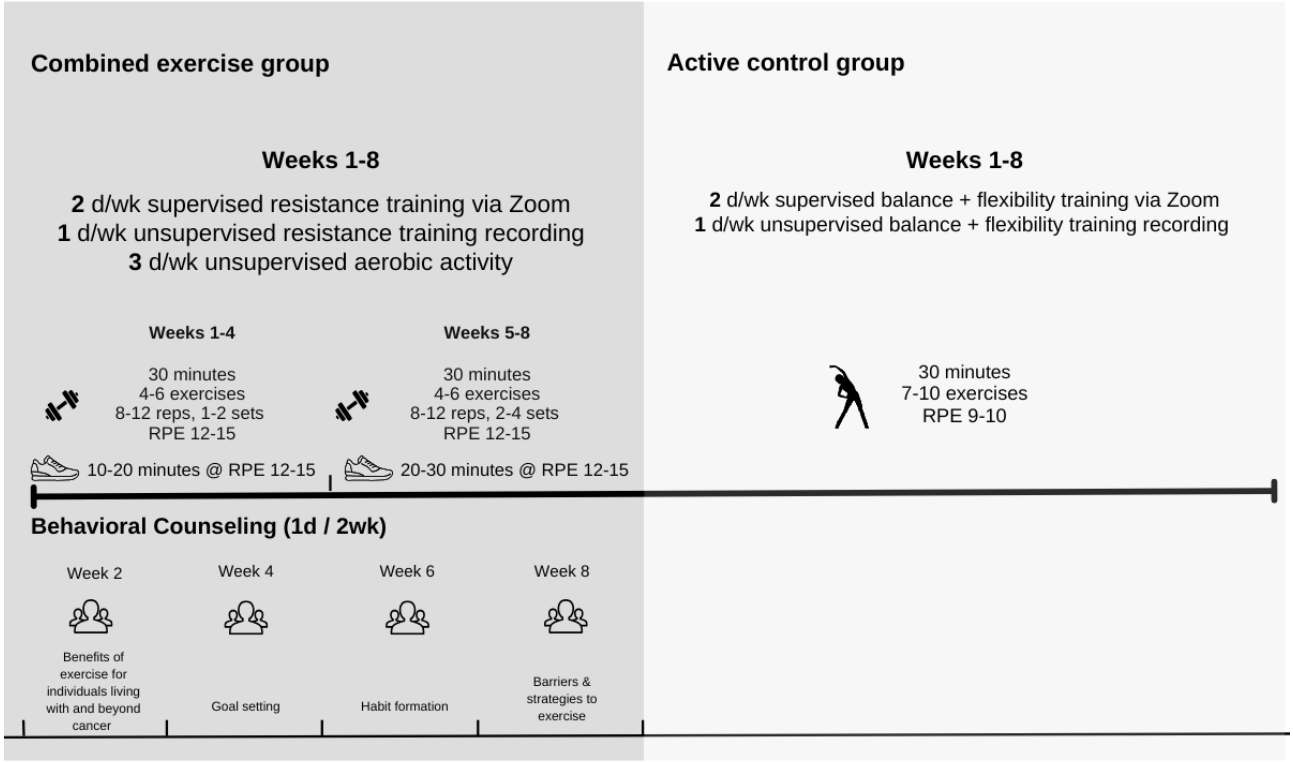
Study Design

This 2-armed, parallel-design pilot RCT evaluated the effects of an 8-week, remotely delivered combined (aerobic + resistance training) exercise program compared to an active control group. Participants were randomized in a 1:1 allocation ratio. Reporting of the trial outcomes followed the CONSORT-eHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth; Multimedia Appendix 1) 2011 guidelines [45,46].

XSL•FO
RenderX

Participants

Participants were recruited from cancer care organizations, support groups, university listserves, an existing database of research individuals who participated in prior research studies in the laboratory, and social media advertisements (ie, Facebook [Meta Platforms, Inc], Instagram [Meta Platforms, Inc], and X [X Corp]) across Canada between February and July 2023. Eligibility criteria included (1) 40-65 years of age, (2) a history of stage I-III BC (nonmetastatic), (3) a history of receiving chemotherapy within 48 months prior to enrollment, (4) mild cognitive impairment as determined by the Modified Telephone Interview of Cognitive Status (TICS-M) [scores between 21 and 24 to separate individuals with mild cognitive impairment and normal cognition (>24)] [47], (5) self-reported low-activity, defined as <3 days of exercise (<20 min/d) per week in the previous 6 months [48], (6) physician clearance to participate in exercise if required, (7) no previous invasive cancer, (8) no neurological or musculoskeletal comorbidity inhibiting exercise, (9) access to a webcam and internet for videoconferencing, and (10) fluency in English. Participants who were interested in the study contacted the study team to schedule a screening call to further assess their eligibility. Additionally, participants were asked to provide their tentative availability for attending 2 live, remotely delivered classes each week.



Randomization and Blinding

Eligible participants were randomized in a 1:1 ratio to either the combined exercise group or the active control group using REDCap (Research Electronic Data Capture; Vanderbilt University) [49,50] by a graduate research assistant (NC). Randomization was conducted upon completion of the informed consent form, all baseline measures (ie, PA) assessment, and a battery of questionnaires. Participants were blinded to the study hypotheses and were only informed of their assigned group. Outcome assessors were kept blinded to the allocation.

Intervention

Participants in both groups participated in an 8-week, remotely delivered, supervised exercise program conducted via videoconferencing (Zoom [Zoom Communications, Inc]). The program consisted of two 30-minute live sessions and one 30-minute recorded session per week (Figure 1). Recorded sessions aligned with live classes to maintain consistency and allowed for individualized adjustments. All live sessions were led by Qualified Exercise Professionals (QEPs) certified as Registered Kinesiologists or through the American College of Sports Medicine (ACSM) or Canadian Society of Exercise Physiologists (CSEP). Participants were encouraged to keep their cameras on during live sessions to facilitate safety monitoring and provide real-time exercise modifications.

Figure 1. Combined exercise group.

XSL•FO
RenderX

Participants received resistance bands, a Fitbit Inspire 2 heart rate (HR) monitor, and an exercise log. The program included 30 minutes of unsupervised aerobic exercise (eg, walking) 3 times per week, gradually increasing intensity and duration from 40% to 59% of the maximum HR reserve initially to 60%-70% by the end of the program. The program also included 30-minute supervised resistance training sessions 2 times per week. Resistance training focused on major muscle groups using 2-3 sets of 8-12 repetitions at a Rating of Perceived Exertion (RPE) of 12-15, progressively adjusted with stronger resistance bands. A 30-60 second rest was provided between sets and 60 seconds between exercises, during which the QEP demonstrated the next exercise and offered modifications. Participants recorded their HR and RPE in exercise logs after each session. Participants also attended 4 remotely delivered, biweekly, 30-minute behavioral counseling sessions based on the multi-process action control (M-PAC) framework, emphasizing goal-setting, habit formation, and behavioral control to support long-term PA (Table 1 [51-54]).

Table 1. Overview of biweekly behavioral counseling sessions in the combined exercise group.

Week	Topic	Description
2	Benefits of exercise for individuals living with and beyond cancer	Participants learned about the exercise guidelines for general health benefits and the cancer-specific exercise guidelines. Participants were invited to share their meaning of the term "exercise" and some of the exercises they have engaged in or would like to engage in.
4	Goal setting	Participants learned about the importance of goal setting, the difference between short- and long-term goals, SMART[a] goals, and intrinsic and extrinsic rewards. Participants created and discussed their short- and long-term SMART goals and their prospective intrinsic and extrinsic rewards. Participants were invited to share their responses with the group.
6	Habit formation	Participants learned about habits and how to develop PA[b] habits, including "tagging" activities to existing environmental cues and creating "cues to action." Participants brainstormed ideas for creating PA habits using environmental cues that exist within their work and nonworkdays. Participants were invited to share their responses with the group.
8	Barriers and strategies to exercise	Participants learned about cancer-specific barriers and facilitators to exercise. In addition, participants were provided with solutions that may help them overcome some of the barriers to PA. Participants were reminded of past behavioral counseling sessions (ie, revisiting SMART goals and habit formation). Participants applied these concepts into practice by creating a new SMART goal and reward, identifying an environmental cue that will trigger the behavior, and a strategy to overcome any barriers that may arise (or arose) that may get in the way of completing this goal. Participants were invited to share their responses with the group.

[a]SMART: specific, measurable, achievable, relevant, and time-bound.

[b]PA: physical activity.

Active Control Group

The active control group participated in a low-intensity, whole-body stretching and toning program designed to improve balance and flexibility. Exercises targeted major muscle groups potentially affected by cancer treatments, such as steroid use, radiation therapy, or surgery [55]. Flexibility exercises, incorporating both static and dynamic movements, were introduced weekly to maintain engagement and progress using resistance bands. Intensity was maintained at a light level (RPE 9-10) [56]. Participants recorded their HR (using Fitbit devices) and RPE in exercise logs after each session.

Measures

Primary Outcome: Feasibility

Feasibility was assessed by evaluating the enrollment, adherence (ie, attendance and exercise prescription adherence), attrition rates, measurement completion rates, adverse events, program satisfaction, and therapeutic alliance with the QEP. The enrollment rate was determined by the percentage of participants assessed for eligibility who subsequently enrolled. Attendance was expressed as a percentage of exercise sessions attended. Exercise prescription adherence was determined by assessing self-reported RPE and Fitbit Inspire 2-measured HR during each exercise session. Attrition was measured as the percentage of participants who did not complete the intervention. Participants completed a patient satisfaction and therapeutic alliance questionnaire following the 8-week intervention. The Working Alliance Inventory Short Revised (WAI-SR) [57,58] was used to assess therapeutic alliance, with higher scores representing better therapeutic alliance. Closed-ended questions with response options on a 7-point Likert scale ranging from 1 (not at all) to 7 (very much) were used.

Secondary Outcomes

Objectively Measured Cognitive Outcomes

Cognitive function was assessed at baseline and post intervention using the remotely administered National Institutes of Health (NIH) Toolbox Cognition Battery (v2), a validated tool with minimal practice effects comparable to other widely used gold-standard cognitive measures [59,60]. The NIH Toolbox Cognition Battery included 4 tests: the Picture Vocabulary Test, which assessed language and vocabulary knowledge; the Picture Sequence Memory Test, which measured

XSL•FO
RenderX

episodic memory; the List Sort Working Memory Test, which evaluated working memory and executive function updating; and the Auditory Verbal Learning Test, which assessed immediate memory and verbal learning [59,60]. A supplementary measure of executive function shifting—a domain frequently impaired in BC survivors treated with chemotherapy [14,61]—was measured using the PsyToolkit software platform (Gijsbert Stoet) to administer Task Switching cognitive test [62,63].

All cognitive assessments were administered remotely via Zoom at both time points through a shared iPad (9.7" iPad 2; Apple) screen in a quiet, distraction-free room, with each session lasting about 45 minutes. The examiner completed the remote administration training protocol [64] under the guidance of researchers with expertise in cognitive psychology (AFK and JDR). To ensure standardized administration across participants, a single examiner conducted all assessments through screen-sharing to monitor participants and their responses in real-time.

Device-based exercise minutes were measured at baseline and post intervention with ActiGraph GTX3+ accelerometers. Participants wore the accelerometer on their nondominant hip during waking hours for 7 consecutive days. Data were analyzed if there were no extreme counts (> 20,000) and if participants had at least 10 valid hours of wear time on 4 or more days. Data were downloaded in 60-second epochs, processed, and converted to mean counts per minute in the ActiLife software package (v6.13.5; ActiGraph). These counts were used to estimate daily minutes of light (101-1951 counts min^{-1}), moderate (1952-5724 counts min^{-1}), vigorous (≥5725 counts min^{-1}), and total moderate-to-vigorous intensity exercise (≥1952 counts min^{-1}) based on established cut points [65]. Further, weekly minutes spent in each exercise intensity category were calculated and presented.

Demographic and Clinical Information

Demographic and clinical information were collected at baseline using a self-reported standardized health history questionnaire used in previous studies [44,66,67]. Demographic variables included age, marital status, education, employment, ethnicity, smoking, and alcohol use. Clinical information included months since diagnosis, months since treatment, type of cancer treatment received, current cancer status, and general health status. Additional data on comorbidities, such as high blood pressure, high cholesterol, diabetes, and arthritis, were also obtained.

Data Analyses

Data analyses were performed using IBM SPSS Statistics (version 29). As this was a feasibility study, an a priori power calculation was not performed [68,69]. Descriptive statistics (ie, means and SDs) characterized the sample for demographic, clinical, and feasibility outcomes. z-scores were used to identify any outliers in the field. Analyses of covariance (ANCOVA) were used to assess both primary and secondary outcomes of the study. The dependent variable was the mean difference of each intervention outcome (ie, the difference between post- and preintervention scores), while the independent variable was the group (ie, combined exercise or active control). All analyses were conducted while controlling for the baseline values of each outcome. All analyses were conducted on an intention-to-treat basis. Given that the purpose of this feasibility trial was to inform a larger RCT, outcomes were interpreted for potential clinical significance based on the direction and magnitude of numerical differences. Partial eta squared (ηp^2) values were reported to describe the observed effect sizes.

Ethical Considerations

The trial protocol was approved by the Research Ethics Board at the University of Toronto (number 43675), and all participants provided written informed consent. Participant privacy and confidentiality were strictly maintained throughout the study; all data were deidentified and stored on secure, password-protected servers accessible only to authorized research personnel, in accordance with institutional and ethical guidelines. Participants received a total of $20 CAD compensation, plus a Fitbit Inspire 2 for their time and participation, consistent with the approved ethics protocol.

Results

Sample Characteristics

Demographic and clinical characteristics of the participants are summarized in Table 2. Overall, all participants were women (21/21, 100%), predominantly White (16/21, 76%), with an average age of 51.9 (SD 7.2) years. The majority were married (17/21, 81%), some had completed university or college (10/21, 48%), and many were employed full-time (13/21, 62%). All participants had chemotherapy and were, on average, 22.9 (SD 13.9) months post diagnosis and 11.8 (SD 12.9) months post treatment. Regarding weekly exercise minutes, participants engaged in 149.4 (SD 96.1) moderate-to-vigorous intensity exercise minutes per week.

Total moderate-to-vigorous intensity	149.4 (96.1)

Feasibility Outcomes

Participant flowchart is presented in Figure 2. Feasibility outcomes are summarized in Table 3. Of the 41 women who responded to the invitation, 22 were eligible, and 21 consented to be randomized into either the combined exercise group (aerobic+resistance training; n=10) or the active control group (balance and flexibility; n=11), representing a 51.2% enrollment rate. Participants were divided into two cohorts: (1) the first cohort (n=11) began in May 2023, and (2) the second cohort (n=10) began in July 2023. The sample size aligns with previous research on feasibility and group cohesion for counseling programs for patients with BC [70,71]. Overall, 18 participants completed the 8-week intervention. Three participants withdrew after randomization, but before starting the intervention for reasons, including a change in BC treatment plan (n=1), an issue with the timing of the programming and their schedule (n=1), and a change of interest in participating (n=1). An intention-to-treat analysis was conducted, and therefore adherence was calculated based on attendance and included the dropouts (n=3), since they were enrolled and randomized at the start of the intervention. Consequently, the attrition rate was 14.3%. For the ANCOVA analyses, a complete case analysis was applied (n=18).

Table 3. Feasibility and acceptability outcomes.

Feasibility variables	Definition	Adherence and completion, n/N (%)
Enrollment rate	Consented and randomized divided those invited	21/41 (51.2)
Attendance adherence (exercise sessions)	Attendance rate in exercise sessions	34/48 (70.8)
Attendance adherence (counseling sessions)[a]	Attendance rate in counseling sessions	31/40 (77.5)
Adverse events	Number of adverse events reported	0/0 (0)
Participant satisfaction questionnaire	Completion rate	18/21 (85.7)
Working Alliance Inventory	Completion rate	17/21 (81)
Remotely delivered NIH[b] Toolbox Cognition Battery	Completion rate	18/21 (85.7)
PsyToolkit executive function test	Completion rate	17/21 (81)
Accelerometer wear compliance	Met wear-time criteria rate	14/21 (66.7)
Attrition	Dropouts after randomization	3/21 (14.3)

[a]Counseling sessions based on the multi-process action control were delivered only to participants assigned to the combined exercise group.

[a]NIH: National Institutes of Health.

XSL•FO
RenderX

Attendance adherence (Table 3) rate for the remotely delivered, combined exercise classes was 70.8% (17/24) and 77.5% (3/4) for behavioral counseling sessions based on the M-PAC that was delivered only to those in the combined exercise group (n=10). Attendance adherence for the active control group was 70.8% (17/24). Participants in the combined exercise group who completed the intervention and postintervention measures (n=9) reported an average RPE of 12.8 and a HR of 111.8 during the resistance training classes. This corresponds to a moderate-intensity RPE and an HR within the light-moderate target HR zone. In addition, participants in the combined exercise intervention (n=9) reported a mean RPE of 12.2 and a mean HR of 119.7 during the unsupervised aerobic (ie, walking) sessions, which corresponds to moderate-intensity RPE and a HR within the moderate-intensity target HR zone. Participants in the active control group who completed the intervention and postintervention measures (ie, including the exercise log; n=8) reported a mean RPE of 11.1 and a mean HR of 85.5 during their balance and flexibility program, which corresponds to a light-moderate intensity RPE and light-intensity target HR zone. There were no adverse events during the intervention in either group. The measurement completion rates for the study were as follows: 85.7% (18/21) for the participant satisfaction questionnaire and 81% (17/21) for the Working Alliance Inventory. For objectively measured cognitive function, completion rates were 85.7% (18/21) for the memory test and 81% (17/21) for the executive function test. Additionally, accelerometer wear compliance was achieved by 66.7% (14/21) of participants.

Participant responses regarding program satisfaction are summarized in Tables 4 and 5. Overall, participants reported high satisfaction with the intervention. The majority of participants (17/18, 94.4%) agreed or strongly agreed that the program was rewarding and appreciated the virtual delivery format. Most participants (15/18, 83.3%) agreed or strongly agreed that the intervention helped them increase their PA levels, and 77.7% (14/18) indicated that they would recommend the program to other patients with BC. Most participants found the intervention beneficial, and participants 62.5%) agreed or strongly agreed that the behavioral counseling sessions were personally useful. Similarly, 61.1% of participants agreed or strongly agreed that the intervention was not burdensome.

Table 4. Satisfaction scores from the participant satisfaction questionnaire in patients with breast cancer at post intervention (ie, 8 weeks; n=18).

Variable	Value, mean (SD)	Strongly agree and agree (%)
Overall intervention participation		
I found the exercise intervention rewarding.	4.6 (0.6)	94.4
I enjoyed the virtual delivery of the exercise intervention.	4.6 (0.6)	94.4
The exercise intervention helped me to increase my physical activity levels.	4.0 (1.1)	83.3
The exercise intervention helped me to increase my overall fitness.	3.9 (1.1)	72.2
The behavioral counseling sessions were useful for me personally.	3.1 (1.5)	62.5
I am more confident in my goal-setting and coping abilities after participating in the intervention.	3.7 (1.1)	61.1
The research study was useful for me personally.	3.7 (1.0)	83.3
I would recommend the exercise intervention to other patients with breast cancer.	4.2 (0.7)	77.7

Table 5. Burden scores from the participant satisfaction questionnaire in patients with breast cancer at post intervention (ie, 8 weeks; n=18).

Burden	Value, mean (SD)	Strongly disagree and disagree (%)
The exercise intervention was a waste of time.	1.8 (1.3)	83.3
The behavioral counseling sessions were a waste of time.	2.3 (1.5)	75.0
The questionnaires were a burden.	2.3 (1.2)	61.1
The neurological assessments (iPad cognition tests) were a burden.	2.1 (1.1)	77.8
The 3-times weekly exercise class was a burden.	2.1 (0.9)	77.8
It was difficult to participate in the exercise classes because of cancer or chemotherapy-related side effects.	2.5 (1.3)	55.6

Participant responses on the WAI-SR are summarized in Table 6. Overall, participants reported positive perceptions of their alliance with the QEP. Most (16/18, 88.2%) indicated that they very often or always felt mutual respect, and a substantial majority (14/18, 76.5%) felt appreciated and cared for.

XSL•FO
RenderX

Table 6. Working alliance inventory-short revised scores in patients with breast cancer post intervention (ie, 8 weeks; n=17)[a].

Variable	Value, mean (SD)	Very often or always (%)
As a result of these sessions, I am clearer as to how I might be able to change.	2.9 (1.2)	35.3
What I am doing in therapy gives me new ways of looking at my problem.	3.2 (1.3)	41.2
I believe [INSTRUCTOR] likes me.	4.1 (0.8)	70.6
[INSTRUCTOR] and I collaborate on setting goals for my therapy.	2.9 (1.4)	35.3
[INSTRUCTOR] and I respect each other.	4.5 (0.7)	88.2
[INSTRUCTOR] and I are working towards mutually agreed upon goals.	3.2 (1.2)	47.1
I feel that [INSTRUCTOR] appreciates me.	4.2 (0.9)	76.5
[INSTRUCTOR] and I agree on what is important for me to work on.	3.2 (1.2)	35.3
I believe the way we are working with my problem is correct.	3.7 (1.3)	64.7
I feel that the things I do in therapy will help me to accomplish the changes that I want.	3.6 (1.3)	64.7
[INSTRUCTOR] and I have established a good understanding of the kind of changes that would be good for me.	3.1 (1.5)	41.2
I feel [INSTRUCTOR] cares about me even when I do things that he/she does not approve of.	4.2 (0.9)	76.5

[a]Participants rated items on a 5-point Likert scale, where 1=seldom, 2=sometimes, 3=fairly often, 4=very often, and 5=always. Participants were told to replace the term “therapy” with “exercise program” when thinking about their responses to each item.

Objectively Measured Cognitive Outcomes

Changes in objectively measured cognitive function scores from baseline to post intervention for the combined exercise group vs the active control group are presented in Table 7. There were no statistical differences in objectively measured cognitive function in the combined exercise group compared to the active control group. However, adjusted group mean differences trending toward the combined exercise group were observed in the scores for the Picture Sequence Memory Task (mean difference +5.33, 95% CI –12.5 to 23.2; ηp^2=0.03), List Sorting Working Memory Test (mean difference +8.17, 95% CI –4.2 to 20.6; ηp^2=0.12), and Auditory Verbal Learning (mean difference +3.22, 95% CI –2.0 to 8.5; ηp^2=0.12). Table 7 also shows the 4 cognition outcomes from the PsyToolkit: repeat trial time (ms), switch trial time (ms), repeat trials correct (%), and switch trials correct (%). No significant differences were found between the combined exercise group compared to the active control group. However, a reduction in repeat trial time trended toward the combined exercise group (mean difference –146.14, 95% CI 420.87 to128.59 ms; ηp^2=0.04). Likewise, a greater decrease in the switch trial time trended toward the combined exercise group (mean difference –394.35, 95% CI –1035.67 to 246.96 ms; ηp^2=0.07) compared to the control group (mean difference –124.39 95% CI –522.06 to 273.27 ms; ηp^2=0.07). For accuracy, improvements in repeat trials correct (mean difference +4.86%, 95% CI –0.61 to 10.36; ηp^2=0.02) and switch trials correct (mean difference +19.70%, –0.30 to 39.70; ηp^2=0.02) also trended towards the combined exercise group, while the control group exhibited decreases in these measures.

Switch trials reaction time (ms)				.34	0.07
Combined exercise (n=9)	2268.51 (205.67)	1874.16 (123.64)	–394.35 (–1035.67 to 246.96)		
Active control (n=8)	2227.06 (114.37)	2102.67 (187.89)	–124.39 (–522.06 to273.27)		
Percentage of correct repeat trials (%)				.62	0.02
Combined exercise (n=9)	90.59 (1.61)	95.46 (1.67)	4.86 (–0.61 to 10.36)		
Active control (n=8)	96.68 (0.92)	92.86 (2.66)	–3.83 (–10.62 to 2.96)		
Percentage of correct switch trials (%)				.63	0.02
Combined exercise (n=9)	69.70 (6.86)	89.39 (2.83)	19.70 (–0.30 to39.70)		
Active control (n=8)	92.05 (2.06)	81.25 (5.26)	–10.80 (–24.26 to 2.67)		

Table 8 presents the changes in device-based exercise levels among patients with BC. There were no statistical differences between the two groups. However, an increase in total moderate-to-vigorous intensity exercise minutes was observed from pre to post intervention, trending toward participants in the active control group compared to those in the combined exercise group (mean difference in change 58.8, 95% CI 105.8.8-223.6 minutes; ηp^2=0.06).

Table 8. Effects of supervised, remotely delivered, combined exercise or active control program on total moderate-to-vigorous exercise in patients with breast cancer at pre and post intervention (ie, 8 weeks; n=14).

Variable	Pre intervention, mean (SD)	Post intervention, mean (SD)	Adjusted mean difference between groups[a]		
			Mean difference (95% CI)	*P* value	Partial n^2
Total moderate-to-vigorous intensity exercise			58.8 (105.8.8-223.6)	.44	0.06
Active control (n=6)	179.3 (110.3)	272.0 (230.6)			
Combined exercise (n=8)	127.0 (96.0)	148.5 (162.9)			
Light-intensity exercise			74.5 (–625.0 to 774.1)	.82	0.15
Active control (n=6)	1940.3 (431.9)	1991.6 (319.9)			
Combined exercise (n=8)	2140.4 (388.8)	2168.3 (555.5)			
Moderate-intensity exercise			26.6 (–89.8 to 143.0)	.62	0.02
Active control (n=6)	158.6 (89.8)	211.6 (153.3)			
Combined exercise (n=8)	123.2 (88.1)	144.1 (154.5)			
Vigorous-intensity exercise			48.2 (–6.6 to 103.0)	.08	0.28
Active control (n=6)	17.3 (41.9)	55.2 (71.1)			
Combined exercise (n=8)	3.75 (10.6)	4.25 (9.01)			

[a]Mean differences were adjusted for the baseline value of the outcome and total minutes of wear time.

Discussion

Principal Findings

To our knowledge, this is the first study to pilot a remotely delivered, supervised combined exercise program for patients with BC following chemotherapy, exhibiting mild cognitive impairment. The findings of this study will be used to inform larger, definitive RCTs by examining which aspects of the trial were feasible, as well as further refinements that need to be made. Specifically, there are few exercise training studies that target BC treatment-related cognitive impairment as a primary outcome. Recent reviews examined evidence for the use of exercise as an intervention for CRCI [25,31,72]. However, these studies did not consistently measure cognitive function as a primary outcome, and less than half assessed cognitive function with well-normed objective measures. The varied results within neuropsychological testing and the recent emphasis on individualized care all highlight the critical need to identify patients with BC who are especially at risk for cognitive decline. Our pilot is noteworthy, as it addressed some of these conceptual and methodological issues that may advance progress in the field. These include having an active control condition to match contact time, examining different types of exercise, such as combined exercise, including computer-based objectively measured cognitive function, as well as theory-based, behavioral counseling for exercise uptake and adherence.

This study was feasible and exceeded the a priori feasibility indicators of adherence rate ≥70%, attrition rate <30%, and no adverse events, and was well received by patients with BC. Adherence rates in our remotely delivered trial were consistent (63%-100% [28,30,73]) or lower (88% [72]; 87.9% [26]; 80% [74]; 99.9% [75]) than previous exercise trials targeting CRCI. However, it is important to note that these exercise trials were supervised (in person) sessions that included different exercise modalities, such as high-intensity interval training [28,73], combined exercise with Nordic or power walking [30], home-based walking [71], and aerobic exercise [26,72,75]. Nevertheless, our adherence rates are encouraging when compared to other virtually supervised exercise interventions delivered via Zoom in a group format, with various combinations of aerobic and resistance exercises, where adherence ranged from 78% to 100% [76]. Our trial also had low attrition rates, which were consistent with prior research with remotely delivered exercise interventions (0%-29%; [76]).

Recruitment rates for virtually supervised exercise interventions vary widely, with reported rates between 8% and 60% [76] likely due to the heterogeneity of recruitment methods. While our recruitment rate (51.2%) was consistent with previous research, our study relied mainly on self-referrals, which tended to attract highly motivated cancer survivors who were well-educated, White, and in better overall health and physical functioning. Homogeneous samples (eg, White, young, and highly educated) are a common limitation across distance-based exercise oncology trials [77]. Recruitment strategies and partnerships with organizations that serve racial and ethnic populations of cancer survivors should be strengthened at the onset of the intervention, which may assist with recruitment efforts [78].

In our secondary outcomes, no statistical differences were observed in objectively measured cognitive function. Small to medium effect size improvements were observed in episodic memory (Picture Sequence Memory Task), working memory, and executive function updating (List Sorting Working Memory Test), and immediate memory and verbal learning (Auditory Verbal Learning), trending toward the combined exercise group. On the other hand, large effect size improvements were observed in crystallized abilities (Oral Reading Recognition Test) plus language and vocabulary (Picture Vocabulary), slightly trending

XSL•FO
RenderX

toward the active control group. For executive function shifting, greater accuracy and reductions in reaction time (small to medium effect sizes) were observed for the switch trials in the combined exercise group. To date, few studies have tested the effects of exercise on objectively measured cognitive function outcomes in patients with BC following chemotherapy, with mixed results [40,72,75]. Preliminary results from these trials support cognitive changes following an exercise intervention, which is consistent with a study that examined the effects of a 3-month PA intervention compared to a waitlist control arm on cognitive functioning in patients with BC [43]. The intervention improved processing speed only among patients with BC diagnosed within the past 2 years. One proof-of-concept aerobic exercise intervention examined cognitive function using objective neuropsychological testing and functional magnetic resonance imaging in patients with BC. This study found improvements in cognitive symptoms with notable patterns of neural activation. However, the changes either did not reach statistical significance or had small effect sizes [72]. Finally, one of the first large-scale studies to examine the effects of aerobic exercise on neurocognitive function tested the effects of 6 months of moderate-intensity aerobic exercise on neurocognitive function in patients with BC receiving endocrine therapy. The trial focused on women who initiate exercise within 2 years of completing primary therapy (surgery +/− chemotherapy) [75]. Findings show improved performance in processing speed and verbal memory in the exercise group and no change in the usual care control group. It is important to note that these studies were either home-based aerobic programs or in person supervised aerobic activity. They also used a wide range of cognitive measures that were collected in person, whereas our study used a cognitive battery that was assessed remotely.

Recent reviews on the use of exercise as a potential intervention for cognitive deficits associated with cancer and its treatment demonstrated notable improvements in the cognitive domains of working and visual memory, attention and concentration, cognitive flexibility, inhibitory control, and verbal fluency [26,79], consistent with our study. Null effects were observed in other RCTs with a walking intervention [74], exercise intervention with supervised aerobic and strength training, as well as Nordic or power walking [30], and interval and continuous aerobic exercise in patients with BC following chemotherapy [73]. While findings from previous trials have been inconclusive, the positive improvements in cognitive function reported in our study could be attributed to recruiting patients with BC who exhibit mild cognitive impairment at the onset of the intervention. This may have provided greater room for improvement post intervention. Also, a range of cognitive assessments measuring cognitive domains that are most impaired by chemotherapy (eg, memory, attention, and executive function) increased the sensitivity to detect impairments post intervention. Finally, patients with BC in the combined exercise intervention were adhering to the prescribed exercise dose (ie, moderate-to-vigorous intensity physical activity [MVPA]), which is critical in achieving greater cognitive benefits and is consistent with reviews demonstrating that sustained MVPA elicits changes in cognitive function in patients with BC [3,25,80]. One of the most important mediators of cognition in patients with BC may be cardiorespiratory fitness [81,82]. Exercise-induced changes in cognitive function can be explained by alterations in brain morphology and functional dynamics (ie, prefrontal cortex and hippocampus) and may be partially mediated by improvements in cardiorespiratory fitness [82]. This underscores the pivotal role of cardiorespiratory fitness in amplifying the neuroprotective effects of MVPA. Given the link between cognition and cardiorespiratory fitness and the established effects of exercise on cardiorespiratory fitness, exercise might also remediate CRCI in patients with BC.

Notable improvements were also observed in the active control group performing light-intensity exercise, but these improvements were not in the cognitive domains most impaired by chemotherapy. The active control group engaged in a light-intensity exercise, which is insufficient to elicit improvements in cardiorespiratory fitness. Previous reviews demonstrated that both aerobic and resistance training that were moderate-to-vigorous intensity may be required to elicit cognitive benefits [3]. Nevertheless, improvements in the Oral Reading Recognition Test and Picture Vocabulary Test trended toward the active control group (although exploratory). These domains are related to language and/or crystallized abilities, and it is possible that increases in cognitive performance likely reflect expectancy or practice effects from repeated exposure to the assessments. Therefore, the remote administration of the NIH Toolbox Cognition Battery may not fully capture subtle CRCI-related changes.

In terms of changes in exercise minutes, improvements in MVPA from pre to post intervention trended toward the active control group (although exploratory). This finding is inconsistent with previous studies, which demonstrated improvements in device-based exercise minutes in patients with BC [30,43]. Given that we had an active control group, both groups were motivated to engage in exercise. Accelerometers do not accurately measure resistance training, which may not have been captured in patients with BC, especially in the combined exercise group, who continued engaging in resistance training. Patients with BC in the combined exercise group may have engaged in less structured exercise outside of the planned classes because they were receiving a moderate-intensity multicomponent exercise program compared to the active control group. Therefore, the reported effect sizes between our groups are possibly smaller given the active comparator group. Also, patients with BC self-reported not meeting exercise guidelines at screening but subsequently showed higher levels of activity with device-based measures at baseline. Future research should consider using device-based measures to screen patients with BC not meeting exercise guidelines to ensure that the inclusion criteria are met.

Lessons Learned and Future Research Directions

Overall, patients with BC were highly satisfied with the intervention. Most patients with BC found the study rewarding, enjoyed the virtual delivery format, would recommend the study to other patients with BC, and did not find the study assessments burdensome. Patients with BC also felt a mutual respect with their QEP and felt appreciated by their QEP, further contributing to their positive experience. This suggests that few adjustments

XSL•FO
RenderX

need to be made to the intervention or the study design before implementing a future RCT. In our study, an additional QEP attended the classes to monitor participant safety and to assist the lead QEP in managing the virtual environment. This was beneficial to both the lead QEP and patients with BC, and future remotely delivered interventions should consider a second QEP. Additionally, the QEP's personality, approachability, and teaching style played an important role in the enjoyment and feasibility for patients with BC. Future studies should consider QEPs with cancer-specific training to offer exercise modifications to patients with BC with limitations or injuries. Finally, our classes included 15 minutes of optional time before or after each class for patients with BC to interact for overall class enjoyment and accountability and to help foster a sense of community. This was beneficial to the overall satisfaction of the trial and should be implemented in future studies.

Strengths and Limitations

Our trial should be interpreted within the context of important strengths and limitations. The remotely delivered component of the trial was a strength, as it removed preexisting barriers to exercise (eg, time constraints, access, and hesitancy toward public space). The combined exercise and active control group sessions were delivered by knowledgeable QEPs who were engaging and provided modifications that allowed all patients with BC to participate in exercise, despite any physical limitations. The addition of a recorded session reduced participant burden by providing flexibility and autonomy. Our study was strengthened by the inclusion of behavioral counseling sessions, which were guided by the M-PAC framework to encourage exercise adoption and adherence [51]. The inclusion of a rigorous comparison group was an additional strength since both groups received supervised, remotely delivered exercise programs at differing intensities. Finally, the use of a standardized, well-validated battery of cognitive tests via the NIH Toolbox was another strength and in line with the ICCTF's recommendations [6].

Although this study had a small sample size and a heterogeneous population, which limits the generalizability of the findings, this feasibility study is crucial for calculating sample sizes and refining methodologies for larger, future trials. In addition, the sample was predominantly White, highly educated, middle- to older-aged, and within the early cancer survivorship period. The focus on early-stage patients with BC within 48 months of completing treatment may not be generalizable to other cancer populations, such as individuals with metastatic disease or patients who are pretreatment, undergoing treatment, or immediately post treatment. Furthermore, the heterogeneity in the time since treatment in our study may preclude identifying the optimal exercise timing to prevent or ameliorate CRCI, which requires future investigation. It is important to note that patients with BC may be more likely to seek out care for cancer rehabilitation and view themselves as research participants compared to patients with BC who are more culturally and socially diverse populations. Future research should consider the recommendations for increasing racial and ethnic diversity in cancer clinical trials by the American Society of Clinical Oncology and Association of Community Cancer Centers Joint Research Statement [78]. Another limitation of this study was not accounting for menopausal status, which could be a confounding variable that may impact cognitive function in patients with BC. Future studies should consider chemotherapy-induced menopause as a possible mechanism for CRCI. Furthermore, our study did not include self-reported cognitive function, which is another important indicator of CRCI, as it taps into day-to-day cognitive performance in relation to cancer and its treatments [6,83]. Therefore, including both self-report and objective cognitive function assessments in future research is warranted.

Conclusions

In conclusion, this feasibility study provides preliminary evidence that a remotely delivered, combined exercise program is feasible and may improve objectively measured cognitive function. There are a few exercise studies that have rigorously evaluated CRCI as a primary outcome in patients with BC. The limited number of studies conducted makes it difficult to draw conclusions about the efficacy of exercise for improving cognitive function in patients with BC. There is a need for rigorous and well-designed RCTs. While the use of shorter exercise protocols like our study provides preliminary evidence for cognitive benefits, long-term exercise is more efficacious in addressing age-related cognitive decline and improving cognition [84]. Future trials should include active control conditions, test multicomponent exercises (ie, aerobic and resistance training), and examine the mechanisms underlying the relationship between exercise and cognitive function. Given that CRCI is an emerging cancer survivorship issue, the next step for this work is to conduct a larger RCT that is adequately powered to examine the effects of a remotely delivered, combined exercise intervention on cognitive function in patients with BC following chemotherapy. If replicated, these findings have the potential to identify effective and modifiable management strategies to enhance cognitive health in patients with BC.

Abstract

Background: Digital health interventions are increasingly being integrated into oncological care to support patients in managing treatment-related symptoms and psychological distress. In a randomized controlled pilot trial, we investigated the feasibility and preliminary efficacy of a digital health app (SOFIA) among patients with cancer, including those in palliative care. SOFIA consists of an electronic patient-reported outcome (ePRO) assessment and coaching component. We showed good feasibility and high acceptability of SOFIA in routine clinical care.

Objective: This pilot study aimed to evaluate user experiences and behavior with SOFIA. We applied a mixed methods design, combining a qualitative exploration of patients' experiences and a quantitative analysis of app usage patterns. The integrated findings are intended to inform the refinement and further development of digital health interventions to better address the needs, preferences, and engagement behaviors of this patient population.

Methods: Patients randomly assigned to the intervention group participated in semistructured interviews at 2 time points during the 12-week intervention period: midway through the intervention (at week 6) (T1) and postintervention (at week 12) (T2). Qualitative data were analyzed using content analysis. User data were descriptively analyzed with Python and the Pandas library (version 2.2.3).

Results: Our qualitative analysis of 29 patients revealed benefits regarding the ePRO assessment (empowerment, support, user-friendliness, and facilitation of patient-physician communication), as well as some criticism (inflexible design and insufficient use by physicians). Benefits of the coaching tool included the availability of helpful information and design aspects such as clarity and user-friendliness. Quantitative data from 32 active users of the app showed that 16 (50%) of patients read articles, 28 (87.5%) started journeys, and 15 (46.9%) completed exercises at any point during the study.

Conclusions: The results of this mixed methods study may provide important indications for digital interventions, including ePRO assessment, for patients with cancer. From the patients' perspective, key features include intuitive design, relevant symptom items, reliable reminder functions, the translation of ePROs into clinically actionable information, clear symptom visualizations, seamless integration into electronic health records, and effective physician engagement. Both our qualitative and quantitative data show the importance of therapy-specific content. These results might increase acceptance and usage, and thereby also the clinical benefit, of future digital interventions for patients with cancer.

Introduction

Digital health interventions (DHIs) and the recording of electronic patient-reported outcomes (ePROs) have become an important part of psycho-oncological care. The systematic collection of ePROs has demonstrated substantial benefits in oncology, enhancing communication, quality of care, and clinical efficiency. ePROs foster more effective dialogue between patients and healthcare professionals by providing structured, continuous insights into patients' symptoms and well-being [1]. This facilitates more open, targeted, and meaningful communication during clinical encounters [2]. Evidence further indicates that integrating ePROs into oncology care leads to improved outcomes, including higher health-related quality of life (HRQoL) [3], more effective symptom management, and even prolonged survival among patients with cancer [4,5]. The use of ePROs supports a patient-centered approach by enabling treatment decisions that are more closely tailored to the individual needs, preferences, and experiences of patients. Moreover, ePRO systems allow for the early detection of clinical deterioration and deterioration of HRQoL [6]. Finally, regular monitoring enables timely interventions that can prevent complications and reduce emergency room visits [7].

DHIs are increasingly being integrated into oncological care to support patients in managing treatment-related symptoms and psychological distress. Previous qualitative research with patients with breast cancer has shown that such interventions are perceived as acceptable and hold strong potential to reduce anxiety, address gaps in care, and provide reassurance throughout the treatment process [8]. Similarly, in the study by Krakowczyk et al [9], patients with various cancer entities evaluated the usefulness and usability of *Make It Training*, a modular digital mental health intervention designed to reduce psychological distress and improve coping and HRQoL. Patients described the intervention as user-friendly and supportive in developing functional coping strategies, highlighting its potential for integration into daily life and routine oncological care. However, to date, evidence on the acceptability and perceived usefulness of such DHIs [10] among palliative patients remains scarce, although this group faces particularly severe physical and psychological challenges due to the advanced stage of their illness.

In the SOFIA pilot trial, we developed and tested a mobile app for patients undergoing immunotherapy with immune checkpoint inhibitors (ICIs) within a randomized controlled design. The SOFIA app comprised 2 components: *SOFIA Monitoring*, which involved the regular assessment of ePROs, and *SOFIA Coaching*, which provided tailored information related to treatment and illness management. In a previous publication, we demonstrated the high feasibility and acceptance of the app in clinical routine, with an adherence rate of 91% for completing ePRO assessments twice weekly over a 3-month intervention period. Patients in the intervention group (IG) reported significantly lower levels of depression and distress, as well as improved HRQoL, compared to those receiving treatment as usual [11].

Several studies have qualitatively investigated expectations and experiences with DHIs in patients with cancer. In a recent meta-analysis, Zhang et al [12] synthesized 12 qualitative studies on user experiences among older patients with cancer, identifying 3 overarching themes: (1) positive experiences, (2) barriers to use, and (3) user expectations. The included studies varied in terms of app content (eg, ePRO assessment, physiological tracking, or combined DHIs such as ONKOkompass) and also addressed expectations and needs. The review provides an important overview of key themes and topics. However, to compare specific benefits and barriers, it is necessary to investigate these aspects separately for each component (ePRO assessment, coaching tools) in patients who have actually used the app.

Similarly, a recent systematic review by Lai-Kwon et al [10] reported that ePRO-based systems for monitoring immune-related adverse events are generally feasible and acceptable in patients receiving immunotherapy. However, the included studies predominantly focused on symptom monitoring, with limited or no systematic evaluation of additional intervention components such as coaching modules.

Evidence on the usefulness of ePRO-based and combined eHealth interventions in patients receiving ICI therapy remains limited. Tolstrup et al [13] investigated the usefulness of an ePRO assessment in 14 patients with melanoma receiving ICI therapy and found that patients perceived the tool as easy to access and meaningful to complete. In addition, Glaser et al [14] evaluated the CAPABLE system, an eHealth intervention including symptom management and coaching features in patients undergoing ICI therapy. Their mixed methods study reported high overall perceived usefulness, with more than 75% of participants rating the system positively. However, the evaluation was conducted at the system level and did not distinguish between experiences with the ePRO and coaching components.

Overall, to date, no study has included a mixed sample of patients with cancer undergoing ICI therapy and quantitatively investigated their experiences with ePRO assessment and coaching components separately. Furthermore, no study has combined qualitative data with user log data, which provide important insights into actual usage behavior.

This study aimed to investigate acceptability and patient engagement with the app, operationalized as (1) qualitative patient perspectives on using the SOFIA app, assessed separately for the ePRO assessment and coaching components, and (2) quantitative usage behavior. These insights are intended to inform the future development and optimization of DHIs for patients with cancer, including those in palliative care and undergoing ICI therapy.

Methods

Study Design

This study was embedded within a pilot study and used a convergent parallel mixed methods approach [15], combining (1) qualitative exploration of patients' experiences of app use and (2) quantitative analysis of user behavior. The underlying

XSL•FO
RenderX

phenomenon of interest was patient experience with both components of the SOFIA app, conceptualized as the interplay between patients' subjective experiences and their observable usage behavior. The mixed methods design was chosen to capture both dimensions and to better understand the mechanisms shaping engagement.

The study was a prospective single-center, 2-arm randomized controlled external pilot trial. The study protocol and details of the study methods are described elsewhere [11,16].

To estimate the key parameters for the main trial, a total of 70 participants (35 per group) were required, based on the simulation-based approach for determining sample size in external pilot trials with continuous outcome variables [17].

Intervention

Participants in the IG received access to the SOFIA app (for a detailed description, [11]). SOFIA was integrated into the Mika app, a digital therapeutic providing individualized supportive care and aiming to reduce psychological distress in people with cancer. The app entails different components, including symptom monitoring and coaching modules (for a detailed description, [11]).

Monitoring: SOFIA Monitoring comprised 11 physical and up to 9 mental ePROs, assessed twice weekly with email reminders. Physical symptoms were selected by experienced medical oncologists based on European Society for Medical Oncology guidelines [18] and included weakness, diarrhea, melena, dry cough, dyspnea, reduced urinary output, joint and muscle pain, skin toxicity, fever, and jaundice.

Coaching: The coaching component included modules such as Discover and Journeys. The module "Discover" is the content library of the Mika app, consisting of articles and videos with easily understandable and evidence-based information on several cancer-related topics (eg, cancer and treatment types, nutrition in cancer; Table S1 in Multimedia Appendix 1), written and peer-reviewed by medical experts. An integrated statistical content recommendation engine delivers individual content recommendations to the user based on age, gender, cancer type, therapy type, and reported symptoms. By considering the symptoms the patient has reported in the symptom monitoring module, as well as patterns in their reading behavior, the algorithm predicts the likelihood of the user engaging with specific content and, based on the estimated read probability, presents the respective content to the user.

"Journeys" are the resource-activating psycho-oncological training courses of the Mika app that aim to help patients cope with cancer-associated distress in different areas (eg, living with immunotherapy; Table S1 in Multimedia Appendix 1). There are 13 journeys, each of which entails 3 subsequent stages, which in turn include 3 exercises. Exercises can be allocated to 1 of 4 categories: knowledge, mindfulness, relaxation, or physical exercise.

Study Procedures and Analyses

Qualitative Approach

Reporting of the qualitative part adheres to the COREQ (Consolidated Criteria for Reporting Qualitative Research) [19] (Checklist 1). Patients in the IG participated in semistructured interviews at 2 time points during the 12-week intervention period: midway through (at week 6) (T1) and postintervention (T2). The interview guide is available in Multimedia Appendix 2. Questions were developed based on expert discussions and experiences from previous studies, with the aim of gathering information on experienced benefits and suggestions for improving SOFIA Monitoring and Coaching. The 1:1 interviews were conducted in German by 3 female study assistants who were master's-level psychology students. Owing to their psychology background, all had well-developed communication skills and received additional briefing and supervision from the study coordinator (CS) prior to data collection. To minimize the burden on participants, the interviews were conducted by telephone. Some participants were already acquainted with their individual interviewer through the recruitment contact. At the beginning of each interview, the study assistants introduced themselves as study assistants in the SOFIA project; no other interviewer characteristics were shared. The interviews lasted about 10 minutes, depending on how detailed the answers were. Due to the brevity of the questionnaire and the limited selection of questions, no pilot testing or audio recording was conducted. The study assistants wrote down the statements by hand (either verbatim or summarized in bullet points) and then transferred them anonymized into an Excel spreadsheet. Additional field notes were not made. Interview notes were not returned to participants for comment and/or correction.

Statements were analyzed using structured qualitative content analysis, combining deductive and inductive approaches [20]. While the interview guide provided an initial set of categories (deductive), these categories were refined inductively based on the participants' responses, with subcategories and hierarchical levels being developed during the course of the analysis. Initially, meaningful content aspects within each statement were identified as coding units and assigned to the overarching categories from the interview guide by 2 independent raters. As individual statements could contain multiple content aspects, more than 1 category assignment per statement was possible. The allocation was subsequently discussed within the research team. Disagreements were discussed until consensus was reached. In cases where differing opinions persisted, the senior researcher and study coordinator (CS) made the final decision. This procedure for resolving disagreements was applied consistently across all stages of the coding process. In the next step, common groups (subcategories) were formed within the overarching categories based on the assigned content aspects. Where appropriate, these subcategories were further consolidated into generic categories through additional team discussions. The final category structure emerged through an iterative, consensus-based coding process involving multiple rounds of analysis and regular team discussions. During this process, categories and subcategories were continuously reviewed, refined, and reorganized where substantial overlap

XSL•FO
RenderX

was identified. In our overview, we have summarized all statements that were mentioned more than twice.

Quantitative Approach

SOFIA app usage was analyzed using log data of patients' in-app activities, providing detailed insights into the types of content and exercises with which patients were most engaged. After participants in the IG received a study access code and consented to the app's privacy terms, their pseudonymized in-app activities were automatically recorded, allowing the evaluation of engagement with different coaching features of the app. For the current analyses, the app modules "Discover" and "Journeys" were of interest.

The raw log files were preprocessed by the app provider (Fosanis GmbH), resulting in several spreadsheets containing general user data and logs of articles read in the "Discover" module, as well as logs of journeys started or completed and exercises performed. The spreadsheets included the following information: unique user ID; name of the article, journey, or exercise with which the user was engaged; period during which the engagement took place (weeks 0 - 12: intervention phase; weeks 12+: follow-up phase); and the duration (in seconds) of the engagement.

The spreadsheets were then processed further using a customized Python script and the Pandas library (version 2.2.3) for data processing. Sessions of zero duration were removed, and the time unit was converted from seconds to hours. Finally, the descriptive statistics of user engagement presented in the *Results* section were produced.

Ethical Considerations

The Ethics Committee of Heidelberg University Hospital (reference S-581/2018) approved the trial protocol, and the study was registered in the German Clinical Trial Register (reference DRKS00021064). All participants were informed about the study procedures and signed informed consent before being included in the study.

Results

Participant Characteristics

Of the 34 patients in the IG, 2 patients left the study directly after randomization. For the remaining 32 participants, user data were available. Regarding the availability of interview data, 29 patients participated in the midway assessment (T1), while 23 patients participated in the postintervention assessment (T2). One patient discontinued participation due to dissatisfaction with the application, 2 patients died during the study period, 1 patient was physically unable to participate in the interview, and 2 patients could not be reached by phone.

Patient characteristics are presented in Table 1. The study flow chart can be found in Multimedia Appendix 3. For a detailed explanation of the study flow [11].

XSL•FO

Psychiatric side diagnosis, n (%)	1 (3.4)

[a]ECOG: Eastern Cooperative Oncology Group Performance Status

[b]ICI: immune checkpoint inhibitor.

[c]TKI: tyrosine kinase inhibitor.

[d]CHX: chemotherapy.

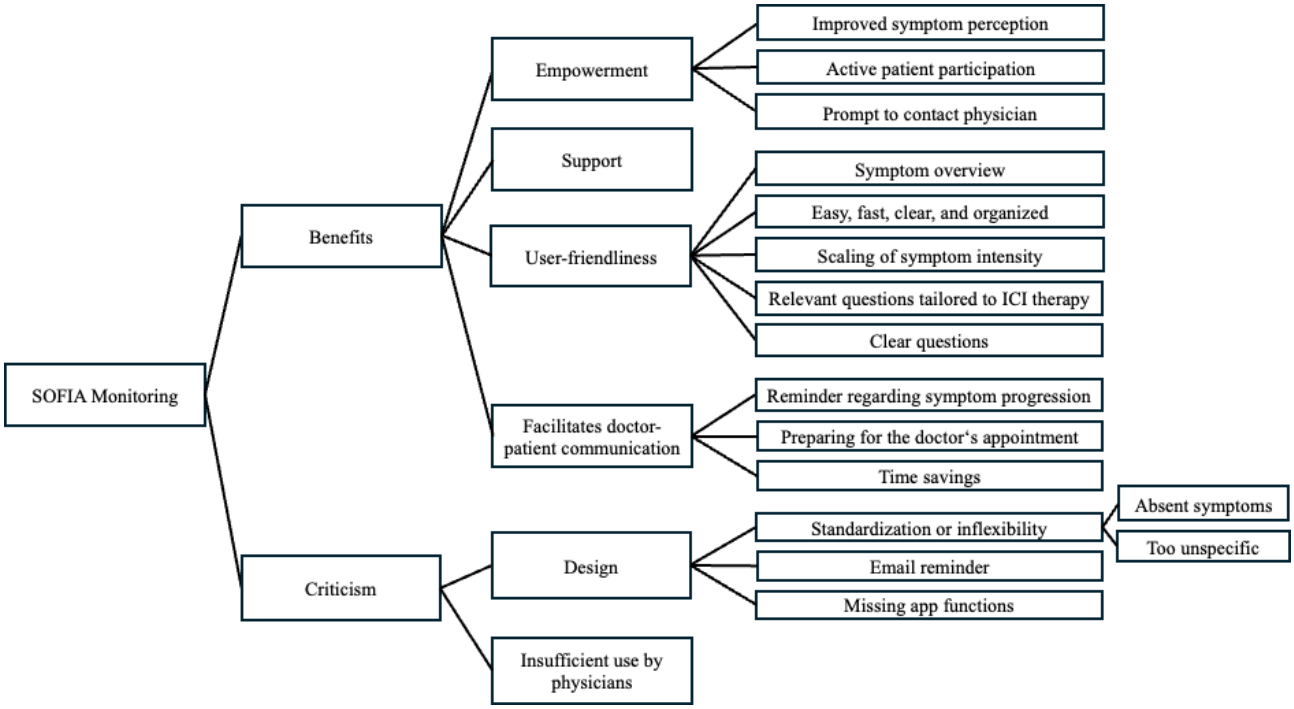
In our IG sample, 6 patients received steroids due to adverse events after the start of immunotherapy. Five patients had brain metastases, resulting in 1 patient undergoing surgery, 3 receiving radiotherapy, and 1 death. No patients had meningeal metastases. Five patients had thyroid dysfunction: 3 alone and 2 combined with other side effects.

Qualitative Results

For both SOFIA Monitoring and SOFIA Coaching, we identified two main categories: (1) perceived benefits and (2) criticism or recommendations. In the following, we describe the corresponding generic categories and subcategories for each and present illustrative quotations from the interview notes. The quotations were translated into English by CS. The numbering is based on the order in which the statements (eg, #1) and their documentation appear in the Excel spreadsheet (eg, *a*=first data spreadsheet), as well as the measurement time (T1 vs T2). Figures 1 and 2 summarize the results of the qualitative analysis by presenting the coding structure with main categories and subcategories.

XSL•FO
RenderX

Figure 1. Main categories, generic categories, and subthemes of SOFIA Monitoring. ICI: immune checkpoint inhibitor.



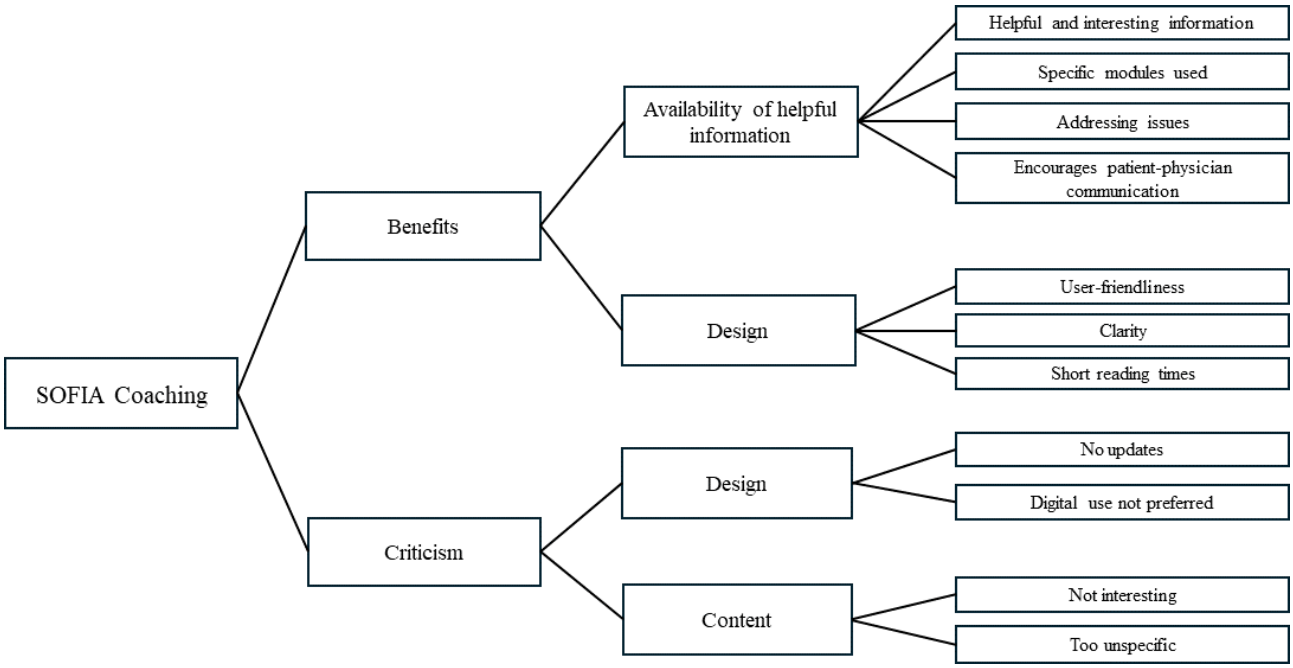


Figure 2. Main categories, generic categories, and subthemes of SOFIA Coaching.

SOFIA Monitoring

Main Category 1: Benefits of SOFIA Monitoring (Assessment of ePROs)

Generic Category: Empowerment

Patients reported at T1 and T2 that the ePRO assessment improved their symptom perception (subcategory: improved symptom perception), strengthened their patient participation (subcategory: active patient participation), and the prompt to contact the physician (subcategory: prompt to contact the physician) encouraged them to become active or more aware of severe symptoms. These subcategories were combined to create the generic category called "empowerment," since empowerment is the process by which patients gain the knowledge, skills, confidence, and control necessary to make informed decisions about their health and to play an active role in their own care [21].

Subcategory: Improved Symptom Perception

Patients reported that the ePRO assessment actively encouraged them to recognize their symptoms, including psychological ones, and that this helped them classify the symptoms:

XSL•FO
RenderX

This is very helpful for assessing yourself better. Example: When you subjectively feel unwell and then objectively evaluate that feeling in the app. [#1a, T1]

Also good for recording changes [was it just a one-off?]. If you just wrote it down, you wouldn't have such a clear overview. [#3a, T1]

You become aware of the questions and symptoms. Otherwise, I would not concern myself with them, but rather suppress them, especially when they concern depression. [#29a, T1]

This helped me realize that I am doing well. [#1a, T2]

Paying more attention to side effects ['listening to my body more closely,' 'checking more often for certain symptoms,' being more attentive to my body]. [#38a, T2]

Deciding whether to go to the doctor or not. [#40a, T2]

Subcategory: Active Patient Participation

Patients reported that the ePRO assessment enabled them to play an active role in managing their condition:

Being actively involved in documenting one's own recovery and being able to observe progress and see where the journey is headed. [#25a, T1]

Being part of something bigger and, therefore, being able to help future patients. [#26a, T1]

Subcategory: Prompt to Contact the Physician

Patients found the warning notice, along with the contact details, helpful in determining when to contact a physician:

[...] A notification to contact a doctor, because not everyone does that ['there's time/it's not urgent'], but when the notification keeps appearing, you decide to take action. [#4a, T1]

You can see when something is above range and are informed to contact your doctor in that case, or that everything is OK. [#45a, T1]

Generic Category: Support

Patients reported that they had the feeling that somebody was interested in their symptoms and that they were not alone with their fears. The patients felt reassured knowing what the typical symptoms were, which gave them a sense of security.

I don't feel left alone with my fears; I feel like someone cares about me. [#52a, T1]

It's good that someone is asking about my symptoms twice a week, not just every 3 weeks. [#2a, T2]

Generic Category: User-Friendly Application

The patients appreciated the clarity of the presentation, the scaling of symptom intensity, and the relevant questions tailored to immunotherapy. They found the application easy and quick to use. See Table 2 for subcategories and examples.

Table . Subcategories of user-friendliness.

Subcategory	Statement (example)
Symptom overview	#5a (T1): You can view the scale yourself over a period of 30 days to get a good overview.
Easy, fast, clear, and organized handling	#42a (T2): Questions clear, given answer options good. #10a (T1): […] fast, clear questions.
Scaling of symptom intensity	#10a (T1): The range of 1 - 10, because it can fluctuate daily. #23a (T1): The alignment with immunotherapy is satisfactory.
Relevant questions for ICI-therapy[a]	#12a (T1): You don't have to figure out what is relevant yourself.
Clear questions	#73-74a (T2): Very easy, works well. #43a (T2): The questions are clearly formulated, and the predefined response options are well constructed.

[a]ICI: immune checkpoint inhibitor.

Generic Category: Facilitation of Patient-Physician Communication

Some patients reported that the ePRO helped them remember symptoms for the physician-patient consultation and to report them during the consultation (subcategory: reminder regarding symptom course). Patients also used it to prepare for consultations with their physicians (subcategory: preparation of questions for the medical consultation). They also saw it as a time saver, as it meant that physicians were already able to obtain a detailed overview, facilitating communication and the identification of relevant symptoms (subcategory: time savings). Examples are depicted in Table 3.

XSL•FO
RenderX

Table . Subcategories of facilitation of patient-physician communication.

Subcategory	Statement (example)
Reminder regarding symptom course	#1c (T2): Yes, in the sense that you don't forget anything and have accurate information (even if something only happened once, which you would otherwise have forgotten to mention).
Preparation of questions for the medical consultation	#10c (T1): Yes, because you are more aware of what happened and what you want to say.
Time savings	#3c (T2): Yes, because the doctor already had my medical history, I didn't have to explain everything again and could focus on what was important.

Main Category 2: Criticism or Recommendations of SOFIA Monitoring

Generic Category: Design

Subcategory: Standardization or Inflexibility

The main criticism from patients concerned the standardization of the ePRO assessment in the app. Some patients reported missing symptoms (eg, hypertension or hypotension, weight gain/loss) and expressed a desire for greater specificity of items or a free text field for entering symptoms.

> *Option to enter an individual symptom.* [#2e, T1]
>
> *Precise definition, what kind of pain, more specific.* [#26e, T1]
>
> *Difficult 'in recent days' because I always have muscle pain [unrelated to cancer].* [#29d, T1]

Subcategory: Email Reminder

Patients reported that they were unsatisfied with the email reminder function. They missed a direct reminder of the ePRO assessment via the app because, in some cases, there was no connection between the email reminder and the app (eg, #21d(T2): "Difficulties remembering to enter Mondays and Thursdays (as there is no link between mobile phone), did not make good use of the reminder function in the app.").

Subcategory: Missing App-Function

Some patients reported that they missed some functions in the SOFIA Monitoring component, for example,

> *You cannot enter anything if there are changes in the therapy.* [#13f, T1]
>
> *Doctors should be more proactive in approaching patients; if abnormal values are detected, it should not be up to the patient [who is already under stress] to report them.* [#15f, T1]

Generic Category: No Usage of Physicians

At T1, 62% (18/29) of patients reported that physicians did not use their input during the consultation; 17% (5/29) indicated that physicians used it partially, and 7% (2/29) reported that their input was used; 14% (4/29) were unable to judge that. At T2 (n=21 answers were available for this question), 14 (67%) patients reported no use of their input, 3 (14%) reported partial use, and 4 (19%) reported use. Patients expressed a desire for more feedback and a better integration of the ePRO assessment into their treatment.

SOFIA Coaching

Main Category 3: Benefits of SOFIA Coaching

Generic Category: Availability of Helpful Information

Patients appreciated the availability of helpful and interesting information about their illness and treatment (subcategory: helpful and interesting information), as well as specific modules such as thematic journeys, the contact module, and a video interview (with an immunotherapy expert from the National Center for Tumor Diseases Heidelberg) (subcategory: specific modules used). Patients also valued being made aware of relevant issues (subcategory: addressing issues), which in turn facilitated communication with their physician (subcategory: encourages patient-physician communication). Examples are depicted in Table 4.

XSL•FO
RenderX

Table . Subcategories of availability of helpful information.

Subcategory	Statement (example)
Helpful and interesting information	#2f (T1): One can glean useful tips from it.
	#7f (T1): I liked it. Explanation of immunotherapy, themed trips, finding your way to cope with cancer-Positive: Content seemed very diverse, eg, something for all age groups (children/pensioners)
Specific modules used	#33f (T1): Thematic journeys, approximately every 2 days for half an hour to an hour, are helpful.
	#13f (T1): Video interview was good.
	#3f (T1): It's good to know who to turn to (contact persons just a click away), in good hands. (contact module)
Addressing issues	#1f (T1): It's good that it's included in the app, because otherwise you might not bother with it. Depending on what's happening that day, you can take another look at it
Encourages patient-physician communication	#40f (T1): I looked at thematic journeys, which raised questions that I then asked during my consultation with the doctor

Generic Category: Design

We identified 3 subcategories (user-friendliness, clarity, and short reading times) in the Design category. Patients appreciated the user-friendliness of SOFIA Coaching. They highlighted its ease of use, clarity, and short reading time (eg, #15f (T1): "The reading time is very helpful because my ability to concentrate is limited by my illness").

Main Category 4: Criticism or Recommendations for SOFIA Coaching

Generic Category: Design

Patients criticized missing updates (subcategory: missing updates). Some patients reported they generally preferred an analog information (subcategory: digital use not preferred). Examples are depicted in Table 5.

Table . Generic categories of improvable design aspects.

Subcategory	Statement (example)
Missing updates	#13f (T1): There are no updates/news that would encourage one to revisit the site.
	#15f (T1) Push notifications for new (would be helpful)
Digital use not preferred	#21g (T1): Does not use Coaching because he does not spend much time in front of the screen and is not a "computer freak."
	#45g (T2): Technical side: He has to print out anything he finds interesting. There is no offline/paper function for marking things or making notes. He would prefer a kind of "wiki" to better manage the information (information on study results). (…)

Generic Category: Content Not Interesting or Unspecific

Few patients reported they experienced the content and wished partly more detailed information about specific topics (eg, cancer and genetics).

> *Individual to each person; article very general, much of it did not apply.* [#52g, T2]
>
> *I would like more information about the specific type of cancer.* [#44f, T2)]

Quantitative Results

Based on the log data of the 32 active users of the coaching features of the SOFIA app, we found that 16 (50%) of them had read at least 1 article from the "Discover" module. The median number of articles read per user in this group was 7.5. The corresponding mean value of 14.8 (SD 19.9) was distorted by 2 outliers (52 and 72 articles). As seen from the more detailed analysis in Table 6, more articles were read in the intervention period of the study than in the follow-up period.

Table . Analysis of articles read per user in the "Discover" module of the SOFIA app (N=32).

Time period	Users with ≥1 articles read, n (%)	Number of articles read in this group, median (IQR)	Number of articles read in this group, mean (SD)
Any period	16 (50)	7.5 (12.5)	14.8 (19.9)
Intervention period only	16 (50)	4 (10)	10.6 (14.6)
Follow-up period only	7 (21.9)	4 (9)	9.6 (11.6)

XSL•FO
RenderX

The app organizes articles in different categories. The most frequently read category was "cancer therapy" (*k*=47), closely followed by "COVID and cancer" (*k*=38), "relieving symptoms" (*k*=37), "healthy lifestyle" (*k*=33), and "nutrition and cancer" (*k*=28). All data are depicted in figures in Multimedia Appendix 4 (pie chart, bar chart, and box plot).

The log data of the "Journeys" module of the SOFIA app revealed that 87.5% (28/32) users started at least 1 journey; 25% (8/32) of them completed at least 1 journey. Table 7 shows that most of the engagement in journeys took place in the intervention period.

Table . Analysis of journeys started or completed in the "Journeys" module of the SOFIA app (N=32).

Time period	Users with ≥1 journey started, n (%)	Number of journeys started in this group, median (IQR)/mean (SD)	Users with ≥1 journey completed, n (%)	Number of journeys completed in this group, median (IQR)/mean (SD)
Any period	28 (87.5)	1 (1.25)/1.96 (1.62)	8 (25)	1 (2.00)/1.75 (1.04)
Intervention period only	26 (81.3)	1 (1.75)/1.96 (1.46)	6 (18.8)	1.5 (1.75)/1.83 (0.98)
Follow-up period only	4 (12.5)	1 (0.00)/1.00 (0.00)	3 (9.4)	1 (0.00)/1.00 (0.00)

Table 8 shows the popularity of journeys among users. By far, the most popular journey was "Living with immuno-therapy." Figures in Multimedia Appendix 5 show the titles and frequencies of journeys completed.

Table . Frequency of journeys started.

	Users, n
Living with immunotherapy	24
Find your way	8
Relieve exhaustion	6
Gain control	5
Activate power source	4
Reduce stress	4
Nutrition and cancer	2
Managing emotions	1
Yoga and cancer	1

In the SOFIA app, journeys include exercises. Fifteen out of 32 (46.9%) users were engaged in at least 1 such exercise. In this group, an average of 9.1 (SD 8.8) exercises were started (median 9, IQR 6.5). Figures in Multimedia Appendix 6 show the most frequently started exercises. Multimedia Appendix 7 includes a joint display table linking the main qualitative themes of SOFIA Coaching to their respective quantitative usage patterns.

Discussion

Principal Results

DHIs are an integral part of oncological care. The evidence for this is very clear. Many efficacy studies do not provide accurate user information. The results of our convergent parallel mixed methods approach showed that, qualitatively, patients reported feelings of empowerment and support, appreciated the user-friendly design, and reported perceived improvement of patient-physician communication (ePRO assessment) as well as access to helpful and validated information (coaching component). Simultaneously, they wished for more flexibility in the ePRO assessments and more integration of the ePRO assessment into the clinical routine, as well as more specific data. Regarding the coaching component, some participants wished for more updates or did not prefer digital use. Quantitative user data indicated that over 50% (16/32) of patients read articles, engaged with journeys, and performed exercises, with immunotherapy-relevant articles, the management of side effects, and living with immunotherapy being of particular interest.

Implications for ePRO Assessments

The results of our main study revealed high acceptability and feasibility of the ePRO assessment in patients undergoing ICI therapy, with an adherence rate of 91% [11]. We conducted qualitative interviews to gain deeper insights into user perspectives and needs. The findings of our accompanying qualitative study corroborate those of a previous investigation involving 186 patients with various cancer entities undergoing diverse cancer therapies, as well as 55 clinicians [22]. That study examined patient and clinician perspectives on the use of a DHI for collecting ePROs. Three overarching themes were identified for both stakeholder groups: (1) acceptability and functionality (relevance of symptom items, usability, reminders, perceived health status); (2) impact on clinical care (information and resource provision, contribution to research, self-monitoring, reassurance, connection to the hospital, and support for guided decision-making); (3) personal value of using eRAPID—the tool used for ePRO assessment (clinician engagement with eRAPID, facilitation of consultations, and support for medication or treatment adjustments) [22]. Furthermore, the

XSL•FO
RenderX

results are in line with the recently published systematic review of qualitative data [12] identifying "improved self-management," "safe and accessible support," and "better access to health information" as key benefits, and "inadequate content design," "technical difficulties," and "negative user perceptions and behaviors" as key barriers. Consistent with our generic categories—user-friendly application (acceptability and functionality), facilitation of patient-physician communication (impact on clinical care), and empowerment, support, or availability of helpful and interesting information (personal value)—these findings provide several implications for the development of future DHIs including ePRO assessments in oncology. First, ePRO systems should prioritize high acceptability and usability by ensuring intuitive design, relevant symptom items, and reliable reminder functions (eg, directly via the app) [2]. Second, features that translate PROs into clinically actionable information—such as automated alerts or structured summaries—are essential to support timely decision-making. Third, future tools should actively facilitate patient-physician communication through clear symptom visualizations and seamless integration into electronic health records. In this context, ePROs could be particularly useful for gathering information about how patients tolerate therapies such as tyrosine kinase inhibitors. These therapies are often used in combination with ICIs and are frequently associated with chronic side effects that are difficult to assess during routine consultations, but which can have a significant impact on HRQoL [23].

Moreover, ePRO systems should promote patient empowerment by enabling self-monitoring, offering feedback on symptom trajectories, and providing access to supportive resources. Successful implementation further requires strong clinician engagement and incorporation into routine workflows. The results of our previously published study [11] revealed that 65% (n=28) of physicians (who treated patients in the IG) never or seldom used the graph for monitoring patients' care—even though over 50% of physicians evaluated ePROs as useful and saw significant benefits in managing treatment with ICI (eg, in preparing for consultations or detecting side effects). These reports are in line with the results of the answers of our patients, as over 60% of patients reported no usage of their ePRO assessments in the clinical routine, but patients wished that their reports would be better integrated into the patient-physician consultation. It is important to note that these implications are derived from qualitative perceptions and descriptive usage patterns and should not be interpreted as evidence of causal mechanisms at an individual level.

In future studies, the integration of ePRO data into clinical workflows should be systematically evaluated, including the role of physician training. In line with studies showing that the assessment of ePROs and screenings should have consequences and aftercare [24], this is important for patients' adherence to reporting ePROs regularly. It would then be particularly interesting to gain a deeper understanding of patients' and physicians' perspectives when ePROs are more integrated into clinical encounters.

Finally, offering flexible assessments while simultaneously enabling standardized data capture for research and quality improvement will be crucial for maximizing the clinical utility of next-generation ePRO solutions.

Furthermore, the factor of personal value (empowerment, support, availability of helpful information) might have led to improved HRQoL and reduced psychological burden in patients in the IG compared with the control group in our sample [11]. However, this interpretation should be viewed with caution, as our small sample size did not allow us to demonstrate the mediating effects of these factors.

Implication of Coaching Components and Integration of Quantitative Findings

Patients reported benefiting from the availability of relevant and helpful information, as well as from the user-friendly and clear design. This is consistent with previous studies showing that access to helpful information and safe, accessible support is a key factor in eHealth interventions for patients with cancer [12,22]. These findings underline the importance of providing reliable and accessible information. In particular, patients benefited from the journeys and topics addressing side effects and preparation for physician consultations. These findings are further supported by our user-data analyses, which show that patients actively engaged with the app's content. During the observation period, 81% (26/32) started a Journey module, and 50% (16/32) accessed written articles. In the follow-up period, engagement declined, but 22% (7/32) read articles, and 12% (4/32) started journeys. The frequent use of Journey modules reflects the Journey format's strong appeal. Content analyses indicated that users were particularly interested in topics related to immunotherapy, current developments, and the management of treatment-related side effects, which was underlined by our qualitative data (ie, availability of helpful information; dealing with issues). These patterns are consistent with recent studies demonstrating that patients with cancer seek timely, therapy-specific information and guidance [25]. Future studies should take this into account when developing digital contents for patients with cancer.

However, 50% (16/32) of users did not engage with the SOFIA app's articles. Criticisms identified in the qualitative evaluation of the SOFIA Coaching program may explain the limited use (eg, low preference for digital formats, lack of updates, or articles perceived as too general or insufficiently relevant). Future studies should provide cancer-entity-specific information, ensure regular content updates, and consider that DHIs alone may not reach all patients. To avoid disadvantaging individuals who are less digitally inclined, alternative, nondigital information formats, which are often provided by cancer-specific nongovernmental funding and nonprofit-making organizations, should continue to be offered in parallel.

Limitations

Our study provides important insights into the assessment of ePROs and the use of DHIs in patients with cancer and represents an important addition to our feasibility study. In particular, the mixed methods approach, combining qualitative and quantitative data, represents a major strength of this study. However, several limitations have to be discussed. We only assessed the patients' perspective in our qualitative approach.

XSL•FO
RenderX

Although we quantitatively assessed physicians' views on the benefits, usability, and use of the ePRO assessment in a sample of 33 physicians involved in treating patients in the IG [11], a complementary qualitative study would likely have provided deeper insights into perceived benefits and barriers. Due to anonymization processes, it was not possible to match the user data with other PROs and the qualitative data. Furthermore, we were unable to provide a detailed analysis of user behavior, such as engagement over time, weekly trajectories, dropout curves, and patterns of sustained vs early disengagement. Nevertheless, the data provide important insights in the usage of DHIs.

The sample for the qualitative analysis was constrained by the number of participants in the intervention, as determined by the sample size calculation for the primary outcomes of the main trial. Therefore, data saturation was not explicitly addressed in the qualitative part. However, recurring themes were identified across interviews, and our sample is larger than in comparable previous studies [12]. The concept of saturation has also been critiqued, as it assumes that no additional insights can emerge beyond a certain point [26]. Further, since the interviewers had prior contact with the participants during the recruitment phase of the study, a potential influence of social desirability has to be taken into account. However, we consider this influence to be minor, as the first contact was brief and participants also raised critical points during the phone interviews.

Conclusions

This mixed methods study revealed the benefits and criticisms of ePRO assessments and digital coaching tools for patients with cancer under ICI-therapy. Results indicated that a user-friendly app, perceived facilitation of patient-physician communication, and several dimensions of personal value (eg, empowerment, support, or availability of helpful and interesting information) (personal values) may represent pivotal aspects for patients with cancer using DHIs. Quantitative data underline the importance of therapy-specific contents. In sum, we derived several indications for future DHIs in patients with cancer, which may contribute to the improvement of acceptance and usage and thereby further support the clinical benefit.

Acknowledgments

The authors thank all patients who participated in this study. They also thank Andreas Siebert for his contribution to the qualitative analysis. Parts of the manuscript were proofread by ChatGPT (GPT-5; OpenAI) to increase readability. Following the use of this tool, the authors examined and revised the content as required, assuming complete responsibility for the publication's material.

Abstract

Background: Electronic patient-reported outcomes (ePROs) have demonstrated greater sensitivity in detecting adverse events than clinician-reported outcomes. However, conventional care faces challenges related to recall bias, and evidence from real-world populations of older adults is limited. This study evaluates the feasibility of an ePRO system integrated with ecological momentary assessment and ecological momentary intervention (EMI) to facilitate a concordance model within the framework of digital transformation in health care.

Objective: This study aimed to evaluate the satisfaction, usability, and clinical impact of an ePRO system integrated with ecological momentary assessment and EMI in a real-world cohort of older patients with lung cancer and to investigate its ability to facilitate a patient-centered concordance model within the framework of digital transformation in health care.

Methods: In this single-center prospective cohort study, 35 patients with lung cancer used the Welby My Carte ONC app to record daily symptoms and visual data. Satisfaction and usability were evaluated using 10-point scales at the end of the first and third treatment cycles. The study focused on the clinical impact of EMI triggered by ePRO data, such as early detection of toxicity.

Results: The cohort included a high proportion of older patients (20/35, 57%) aged 70 to 89 years. Satisfaction and usability scores significantly improved over time (satisfaction: 6.0 to 8.0, $P<.001$; usability: 5.0 to 8.0, $P<.001$). ePRO monitoring enabled the early detection of critical events, including immune-related uveitis (case 1), Stevens-Johnson syndrome (case 2), rare drug-induced purpura (case 3), and the monitoring of infusion-related reactions (case 4).

Conclusions: ePRO monitoring is feasible for older patients with lung cancer and enhances safety through timely EMI. It serves as a core component of a comprehensive patient support program and supports the transition to a more active concordance model, ultimately improving patient well-being.

(JMIR Cancer 2026;12:e97890) doi:10.2196/97890

KEYWORDS

lung cancer; electronic patient-reported outcome; ePRO; digital transformation; geriatric oncology; ecological momentary assessment; EMA

Introduction

Patient-reported outcomes are measures of a patient's health status that come directly from the patient, without interpretation by a clinician. In oncology, electronic patient-reported outcome (ePRO) systems have gained significant attention for their potential to enhance symptom management and clinical outcomes. Previous research, most notably the landmark study by Basch et al [1], demonstrated that ePRO systems are more sensitive and reliable in detecting adverse events, such as fatigue, nausea, and diarrhea, than clinician-reported outcomes. Furthermore, subsequent large-scale randomized trials have shown that ePRO-based symptom monitoring during routine cancer treatment can significantly improve overall survival and quality of life [2]. Recent evidence has further expanded on this by highlighting that high patient satisfaction and acceptability are critical for successful ePRO implementation, particularly among older populations who may initially perceive digital tools as burdensome. Despite these advantages, conventional outpatient care is inherently limited by recall bias, as patients are often required to retrospectively report their symptoms over several weeks during periodic clinic visits. To address this limitation, ecological momentary assessment (EMA) and ecological momentary intervention (EMI) have been proposed [3]. EMA allows real-time symptom recording in a patient's

XSL•FO
RenderX

natural environment, thereby enhancing ecological validity and eliminating recall bias, while EMI uses these data to provide immediate, personalized clinical support [3]. For older patients, who frequently face specific challenges such as cognitive decline, visual impairment, limited digital literacy, and social isolation, the real-time nature of EMA and EMI is particularly important for preventing the oversight of subtle but critical symptom changes. The integration of these digital tools is a cornerstone of digital transformation in health care. In this study, the ePRO system is positioned not merely as a stand-alone monitoring tool but as a central component of a comprehensive patient support program (PSP) [4]. This program integrates education, symptom management, and multidisciplinary collaboration to bridge the communication gap between clinic visits, similar to integrated care models that have shown benefits for patients with lung cancer [5]. In the context of lung cancer treatment, digital transformation in health care aims to move beyond passive patient compliance toward a patient-centered concordance model [6]. This model emphasizes a partnership between health care providers and patients, in which decisions are made based on shared goals and the patient's lived experience. Such shared decision-making is further supported by the integration of outcome information into clinical conversations [7]. However, a gap remains in the evidence regarding the longitudinal feasibility and patient satisfaction associated with such systems in real-world aging populations with cancer. Therefore, this study aimed to bridge the gap between clinical trial evidence and real-world practice. By evaluating the satisfaction, usability, and clinical impact of an ePRO-EMI system in older patients with lung cancer, we investigated whether digital transformation in health care can effectively support a patient-centered concordance model and improve patient well-being in a real-world setting.

Methods

Study Design and Setting

This single-center prospective cohort study was conducted at Himeji St Mary's Hospital in Himeji, Japan, between 2023 and 2024. The institution was selected as it serves as a regional core center for oncology, providing a high volume of systemic therapies for a diverse, real-world population of patients with lung cancer. The study analyzed longitudinal data obtained from routine clinical practice to bridge the gap between clinical trial evidence and real-world implementation.

Participants and Enrollment

Eligible participants included patients with lung cancer receiving systemic therapy, including cytotoxic chemotherapy, immune checkpoint inhibitors (ICIs), and molecularly targeted therapies. Sampling was conducted on a consecutive basis for all eligible patients at our institution during the study period. As the ePRO system was implemented as part of standard care for self-monitoring, all eligible patients were encouraged to participate. The decision to use or withdraw from the app did not affect the standard of medical care provided.

The ePRO Software and Workflow

The ePRO system used was Welby My Carte ONC (Welby Inc). The software interface allowed patients or their caregivers to record daily symptoms (eg, fatigue and appetite loss), psychological status, and physical findings through photographs (eg, skin rashes). To support adherence, particularly among older patients, the app provided push-notification reminders and visual tracking of symptom trends. Training and onboarding were provided by health care staff at the time of treatment initiation. Data were transmitted in real time to a secure dashboard accessible by the clinical team, facilitating immediate clinical decision-making through an integrated EMA-EMI framework. Representative screenshots of the Welby My Carte ONC platform are provided in Multimedia Appendix 1. A schematic overview of the EMA-EMI clinical workflow is shown in Multimedia Appendix 2.

Measures and Clinical Data

Patient-reported outcomes were evaluated using structured questionnaires at the end of the first cycle (interim evaluation) and the third cycle (final evaluation). The questionnaire assessed four quantitative items: (1) satisfaction with the app, (2) ease of use (usability), (3) willingness to continue using the app, and (4) clarity of the instructions provided by staff. Each item was scored on a 10-point Likert scale, where 1 represented "strongly disagree" or "very poor" and 10 represented "strongly agree" or "excellent." Open-ended responses were also collected to identify perceived advantages and challenges. Clinical covariates, including age, sex, Eastern Cooperative Oncology Group performance status (PS), disease stage, and line of therapy, were extracted from electronic medical records. Because the questionnaire was designed as a pragmatic usability assessment tool for routine clinical implementation, formal psychometric validation was not performed. The complete questionnaire items used for patient evaluation are provided in Multimedia Appendix 3.

Clinical Impact and Case Selection

The clinical impact of the system was evaluated based on the frequency and nature of physician-initiated interventions (EMIs) triggered by ePRO data, such as telephone consultations, early clinic visits, and dose modifications. To illustrate the clinical utility of the system, 4 representative cases were selected based on their diversity of toxicity types (eg, immune-related and drug-induced) and their demonstration of how real-time monitoring can lead to improved safety.

Statistical Analysis

Descriptive statistics were used to summarize patient characteristics and clinical data. For longitudinal comparisons of ePRO scores between cycle 1 and cycle 3, the Wilcoxon signed-rank test was used. This nonparametric approach was selected because of the ordinal nature of the 10-point scale data and the relatively small sample size. Missing questionnaire data were handled using complete case analysis. Qualitative data from open-ended responses were analyzed using a descriptive thematic analysis framework. The process involved an inductive approach in which 2 researchers independently reviewed the free-text comments to identify recurring patterns and codes.

XSL•FO
RenderX

These codes were then grouped into overarching themes. Discrepancies in thematic assignment were resolved through consensus among the research team. The qualitative findings were intended to provide exploratory supplementary insights that complemented the quantitative results.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki and was approved by the institutional review board of Himeji St Mary's Hospital (S024-001). All participating patients provided written informed consent prior to data collection.

Reporting Guidelines

This study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guideline for observational cohort studies. The completed STROBE checklist is provided in Multimedia Appendix 4.

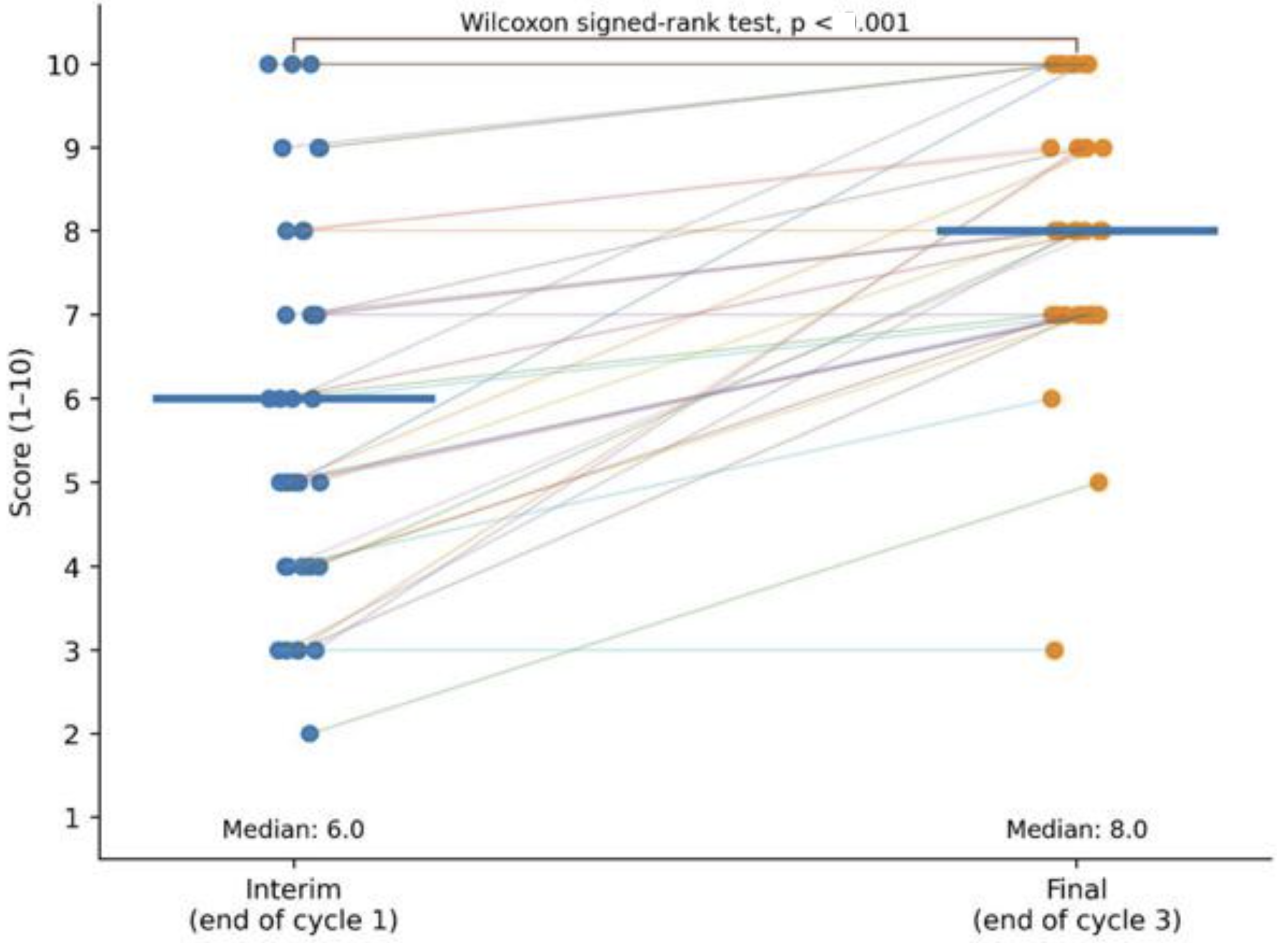
Results

Patient Characteristics

A total of 35 patients with lung cancer were included in the analysis (Table 1).

The cohort was characterized by a high proportion of older individuals, with 20 (57.1%) of the patients aged ≥70 years (n=11 aged 70-79 years and n=9 aged 80-89 years). Most participants were male (24/35, 68.6%) and maintained a good PS (PS 0: n=23; PS 1: n=10). Treatment regimens were diverse, reflecting real-world practice: 19 patients received chemotherapy combined with ICIs, while others received cytotoxic chemotherapy (n=6), ICI monotherapy (n=4), tyrosine kinase inhibitors (TKIs; n=4), or TKI-chemotherapy combinations (n=2).

Table . Patient characteristics (N=35).



Characteristics	Patients, n (%)
Age group (years)	
40-49	1 (2.9)
50-59	5 (14.3%)
60-69	9 (25.7)
70-79	11 (31.4)
80-89	9 (25.7)
Sex	
Male	24 (68.6)
Female	11 (31.4)
Performance status	
0	23 (65.7)
1	10 (28.6)
≥2	2 (5.7)
Treatment regimens	
Cytotoxic chemotherapy	6 (17.1)
Chemotherapy+immune checkpoint inhibitor	19 (54.3)
Immune checkpoint inhibitor–based therapy	4 (11.4)
Tyrosine kinase inhibitor–based therapy	4 (11.4)
Chemotherapy+tyrosine kinase inhibitor	2 (5.7)

Quantitative Patient-Reported Outcomes

Quantitative evaluations revealed that patients successfully adapted to the ePRO system over the course of 3 treatment cycles. All measured items showed significant improvement from the interim evaluation to the final evaluation. Specifically, the median patient satisfaction score increased from 6.0 at the interim evaluation (cycle 1) to 8.0 at the final evaluation (cycle 3; P<.001; Figure 1). Usability scores, reflecting ease of use, increased from a median of 5.0 to 8.0 (P<.001; Figure 2). Willingness to continue using the app improved from a median of 6.0 to 8.0 (P<.001; Figure 3). Furthermore, the clarity of the instructional guidance provided by the clinical staff showed a significant upward trend, with median scores increasing from 5.0 to 8.0 (P<.001; Figure 4). These findings suggest that even older patients can achieve high levels of proficiency and satisfaction with digital monitoring tools through repeated use.

Qualitative Feedback: Advantages and Challenges

The thematic analysis of qualitative feedback identified 4 primary areas of focus regarding the patient experience. First, daily ePRO input was found to enhance self-monitoring and provide a significant sense of psychological security. By recording symptoms daily, patients reported that they could more effectively distinguish between expected treatment-related adverse events and general daily fatigue, thereby reducing unnecessary anxiety. Real-time connectivity with the clinical team further contributed to a perceived sense of security, particularly during the early phases of treatment. Second, patients consistently preferred the digital interface over traditional paper-based documentation. Participants highlighted the convenience and low burden of mobile data entry, as well as the clinical utility of longitudinal symptom visualizations, which enabled clearer communication of symptom trajectories during outpatient visits and reduced reliance on retrospective recall. Third, the system facilitated multigenerational support, particularly among the oldest participants. Family members frequently assisted with data entry, allowing them to become more actively involved in the care process while also providing a practical means of monitoring the patient's condition remotely. Finally, despite these benefits, several technical and functional barriers were identified. Some patients expressed uncertainty regarding successful data transmission and suggested the inclusion of automated confirmation messages following submission. Participants also indicated that the integration of educational resources, such as a built-in reference guide to treatment-related adverse events, would enhance their ability to interpret symptom changes and manage treatment expectations. Collectively, these findings suggest that the perceived benefits of ePRO extended beyond symptom monitoring to include psychological reassurance and family engagement, while the principal challenges were related to communication feedback mechanisms and patient education.

Clinical Impact and Representative Case Narratives

The clinical utility of the ePRO-EMI framework was demonstrated through its ability to capture clinically significant adverse events that might otherwise have remained undetected between standard outpatient visits. The system facilitated rapid physician-initiated interventions (EMI) across a variety of toxicity profiles, as illustrated by the following 4 representative cases selected to show the diversity of detected events. In the first case, a 71-year-old male reported "foggy vision" via the app on the first day of pembrolizumab treatment. This early EMA data led to a prompt hospital visit on day 9, resulting in the diagnosis and successful management of grade 2 immune-related uveitis without treatment interruption. Similarly, a 40-year-old female used the image upload function to report a skin rash. Real-time monitoring of these images allowed clinicians to detect the rapid progression of toxicity from grade 2 to grade 3, leading to an immediate diagnosis of Stevens-Johnson syndrome and life-saving corticosteroid intervention.

XSL•FO
RenderX

The system also proved effective in identifying rare toxicities, as demonstrated by the case of a 83-year-old female who uploaded photographs of lower-extremity skin lesions. This led to the diagnosis of epidermal growth factor receptor-TKI–associated purpura and enabled a flexible dose modification to maintain treatment continuity. Finally, the ePRO system provided a continuous layer of safety monitoring for a 50-year-old female who had experienced severe infusion-related reactions to amivantamab. Postdischarge monitoring confirmed the absence of symptom exacerbation, allowing safe continuation of therapy in an outpatient setting and reducing patient anxiety. These cases highlight how the integration of real-time patient data into clinical workflows can directly enhance patient safety.

Discussion

Principal Findings

This study demonstrated that an ePRO system integrated with the EMA-EMI framework significantly enhanced patient satisfaction and usability over time while enabling the early detection of critical adverse events in a real-world population of older adults with lung cancer. Specifically, the longitudinal improvement in median scores from 6.0 to 8.0 across satisfaction and usability metrics suggests that older patients can effectively adapt to digital health tools when provided with continuous institutional support. Our findings regarding feasibility and satisfaction align with recent evidence highlighting the potential of ePRO systems in older adults. While previous studies have often noted lower completion rates in older adult cohorts, Riedl et al [8] observed that home-based ePRO systems are feasible for >80% of older adults who survived cancer when family and staff support are integrated. The significant increase in scores for clarity of instructions (Figure 4) in our cohort suggests that the initial digital barrier can be overcome through repeated use and proactive staff engagement, leading to high levels of acceptance. The clinical impact of the ePRO-EMI system was particularly evident in the early detection of potentially life-threatening toxicities, bridging the gap between periodic outpatient visits. For instance, the detection of immune-related uveitis (case 1) within the first week of treatment is crucial, as this condition can manifest much earlier than the reported median latency of 12 weeks [9]. Similarly, real-time monitoring of image data in case 2 allowed the immediate diagnosis of Stevens-Johnson syndrome, which is characterized by a high mortality risk among patients receiving combination immunotherapy [10]. For targeted therapies, ePRO facilitated the management of rare toxicities, such as osimertinib-induced cutaneous vasculitis (case 3) [11], and provided an additional safety layer for outpatient monitoring of infusion-related reactions (case 4) [12]. These cases collectively illustrate how the EMA-EMI framework mitigates recall bias and enhances ecological validity by capturing subtle symptom changes in the patient's natural environment. Furthermore, our results suggest that ePRO should not be viewed as a stand-alone monitoring tool but as a core component of a comprehensive PSP [4]. The integration of real-time data into clinical workflows supports a transition from passive compliance to an active concordance model, in which treatment decisions are made through shared decision-making based on the patient's lived experience and real-time status [6,7]. Despite these promising results, several challenges remain. Adherence tended to decline during periods of symptom stability, suggesting that future iterations of the system could benefit from behavioral economics or gamification strategies to maintain long-term engagement [13]. Additionally, as 57.1% of our cohort was aged ≥70 years, family members often assisted with data entry. This introduces the potential for interrater variability, as proxies may overestimate symptom severity compared to patient self-reports [14]. This study has several limitations. First, as a single-center prospective cohort study with a relatively small sample size (N=35), the generalizability of our findings to broader populations may be limited. Second, the absence of a control group receiving conventional care makes it difficult to definitively determine whether the ePRO-EMI approach is superior to conventional care. Finally, although we used a descriptive thematic analysis to categorize patient feedback, the qualitative analysis was conducted on a limited dataset from a single-center cohort. Therefore, these findings should be interpreted as exploratory and illustrative of this specific clinical setting, rather than as fully generalizable to all older adults with cancer. In addition, the long-term sustainability and scalability of digital health interventions remain challenging, particularly in aging populations with heterogeneous levels of digital literacy and varying support systems [15]. In conclusion, this study provides real-world evidence that ePRO-based monitoring is feasible and beneficial for older patients with lung cancer. Future research should integrate artificial intelligence to provide automated, predictive warnings of toxicities and to foster deeper collaboration with regional health care systems [16]. Ultimately, digital transformation in health care, centered on patient-reported data, holds the potential to significantly improve patient well-being and safety in an aging society.

Conclusions

ePRO integrated with EMA and EMI is feasible and clinically valuable for older patients with lung cancer in real-world settings. Real-time monitoring enabled the early detection of clinically significant adverse events and supported patient-centered care beyond routine outpatient visits. However, successful implementation requires continuous institutional support, improved digital literacy, and integration into comprehensive PSPs. Future research should focus on artificial intelligence–assisted toxicity prediction and broader regional health care collaboration to optimize sustainable implementation in aging societies.

Abstract

Background: Pediatric cancer presents many challenges for young patients and families that extend beyond active treatment. Families report significant unmet information and supportive care needs at the end of treatment (EOT). Digital health solutions, such as patient apps, offer a potential solution to address current gaps in care.

Objective: This study aimed to develop and test a smartphone app called LotusLab, designed to improve access to survivorship information for parents of childhood cancer survivors aged 0 to 18 years, and for young people (aged 12 years and older) at the EOT. In addition, this study aimed to examine parents’ and health care providers’ (HCPs) perceptions of LotusLab during β-testing to inform further app development and refinement.

Methods: Participants were invited to explore the content and key functionality of LotusLab, including an embedded patient-reported outcome measure (PROM). Evaluation of the usability, acceptability, usefulness, and feasibility of the app was conducted through quantitative surveys and qualitative semistructured interviews.

Results: Participants comprised 8 parents whose children had completed cancer treatment, and 9 HCPs. All participants (100%) “agreed” or “strongly agreed” that the app was acceptable; however, HCPs reported more neutral acceptability responses compared with parents. Parents scored app usability more highly, with a mean System Usability Scale (SUS) score of 86.88 (SD 8.74), than HCPs’ mean SUS score of 66.39 (SD 10.16). A common perceived benefit of LotusLab was the provision of trusted information and psychosocial resources. Suggestions for improvement included adding a search function, enhancing the layout, and adding additional topics. All parents completed the app-embedded PROM. Both cohorts noted the value of the PROM in enhancing EOT consultations, while highlighting considerations for the effective integration of and response to PROM data.

Conclusions: Initial data indicate that LotusLab is easy for parents to use and provides value through the provision of EOT information and the opportunity to enhance the use of the PROM. Consistent with the co-design methodology, these findings are guiding the ongoing development and implementation of LotusLab.

Introduction

A cancer diagnosis in childhood presents extraordinary challenges for patients and families who must navigate complex treatments and profound impacts on family life. The end-of-treatment (EOT) period represents a critical transition period for families, as they re-establish regular family routines while managing treatment side effects and fear of relapse. Multiple studies highlight that this period is marked by significant unmet information and supportive care needs for families [1-4]. Provision of relevant and timely information at the EOT represents a critical strategy for bridging identified gaps in care and mitigating associated psychological distress [5,6]. However, families continue to report barriers to accessing information when needed [2,7-9]. Research examining the optimal delivery of early survivorship information indicates that such information should be tailored to the needs and preferences of the individual, presented in multimodal formats (eg, short videos, animations, and testimonials), and available electronically [10-12].

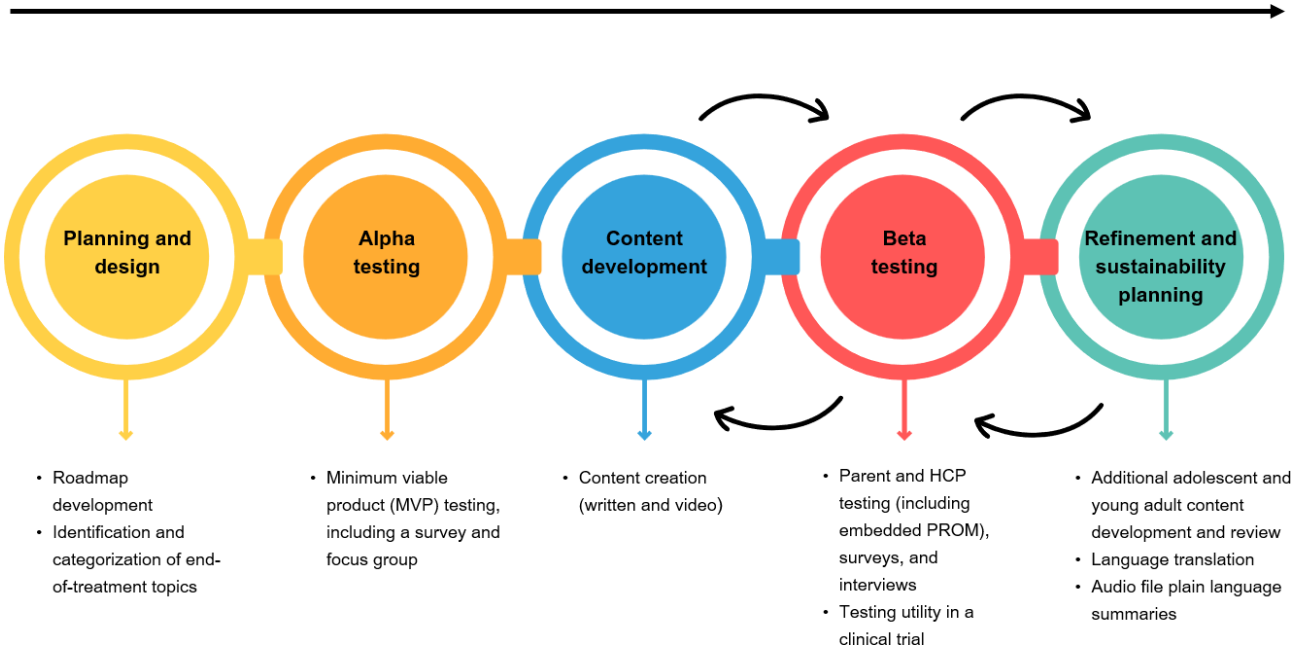
Mobile apps have been found to be useful and acceptable support tools for young people and caregivers experiencing cancer [13-21]. The potential benefits of apps include increased accessibility to trusted information due to high levels of mobile phone use and opportunities to actively engage users in their health care, including through the delivery of personalized care plans and patient-reported outcome measures (PROMs) [19,21-26]. Notably, there are examples of co-designed digital PROM tools in pediatric oncology that have demonstrated strong and sustained user engagement, particularly during active treatment, providing symptom monitoring and delivery of tailored information [21,27].

Although there are positive examples of progress in the development of apps and digital PROMs, real-world uptake and ongoing engagement with digital health tools remain low, often due to a lack of robust co-design and testing [28,29]. Therefore, to ensure ongoing sustainability, it is essential to actively engage users in all phases of the development and testing of mobile interventions [24,30].

Despite an increasing number of apps developed for families experiencing a cancer diagnosis [23], none were identified that provide information for both young people and parents, and specifically target the EOT transition within a pediatric setting. This paper reports the findings from a study undertaken during the β-testing phase of the co-design of a digital survivorship companion app called LotusLab. The aim of this study was to examine parent caregivers' and health care providers' (HCPs) perceptions of the app, including early-phase testing and perspectives on the use of a proxy-reported outcome measure embedded within the app.

Methods

Setting



This study was conducted at The Royal Children's Hospital (RCH), a major tertiary pediatric hospital in Melbourne, Australia.

Study Design

Study Phases

Our research team has undertaken a 3-year mixed method study to co-design, develop, and test LotusLab, a digital hub for information after childhood cancer. LotusLab is designed for caregivers of childhood cancer survivors and for young people (aged 12 years and older) at EOT. LotusLab has been co-designed with young people, caregivers, and HCPs in alignment with participatory design principles [31]. Figure 1 shows an overview of the co-design activities across the app development and testing process.

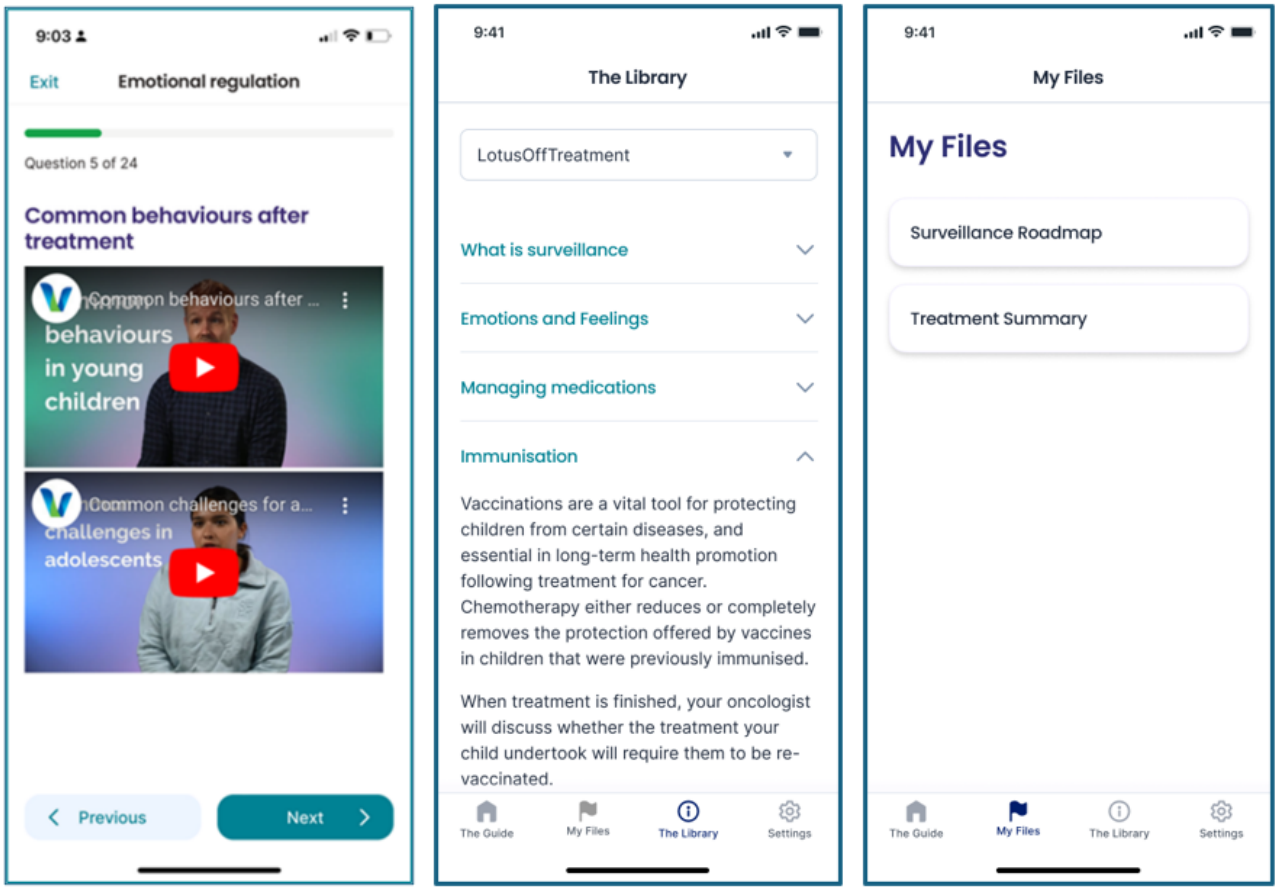


Figure 1. LotusLab co-design and development process. Co-design activities with parents, young people, and HCPs. HCP: health care provider; PROM: patient-reported outcome measure.

XSL•FO
RenderX

As a result of this iterative development process, the LotusLab prototype, available for β-testing, provided tailored information and videos, surveys, PROMs, notifications and reminders, and storage of personal survivorship documentation (manuscript under review). Figure 2 shows screenshots of the prototype.

Figure 2. LotusLab screenshots. Both individuals in the screenshots have provided written consent for their images to be used for the purposes of this manuscript.

Following planning, design, α-testing (ie, early-phase internal testing), and content development phases, the current study was conducted during the β-testing phase, which focused on testing performance and experience in "real-world" environments. The aim was to evaluate parents' and HCPs' perceptions of LotusLab and the use of a proxy-reported outcome measure embedded within the app. Usability, acceptability, usefulness, and feasibility (refer to Table 1 for descriptions) were evaluated through quantitative surveys and qualitative semistructured interviews. Descriptions of these 4 domains were informed by digital health evaluation and implementation science literature [32-34] to ensure that we captured technical outcomes related to the app itself, as well as implementation factors.

Table . Template analysis theme descriptions.

A priori themes	Description theme inclusions
Theme 1: usability	User-friendliness, ease of use, and efficiency, including navigation, interface, intuitiveness, and ideas for improved functionality
Theme 2: acceptability	Content suitability, relevance, alignment with expectations, and likelihood of recommending. Encompasses all content feedback
Theme 3: usefulness	Ability of the app to provide benefit/value add/impact. Usefulness in meeting needs/requirements. Effectiveness in delivering desired outcomes
Theme 4: feasibility	Practicalities of implementation including timing, barriers, enablers, and ongoing sustainability

Participants

Parents or caregivers (hereafter referred to as parents) were eligible to participate if their child (aged 0 - 18 y) had finished cancer treatment for any cancer diagnosis within the previous 14 months and was receiving medical cancer surveillance at The RCH's Children's Cancer Center (RCH CCC). Eligible clinicians included RCH CCC medical or specialist nursing staff who provided direct clinical care and coordination to families recruited into the study.

XSL•FO
RenderX

Procedure

Parent participants were identified by RCH CCC clinical staff, who introduced the study and provided an information letter. A member of the research team contacted the parent within 2 weeks to ascertain their willingness to participate. Medical and specialist nursing staff who were directly involved in the care of the recruited families were approached via email to participate in the study. All participants provided written consent. Following parent and HCP consent, the study team used the hospital appointment booking system to identify and record the date of the patient's next medical surveillance appointment.

Parents and HCPs were sent instructional emails detailing how to download and explore LotusLab, including how to enroll in the "Lotus Off Treatment" program. HCPs are integral to the successful implementation of digital health interventions. Therefore, as potential deliverers and trusted advocates, HCPs were asked to explore the parent (end user) interface and to evaluate the potential value and use of LotusLab to support their patients and families.

Once enrolled, participants had access to 15 topics, comprising videos and written information and resources tailored to parents and related to the EOT period. If available, the patient's personalized treatment summary and surveillance roadmap were uploaded to the app. All participants were encouraged to explore the LotusLab layout and content. In addition, parents were asked to complete an in-app survey called "About You and Your Child" to provide basic demographic data and to self-rate their digital literacy. Within the survey, parents provided details about their child's age, which triggered the in-app release of the corresponding parent proxy-reported Pediatric Quality of Life Inventory (PedsQL; version 4.0), a widely used, validated 23-item measure assessing child health-related quality of life across 4 dimensions: physical, emotional, social, and school functioning [35]. Participants received email and mobile notifications alerting them to the availability of the PedsQL for in-app completion.

Parents were asked to complete the PedsQL within 2 weeks prior to their child's appointment. Although the PedsQL is validated for self-reporting by children aged 5 to 18 years [35], this early-phase testing was designed to capture parents' experiences only and therefore included proxy reports for children aged 2 to 4, 5 to 7, 8 to 12, and 13 years and older. Further development and testing of the adolescent and young adult interface are ongoing.

PedsQL results were exported from the app by the study team, and subscale and total scores were manually calculated as per standardized scoring instructions. This procedure was undertaken due to app capability limitations at this phase of testing and the ongoing development of the clinician user interface. Preliminary testing focused on initial perceptions of parents and clinicians regarding the use of and discussion of the PROM in the real-world clinical setting. To support HCP understanding and interpretation of PedsQL domains and scores, and to aid consultation discussions, a custom PedsQL report was shared via email with the relevant HCP prior to the patient's upcoming appointment (Multimedia Appendix 1). Parents and HCPs were encouraged to discuss the results of the PedsQL during the medical consultation. A retrospective note audit was undertaken to capture any documentation of the PedsQL results and discussion.

Following the consultation, participants were invited to complete usability and acceptability surveys administered via REDCap (REDCap Consortium) software [36] and to take part in an online semistructured interview to discuss their experience with LotusLab.

Measures

Demographics

Brief demographic data related to patient and family factors (eg, diagnosis, age of the child, etc) were captured via an inbuilt survey titled "About You and Your Child." Additional treatment information or relevant dates were accessed via the electronic medical record (EMR) and stored securely. Information related to HCPs (eg, discipline, role, primary institution, and years of oncology experience) was gathered during the consent process, either verbally or via email.

Digital Health Care Literacy Scale

Parents' digital literacy level was captured to enhance the accuracy of usability testing and to interpret differences between user abilities and issues with the LotusLab design and functionality. The validated 3-item Digital Health Care Literacy Scale was selected to assess participants' comfort and confidence with mobile technology, specifically the ability to install and use apps and solve technical issues on their own [37].

System Usability Scale

Usability was measured and benchmarked with the System Usability Scale (SUS), a validated and widely used measure for assessing the usability of digital products [38,39]. The short 10-item questionnaire shows strong internal consistency and construct validity [40], and the benchmark mean usability score of 68 (SD 12.5) is considered appropriate for assessing the usability of digital health apps across different contexts [39]. Scores greater than 51 can be interpreted as "okay," scores of 75 and above can be interpreted as "good," and scores of 86 and above as "excellent" [41].

Adapted Abbreviated Acceptability Rating Profile

Acceptability was measured using a study-specific scale that was adapted from the 8-item abbreviated acceptability rating profile (AARP) [42]. Wording of the items was adapted to assess the app (eg, "I would be willing to recommend this app to other parents"), and items were scored on a 5-point Likert scale (strongly disagree, disagree, neutral, agree, and strongly agree; Multimedia Appendix 2).

Semistructured Interviews

Semistructured interviews were conducted with parents and HCPs to elicit in-depth perceptions of the app. Interviews were recorded, transcribed, and deidentified for analysis in NVivo (version 15), a software program for data analysis [43] (Multimedia Appendix 3).

XSL•FO
RenderX

Data Analysis

Descriptive statistics were used to summarize data from the measures outlined above. For the Digital Health Care Literacy Scale, frequencies of responses were calculated. SUS mean scores and score ranges were calculated to provide an overall indicator of usability; frequencies and percentages from the adapted AARP were summarized, describing the proportion of participants who rated the intervention as acceptable.

Template analysis was selected for qualitative analysis of semistructured interviews. Template analysis involves the development of a predetermined coding template that can be adapted in response to the data. It is considered a practical and rapid method well suited to iterative design cycles [44]. In our study, 4 a priori themes were selected to guide analysis and address the study objectives: usability, acceptability, usefulness, and feasibility. Although some additional subthemes were predetermined (eg, barriers and enablers to implementation), others were generated and validated using thematic analysis. To enhance reliability, 2 research team members (HP and MCM) independently coded 3 interviews with parents and HCPs and compared their coding. Consensus on the type of content that related to each a priori theme was reached (see Table 1 for definitions). Remaining transcripts were analyzed by HP with ongoing review by MCM.

Ethical Considerations

The study was approved by the RCH Human Ethics and Research Committee (#85334). Informed consent was obtained from all participants. All data were securely stored on servers and software approved for the use of protected health information. Additionally, data were deidentified upon collection and stored under a study identification number. Participants did not receive compensation for participation in this study.

Results

Study Participants

Eight parents (7 mothers) of children with a range of diagnoses, aged between 3 and 17 years, were approached and consented to participate in the study. All participants (100%) reviewed the app content and provided feedback via online surveys and semistructured interviews.

Twelve HCPs consented to the study; 3 did not respond to follow-up and did not participate in interviews or surveys (75% response rate). Nine HCPs (5 oncologists and 4 advanced practice nurses) reviewed the app content and completed the online usability and acceptability surveys. Eight participated in interviews; 1 HCP was unavailable due to extended leave. Participant characteristics are presented in Table 2.

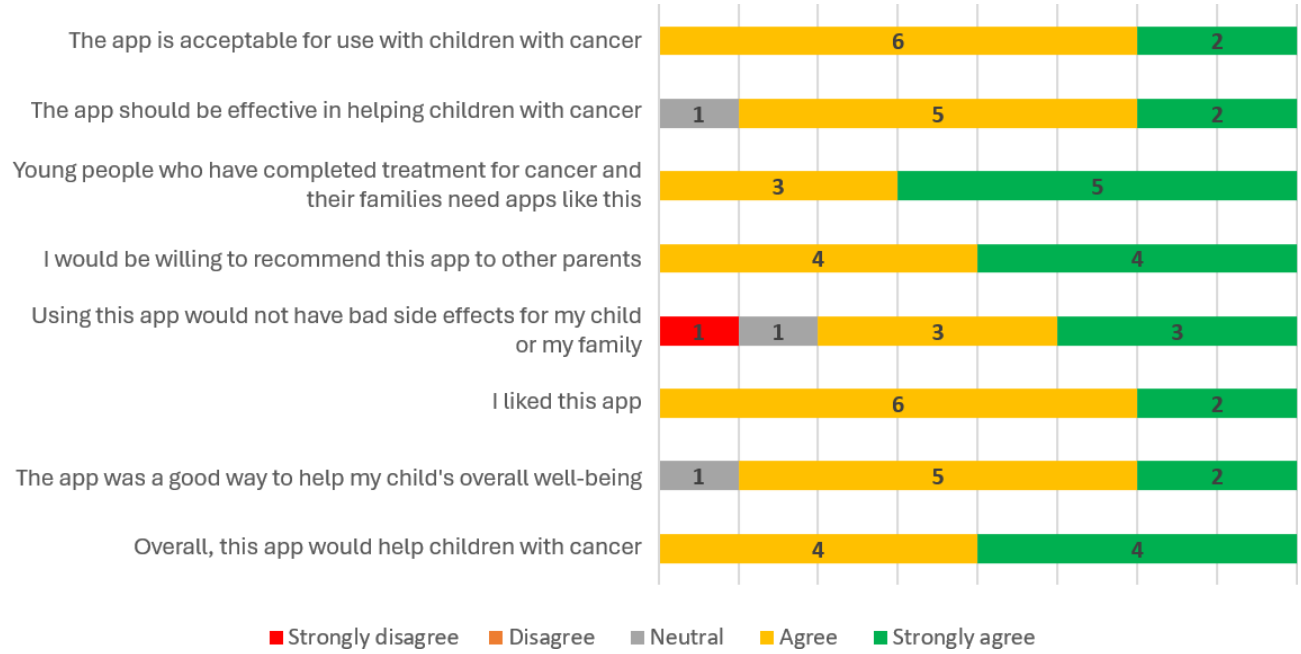
Parent Results

Digital Health Literacy Scale

Figure 3 presents digital literacy results. Six of the 8 parents (75%) "agreed" or "strongly agreed" that they could use or install an app on their device without asking for help and indicated that they could solve basic technical problems on their device. Two (25%) parents "strongly disagreed" that they could do this.

Figure 3. Parent Digital Health Literacy Scale summary.



Usability and Acceptability of the App

Parents responded with a high mean SUS usability score of 86.88 (SD 8.74; range 75 - 100) compared with the benchmark usability score of 68 [39]. All parents "agreed" or "strongly agreed" that the app was "quick to learn" and that they felt confident using the app. Parents individually rated usability as either "excellent" (5/8) or "good" (3/8).

All parents "agreed" or "strongly agreed" that the app was fit for purpose and that a digital solution such as LotusLab was needed for young people who had recently completed treatment for cancer. Figure 4 shows parent ratings of LotusLab's acceptability.

XSL•FO
RenderX

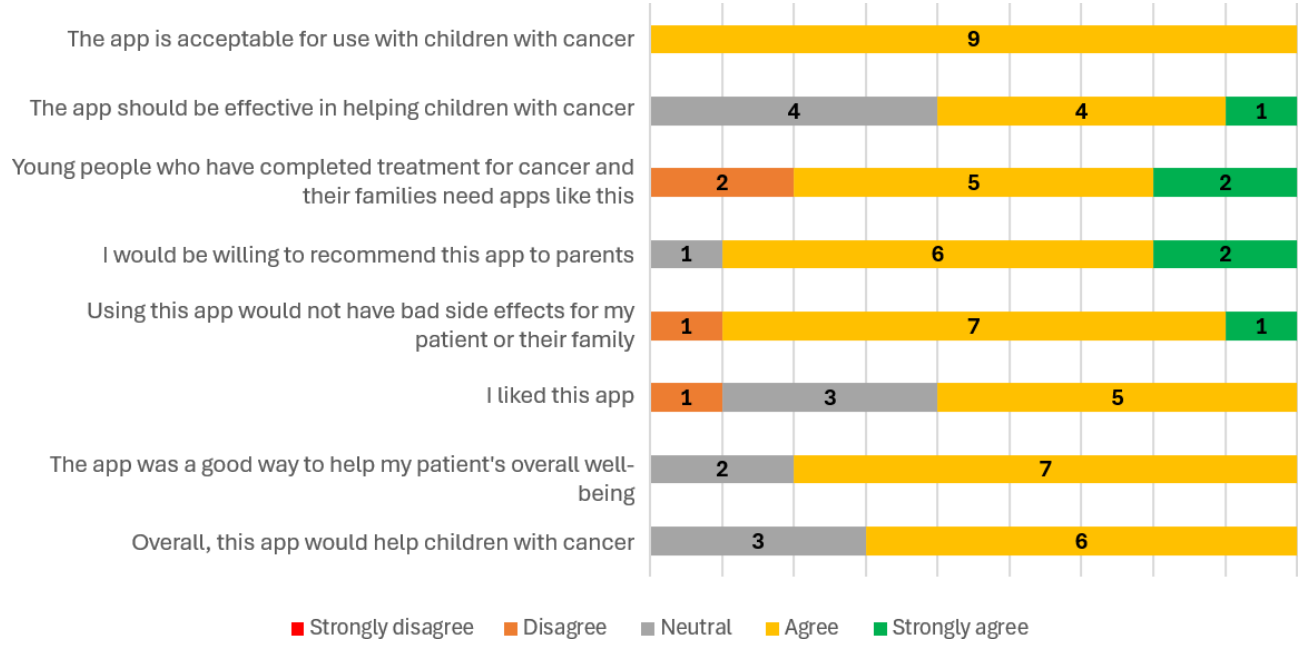


Figure 4. Parents' ratings of LotusLab acceptability.

HCP Results: Usability and Acceptability of the App

HCPs rated the usability of the parent-facing app in the "okay" range, with an overall mean SUS score of 66.39 (SD 10.16; range 45.0 - 77.5). All providers "agreed" that the app was "acceptable for use with children with cancer." Seven of 9 HCPs (77.8%) "agreed" or "strongly agreed" that young people who had completed treatment and their families need apps like this, and 8 (88.9%) "agreed" or "strongly agreed" that they would be willing to recommend the app to parents. Figure 5 shows HCP ratings of LotusLab acceptability.

Figure 5. Health care providers' ratings of LotusLab's acceptability.

Usage of the App-Embedded PROM (PedsQL)

All 8 parents completed the PedsQL measure embedded within the app. Four participants had a discussion with the oncologist regarding their questionnaire results. One parent stated that, although they did not discuss the questionnaire specifically, they felt the results informed the consultation, as areas of concern were brought up by the consultant and addressed. For 1 parent, the survey was brought up for discussion by the consultant; however, the parent "didn't bother going into it," as they felt a different HCP would be better placed to discuss the results. One parent was unsure whether the PedsQL was discussed, as their partner attended the consultation. One parent stated that the PedsQL was not discussed.

A retrospective review of EMR notes found that 4 of 8 clinicians documented the areas of need identified by the PedsQL and the outcomes of the discussion. One clinician documented the parent's participation in the study but did not directly reference

XSL•FO
RenderX

the PedsQL, and 3 clinicians did not reference the PedsQL in the medical record. Parents' experiences of completing the questionnaire within the app and discussing the PedsQL are captured in the semistructured interviews, as are HCPs' experiences of receiving and using the PedsQL results. Reporting of PedsQL scores is outside the scope of this study.

Qualitative Interview Results

Interview Characteristics

Semistructured individual interviews were conducted online (using Microsoft Teams) with both parents and HCPs. Interviews ranged from 19 to 41 minutes and were conducted between October 2023 and April 2024. Refer to Table 1 for a priori theme definitions and Table 3 for themes, subthemes, and exemplar quotes from parents and HCPs.

XSL•FO
RenderX

Table . Exemplar quotes from semistructured interviews with parents and health care providers (HCPs).

Themes and subthemes	Quotes
Theme 1: usability	
Navigation	"Usability...was spot-on...it seemed to be...very clear and clean." (Parent 6)
	"I liked the idea of all the activities which allowed people to pick and choose the ones that they liked to do." (HCP 10)[a]
Look and feel/design	"...whilst aesthetically some people might think it's a bit basic I actually just found that the basic works so why mess with it?" (Parent 1)
	"...more navigational like a 'Choose Your Own Adventure'..." (HCP 7)
Functionality	"...I can't see the completed activities. I think that's – definitely should be fixed because it would be good to go back and redo some of these or just as a bit of a memory trigger." (Parent 6)
	"I do think that search function would be valuable." (HCP 5)
Theme 2: acceptability	
New content suggestions	"Quick links...I've got some patients now off therapy a year and they're asking me about immunisation...on a weekly basis." (HCP 11)[a]
Content relevancy	"All the videos are really good, especially all the videos that had parents...just made everything so much more relatable and also really calming..." (Parent 3)
	"...the things that are more of value in the app...you know the emotional development of kids or the emotional responses that they might have after finishing treatment." (HCP 1)
Content accessibility	"The videos were good perhaps from another language perspective too. Some people find it easier to listen than to read." (Parent 2)
	"...obviously the topics are good, but if someone is not as health literate then the text heavy thing actually might be a barrier to them..." (HCP 2)
AYA[b] acceptability	"...it depends on the kid...if it's really wordy with modules and things they might feel like it's homework..." (Parent 4)
	"...I think there's some really good key bits but...for a young person I think would look very different." (HCP 7)
Overall experience	"...I was like oh god, I wish I had this app 12 months ago because...I could have just gone to the app and navigated my way through and got the information that I needed." (Parent 1)
Theme 3: usefulness	
Benefits/value add	"I think that this is like a really nice CNC [Clinical Nurse Consultant] in your pocket...you can just refer back to it." (Parent 3)
	"...a nice kind of point of connection still between our service and then coming off treatment...I think, to give them a bit of security..." (HCP 2)
PedsQL[c] usefulness	"It's quite meaningful to be asked those kinds of questions...really nice to feel like...someone's checking in with us." (Parent 3)
	"...a really nice kind of segway...I've got this survey I can see that sleep, pain and mood are a problem...So I think that using them in a consult...would be super helpful..." (HCP 3)
	"...it can take up a lot of time and you're not in the right position to solve a lot of those issues either..." (HCP 6)
Treatment summary and surveillance roadmap	"But if it's there on an app and you can say look, they said I was to do this or do this...and if you can show them it's going to make things so much easier. So it would be really good to have access." (Parent 6)
	"...he can just go like this and say this is my diagnosis and my treatment. Wouldn't that empower him? Wouldn't that have been amazing?" (HCP 11)[a]
Theme 4: feasibility	

XSL•FO
RenderX

Themes and subthemes	Quotes
Barriers to implementation and ongoing engagement	"I know that my son has been resistant to...Who have I got to talk to now?...I'm ready to move on with the next phase of my life." (Parent 4) "...like I've got loads of apps on my phone...like I turn off a lot of notifications...I think that's the tricky thing about an app." (HCP 3)
Enablers to implementation and ongoing engagement	"...I don't know if she [CNC] has like an orientation checklist...or maybe even like a welcome email from her where maybe she...can just send out the link to this app maybe." (Parent 3) "I think it's just the exposure to it...the CNCs who have the relationships with the family...getting it into the Facebook groups and all of those sorts of things, that's where it'll all take-off..." (HCP 10)[a]
Timing and introduction	"I know it's an app for after treatment but for me it was very lonely during treatment...I think if there was a whole aspect of the app where it was what to expect going into it 'cause it's so scary and you've got no idea." (Parent 5)

[a]A total of 12 HCPs were recruited, and 8 participated in interviews; the HCP number aligned with the quote represents the number allocated during sequential recruitment.

[b]AYA: adolescent and young adult.

[c]PedsQL: Pediatric Quality of Life Inventory.

Theme 1: Usability

Parents felt that LotusLab was easy to navigate and appreciated the "clean" and "clear" look and feel. They valued the ability to choose topics according to personal interest and importance. Practical suggestions for improvement centered on the ability to view completed topics and PROM results once submitted, the ability to share content with others (eg, friends, medical team, and community health), as well as a search facility.

Overall, HCPs also found the app easy to navigate; however, they had more suggestions about the app layout, suggesting topic groupings such as "emotions" and a "more colorful and tiles layout" could help make it easier to navigate. HCPs echoed parents' comments that the ability to share content and reaccess information through a search function and "Quick Links" sections would enhance the user experience.

Theme 2: Acceptability

Parents commented positively on the relevant and relatable content. Two parents stated they wished they had access to the app earlier. There were many suggestions for additional content (eg, development of a frequently asked questions section, information on how parents can support adolescents, and the need for additional videos from the perspectives of children and young people). Specifically, 2 parents reflected on the need for additional content for young people diagnosed with brain tumors, addressing the impacts of cognitive impairment on returning to school and maintaining friendship groups. Parents provided positive feedback about the video content and its ability to enhance accessibility for users with low general and health literacy levels.

HCPs provided positive feedback on the app content, particularly in relation to the videos and psychosocial and emotional needs information at the EOT. There was feedback that additional app content would be needed to enhance its relevance and suitability for patients who had undergone bone marrow transplant and those with brain tumors, due to specific medical and psychosocial needs. HCPs felt that while an app is an appropriate mechanism for young people to access information, LotusLab required enhancements to make it more engaging for young people, such as reducing the amount of text, reordering content to ensure videos always appear at the top, and making it look less like a "learning module." HCPs suggested that information relating to the LotusLab sign-up process should also be available in languages other than English to ensure equity of access.

Theme 3: Usefulness

Parents felt the app provided additional value by collating trusted information in one place (taking out the "legwork"), providing education, alleviating concerns, and allowing people to digest information in their own time.

All parents reported that they found the technical process of completing the PedsQL within the app easy. In addition, most found the process meaningful as a mechanism for "checking in." Two participants did not discuss the survey results with their oncologists, as they felt that these medical practitioners were not best placed to support their identified needs and that it would have been more beneficial to discuss the results with a different member of the health care team, for example, an occupational therapist. One parent found some of the specific survey questions challenging to answer. They felt some questions were not appropriate to their child's current situation due to the long-term and evolving cognitive impacts of their diagnosis and treatment. This participant cautioned about the importance of delivering surveys like the PedsQL on a case-by-case basis to ensure relevance to a family's current situation.

Some participants had difficulty accessing their treatment summaries and roadmaps uploaded to the "My Files" section of the app. Despite this challenge, all parents felt that access to these documents would be useful, especially when visiting other health professionals or when they were unable to access the existing EMR patient portal.

HCPs felt the value of LotusLab centered on its ability to address identified gaps by providing connections to information at the

XSL•FO
RenderX

EOT, and they regarded the app as "a good bridge." In addition, HCPs considered that the app could help normalize experiences. Multiple HCPs felt that LotusLab could potentially reduce the need for parents to consult Google and save HCPs time in answering common questions.

HCPs responded positively to the concept of using the app for PROMs, streamlining the data collection process, and using the results as a mechanism for meaningful discussion of broader quality of life issues and concerns. However, HCPs flagged potential concerns about their capacity to review results captured in the app prior to a consultation, and about the risk of identifying needs but feeling they were "not in the right position to solve a lot of those issues." They acknowledged that identifying a need that is not addressed introduces risk and could potentially result in a negative experience for patients and caregivers.

HCPs noted that access to personalized survivorship documents, such as a treatment summary, could be empowering, especially for young people who do not always have ownership of these documents. One clinician cited specific examples from their career when access to a treatment summary would have been beneficial for both the treating clinician and the patient, for example, when a childhood cancer survivor presented as an adult to an emergency department but had "no idea" which cancer they had or what treatment they had received for their cancer.

Theme 4: Feasibility

The interviews explored in detail the potential barriers to engagement and sustainability of the app. Some parents felt they would be less likely to continue engaging with the app the further off treatment they were, or when feeling "ready to get back to normal" and "not wishing to revisit the past." Two participants noted that there was a risk the app could feel like "homework," which could reduce engagement among young people.

Parent-identified enablers to engagement and sustainability included promotion of the app by staff, such as specialist nurses, who know the families well and are best placed to discuss what to expect during the EOT period. Parents noted that embedding the app within existing discussions, such as "EOT reviews," would be helpful and suggested the app could be advertised through posters in waiting areas.

There were mixed perspectives on the timing of the introduction to LotusLab. Although LotusLab was designed to provide EOT information, many parents felt that access to the app would be beneficial in the months leading up to completion of treatment. One parent felt that introduction to the app should be on a case-by-case basis, as the EOT period can be complex and a specific time point can be hard to determine, but most agreed on the value of knowing what to expect. It was also suggested by several participants that the app could have value during active treatment, lending itself well to "different starts."

HCPs identified barriers to engagement and sustainability, including the risk that only a self-selecting cohort of people would download and access the app and that those with the greatest unmet information needs might require additional support to engage with the app. One HCP noted that many people turn off their notifications; therefore, ongoing engagement could be challenging. In relation to the collection of PROMs, multiple HCPs raised concerns about the capacity to review survey results prior to consultations due to time constraints, as well as safety concerns centered on ensuring that all results are reviewed and acted upon by an appropriate professional in a timely manner.

HCP-suggested enablers also centered on embedding the implementation of LotusLab within existing roles or services, for example, integrating it into a survivorship clinical nurse coordinator role and including it in "new patient packs." One HCP suggested that the app could be shared through family networks, such as social media groups. One HCP noted that, in order to streamline LotusLab implementation, it could be helpful to undertake robust change management processes with staff. As per parent feedback, HCPs also suggested creating "a version of this at diagnosis" so that the app could become a longer-term companion across the cancer pathway.

Discussion

Principal Findings

This study assessed parents' and HCPs' perceptions and experiences of a newly developed app and generated key insights for app refinement, further development, and successful implementation within real-world clinical settings.

Overall, survey and interview data indicated that LotusLab is easy to use and acceptable, and is particularly valuable for the provision of survivorship information. Exploration of usefulness and feasibility highlighted the potential benefits of using LotusLab in bridging care gaps and building engagement during the EOT period. Study participants recommended practical suggestions to enhance the user experience and encourage ongoing engagement.

Throughout the development of LotusLab, parent perspectives as end users have been central; however, effective co-design incorporates input from all stakeholders [45]. In this study, we found similarities and differences in feedback between parents and HCPs. Both cohorts found the app easy to use, even for 2 parents who self-rated their digital literacy as low, and both cohorts suggested similar enhancements to improve usability: primarily a search function, additional content for specific cohorts, and quick links. Interestingly, the HCPs scored overall app usability more variably and acceptability lower than the parents, and 1 clinician did not like LotusLab, providing feedback that they personally did not like using apps in general. HCPs provided more feedback on the design and layout of LotusLab, whereas parent feedback focused heavily on the app content. These findings could reflect the fact that the interface and content were designed with and for parents and not HCPs. Higher parent scores could also reflect the significant unmet information needs experienced by families at the EOT [2,3,8], resulting in parents prioritizing access to information over appearance. This notion of significant unmet needs was further supported by several parents who stated they wished LotusLab had been available to them earlier in the care delivery pathway.

XSL•FO
RenderX

PROMs and proxy-reported outcome measures are increasingly identified as critical components of pediatric cancer care. During this early-phase testing, our aim was to explore the potential benefits of developing a PROM interface and how this could be used to support families at the EOT. Although both parents and HCPs placed significant value on being able to complete the PedsQL within LotusLab, both raised concerns about the ability of HCPs to review and adequately act on identified needs. These findings are echoed in other studies exploring the use of PROMs in pediatric oncology settings, identifying challenges with HCP time pressures, lack of workflow integration, and concerns over the inability to translate results into tangible actions and improved outcomes for families [46-48]. Although clinicians found the provision of meaningful summaries helpful in guiding consultations, this approach did present an additional administrative burden for other team members. Although not specific to the EOT, to address these challenges, apps such as Oncology Hub [21] have opted to deliver algorithm-driven tailored information directly to patients, based on PROM scores at the point of completion and time of need.

From a local implementation perspective, further exploration of the LotusLab algorithm's capabilities and efficient information exchange is warranted. Our findings highlight that health service capacity and approaches to sharing identified issues and concerns are key considerations for the safe, sustainable, and best-practice management of PROMs through apps such as LotusLab, particularly during the EOT and survivorship phases.

Overall, positive findings relating to LotusLab's usability and acceptability align with other studies of mobile apps for cancer survivors [14,49]. There was agreement that the most significant value of LotusLab was its provision of practical and psychosocial information at the EOT. Parents and HCPs felt the app had the potential to reduce the burden on young people, parents, and clinicians by providing easy access to trusted information during a time associated with significant uncertainty.

Both cohorts identified barriers to long-term app engagement in alignment with a systematic review of smartphone applications for cancer survivors [14], for example, the risk of diminishing engagement over time. This study suggests that the unique feature of inclusion of a personalized treatment summary and roadmap within the app could encourage repeat use and empower young people to actively manage their future health care when no longer in the pediatric setting. Other barriers included users turning off key app features (eg, notifications) and treatment side effects (eg, cognitive impacts) affecting users' ability to engage with the app [14].

The impact of digital health apps on patient and family survivorship outcomes is poorly understood, often attributed to a lack of relevant randomized controlled trials [14,50]. In addition, many apps in health care settings do not progress past the initial pilot phase. This is often due to limited, short-term funding that affects the capacity to collect long-term outcomes and cost-effectiveness data, preventing the demonstration of value for both health services and families [14,51-53]. As part of our co-design and evaluation process, we aimed to proactively identify and mitigate potential barriers to sustainability and maximize future impact. A larger "real-world" implementation phase is required to fully quantify the value and impact of LotusLab. Implementing LotusLab within existing systems and workflows, as suggested by participants and similar studies [29], and embedding the app within the standard of care could provide an avenue for sustainable operational costs and increased app success. In addition, LotusLab has the potential to support families across the treatment trajectory (not just EOT), thereby providing a user-friendly way to collect important long-term outcomes data and build the case to support ongoing delivery.

Limitations

This is a small, single-institution study limited to parents and HCPs. Adolescent and young adult (AYA) perceptions were not evaluated during this specific phase. Engagement with young people to develop age-appropriate content and tailor the app to meet their specific needs is currently being undertaken. In addition, a proxy-reported tool was used in this study; therefore, exploration of AYA perspectives on the use of LotusLab for the collection of PROMs is warranted.

Although some existing content is relevant to all families, further stakeholder engagement would be required for implementation in other health service settings and to increase relevance to specific tumor streams and diagnoses. While there are advantages in using generic quality of life measures like the PedsQL, these tools may lack sensitivity related to disease-specific symptoms [26], a finding corroborated by one parent in this study. This finding corresponds to the broader challenge of developing one digital health intervention for a heterogeneous population of childhood cancer survivors and highlights the significance of including tailored measures and content to provide value and improve the user experience.

All study participants were English-speaking; therefore, feedback is not generalizable to families from culturally and linguistically diverse backgrounds. To support the broader LotusLab project goal to increase equitable access to information at the EOT, the translation of app content into other languages is a key component of "Phase 5: Refinement and Sustainability" (Figure 1). Phase 5 also includes the development and testing of audio summaries in languages other than English.

Although the collection and sharing of outcomes data from the PedsQL were considered valuable, further work is required to build LotusLab's capability to effectively house and address PROM results. At this stage of β-testing, the app had technical limitations related to automated scoring and the generation of clinically meaningful reports. At a systems level, there are known limitations that affect the collection, sharing, and clinical use of electronic PROMs, such as poor platform interoperability and difficulty integrating PROMs into the EMR [48]. We will continue exploring the optimal approach to using LotusLab to support the integration of PROMs in the pediatric EOT setting.

Conclusions

Initial β-testing data indicate that LotusLab is easy to use, acceptable, and valuable for parents. Parents and HCPs responded positively to using the app to provide trusted

XSL•FO
RenderX

information and contributed actionable insights and practical feedback related to enhancements, PROM use, and app implementation and sustainability. Next steps include app refinement, ongoing engagement with AYA, expansion of content development, integration within real-world EOT models of care, and exploration of effectiveness and outcomes.

Acknowledgments

The authors acknowledge the support provided by the Victorian Paediatric Integrated Cancer Service and sincerely thank the participating parents and health care providers. No AI tools were used in this study.

Funding

The funding for this study is provided by a grant awarded to MCM from the Cancer Trials Management Scheme Competitive Grants Program (2021-2025), administered by Cancer Council Victoria and the Victorian Government, through the Victorian Cancer Agency. MCM is supported by a Victorian Cancer Agency Fellowship (MCRF 20042) and the My Room Children's Cancer Charity.

Data Availability

The datasets will not be publicly available for privacy reasons but may be obtained from the project's principal investigator (MCM) upon reasonable request.

Authors' Contributions

MCM and CRDL conceived the study design, devised the study protocol, assembled the measures, and provided scientific project management. HP conducted the study and drafted the manuscript, with critical review from MCM. CW, CRDL, GT, and DDE contributed to the study design and implementation, provided content expertise and project management, and critically reviewed the manuscript. MN contributed expertise in digital innovation and sustainability planning. All authors read and approved the final manuscript.

Abstract

Background: Mobile health (mHealth) apps promise to enhance patient empowerment, enable real-time health monitoring, and support self-management. Patients with breast cancer stand to benefit particularly from these capabilities, given the demanding pre- and posttreatment procedures they face. However, the effective adoption of these tools is challenged by issues including accessibility, usability limitations, and privacy concerns.

Objective: This study aimed to investigate the current usage behavior and attitudes toward mHealth apps among patients with breast cancer in Germany, focusing on acceptance, usefulness, empowerment, and data-sharing. Specifically, we aimed to identify the incentives and barriers influencing use and the intention to use mHealth apps at the time of this writing to guide their further implementation and use.

Methods: A cross-sectional online survey was conducted between November 2023 and June 2024 using a structured questionnaire developed in German. Participants with a self-reported breast cancer diagnosis were recruited via university hospital channels, patient associations, and social media. Topics included technology and health app usage, perceived usefulness, personal empowerment, and attitudes toward data sharing. The survey comprised both closed- and open-ended questions to capture quantitative patterns and qualitative insights into participants' experiences and perspectives.

Results: We collected responses from 90 participants with breast cancer. Participants demonstrated high engagement with digital technology; 97% (87/90) reported daily smartphone use, and 70% (63/90) owned a smartwatch or fitness tracker. Approximately 67% (60/90) of respondents had used health apps in the past year, with many relying on general fitness and lifestyle apps to support their health management. Most participants (62/90, 69%) indicated that health apps contribute to a better understanding of their personal health. Health apps were generally perceived as useful, with users highlighting their ability to provide continuous support and timely, reliable health information (n=31). This, in turn, was seen as instrumental in promoting self-management and empowerment. Respondents also showed a conditional willingness to share personal health data for research, particularly when clear benefits for treatment advancements were evident (n=82). Nonetheless, concerns were raised regarding data privacy, app usability, the need for multiple apps to cover all necessary features, and the potential increase in fear of illness (cyberchondria).

XSL•FO
RenderX

Conclusions: The findings underscore the potential of mHealth apps to empower patients with breast cancer by improving health literacy and supporting self-management. To maximize their impact, future digital health tools must align closely with patient needs by incorporating adaptive, interactive features and integrating seamlessly with clinical care. Addressing key barriers—particularly data privacy and usability issues—is essential for broader adoption. Longitudinal studies are warranted to evaluate the long-term effects of health app usage on patient empowerment, quality of life, and clinical outcomes.

(JMIR Cancer 2026;12:e77750) doi:10.2196/77750

KEYWORDS

mHealth applications; women's health; smartphone; digital health; data sharing

Introduction

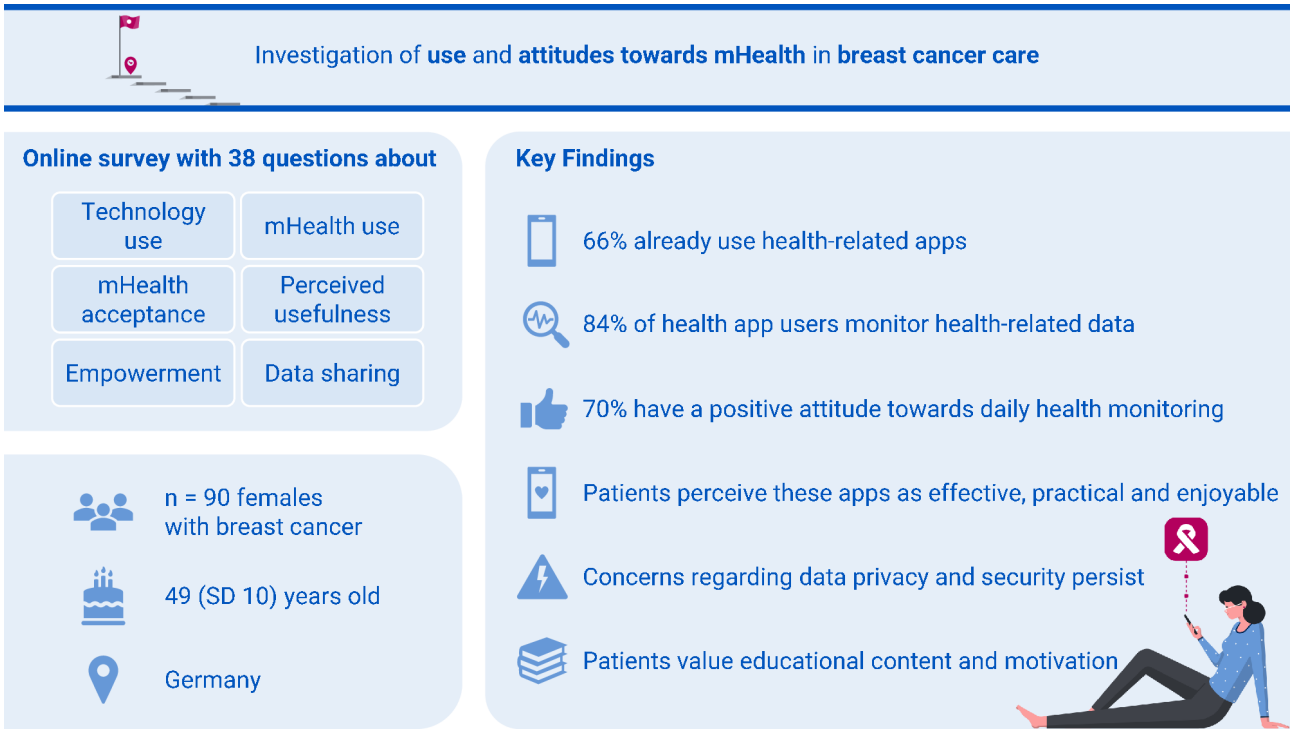
The intersection of technology and health care has introduced new pathways in mobile health (mHealth) apps. These digital tools promise enhanced patient autonomy, real-time health monitoring, and personalized care, capabilities particularly appealing for managing chronic diseases as well as long-lasting, complex, and potentially recurring conditions [1]. For patients with breast cancer, mHealth apps could represent a vital resource during their health treatment process [2,3].

Breast cancer is one of the most commonly diagnosed cancers among females worldwide, with approximately 2.3 million new cases annually [4-6]. The diverse nature of the disease requires targeted and individualized treatment [7]. Beyond the physical health implications, breast cancer impacts the emotional and psychological well-being of patients, often leading to anxiety, depression, and a reduced quality of life (QoL) [8]. These effects frequently extend to their families and support networks, who may experience emotional distress and caregiver burden [9]. Hence, effective management and care for breast cancer demand a holistic approach that incorporates medical, psychological, and social support to mitigate these effects [10,11].

By helping navigate the complexity of treatment, emotional distress, and long-term care, mHealth apps have great potential. The technology has the potential to help patients better understand their personal health status, contribute to self-management strategies, and thus improve health outcomes and QoL. Yet the promise of technological innovation often collides with realities of patient experience, where acceptance and adoption are shaped by more than functionality. On the one hand, existing solutions in women's health available in app stores often lack trustworthy resources, a user-centered design with high usability, and research-supported effectiveness [12,13]. Some might even represent risks for patients through outdated health information. Apps developed within a thorough research process and evaluation, on the other hand, usually represent island solutions that were never made available to the general public [14].

Furthermore, existing literature primarily addresses technical and usability aspects, often overlooking the multifaceted needs of patients. While ensuring technical functionality and user-friendly design is critical, these aspects alone do not guarantee the effective integration of mHealth tools into the daily lives of patients. The development requires a comprehensive, patient-centered research approach that prioritizes emotional, cultural, and ethical considerations alongside technological development.

The primary aim of this survey study is to examine this usage behavior, acceptance, perceived usefulness, empowerment, and data-sharing attitudes related to mHealth apps among patients with breast cancer. Secondary objectives were to identify strategies to enhance adoption, engagement, and effective data sharing for future mHealth apps.



Methods

Survey Design

A questionnaire was designed to investigate several aspects related to the use of health apps among individuals with breast cancer. This study is embedded in the DigiOnKo project [15], an interdisciplinary initiative aimed at advancing digitally supported oncology care pathways by developing, evaluating, and implementing digital tools to support patients and clinical teams. An overview of the study is provided in Figure 1. Based on our research goal, we defined 2 exclusion criteria, individuals who had never been diagnosed with breast cancer in their lives or were under the age of 18 years. The questionnaire was designed in German. Besides basic demographic information, questions covered technology access, health app use, perceived usefulness of health apps, personal empowerment, health app acceptance, and data sharing. Further details about the survey instrument will be presented in the following chapters.

XSL•FO
RenderX

Figure 1. Visual abstract summarizing the objectives, methodology, and key findings of our survey study on health app usage among patients with breast cancer.

The survey was implemented in Unipark (Tivian XI GmbH). The questions included both open and closed questions; answer options were mainly on a 5-point Likert scale for closed questions. All items of the questionnaire were mandatory. All questions asking sensitive information provided a nonresponse option of "Prefer not to answer," "not applicable," or "neutral." Participants were able to review all answers before finishing the survey. The question order was not randomized; 9 questions were conditional, depending on answers to previous questions.

The minimum number of items was 29 and the maximum number was 38. These questions were distributed over 21 survey pages in total. The full questionnaire can be found in Multimedia Appendix 1. Before submitting the questionnaire, an optional feedback field was provided for any further comments or remarks. The survey included 6 open questions, where participants were instructed to provide short written answers in bullet points. Additionally, a text field for further comments and feedback was provided.

Technology and Health App Use

To gain an overview of the usage of technology in general and related to their personal health, all participants were asked about the use and usage frequency of smartphones, tablets, and wearables. The aim was to gain insights into the engagement and adoption of technology in general and mHealth in particular. This was complemented by questions regarding internet usage frequency and the confidence in using smartphones and mobile apps.

Related to personal health, participants were asked about recently used resources to improve their personal health (podcasts and audiobooks, social media, video calls, smartphone apps, printed materials, and internet). Specifically, we asked which health apps they have installed on their devices, how often they use them, what they use them for, and whether they felt informed about the risks and benefits associated with these apps at the time of this writing. The question was targeted specifically at all health-related apps and was not limited to specific breast cancer apps, as patients might use a variety of different apps to manage their condition (eg, general fitness apps or meditation apps).

Perceived Usefulness

According to the Technology Acceptance Model (TAM), the perceived usefulness of a technology is closely linked to their attitude toward it as well as their intention to use it [16]. If patients perceive mHealth apps as useful, they are more likely to engage with them regularly. As shown in a meta-analysis by Gan et al [17], greater engagement in mHealth apps was significantly associated with mental health improvements. Perceived usefulness was measured through a questionnaire developed by Voss et al [18] that has been used in previous work and captures the hedonic and utilitarian dimensions of attitudes toward a product category. With 10 different adjective pairs, it captures the perceived usefulness on a 5-point Likert scale, for example, effective-not effective and boring-exciting. Additionally, participants were asked about the perceived benefits and risks in 2 open questions.

Personal Empowerment

Patient empowerment is fundamental for effective chronic disease management, as it is closely linked to improved self-management, better adherence to treatment, and enhanced overall well-being. Empowered patients are more likely to engage in informed decision-making, feel confident in managing their condition, and experience greater autonomy in their care journey [19,20]. In this study, all measurement items were adapted from Lemire et al [21] and included items related to

XSL•FO
RenderX

the ability to apply gained knowledge to effectively make decisions related to personal health [22]. To further explore this dimension, participants were also asked whether they experience discrimination in their daily lives and whether they fear additional disadvantages or discrimination related to using mHealth apps.

Acceptance of Health Apps

Daily interaction with an mHealth app can induce psychological harm from health anxiety or cyberchondria, the excessive or compulsive seeking of online health-related information that exacerbates anxiety [23,24]. For patients with breast cancer, this phenomenon can be particularly pronounced, as apps often encourage users to continuously monitor their health, presenting daily reminders of their condition.

To investigate the acceptance toward health apps in breast cancer care, we used questions from Potdar et al [25] that have been used to investigate acceptability toward mHealth among patients with cancer in general. The questions targeted features for monitoring the health status, tracking information on the smartphone, and using a health app to improve their health-related knowledge, as these represent features often used in mHealth apps for breast cancer [26]. With an open question, we then asked participants about specific features they would expect or want in an mHealth app designed to support patients with breast cancer.

Data Sharing

According to the Privacy Calculus Theory, individuals weigh perceived benefits, such as improved therapies or valuable research contributions, against potential risks, like loss of privacy or misuse of data [27]. By targeting data-sharing scenarios under specific conditions—such as offering incentives, ensuring transparency in data use, or highlighting therapeutic advancements—we aimed to identify the factors that encourage or discourage data sharing. For this purpose, we used an adapted version of the questionnaire developed by Pletscher et al [28]. Questions targeted specifically at sharing data with research institutions under certain conditions, for example, if incentives are offered, therapies can be improved, or the purpose for the data use is known. Additionally, reasons why participants would want to share or not share their data were asked in an open question.

Survey Pretesting

The final questionnaire went through a test run with 4 independent assessors to identify any usability issues, verify that questions are clear and understandable, and reduce any possible biases in questions.

Recruitment Process

The survey was designed as an open, online-only survey; everyone with access to the link was able to participate on a voluntary basis. On the landing page of the survey, website visitors were informed about the study, the objectives, the estimated duration, the types of data collected within the survey, storage of the data, and the contact information of the investigators in charge. In order to start the survey, active consent for participation was required. After consent, 2 eligibility questions were asked; all participants had to be at least 18 years old and had to have a breast cancer diagnosis at some point in their lives, as the target population was patients with breast cancer.

A convenience sampling strategy was chosen. The survey was distributed through a combination of clinic-based recruitment and online channels. The survey was promoted by posters and flyers in the university hospitals in Erlangen and Würzburg (Bavaria, Germany); via personal contacts; as well as various mailing lists and patient associations. Online recruitment included the university website and social networks such as Instagram (Meta Platforms), Facebook (Meta Platforms), LinkedIn (Microsoft Corp), and nebenan.de (Good Hood GmbH). On Facebook, the survey was posted in patient groups related to breast cancer. On Instagram, various influencers were asked to distribute the flyer to their followers. Among them, PINK gegen Brustkrebs GmbH (Germany), the company behind the breast cancer app Pink! Coach promoted the survey through an advertisement. Social media recruitment was included to increase reach and accessibility, allowing participation from patients who might not regularly attend the recruiting clinics or who live outside the immediate hospital regions. The data collection was performed between November 2023 and June 2024.

Data Analysis

Quantitative data were analyzed using descriptive statistics (frequencies, percentages, means, and SDs). All analyses were conducted using Python (Python Software Foundation). All answers to open questions were analyzed with an inductive category formation of a qualitative content analysis according to Mayring and Fenzl [29]. The analysis was conducted following Mayring's systematic procedure of iterative category development; initial codes were developed and refined through repeated review. Representative quotes were selected to illustrate key themes. Survey results are reported in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [30]; the full checklist is provided in Checklist 1.

Ethical Considerations

All data were collected anonymously. The dataset did not contain any personal data in accordance with the GDPR. Thus, this study was exempt from institutional review. The exemption was confirmed by the Institutional Review Board of FAU Erlangen-Nürnberg (23 - 333-ANF). Informed consent was obtained from all participants prior to participation in the survey; participants did not receive any compensation.

Results

Survey Statistics

In total, the landing page of the survey was visited 404 times, and 154 individuals agreed to participate in the survey and filled out the eligibility screening. 145 reportedly met the defined criteria and started the questionnaire, and 90 completed it. Therefore, the completion rate was 62%. Only completed surveys are included in the subsequent analysis. On average, participants spent 15.9 (SD 7.8) minutes completing the survey.

XSL•FO
RenderX

No atypical timestamps were detected; therefore, no participant was excluded due to the duration of the participation.

Participant Demographics

The mean age of participants is 49 (SD 10) years, with 88 out of 90 (98%) indicating female sex; 2 (2%) participants out of 90 preferred not to specify. Detailed sociodemographic information about the participants is shown in Table 1.

Table . Demographic information of all survey participants.

Demographics	Participants (N=90)
Age (years)	
Range	26-71
Mean (SD)	49 (10)
Age at breast cancer diagnosis (years)	
Range	25-69

Technology Usage

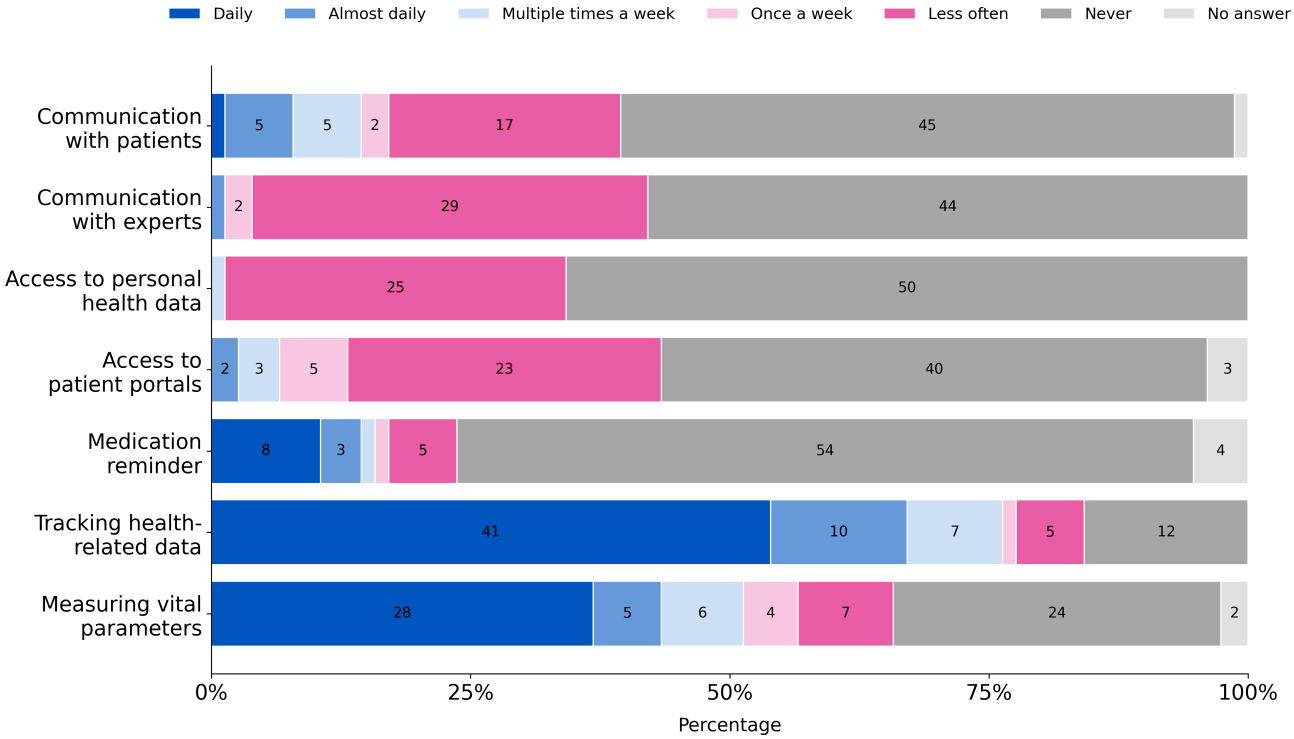
All participants possess a smartphone, and most use it daily (87/90, 97%). A majority (63/90, 70%) have a smartwatch or fitness tracker and use it daily or almost daily (52/90, 83%). Additionally, participants rated how confident they feel using smartphones and apps. A majority feels very confident (46/90, 51%) or rather confident (26/90, 29%); a few participants feel very insecure (4/90, 4%) or rather insecure (2/90, 2%) in smartphone and app use. The majority of participants (86/90, 86%) reported a daily use of the internet; all participants accessed the internet at least once a week.

mHealth Usage

Among all participants, 59/90 (66%) stated that they had used mobile apps to improve their personal health status within the last 12 months. The internet in general was used by 82 (91%),

XSL•FO
RenderX

social media by 72 (80%), and audiobooks or podcasts by 51 (57%).



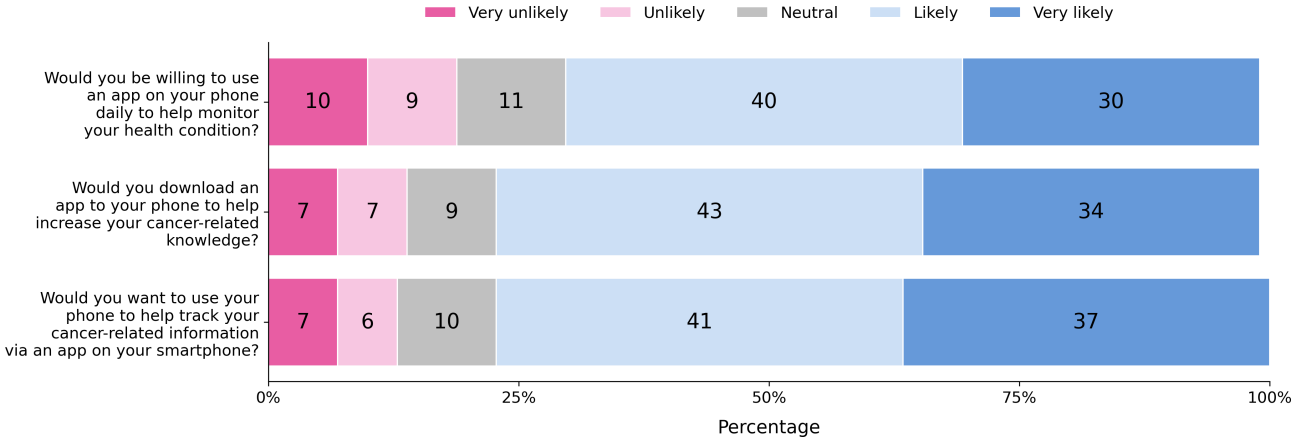
When asked about installed apps on their devices, 70 (78%) participants listed the apps. On average, participants had 2 apps related to their health installed; one participant listed 15 health-related apps.

The most frequently mentioned app was “Pink! Coach” (25/90, 28%), a medically certified app in Germany specifically designed to improve QoL and health literacy in patients with breast cancer [31]. Besides that, general fitness apps such as Fitbit (Fitbit Inc), Garmin Connect (Garmin Ltd), or Apple Health (Apple Inc) are frequently installed.

Regarding the frequency of using these apps, 59 out of 90 (66%) stated at least once a week, and 21 out of 90 (23%) mentioned daily use. Among all participants (n=90), 14 (16%) reported that they are not using health apps. A filter was applied so that only those who indicated app usage (n=76) received the subsequent questions regarding app usage purpose.

The purpose and frequency of using these apps for specific purposes are represented in Figure 2. Most participants use their apps to measure physiological parameters such as heart rate and to monitor other health-related data such as physical activity, steps, or diet. As shown in Figure 2, 67% (n=51) of app users are already monitoring health-related parameters daily or almost daily. In contrast, the use of an electronic health record, contact with health professionals or other patients, and access to patient portals were not common among the participants.

Figure 2. Answer distributions of the usage frequency to different features commonly included in mHealth apps by participants who use health apps (n=76).



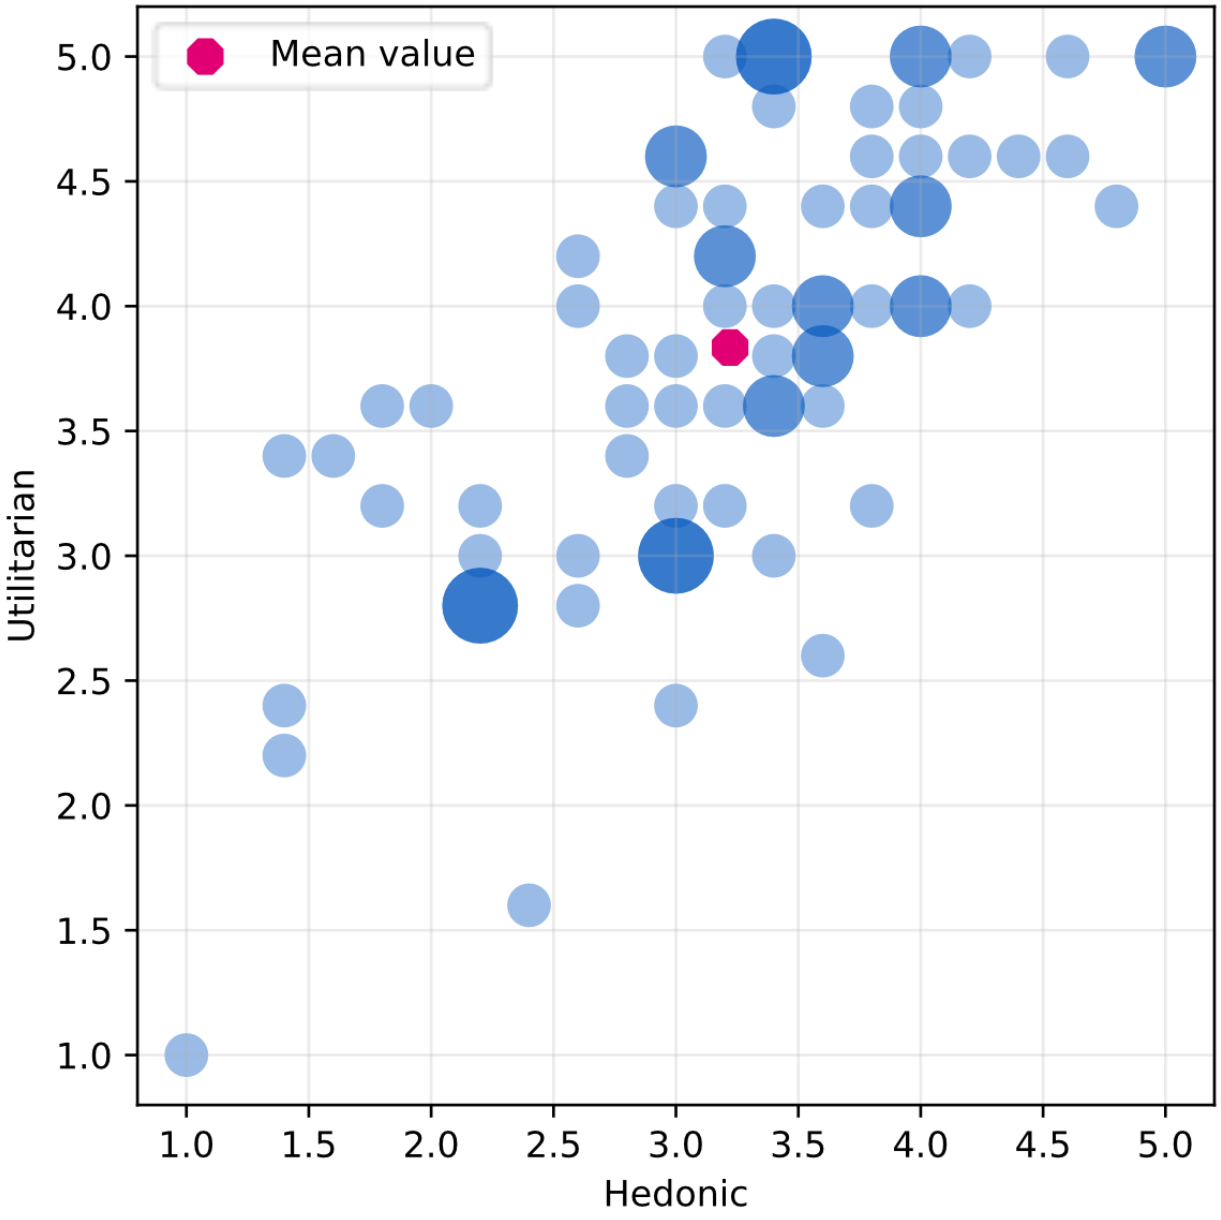
Among the app users, participants were asked whether they had been informed about the benefits and risks of using the health app before starting. A total of 30 (40%) out of 76 app users reported feeling uninformed about the risks associated with the app. In contrast, 36 out of 76 (47%) stated they had been adequately informed about their benefits.

Acceptance

Figure 3 shows the answers of all participants to the 3 questions related to the general acceptance of cancer-related mobile apps. Most participants are willing to use their smartphone for tracking cancer-related information through a mobile app and to use it as a health monitor on a daily basis. Furthermore, a majority of participants would be willing to download a mobile app to increase their knowledge about cancer.

XSL•FO
RenderX

Figure 3. Answers given to the acceptance-related survey items in percentages.



Perceived Usefulness

The utilitarian and hedonic dimensions of the attitude toward health apps of users are shown in Figure 4. Overall, the average on the hedonic dimension was 3.22 (SD 0.87) and on the utilitarian dimension 3.83 (SD 0.87). Thus, the used mHealth apps are perceived as both pleasurable and useful.

XSL•FO
RenderX

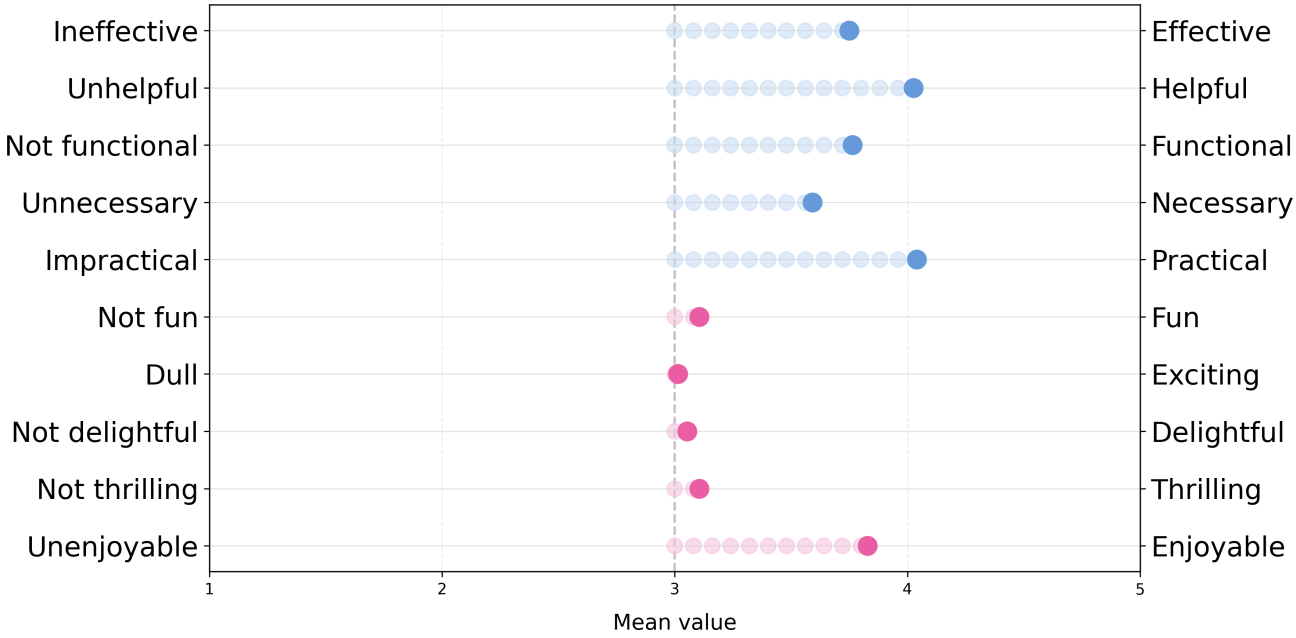


Figure 4. Scatterplot illustrating perceived usefulness scores for all participants (blue), where larger circles indicate multiple participants with the same response. The overall average is highlighted in pink.

In more detail, as shown in Figure 5, participants perceive their apps as effective, practical, and enjoyable.

XSL•FO
RenderX

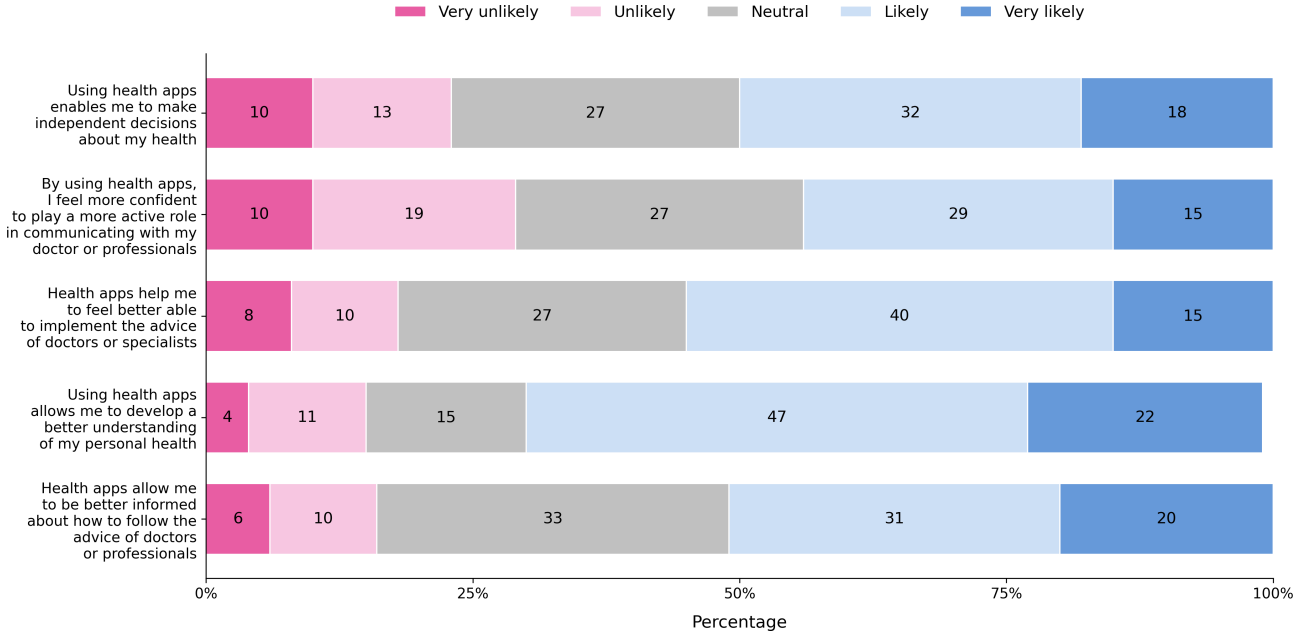

Figure 5. Mean values for all categories of the utilitarian and hedonic dimensions of the questionnaire for perceived usefulness.

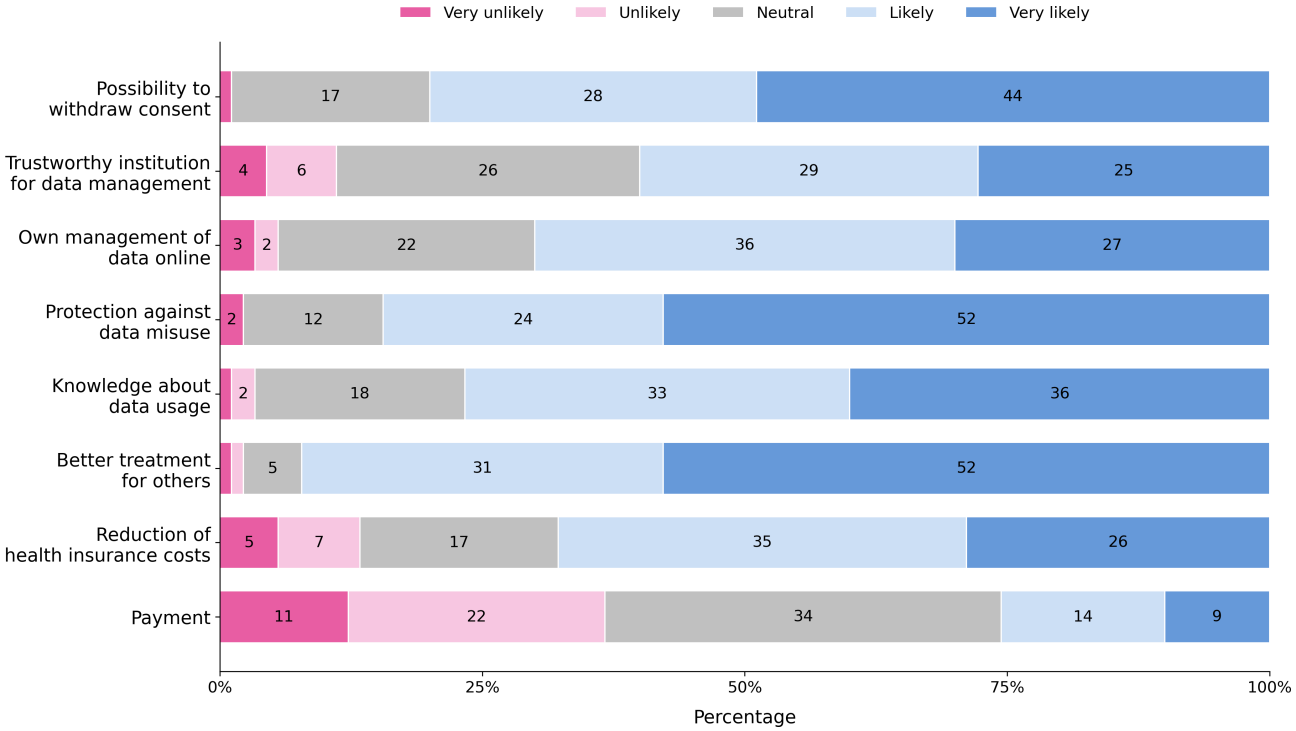
Personal Empowerment

The findings, as illustrated in Figure 6, reveal varying levels of agreement among participants regarding the empowering potential of health apps. A majority of respondents indicated that health apps likely or very likely enable them to develop a better understanding of their personal health (62/90, 69%) and implement advice from doctors or specialists (49/90, 54%). Similarly, 39 out of 90 (43%) of participants felt that using health apps enhances their confidence in communicating with health care professionals, while 45 out of 90 (50%) agreed that these tools help them make independent decisions about their health. Overall, a minority of participants perceived health apps as very unlikely or unlikely to contribute to these empowerment domains. A total of 29% (26/90) think it is unlikely that using health apps could give them a more active role when talking with their doctors. With an overall mean for all items of 3.4 out of 5.0, the participants report a positive contribution of health apps to personal empowerment.

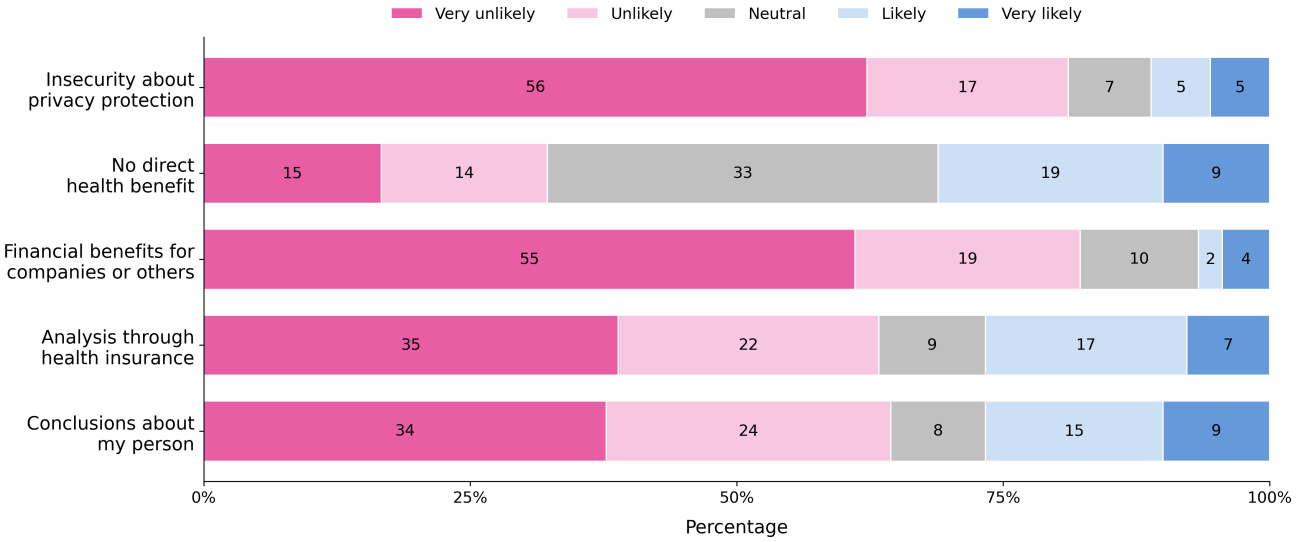
Figure 6. Participants' responses to 5 different aspects of personal empowerment: (1) making independent health decisions, (2) engaging more actively with health care professionals, (3) feeling more capable of following medical advice, (4) gaining a better understanding of personal health, and (5) staying informed on how to follow professional recommendations.



Data Sharing

The most relevant drivers of sharing personal health data for research purposes from the list provided to the participants, as shown in Figure 7, are (1) if people knew that by doing so, others would receive a better treatment (n=82 likely, or very likely); (2) if people were sure that data were protected from misuse (n=75 likely, or very likely); (3) if people could withdraw from the consent of data usage anytime (n=72, 80%); and (4) if it were known what research is done with the data (68/90,

XSL•FO
RenderX



76%). On the other hand, money was perceived as less of an incentive (22/90, 24% likely or very likely).

Figure 7. Suggested incentives and the participants' attitudes toward sharing personal health data for research purposes.

Concerns about privacy protection and financial benefits for companies were the most significant barriers, with the majority of respondents indicating these were "Very likely" to hinder their data sharing. A lack of direct health benefit is perceived as less of a barrier. A detailed overview of the responses to potential barriers is shown in Figure 8.

Figure 8. Attitudes of participants toward 5 barriers to sharing personal health data.

Qualitative Data Analysis

Required App Features and Content

Participants were asked to list specific features they expect in an mHealth app supporting patients with breast cancer. Related to general usability and design features, 6 main categories were identified. Mostly mentioned were notifications and reminders (n=17), followed by clearness and simplicity (n=9), motivational features (n=7), adaptation to individual needs (n=6), and trustworthiness (n=4).

In terms of educational content, in addition to general cancer-related information (n=58), detailed advice and recommendations on diet (n=20), physical activity (n=19), and topics related to mental health and general well-being (n=17) were of particular interest to participants. In addition, more updates on recent research results and ongoing studies were frequently requested (n=16). Participants emphasized the importance of up-to-date information that evolves over time ("Up-to-dateness, continuous expansion of information" P79, translated), as well as concise explanations of medical terms ("Database [Explanation of terminology]" P69, translated).

XSL•FO
RenderX

Benefits and Risks of mHealth Apps

When asked about the benefits mHealth apps offer in the context of breast cancer, 31 specifically mentioned the provision of information, especially up-to-date information (n=2) and trustworthy information (n=2). Furthermore, participants see benefits in motivating users (n=20) to eat healthy or exercise. A large group of participants (n=22) highlighted the personal and mental support of these apps in dealing with disease, therapy, and side effects. Especially since they are available 24 hours a day (n=5). For example, one participant mentioned that these apps offer

> *personal support and helpful input, that can be selected individually, in addition to the often limited time available during consultation hours* [(P33, translated)]

Participants also mentioned that these apps can provide a sense of control and security (n=7). For example, they could help to

> *assess your personal lifestyle and identify opportunities for improvement (gives you the confidence to "do something" yourself)* [(P33, translated)]

In contrast, 23 participants did not see any benefits in health apps. As reasons, participants mentioned, for example, a lack of knowledge about available apps ("I would like more information about the available options," P36, translated) or that information is already available on the internet ("This knowledge can be obtained on the Internet on your own," P23). One participant stated that, in their experience, mHealth apps usually cover only a small aspect, lack usability, and are difficult to activate due to the need for a doctor's prescription (P90).

When asked about the risks of mHealth apps, the majority of participants (n=42) stated that they did not see any risks. Only 10 participants expressed concerns regarding data privacy and security. Furthermore, a few participants were concerned about potential misinformation (n=8) or negative mental health effects (n=6), for example, by providing wrong diagnoses or untrustworthy sources. Additionally, 7 participants mentioned a potential overload, for example, through providing too much information. As obstacles hindering participants in using available health apps, participants mentioned reasons such as insufficient quality, lack of usability, lack of time, or lack of cost coverage by health insurance.

Discussion

Overview

With this study, we investigated self-reported usage patterns, health app acceptance, and views on data sharing among patients with breast cancer in Germany. Our results provide insights into patients' perspectives on mHealth technology, including aspects they perceive as beneficial as well as challenges and barriers that still need to be overcome. Especially, aspects related to usability, effectiveness, and privacy concerns need further attention from the patient's viewpoint.

Participants reported a high prevalence of fitness tracker and smartwatch usage. This could have several reasons; on the one hand, this survey might have been especially interesting to technology-affine people. On the other hand, the popularity of mobile and wearable technology, particularly among older adults, is increasing [32]. Additionally, one of 6 patients with breast cancer in Germany is younger than 50 years old, which could also contribute to higher adoption of digital health tools in our sample [33,34].

In general, the majority of participants expressed openness to using mHealth apps for monitoring their personal health status and enhancing their health knowledge. Also, daily interaction with an app appears to be feasible and not a deterrent for most participants. This positive attitude aligns with the growing trend of integrating technology into health care practices, particularly for older adults [32].

Health Apps as a Tool for Patient Empowerment

The findings suggest that health apps are generally perceived as useful and have the potential to empower patients. Participants specifically highlighted the availability of these apps, offering support around the clock in addition to limited interaction time with health care providers. This availability was mentioned as a key factor in fostering a sense of control and confidence, both of which are central to patient empowerment [35]. Participants valued apps that could deliver timely and reliable health-related guidance, highlighting a broader shift toward digital health literacy as a central component of modern patient care.

When designed effectively, such apps can facilitate quick and reliable answers to users' questions, thereby fostering health literacy and eHealth literacy. This, in turn, has the potential to enhance self-management and improve QoL by supporting informed decision-making, healthy behaviors, and adherence to therapy. Notably, the extent to which these apps actually enhance self-management likely depends on factors such as usability, personalization, and integration with clinical care issues that remain underexplored in the digital health landscape at the time of this writing [36].

Effective empowerment requires not just access to information but also actionable, tailored guidance that aligns with individual health needs. To maximize their impact, future health apps should go beyond providing generic health content and instead offer dynamic, interactive features that support patient autonomy. This includes adaptive recommendations, such as tailored exercise or lifestyle guidance and nudges based on app usage patterns, but also the seamless integration with clinical care, for example, through secure messaging, automated report sharing, or appointment planning. Beyond these, user-driven customization options should be provided, such as adjustable dashboards, modular feature selection, and flexible notification settings. These features can help patients tailor the app experience to their individual needs, literacy levels, and desired depth of information and engagement. Further research is needed to identify which app functionalities most effectively contribute to different dimensions of empowerment and how these functionalities are perceived with different patient characteristics and care contexts.

XSL•FO
RenderX

Widespread Use of Health Apps and Their Limitations

Interest in health apps is high, with many participants using apps not specifically designed for breast cancer management. Fitness apps, in particular, were frequently mentioned, as they support a healthy lifestyle, a key factor for many participants in improving QoL. This suggests that patients are already adopting existing digital tools to support their health, even in the absence of condition-specific alternatives. Furthermore, these findings suggest that patients exhibit intrinsic motivation to enhance their health and actively contribute to their therapy. It highlights their desire to play an active role in their health care journey.

However, while general health apps offer broad functionality, they may not address the unique concerns of patients with breast cancer, such as symptom tracking, treatment side effects, or emotional well-being. This raises an important question. Do patients actually need breast cancer-specific apps, or are they sufficiently served by more general health applications? The widespread use of existing tools suggests that some needs may already be met; however, it remains unclear whether these apps are fully adequate for the challenges of managing a chronic illness. Future research should investigate whether condition-specific features—such as integration with oncology care, personalized symptom management, or peer support—would enhance engagement and health outcomes. Understanding these preferences could inform the development of more targeted digital health solutions that complement, rather than duplicate, existing app functionalities.

Balancing Data Privacy Concerns and Willingness to Share

Data privacy remains a central concern for many participants, with uncertainty surrounding how health apps handle sensitive personal information. This skepticism reflects broader public debates on digital health security and trust in technology providers [37]. However, our findings reveal that privacy concerns do not translate into outright rejection of data sharing. Instead, participants demonstrated a conditional willingness to share their health data, particularly when contributing to research with tangible benefits for future treatment advancements. This highlights a critical balance between risk perception and perceived utility, suggesting that concerns about data security are not absolute barriers but negotiable factors. These findings align with previous research indicating that patients with cancer are particularly open to data sharing when they perceive benefits for themselves or others from the research conducted [38].

Transparent communication regarding data usage, robust security measures, and opportunities for users to maintain control over their data are essential for improving trust. Beyond technical safeguards, actively involving patients in research processes—through co-design initiatives, participatory data governance models, or better communication of research findings—could further shift perceptions, positioning data sharing as an informed and mutually beneficial decision rather than a passive risk.

Structural Barriers

Despite their potential, these health apps often fail to fully meet users' needs. A key challenge was the fragmentation of app functionalities, with users often having to rely on multiple apps to cover different aspects of their health management. This lack of integration creates inefficiencies and may discourage long-term use. Additionally, structural issues—such as unclear reimbursement policies and prescription processes—further complicate the adoption of digital health solutions within formal health care systems. Additionally, our study did not account for individuals who have no structural or material access to mHealth at all, whether due to a lack of technical infrastructure (ie, no smartphone) or knowledge barriers (eg, illiteracy, lack of digital literacy).

Psychological Impact of Health Tracking

Another notable concern was the psychological impact of continuous health tracking. Some participants questioned whether constant app engagement might lead to an excessive preoccupation with their illness rather than providing reassurance. This highlights the need for a balanced approach in app design. Digital tools should support patient autonomy without reinforcing anxiety or over-monitoring. While tracking tools can facilitate behavior change, their effectiveness depends on sustained engagement [39,40]. If apps demand too much attention or become emotionally taxing, users may abandon them over time. Striking the right balance between engagement and cognitive load is crucial for long-term use. Practical design strategies could include adjustable frequencies of self-monitoring, optional data summaries, or modular features that can be enabled or disabled depending on individual needs and preferences.

Toward Integrated and Patient-Centered Solutions

Addressing these challenges requires a more holistic approach to app development. This approach to app development, characterized by fragmented and often redundant solutions, may not be sustainable [41]. Developers should shift their focus toward creating integrated, multifunctional platforms that address a broad spectrum of patient needs, as also identified in other related works [42,43]. Additionally, engaging stakeholders—including health care providers and patients—in the design process can help ensure that apps are practical, trustworthy, and aligned with real-world usage contexts [44]. Beyond design considerations, clear regulatory frameworks, standardized evaluation criteria, and improved access to reimbursement will be crucial in embedding digital health tools into routine care.

Limitations

Overall, this work provides insights into the actual usage and perspectives toward mHealth apps among patients with breast cancer in Germany. Nevertheless, this study is subject to several limitations. The sample size was relatively small, which may limit the generalizability of the findings. The study was conducted as an online survey and was mainly distributed online. Thus, only participants with internet access and at least a computer or smartphone were able to participate. In combination with the general topic of the survey, it is likely that people with

XSL•FO
RenderX

an affinity for technology in particular were addressed and that the group of patients without internet access is not represented in the collective. Due to the survey tool, which did not include cookies, internet protocol address checks, or other measures, repeated participation cannot be ruled out completely.

Since this study investigated self-reported data, actual usage patterns may differ from what participants stated in this questionnaire.

Furthermore, the survey was available only in German. As other countries have different possibilities of mHealth in breast cancer and are at different levels of digitizing health care, acceptance and usage might differ largely.

Furthermore, the participants were, on average, younger than the typical age at breast cancer diagnosis and had a higher level of education, which may limit the generalizability of the findings to the broader patient population. Finally, the small sample size and the fact that we were not able to recruit any non-female participants, even though specific organizations were contacted for that, highlight the need for interpreting the results carefully.

Conclusions

This study provides valuable insights into current usage behaviors and attitudes toward health apps from the perspective of patients with breast cancer. We highlight key aspects that could enhance adoption, engagement, empowerment, and effective data sharing for future mHealth applications and research. Despite the lack of condition-specific apps, patients are already using general health and fitness apps to improve their QoL, indicating a strong intrinsic motivation for self-management in our study population. There is an opportunity to build on existing app usage behaviors by tailoring future digital health tools to meet the unique needs of patients with cancer. However, significant barriers, particularly privacy concerns, must be addressed to enhance trust and encourage broader adoption.

The findings emphasize the importance of aligning health apps with patient needs and preferences to maximize their utility and adoption. For health care, integrating apps into routine care pathways can provide patients with supplementary tools for self-management, potentially reducing the burden on health care providers. Collaboration among developers, health care professionals, and patients will be critical to ensure that future apps effectively address real-world challenges.

Further research is needed to assess the long-term impact of health apps on patient empowerment, including sustained engagement, decision-making autonomy, and self-efficacy. Additionally, studies should examine their effects on QoL, including mental well-being, treatment-related distress, and daily functioning, as well as clinical outcomes such as symptom management, adherence to therapy, and disease progression. Finally, the potential of artificial intelligence, machine learning, and wearable sensors should be explored to address the requirements of patients, such as personalization or real-time health insights.

Acknowledgments

We sincerely thank all participants for their time and willingness to complete the survey, which made this study possible. Generative AI (ChatGPT, GPT-4, OpenAI) was used to assist with language editing and stylistic refinement of the manuscript; the authors retained full control over the content and are responsible for all aspects of the text.

Funding

This project is supported by the Bavarian State Ministry of Health and Care, project grant number PBN-MGP-2010-0004-DigiOnko and by the Federal Ministry for Economic Affairs and Climate Action under grant number 68GX21004F (TEAM-X). Furthermore, this work was partly funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – SFB 1483 – Project-ID 442419336, EmpkinS.

Data Availability

The datasets generated and analyzed during this study are not publicly available, as participants did not provide consent for public data sharing. However, they are available from the corresponding author upon reasonable request.

Authors' Contributions

MF conceived the study, developed the study design, analyzed data, recruited participants, and wrote the manuscript draft. AM and TO assisted in developing the study design, distributed the survey, and revised the manuscript. MN and HL assisted in designing the questionnaire and revised the manuscript. PAF, HH, MWB, BME, and HL initiated and supervised the project. All authors reviewed and approved the final manuscript.

Abstract

Background: Patients with head and neck cancer (HNC) face significant challenges in accessing coordinated care due to the complexity and multimodality of their treatment and the impact on vital functions. The COVID-19 pandemic has disrupted cancer care while accelerating the adoption of digital health solutions. Mobile health (mHealth) apps offer potential solutions for remote symptom monitoring, communication between patients and providers, and continuity of care. Nevertheless, their acceptance among patients with HNC remains limited due to age-related digital divides and concerns about accessibility.

Objective: The aim of this study was to investigate the impact of the COVID-19 pandemic on patients with HNC and to explore their attitudes toward mHealth apps as a supplement to cancer treatment.

Methods: A secondary analysis of a cross-sectional survey was conducted between January 2023 and May 2024 at Julius Maximilian University of Würzburg in Germany. A total of 355 patients with HNC were recruited and completed the structured "Cancer and COVID-19" survey via the Corona Health app or in paper form. The 25-question survey assessed sociodemographic information, the impact of the pandemic on diagnosis/treatment/aftercare, and interest in mHealth apps. Descriptive statistics and bivariate correlations were used for the analysis.

Results: The cohort comprised 261 (74%) men and 94 (26%) women with an average age of 67 (SD 11.5) years. Most participants (n=264, 74%) stated that the pandemic had no impact on their cancer treatment, although 20% (n=71) experienced disruptions, particularly in follow-up appointments and treatment monitoring. Only 10% (n=36) currently used health apps, but 57% (n=203) expressed a willingness to use mHealth technologies. Younger patients, patients with higher education, and participants who were more affected by the pandemic showed greater openness to digital health solutions. The most significant barriers included age, digital literacy, and perceived usefulness, while preferred app features included interaction with physicians (n=160, 45%) and data sharing with researchers (n=153, 43%).

Conclusions: Although the COVID-19 pandemic had only a limited direct impact on HNC care at the institution at hand, it revealed significant patient interest in mHealth apps. However, significant barriers remain, particularly among older adults with lower digital literacy. Future mHealth initiatives should focus on improving digital literacy, addressing privacy concerns, demonstrating clinical benefits, and developing personalized, accessible solutions to optimize cancer care for this vulnerable population.

KEYWORDS

head and neck cancer; COVID-19 pandemic; mHealth; digital health solutions; cancer care; telemedicine; digital literacy; health care access; patient-centered care; mobile health

Introduction

Head and neck cancer (HNC) is a particularly difficult form of cancer due to its impact on vital functions, such as speaking, swallowing, and breathing, as well as its demanding, multimodal treatment pathways [1]. The treatment of these patients requires continuous medical, psychosocial, and logistical support throughout all phases of care. Ensuring continuity of care and patient retention is therefore a key objective in head and neck oncology [2].

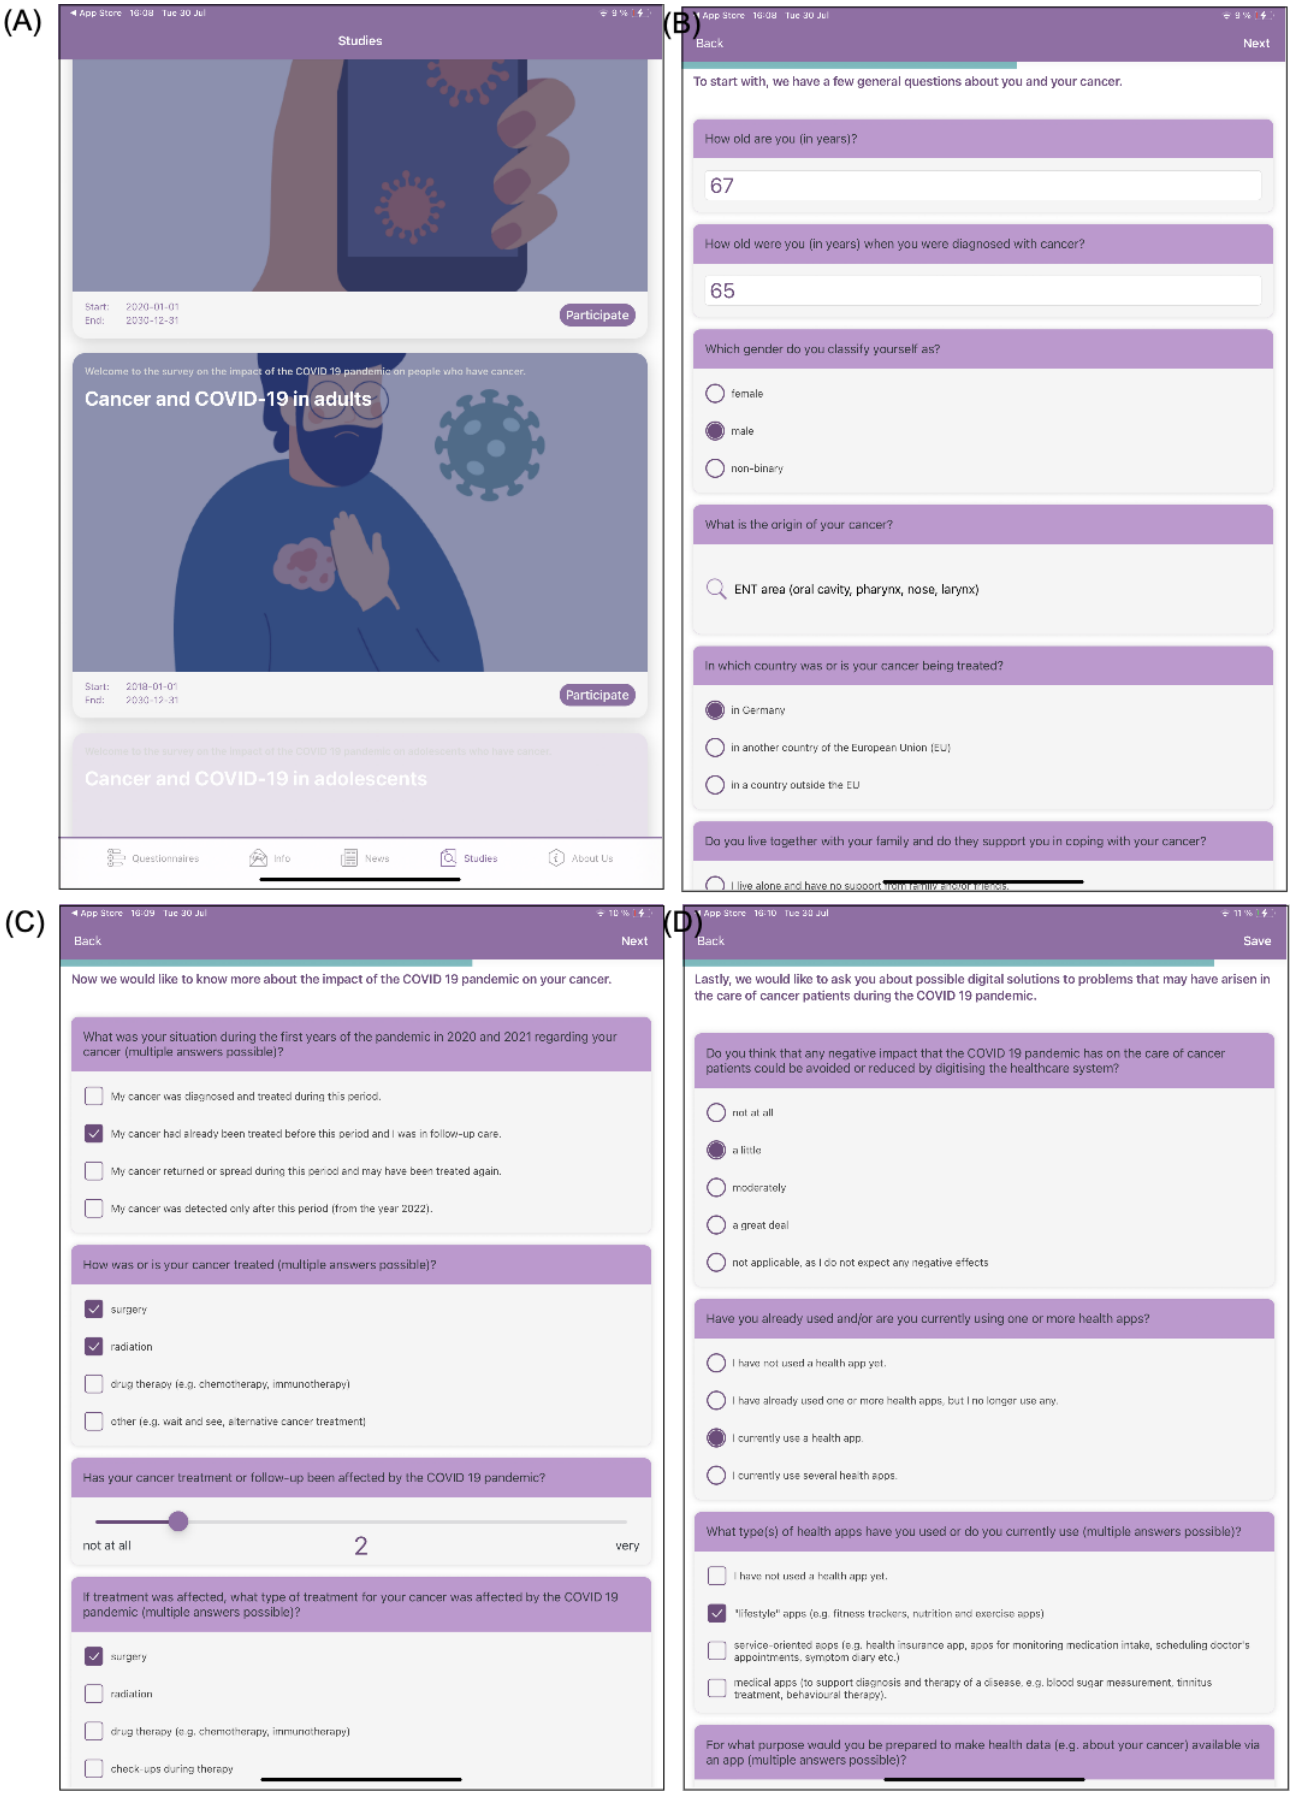
Despite advances in treatment, many patients with HNC face barriers to accessing timely and coordinated care [3]. Advanced age, multiple comorbidities, and the physical and emotional burden of the disease can limit patients' autonomy and complicate long-term follow-up care [4]. In addition, patients often report unmet needs in terms of communication, symptom management, and psychological support—highlighting gaps in traditional care structures [5].

Digital health technologies, particularly mobile health (mHealth) apps, offer new tools to bridge these gaps [6]. By supporting remote symptom monitoring, improving communication between patients and providers, and enabling self-management, mHealth can improve both the quality of care and patient autonomy [7-10]. However, acceptance among patients with HNC remains limited, partly due to age-related digital divides and a lack of tailored, accessible solutions [11,12].

The COVID-19 pandemic posed significant challenges to oncology care, including appointment postponements and treatment interruptions [13,14]. Simultaneously, it accelerated the adoption of telemedicine and digital health tools in many health care systems. For patients with HNC, the pandemic provided a unique opportunity to try out digital solutions—not just as an emergency measure, but as a permanent component of cancer care [15].

This study examines the experiences of patients with HNC during the COVID-19 pandemic and their perception of mHealth apps. Using self-reported patient data from the Corona Health app, we analyze disruptions in cancer treatment, patterns of digital health service use, and the most important factors that promote or hinder the adoption of mHealth. The results may, in turn, promote the development of accessible, patient-centered digital interventions for people with HNC.

Methods



Study Design and Participants

This study is a secondary analysis of data collected via the Corona Health mobile app platform, a study- and sensor-based mHealth infrastructure developed to investigate various aspects of the COVID-19 pandemic and conduct multiple questionnaire-based studies [16]. Details on the technical implementation of the platform, data collection procedures, and characteristics of the initial cohort have been published by Beierle et al [16,17] (2021). For this analysis, we used cross-sectional data from patients with HNC, who participated through a dedicated study module integrated into the Corona Health app. Participants were recruited between January 2023 and May 2024 at the Department of Otorhinolaryngology, Plastic, Aesthetic, and Reconstructive Head and Neck Surgery at Julius Maximilian University of Würzburg, Germany. Recruitment took place primarily within the department's clinical infrastructure. The weekly tumor follow-up clinic for patients with HNC, which offers both initial consultations and follow-up appointments, was the main recruitment site, with approximately 35 to 40 patients participating per week. During waiting times, suitable patients were informed about the study and invited to participate. In addition, inpatients from 2 wards specializing in the diagnostic and therapeutic treatment of HNC were approached to participate. Patients with a confirmed HNC diagnosis were included in the study, whereas patients with cognitive impairments or language barriers that prevented participation were excluded.

Participants who were unable or unwilling to use the app completed a paper version of the same survey (see Figure 1), the responses to which were later digitized and entered into the database. The survey comprised 25 specially designed questions (Q 1 - 25) on participants' sociodemographic characteristics (Part A); the impact of the pandemic on diagnosis, treatment, and follow-up care (Part B); and their interest and willingness to use mHealth apps (Part C).

XSL•FO
RenderX

The response formats included single choice (Q 1 - 9, Q 20 - 22, Q 24), multiple choice (Q 10 - 11, Q 13, F 22 - 23, F 25), and matrix/rating scale questions (F 12, F 14 - 19) with 1 to 8 points to reduce central tendency bias. For analysis, scores were divided into 4 categories (1, 2-4, 5-7, 8) and labeled according to context (eg, never, rarely, sometimes, and often for F 16 - 17; no, low, moderate, and high for F 12, F 14 - 15). Trained health care professionals assisted participants in completing the survey.

The survey was developed by experts in epidemiology and ear, nose, and throat medicine as well as head and neck surgery at the University Hospital of Würzburg, Germany. Before large-scale use, it was tested in 3 oncology outpatient clinics with approximately 30 patients, who evaluated the clarity and relevance of the individual questions. Based on their feedback, questions were refined, added, or removed to improve comprehensibility and validity. This iterative process resulted in a robust, patient-centered instrument that enabled a meaningful assessment of the experiences and perspectives of patients with HNC during the pandemic. The study was also open to anyone who could download the app for free from the Google and Apple app stores.

Data Analysis

Survey responses were analyzed to identify patterns and significant findings related to the impact of the COVID-19 pandemic on HNC treatment and attitudes toward mHealth apps. Descriptive statistics were used to summarize demographic characteristics and survey items.

The relationships between demographic variables and survey variables were examined using Pearson correlation for continuous data and Spearman ρ for ordinal data. Statistical significance was set at $P \leq .05$, with interpretation emphasizing the strength and direction of correlations. Coefficients of approximately |0.10 - 0.29|, |0.30 - 0.49|, and ≥|0.50| were interpreted as weak, moderate, and strong associations, respectively [18]. Positive coefficients indicated that the variables increased together, whereas negative coefficients indicated inverse relationships.

The study was exploratory in nature and aimed to characterize the experiences of patients with HNC during the pandemic and their attitudes toward the use of mHealth. Due to the lack of previous data on mHealth acceptance in this population, formal performance calculations were not possible. The final sample of 355 participants (response rate: 60%) exceeded the typical minimum requirements for correlation analyses (30 - 50 participants per variable) and provided sufficient power (>80%) to detect medium effect sizes ($r \geq 0.15$) at $\alpha = .05$. Subgroup analyses among mHealth users (34/355, 10%) were found to be undersized, and the corresponding results should be interpreted as preliminary and validated in larger samples.

Ethical Considerations

The Corona Health app used was developed and implemented in accordance with medical device regulations and received the appropriate certification [19]. The University of Würzburg ethics committee approved the original data collection for this study (130/20-me), with explicit coverage for both initial collection and future secondary analyses of the data. The primary study describing the Corona Health platform and its data collection across multiple integrated studies has been published by Beierle et al [16]. Therefore, no additional institutional review board approval was required for this secondary analysis. Under local regulations and institutional guidelines [20], the secondary use of existing anonymized data does not require separate ethical review. All procedures complied with institutional ethical standards for research involving human subjects, and participant data were completely anonymized to ensure privacy protection. Participation was voluntary and no financial compensation was provided. Finally, this cross-sectional study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for reporting cross-sectional studies (Checklist 1).

Results

The results are divided into 3 main sections according to the survey structure: (1) demographic data and clinical characteristics of participants, (2) impact of the pandemic on cancer care, and (3) attitudes toward mHealth apps.

Part A: Participant Sociodemographics

A total of 355 individuals with head and neck malignant neoplasms participated in the study, including 261 (74%) males and 94 (26%) females, with a median age of 67 years (IQR 18 - 92 y; Q 1 and Q 3) at the time of the survey.

The median age at cancer diagnosis was 65 (IQR 55-70) years (Q 3). Time since diagnosis was calculated by subtracting age at diagnosis (Q 3) from the current age (Q 2). In addition, 80% (n=283) of the participants received their initial diagnosis within the past 5 years, with the proportion decreasing from 36% (n=102) diagnosed within the past year to 8% diagnosed 5 years ago.

All individuals received their treatment in Germany (Q 5). Additionally, 18% (n=65) of the participants had a history of other cancers, mainly gastrointestinal cancer (n=18, 5%), malignant melanoma (n=10, 3%), and blood or lymphatic cancer (n=10, 3%).

Half of the participants (n=179, 50%) had 8 to 9 years of school education, 158 (45%) had a higher educational level, and 18 (5%) had a lower educational level.

More than half of the participants (n=192, 54%) had completed 3 to 4 years of professional training or higher education. About a quarter (n=92, 26%) had a longer qualification, while a fifth (n=71, 20%) had a shorter qualification.

Approximately 3 quarters (n=261, 74%) of the participants live with and receive support from their families. One in 5 (n=72, 20%) participants lives alone but receives support from family and/or friends. A small number of individuals either live alone without support (n=16, 5%) or live with their families but receive little or no support (n=6, 2%).

At the time of the survey, approximately 1 out of 4 (n=90, 25%) participants was employed, while two-thirds (n=239, 68%) were unemployed. Of those who were unemployed, the majority were either doing housework and/or raising children, retired, or

XSL•FO
RenderX

preretired (n=233, 66%), with a small minority actively seeking work (n=6, 2%).

In summary, a comprehensive summary of all results for Part A can be found in Table 1.

[a]HNC: head and neck cancer.

Part B: Impact of the COVID-19 Pandemic

Among 355 participants, 118 (33%) were diagnosed with cancer before the pandemic (2019 and earlier), 108 (30%) during the pandemic (2020 and 2021), and 126 (35%) of them after the pandemic (2022 and later). Of all respondents, only 13 stated that they had been treated due to a recurrence of their cancer.

Out of 355 participants, 290 (82%) underwent surgery as part of their treatment plan. Radiation therapy was included for 222 (63%) participants, and drug therapy (eg, chemotherapy and immunotherapy) was part of the treatment for 126 (35%) participants. Additionally, 11 (3%) participants received other therapies (eg, watchful waiting and alternative cancer treatments). Combination treatments were common: 170 (48%) participants had both surgery and radiation, 112 (32%) had both radiation and drug therapy, 111 (31%) had surgery only, 14 (4%) had radiation only, 5 (1%) had drug therapy only, and 7 (2%) received solely other therapies.

About 3 out of 4 participants reported no impact of the pandemic on their therapy and aftercare (n=264, 74%), while most of those who experienced disruptions considered them to be minor (n=57, 16%).

Out of 355 participants, 285 (80%) did not report any disruption in their therapy or aftercare. Among the remaining 70 (20%) participants, the most documented disruptions were in follow-up examinations (34, 10%) and checkups during therapy (21, 6%). Fewer participants experienced disruptions in radiation therapy (15, 4%), surgery (14, 4%), drug therapy (10, 3%), and supportive therapy (9, 3%).

More than half of the participants reported no fear of SARS-CoV-2 infection during (n=204, 57%) or after the pandemic (n=205, 58%). Approximately 1 in 4 participants experienced little fear during (n=94, 26%) and slightly more after the pandemic (n=115, 32%). Moderate fear declined from 11% (n=39) during the pandemic to 7% (n=24) after the pandemic, as did very strong fear (n=18, 5% during; n=11, 3% after).

Most participants did not experience cancellations of appointments by the clinic due to the pandemic (n=299, 84%), and even fewer patients canceled appointments themselves (n=309, 87%). About 1 in 10 participants had appointments rarely canceled by the clinic (n=47, 13%) and rarely canceled appointments themselves (n=40, 11%). Almost no participants faced regular appointment cancellations.

Around two-thirds (n=223, 63%) of the participants had no psychological effects due to the pandemic at all, 101 (28%) participants had minor effects, and only 26 (7%) and 5 (1%) of them were affected moderately or highly.

Similarly, around two-thirds of the participants had no fear of negative effects of the pandemic on their own cancer therapy (n=234, 66%), 102 (29%) participants had minor fear, while 16 (5%) and 3 (1%) documented moderate or major fear, respectively.

In summary, a comprehensive summary of all results for Part B can be found in Table 2.

Part C: mHealth App Use

About 1 out of 4 (n=83, 23%) participants expected no positive effect of digital health solutions on cancer care, whereas 1 out of 3 (n=114, 32%) expected minor effects. Only 19% (n=67) and 10% (n=34) of the participants anticipated moderate or major effects. Additionally, 16% (n=57) of the participants saw no need for digitalization in cancer care at all.

About 1 out of 4 participants (n=83, 23%) expected no positive effect of digital health solutions on cancer care, whereas 1 out of 3 (n=114, 32%) expected minor effects.

Only 10% (n=34) of participants were currently using health apps, with 8% (n=27) using only one health app and 2% (n=7) using more than one health app. Additionally, 6% (n=23) had formerly used a health app, whereas the majority of the participants (n=298, 84%) had never used a health app.

Out of the 57 (16%) app users, about half had been using lifestyle apps (eg, fitness trackers, nutrition, and exercise apps; n=28, 49%), and every fourth user had been using a service-oriented health app (eg, health insurance apps, apps for monitoring medication intake, scheduling doctor's appointments, and symptom diaries, etc; n=14, 25%) or medical apps (eg, apps supporting diagnosis and therapy of diseases, such as blood sugar measurement, tinnitus treatment, and behavioral therapy; n=15, 26%).

About two-thirds of the participants expressed willingness to share their health data using a mHealth app. The most frequent possible recipients identified were researchers (n=135, 43%), therapists (n=134, 38%), and the participants themselves (n=112, 32%). Only a minority of participants indicated willingness to share their data for self-help purposes (n=58, 16%) or publicly (n=44, 12%).

Out of 355 participants, 151 (43%) indicated that they would never use a health app to record symptoms of their cancer. The responses varied among those willing to use such an app: 103 (29%) participants preferred to use it symptom-dependent rather than at a fixed frequency. Specifically, 38 (11%) participants would use it once, whereas 63 (18%) participants would use it frequently, with breakdowns as follows: every 3 months (n=15, 4%), monthly (n=15, 4%), weekly (n=15, 4%), multiple times weekly (n=8, 2%), daily (n=7, 2%), and multiple times daily (n=3, 1%).

Asked about their desired interaction within a cancer app, 145 out of 355 (41%) indicated that they would not use it. Among potential users, preferences for interaction varied: 158 (45%) participants expressed interest in interacting with physicians, whereas 98 (28%) participants wanted to interact with researchers. An even smaller proportion preferred interaction with nurses (n=41, 12%) or engaging in self-care activities (n=41, 12%). Only 15 (4%) participants stated they did not desire any interaction within the app.

In summary, a comprehensive summary of all results for Part C can be found in Table 3.

Table . Digital health attitudes and app usage patterns (see Table S1 in Multimedia Appendix 1 for the detailed overview of the questions).

Variable and category	Values, n (%)
Effect of digital health on cancer care	
No effect	83 (23.4)
Minor	114 (32.1)
Moderate	67 (18.9
Major	34 (9.6)
Not necessary	57 (16.1)
Health app usage	
Nonuser	298 (83.9)
Ex-user	23 (6.5)
Single-app user	27 (7.6)
Multiapp user	7 (2)
Type of health app used (n=57/355)	
No app	297 (83.9)
Lifestyle	28 (7.9)
Service	14 (4)
Medical	15 (4.2)
Willingness to share health data	
Public	44 (12.4)
Self-help groups	58 (16.3)
For personal use	112 (31.5)
Not at all	120 (33.8)
Therapists	134 (37.7)
Researchers	153 (43.1)
Intended frequency of app use (n=63/355)	
Multiple times daily	3 (0.8)
Daily	7 (2)
Multiple times weekly	8 (2.3)
3× monthly	15 (4.2)
Monthly	15 (4.2)
Weekly	15 (4.2
Once	38 (10.7)
Symptom-dependent	103 (29)
Never	151 (42.5)
Desired interaction within the cancer app	
Nobody	15 (4.2)
Self-care	41 (11.5)
Nurses	41 (11.5)
Researchers	98 (27.6)
No app use	145 (40.8)
Physicians	158 (44.5)

Relationships Between Patient Characteristics and Study Outcomes

Furthermore, we explored how demographic variables correlated with survey responses. Depending on the measurement level of the variables, either Pearson (for continuous variables) or Spearman (for ordinal variables) correlations were applied, revealing several significant relationships: older age was negatively associated with app usage (P<.001, r=−0.20), psychological stress (P=.009, r=−0.14), and the expected effect of digital solutions on cancer care (P=.39, r=−0.11). In addition, we found the following:

- Male participants showed a negative correlation with fear of SARS-CoV-2 infection during (P=.03, r=−0.11) and after the pandemic (P=.03, r=−0.11).
- Higher education positively correlated with app usage (P<.001, r=0.17) and higher professional qualification with expected effect of digital solutions (P=.049, r=0.10). Moreover, a higher educational level was associated with more significant concern about pandemic-related impacts on personal cancer outcomes (P=.05, r=0.15).
- Perceived disruptions of cancer care due to the pandemic, fear of personal repercussions, and cancellation of appointments by the clinic (P<.001, r=0.39) or by the patient (P<.001, r=0.34) were all positively correlated with fear of SARS-CoV-2 infection and psychological stress (all P<.001, r=0.39; P<.001, r=0.59).
- The perceived impact of the pandemic on participants' cancer care was positively correlated with app usage (P=.03, r=0.12).

To understand relationships between patient characteristics and study outcomes, we examined bivariate correlations between key variables. Table 4 presents all statistically significant correlations, organized to show how demographic factors (age, gender, education, and qualification), pandemic experiences (impact, fear, and cancellations), and mHealth attitudes (digital solutions, app usage, and frequency) relate to one another.

	• Digital solution	.03	0.11
	• Frequency	.003	0.16

[a]Bivariate correlations were calculated between demographic characteristics, pandemic experiences, and mHealth attitudes. Depending on the measurement level of the variables, either Pearson (for continuous variables) or Spearman (for ordinal variables) correlations were used. Correlation coefficients (*r* or ρ) indicate the strength and direction of the relationship: weak correlations=0.10≤*r*≤0.29, moderate correlations=0.30≤*r*≤0.49, else strong correlation. Positive coefficients indicate that variables increase together, whereas negative coefficients indicate that one variable increases as the other decreases.

[b]Weak correlation.

[c]Strong correlation.

[d]Moderate correlation.

Note that it must be emphasized that correlations are not a robust measure of association and do not allow causal inference. Moreover, the analyses did not account for potential confounding variables.

Discussion

Overview of Findings

This study provides new insights into the experiences of patients with HNC in terms of diagnosis, treatment, and follow-up care, as well as their attitudes toward mHealth apps. Although most patients reported no major disruptions to their cancer treatment, a significant proportion (20% - 26%) experienced interruptions—particularly in follow-up appointments and treatment-related checkups. This subgroup highlights the importance of maintaining continuity of care for all patients, even during health care crises.

Correlation analyses revealed several notable patterns. Older participants were less likely to use digital health solutions, whereas higher levels of education were associated with greater acceptance of mHealth. In addition, patients who had experienced pandemic-related disruptions to care reported both increased anxiety and greater interest in digital alternatives. The observed correlations between pandemic-related anxiety, disruptions in care, and psychological distress (r=0.27 - 0.49) suggest that these factors form an interconnected cluster of pandemic-related health care anxieties.

Pandemic Impact on Cancer Care

The COVID-19 pandemic has posed unprecedented challenges to health care systems worldwide and necessitated rapid adjustments in cancer care [21]. At our institution, treatment pathways remained largely stable; however, 20% - 26% of patients reported interruptions in care, which is consistent with international observations of treatment delays, limited access to support services, and changed follow-up appointments [22,23]. Previous studies on head and neck oncology also document pandemic-related delays and increased psychological distress [23], while short-term survival outcomes appear to have remained largely unaffected [24]. These findings suggest that rapid institutional adjustments have effectively mitigated serious clinical consequences despite significant logistical and emotional challenges.

Potential of Digital Health Solutions

Despite current low usage (10%), patients showed significant interest in mHealth solutions for symptom monitoring, communication with health care providers, and data sharing. Greater acceptance was associated with younger age, higher education level, and pandemic-related disruptions to care, consistent with general trends in telemedicine adoption during COVID-19 [25], although regulatory barriers remain in many countries [26].

mHealth offers opportunities for remote symptom monitoring, timely interventions, and personalized patient education. Feasibility in patients with HNC has been demonstrated in pilot studies [27] and randomized controlled trials [28]. However, large-scale implementation continues to be limited by early discontinuation, challenges with scalability, and limited integration into routine clinical workflows [29].

Barriers to Adoption

The findings reveal several barriers to the adoption of mHealth that are consistent with previous research findings. Age, digital literacy, and perceived usefulness remain important determinants of acceptance [30]. Although most participants stated that they had minimal concerns about data security within the university, previous studies show that data protection outside clinical research environments remains a major barrier [31,32]. This is particularly relevant in Germany, where data protection concerns are often cited as a significant barrier to the adoption of digital health services [32].

XSL•FO
RenderX

Implications for Practice

Future strategies to enhance mHealth adoption in HNC care should include the following:

1. Improving digital literacy—targeted training programs for older adults and individuals with lower educational levels [33].
2. Addressing privacy concerns—transparent communication of robust data security measures [31].
3. Demonstrating utility—evidence-based, user-friendly, and personalized app functionalities to enhance trust and sustained use [34].

Previous studies suggest that despite ongoing concerns about implementation, oncologists are generally open to integrating mHealth technologies into patient care [35]. By removing barriers on both the patient and provider sides, mHealth could make the transition from a complementary tool to an integral part of multidisciplinary cancer treatment.

Although the COVID-19 pandemic was unprecedented, the challenges it revealed—such as scheduling constraints, communication gaps between visits, the need for remote monitoring, and increased patient anxiety about accessing health care—are not unique to pandemics. Similar disruptions also occur during natural disasters, staff shortages, transportation barriers, and routine capacity constraints. Our findings that 57% (n=202) of patients were willing to share health data and 45% (n=160) preferred to communicate with their doctors using an app provide actionable insights for strengthening continuity of care under various disruptive conditions.

The rapid digital transformation triggered by COVID-19 has permanently changed the expectations of patients and providers. The pandemic has accelerated a decade of digital health development in a matter of months, revealing both barriers and enablers that will continue to be relevant as health systems drive this transformation forward. The demographic predictors identified in our study—age, education, and prior experience with health care—represent enduring factors that are likely to influence mHealth adoption regardless of future circumstances.

Strengths and Limitations

This study focused on a high-need population—patients with HNC—who often face complex treatments and intensive follow-up care requirements. By examining both pandemic-related disruptions to care and the introduction of digital health solutions within the same cohort, it offers a holistic perspective on health care resilience.

However, there are some limitations to consider. The study design, conducted at a single center in Würzburg, limits generalizability, and the relatively small, specialized cohort may not reflect the broader cancer population. Nonresponse bias cannot be ruled out, as the participation of nonrespondents was not tracked. The use of self-reported data may have led to bias due to recall or social desirability, although the survey design aimed to minimize these effects. The low prevalence of mHealth users (34/355, 10%) limited subgroup analyses and restricts the generalization of user behavior. Finally, correlation analyses do not allow conclusions about causality and did not control for potential confounding factors. Future multicenter studies with larger, more diverse samples and causal modeling approaches are needed to validate and extend these findings.

Conclusion

This study highlights both the challenges and opportunities faced by patients with HNC during and after the COVID-19 pandemic. While most patients continued to have access to essential care, a subset experienced significant disruptions, underscoring the need for resilient care pathways. The pandemic has also sparked interest in mHealth apps; however, barriers remain in terms of age, digital literacy, and perceived usefulness. Targeted education, robust data protection, and clear evidence of clinical benefit will be critical to integrating mHealth into cancer care and improving outcomes and quality of life for patients with HNC.

Acknowledgments

Assistance in writing and editing this manuscript was provided by ChatGPT, a large language model developed by OpenAI. The authors reviewed and verified the accuracy of all content generated with the assistance of this tool.

Funding

This publication was funded by the German Federal Ministry of Education and Research (BMBF) Network of University Medicine 2.0: "NUM 2.0," grant number 01KX2121, project: [Collateral Effects of Pandemics – CollPan].

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Authors' Contributions

CW and MS conceptualized and designed the study and jointly wrote and reviewed the manuscript. JR conducted the survey. JA, CV, MW, JS, and RP developed and managed the Corona Health app and were responsible for data processing. MW, JS, and RP also contributed to manuscript review. SRZ assisted in the development of the questionnaire and reviewed the manuscript. KR and JK supported the study's implementation and coordinated its continuation at an additional site. AS, SH, and RH oversaw study implementation and participated in the manuscript review.

Abstract

Background: Mobile health (mHealth) represents a promising instrument for optimizing symptom management and important lifestyle strategies that enhance self-care and the quality of health care for patients with cancer. The ALIBIRD mHealth platform is a digital health solution specifically designed for the telemonitoring of oncology patients, fostering patient empowerment and supporting clinical decision-making.

Objective: The primary objective of this study was to evaluate the patient experience with the ALIBIRD platform. In addition, the study aimed to assess clinical outcomes, particularly in symptom management, nutritional status, and lifestyle, using patient-reported outcome measures (PROMs).

Methods: The evaluation was conducted over a 30-week period in patients with advanced lung cancer receiving active treatment. Outcome variables included usability, patient experience, symptom burden, lifestyle behaviors (diet, physical activity, and sleep), nutritional status, PROMs, and system-generated clinical alerts. Through the mobile app, patients reported symptoms and completed integrated REDCap (Research Electronic Data Capture) questionnaires assessing lifestyle behaviors and PROMs, while receiving personalized recommendations informed by nutrigenetic and gut microbiota assessments. Daily activity and sleep data were automatically captured using the Fitbit Inspire wearable. Clinicians remotely monitored patient data using a web-based dashboard and performed clinical actions when required, including phone calls, therapeutic adjustments, referrals, and appointment rescheduling. Statistical analysis included descriptive summaries and pre-post comparisons of clinical and patient-reported outcomes.

Results: Out of 20 patients recruited for the study, 14 completed the intervention. The System Usability Scale yielded a score of 90, indicating high usability. Among the 14 completers, adherence to scheduled questionnaires ranged from 94% to 100% for several instruments, and wearable-based monitoring ranged from 66% to 96% across visits. Overall, the ALIBIRD platform collected and processed 3589 patient-reported outcomes related to physical activity, 3468 related to sleep, 679 on-demand symptom entries, and 1524 completed questionnaires. Clinically, 143 alerts were resolved within an average of 2.05 days, resulting in 2 referrals to emergency rooms and 2 early detections of disease progressions. Furthermore, more than 2100 personalized recommendations contributed to a 21% (3/14 patients) increase in adherence to the Mediterranean diet and a 14% (2/14 patients) increase in moderate physical activity.

XSL•FO
RenderX

Conclusions: The evaluation of the ALIBIRD implementation yielded promising results in that it facilitated the adoption of healthier lifestyle habits while enhancing health self-management among oncology patients. The ALIBIRD mHealth platform emerges as an effective digital health tool that enables closer monitoring of patients and thereby more informed clinical decision-making.

Introduction

Clinical Context and State of the Art

Cancer represents a significant health problem that, according to statistics from the GLOBOCAN 2022 database, has an incidence of nearly 2.5 million cases and causes 1.8 million deaths worldwide [1]. Among the different types, lung cancer (LC) is the most commonly diagnosed cancer globally (12.4% of total cases) and is also the leading cause of cancer-related deaths (18.7% of total cancer deaths). Effective management of disease and treatment-related symptoms, alongside the provision of supportive care, is essential for improving the quality of life (QoL) of patients with LC. Nevertheless, health care providers frequently underestimate the severity of symptoms during oncology consultations, a phenomenon attributed to demanding schedules, substantial workloads, and patients' hesitance to articulate their concerns [2,3]. Oncologists often prioritize the identification and management of severe adverse events, thereby overlooking the comprehensive spectrum of symptoms that significantly impact patients' QoL [4,5].

Consequently, patients with advanced lung cancer (aLC) experience multiple unmet needs, including complex symptom management, nutritional deterioration, and emotional distress, which are often insufficiently addressed by traditional care models. These models struggle to provide frequent, personalized follow-up, resulting in suboptimal QoL and potentially avoidable clinical events. Recent literature highlights the need for innovative, patient-centered strategies and hybrid care models that combine in-person and remote monitoring to deliver timely, tailored interventions [6,7]. Digital health solutions, particularly mobile health (mHealth) platforms, offer a promising approach by enabling continuous telemonitoring and supporting a multidisciplinary, multidimensional framework that integrates symptoms, lifestyle, nutrigenetics, and microbiota. Within this context, patient-reported outcomes (PROs) and their validated measures (patient-reported outcome measures [PROMs]) have become key instruments for capturing patients' health status [8,9]. Their electronic implementation (electronic PROs) allows patients to self-report symptoms, lifestyle, and treatment-related information, enhancing self-care and adherence while enabling proactive clinical monitoring. This, in turn, contributes to more efficient health care delivery by reducing unplanned visits, emergency room utilization, and hospital admissions [10,11].

Various lifestyle factors, such as a healthy diet and physical activity, significantly influence cancer treatment and prognosis. In aLC, the high prevalence of malnutrition and risk of cachexia underscore the need for nutritional support and lifestyle interventions [12,13]. Personalized nutrition and lifestyle recommendations have emerged as promising strategies, allowing the design of tailored dietary plans based on clinical and genetic profiles [14]. Nutrigenetics can positively impact cancer treatment by genotyping processes such as lactose, gluten, alcohol, and tobacco metabolism, as well as physical activity tolerance and predisposition to conditions such as constipation or insomnia, thereby informing tailored supportive treatments [15]. Furthermore, the intestinal microbiome is implicated in cancer development, progression, and treatment response, with dysbiosis frequently observed in various malignancies [16,17].

eHealth and mHealth interventions have been increasingly implemented to support follow-up and improve QoL in patients with cancer [18,19]. These approaches build upon broader evidence from information and communication technologies in health care, which have been successfully applied across various medical fields. Such interventions have been associated with reductions in unplanned hospital visits and earlier detection of symptom deterioration [20,21], improvements in health-related quality of life and symptom self-management [22], and high patient adherence and acceptability in clinical use [23]. Evidence from oncology-specific applications reinforces this trend: studies have shown that patients are willing to adopt digital tools when recommended by clinicians and demonstrate sustained engagement and high acceptability in clinical use [7,23]. Complementary evidence from recent mHealth evaluations indicates that these interventions are generally well accepted, with high usability and sustained patient engagement in oncology settings [24-26].

Comparative studies further suggest that mHealth-based follow-up can achieve outcomes equivalent or superior to conventional care in aspects such as physical function, symptom control, and patient satisfaction, supporting the development of hybrid care models that combine in-person visits with telematic monitoring [19,27,28]. Moreover, emerging evidence points to the potential cost-effectiveness of these interventions, which may optimize resource allocation in oncology care [29]. These findings reinforce the potential of mHealth to support integrated, multidisciplinary care models capable of addressing the complex needs of patients with advanced disease, ultimately enhancing patient empowerment and enabling better clinical decision-making.

Description of the ALIBIRD mHealth Platform

The ALIBIRD mHealth platform was developed within the ALIBIRD2020-CM program (S2018/BAA-4343)—a multidisciplinary consortium of 5 institutions from the Community of Madrid, Spain—aimed at designing and validating precision nutrition strategies for patients with cancer [30]. The development followed a user-centered and participatory design framework [31,32], actively involving patients, clinicians, and researchers throughout all stages [33,34]. Agile methodologies were applied [35,36], using iterative cycles of design, prototyping, and validation to ensure usability, clinical relevance, and alignment with user needs. The platform was developed and internally validated over approximately 18 months prior to the clinical study, following this iterative, user-centered process, for its subsequent evaluation in a pilot intervention.

The platform comprises three main components: (1) a mobile app for patients, (2) a web-based tool for health care professionals, and (3) a back-end infrastructure that includes the application programming interfaces, databases, notification services, wearable and REDCap (Research Electronic Data Capture) [37] integration, and a rule-based engine.

The mobile app enables patients to report PROs and PROMs (symptoms, diet, and lifestyle) and to synchronize data from Fitbit devices to monitor physical activity and sleep. It provides personalized recommendations, nutrigenetic and gut microbiota reports, weekly progress summaries, and educational resources to promote self-management. The web-based tool allows health care professionals to remotely monitor patients' symptoms, nutritional status, and lifestyle patterns, providing real-time access to alerts and reports. The back-end processes PROs, lifestyle data, and other clinical inputs to generate automated reminders, positive reinforcement messages, weekly summaries, and clinical alerts. It also incorporates baseline nutrigenetic analyses and gut microbiota profiling as structured inputs that support individualized nutritional guidance and lifestyle advice. These analyses are stored within the platform and contribute to tailoring recommendations delivered through the app and to the content available for clinicians during follow-up. Figure 1 illustrates the overall architecture and interactions of the ALIBIRD platform, including the patient mobile app (Figure 1A), the web-based clinical tool for health care professionals (Figure 1B), back-end services, and third-party platforms such as REDCap and Fitbit (Figure 1C).

Figure 1. Overview of the ALIBIRD mobile health (mHealth) platform and the interactions and functionalities of its main components. The diagram illustrates (A) the patient mobile app, which collects lifestyle variables (physical activity, diet and nutrition, sleep and rest, and toxic habits), and patient-reported outcomes, including symptoms, toxicities, and mood, and delivers personalized recommendations (medication reminders, weekly reports, nutrigenetic and gut microbiota–based advice, and mobile notifications and messages); (B) the web-based clinical tool for health care professionals, which supports follow-up of patients with cancer through visualization of patient-reported data, resolution of symptom and nutritional alerts, and personalized patient contact; and (C) the back-end infrastructure, which enables secure processing and storage of data, generation of personalized recommendations and alerts, application programming interfaces for data connection and transfer, automated notifications, and integration with external cloud services and tools (eg, REDCap and Fitbit). API; application programming interface; REDCap: Research Electronic Data Capture.

Additional details of the rule engine and its logic, along with illustrative screenshots of the patient mobile app and the web-based clinical tool, are provided in Multimedia Appendix 1(Figures S1 and S2).

Personalized Recommendations and Alerts

The ALIBIRD platform includes a rule-based algorithm (rule engine) designed to generate automated recommendations and clinical alerts, informed by clinical guidelines, validated instruments, and expert consensus. The engine systematically analyzes PROs, lifestyle data, nutrigenetic information, gut microbiota findings, and other clinical inputs stored in the platform's database. Within this framework, nutrigenetic and microbiota-derived insights are integrated directly into the decision logic to refine nutritional and lifestyle recommendations according to each patient's biological profile.

XSL•FO
RenderX

Thresholds for dietary recommendations and nutritional risk (including weight management and malnutrition indicators) were derived from the Mediterranean Diet Adherence Screener (MEDAS), the Mediterranean Diet Serving Score, and the ESPEN practical guideline: Clinical Nutrition in Cancer [38-42]. Symptom severity was classified according to the Common Terminology Criteria for Adverse Events (CTCAE v5) [43], while recommendations related to physical activity and sleep patterns were aligned with widely accepted international standards, such as those from World Health Organization.

Four types of outputs are generated: (1) reminders to support adherence, (2) positive reinforcement messages to promote healthy habits, (3) weekly progress summaries, and (4) clinical alerts to notify health care professionals about adverse events or critical changes (eg, severe symptoms, reduced food intake, or significant weight loss). When an alert is triggered, clinicians can take timely actions, such as scheduling an appointment, adjusting treatment, or referring the patient to a specialist.

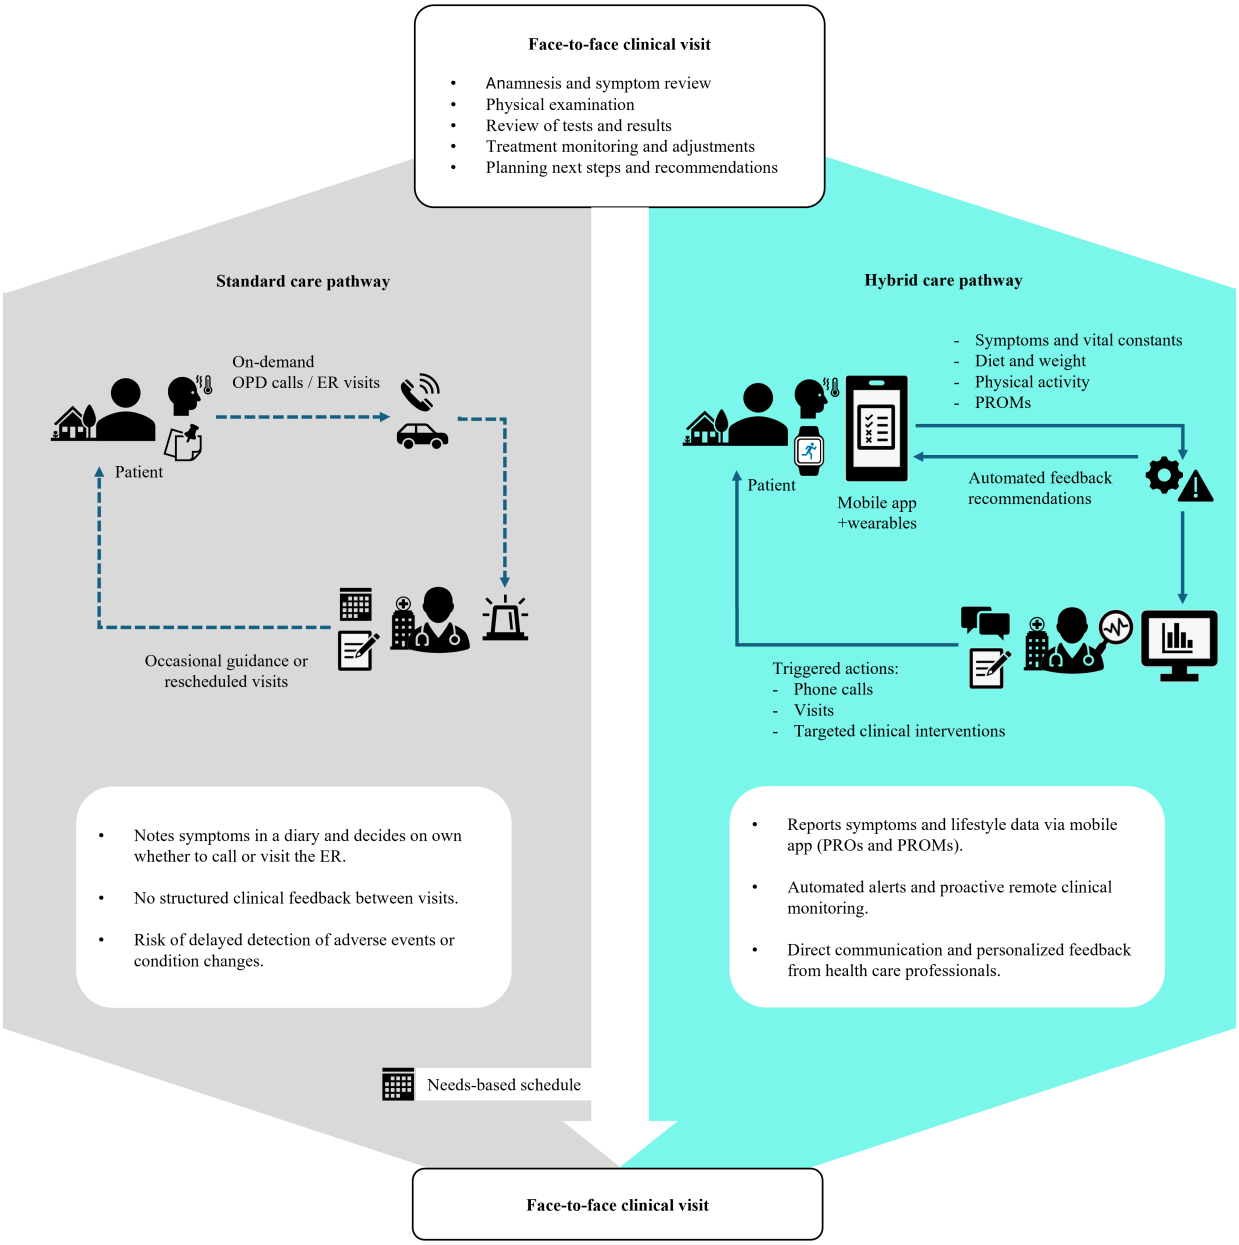
The development of the algorithm was informed by expert input from oncologists, nutritionists, and nursing professionals, with decision rules and thresholds being progressively refined to ensure clinically relevant and accurate outputs. Additional details of the rule engine, including monitored dimensions and a schematic overview of data processing and outputs, are provided in Multimedia Appendix 2 (Table S1 and Figure S1).

The primary objective of this study was to evaluate the usability and patient satisfaction with the mHealth ALIBIRD platform in patients with aLC. The secondary objective was to explore its clinical impact, including early detection of relevant events, resolution of alerts, and the promotion of healthier lifestyle habits.

Methods

Study Design

A single-arm, prospective, interventional study was conducted involving patients with advanced thoracic tumors, mainly non–small cell lung cancer (NSCLC), at the Infanta Sofía University Hospital in Madrid, Spain. The total study duration was 18 months, including a preparatory phase for study setup and patient recruitment, followed by a 30-week intervention period per patient. Patient recruitment occurred between November 2021 and January 2022, with consecutive enrollment as patients met eligibility criteria, resulting in a staggered but overlapping participation across the cohort.



Integration Into Clinical Workflow

In oncology, conventional patient follow-up is typically based on scheduled in-person visits spaced every few weeks, with limited patient-clinician interaction in between. In our study, we implemented a hybrid (mHealth-based) care pathway, integrating the ALIBIRD mobile app and clinical dashboard with usual care to support continuous self-management and remote monitoring.

A multidisciplinary team of 5 clinicians (3 oncologists, 1 nutritionist, and 1 oncology nurse), supported by a data manager and a biomedical engineer, participated in patient monitoring and system oversight. Clinicians performed standard clinical visits (V1-V10) and used the dashboard to review patient-reported data, respond to alerts, and personalize interventions. The data manager conducted regular quality checks on data completeness, while the biomedical engineer ensured technical support and system performance (Figure 2).

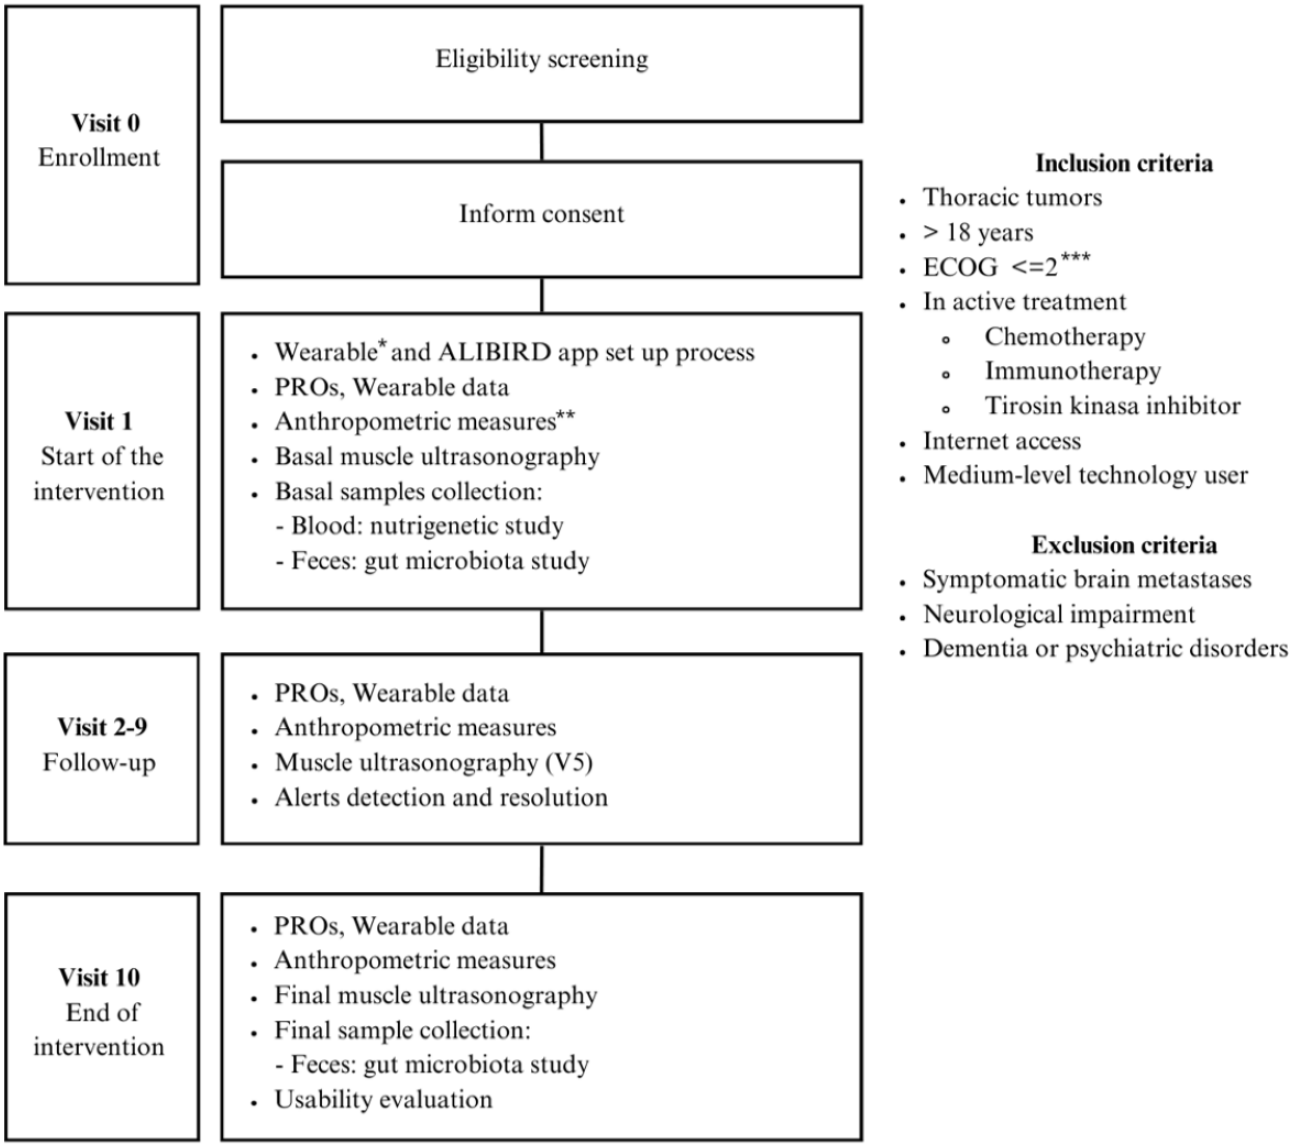
XSL•FO
RenderX

Figure 2. Integrating patient-reported outcomes and supportive oncology. The diagram compares the standard care pathway with the hybrid mHealth-supported pathway implemented in the study using the ALIBIRD platform. In the standard pathway, routine visits are scheduled and structured; however, clinical follow-up between visits relies on patient-initiated contact, leading to unstructured feedback and a higher risk of delayed recognition of adverse events. In contrast, the hybrid pathway incorporates continuous digital monitoring through the mobile app and wearable devices, enabling patients to report symptoms, lifestyle data, and patient-reported outcome measures. Automated algorithms generate alerts and personalized recommendations, prompting timely clinical actions such as phone calls, rescheduled visits, or targeted interventions. Continuous lines indicate structured digital follow-up, while dashed lines represent occasional or patient-initiated contact. ER: emergency department; OPD: outpatient department; PROMs: patient-reported outcome measures; PROs: patient-reported outcomes.

Study Protocol

The primary objective was to evaluate the usability and patient satisfaction with the ALIBIRD platform in patients with aLC. The secondary objective was to explore the clinical impact of the system, including early detection of relevant events, resolution of alerts, and the promotion of healthier lifestyle habits. The intervention period lasted 30 weeks per patient and included 10 scheduled face-to-face visits (V1-V10), complemented by continuous remote monitoring through the ALIBIRD mobile app and a wearable device.

Eligible participants were consecutively identified by the study oncologists during routine outpatient visits for NSCLC. Once a patient met the inclusion criteria—histologically or cytologically confirmed NSCLC, aged 18 years or older, Eastern Cooperative Oncology Group performance status ≤2, ongoing systemic treatment, regular internet access, and sufficient digital literacy—and none of the exclusion criteria applied (eg, symptomatic brain metastases, neurological or psychiatric disorders, or inability to comply with study procedures), the oncologist presented the study and its objectives. Each candidate



XSL•FO
RenderX

received an information sheet and provided written informed consent prior to enrollment.

Following enrollment, a biomedical engineer conducted individualized training sessions covering the purpose, scope, and functionalities of the ALIBIRD mobile app, as well as the proper use of the wearable device and the type and frequency of data to be recorded. Each participant received a Fitbit Inspire model wearable provided by the study team. Fitbit Inspire is an accelerometer-based device for monitoring daily steps, physical activity patterns, and sleep duration in adult populations. Continuous technical support was available throughout the study to address any issues or questions.

During the study, patients reported PROMs and lifestyle-related variables through the mobile app, while the wearable device automatically captured daily activity and sleep data. At each scheduled visit, oncologists conducted clinical assessments, and the nutritionist performed nutritional evaluations, including anthropometric measurements (weight, height, BMI, and body composition determined by bioimpedance and muscle ultrasonography). A research nurse was responsible for collecting biological samples—blood for nutrigenetic analyses and stool for gut microbiota characterization. A data manager supervised data quality and consistency across all data sources to ensure compliance with the study protocol and overall data integrity. Figure 3 illustrates the study flow, main intervention components, and inclusion and exclusion criteria.

Figure 3. Schematic representation of the study protocol for the ALIBIRD prospective pilot intervention in patients with advanced lung cancer. The diagram summarizes enrollment procedures, inclusion and exclusion criteria, and the schedule of assessments across the 30-week study, including baseline setup of the mobile app and wearable device, patient-reported outcomes, wearable-derived activity and sleep data, anthropometric measurements, muscle ultrasonography examinations, and collection of samples for nutrigenetic and gut microbiota analyses. Follow-up visits (V2-V9) included continuous remote monitoring and alert resolution, while the final visit (**V10**) incorporated end-of-intervention assessments and usability evaluation. *Wearable device model: Fitbit Inspire. **Anthropometric measures include weight, BMI, and body composition. ***Eastern Cooperative Oncology Group is a widely used performance status scale in oncology. ECOG: Eastern Cooperative Oncology Group; PROs: patient-reported outcomes.

All PROMs and patient-reported experience measures (PREMs), including the System Usability Scale (SUS), were implemented in REDCap and administered electronically through the ALIBIRD mobile app. Notifications were automatically sent

XSL•FO
RenderX

via the app to remind participants when questionnaires were due, facilitating timely completion and high response rates. An overview of all data sources and assessment tools used in the study is provided in Table 1.

XSL•FO
RenderX

Table . Instruments and measures used for on-demand, continuous, and scheduled data capture during the 30-week ALIBIRD mHealth intervention in patients with advanced lung cancer. The table summarizes all variables and corresponding measurement instruments, including patient-reported outcomes, patient-reported outcome measures, wearable-derived data, nutritional assessments, sleep and physical activity questionnaires, toxicity reporting tools, and usability and experience measures, along with their specific capture frequency.

Acquisition instruments	Capture frequency
Symptoms	
Symptom diary (type and severity):	On demand
Symptoms were selected based on the most frequent events in aLC[a] and classified into 3 severity levels: G1 (mild), G2 (moderate), and G3 (severe)	
European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire—Lung Cancer 13 [44]:	V1-V10
Standard instrument for measuring the quality of life of patients with lung cancer; covers 13 typical symptoms and side effects from treatment. Higher scores indicate a high level of symptomatology	
Nutritional status	
Anthropometric measures:	V1-V10
Included weight, height, BMI, waist and hip circumference, and bioimpedance analysis	
Malnutrition diagnosis: The Global Leadership Initiative on Malnutrition criteria [45]:	V1 and V10
Guidelines to diagnose malnutrition: at least 1 phenotypic and 1 etiologic criterion required	
Muscle ultrasonography:	V1, V5, and V10
Ultrasonography of rectus femoris for sarcopenia assessment: area, y-axis (relaxation/contraction), x-axis	
Diet	
Mediterranean Diet Adherence Screener [42]:	V1 and V10
14-item questionnaire to assess adherence to the Mediterranean diet	
Dietary intake and appetite log:	Weekly
Ad hoc questionnaire including daily number of meals, self-reported appetite, and food frequency for the last week (cereals, dairy, fruits, vegetables, oils, liquids, meats, fish, processed meats, etc)	
Physical activity	
International Physical Activity Questionnaire short form [46]:	V1-V10
Standardized tool to classify activity levels into mild, moderate, and vigorous	
Fitbit: daily steps and physical activity sessions	Continuous capture
Sleep	
Pittsburgh Sleep Quality Index [47]:	V1, V5, and V10
Self-report questionnaire assessing sleep quality (eg, waking during the night and need for medication) and classifies it into 2 groups: poor or good quality	
Fitbit: Sleep sessions	Continuous capture
Toxicity	
Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events [48]:	V2-V10
System developed by the National Cancer Institute to capture symptomatic adverse events in cancer trials	
Quality of life	

XSL•FO
RenderX

Acquisition instruments	Capture frequency
European Quality of Life-5 Dimensions 5 Levels [49]: *Generic self-assessed health-related quality-of-life measure across 5 dimensions (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression); includes a visual analogue scale. Higher index scores indicate worse health*	V1-V10
Emotional status	
Hospital Anxiety and Depression Scale (HADS) [50]: *Self-report rating scale with 14 items on a 4-point Likert scale (0 - 3). It measures anxiety (HADS-A) and depression (HADS-D) through 7 items each, with subscale scores ranging 0 - 21 and a total score summing all items*	V1, V5, and V10
Perceived energy and emotional status: *Two ad hoc self-report questions: (1) overall mood during the past week (good, fair, and poor) and (2) perceived energy level (high, medium, and low)*	Weekly
Usability and satisfaction	
System Usability Scale [51]: *Widely used 10-item questionnaire; provides a 0 - 100 usability score (higher is better)*	V10
Patient-reported experience measures: *3-item measure assessing motivation, satisfaction, and willingness to recommend the app*	V10

[a]aLC: advanced lung cancer.

The sample size of 20 patients was selected for convenience, considering the limited population of patients with NSCLC at our center and the sample sizes reported in similar studies [28,52-56].

Evaluation Methods

Evaluation of the ALIBIRD platform included the analysis of adherence and data completeness, usability and patient experience, and the clinical impact of the intervention. System use and adherence were assessed through the number and consistency of patient-reported entries via the mobile app, as well as data automatically collected by the wearable device. Usability was evaluated using the SUS [51,57], a 10-item questionnaire rated on a 5-point Likert scale, widely used for subjective assessment of system usability. Scores range from 0 to 100, with values above 68 considered above average and indicative of acceptable usability. In addition to patient evaluation, usability was also assessed among health care professionals using the same SUS questionnaire, administered electronically through REDCap via a web-based survey link at the end of the study.

Patient experience was measured through a 3-item PREM, which assessed motivation to adhere to healthy recommendations, overall satisfaction with the app and follow-up, and willingness to recommend the platform. The exact questions are summarized in Textbox 1.

Both the SUS and the PREMs were administered to patients at the end of the intervention (V10).

Clinical impact was explored by analyzing both alerts generated and the corresponding clinical actions, as well as PROs and lifestyle data, including symptoms and toxicities, QoL, diet adherence, physical activity, and sleep parameters.

Textbox 1. Questions about patient experience with the mobile app: 2 of the questions used a 5-point Likert scale, while the third question used a Yes/No format to assess patients' willingness to recommend the app.

- "So far, the app has motivated me to follow guidelines to better control possible symptoms and adopt healthy lifestyle recommendations." (Strongly disagree/Disagree/Neutral/Agree/Strongly agree)
- "How would you rate your level of satisfaction with the app and the follow-up you receive in the study?" (Completely dissatisfied/Dissatisfied/Somewhat satisfied/Satisfied/Completely satisfied)
- "Would you recommend an app with similar features and follow-up to someone you know who is in your situation?" (Yes/No)

Nutrigenetics and Gut Microbiota

Saliva samples were collected at baseline (V1) for nutrigenetic analysis, including genes related to metabolism, nutritional traits, and digestive predispositions. Results were based on single nucleotide polymorphisms (SNPs) and composite scores derived from multiple SNPs, with each SNP weighted according to the strength of scientific evidence (high=1, medium=0.5, and low=0.25). Favorable, intermediate, or unfavorable genotypes contributed to an overall score.

XSL•FO
RenderX

Fecal samples were collected at baseline (V1) and at the end of the intervention (V10) to assess gut microbiota composition and dysbiosis status. Key parameters were derived from the relative abundances of microbial groups associated with positive or negative health effects and the production of beneficial metabolites, such as short-chain fatty acids (Table S1 in Multimedia Appendix 3) [58-63].

The results of both analyses were used to generate personalized reports for patients and health care professionals, which were translated into tailored nutritional recommendations delivered through the ALIBIRD mobile app. Detailed protocols for DNA extraction, genotyping, and SNP scoring (nutrigenetics), as well as 16S rRNA sequencing, taxonomic assignment, and dysbiosis assessment (gut microbiota), are provided in Multimedia Appendix 3.

Data Analysis

Data were analyzed using descriptive statistics (frequencies, proportions, and means, SD), Shapiro-Wilk normality testing, and paired sample tests (*t* test or Wilcoxon) or McNemar test for categorical comparisons (V1 vs V10). The SUS score was calculated following the standard procedure (sum of item scores multiplied by 2.5 to obtain a 0‐100 scale), and PREM responses were summarized as frequencies and percentages. Data were exported from the system database and REDCap, preprocessed in Excel, and analyzed with IBM SPSS Statistics (version 29; IBM Corp).

Ethical Considerations

The study was conducted in accordance with the principles of the Declaration of Helsinki (Fortaleza, Brazil, 2013, and subsequent revisions) and the International Council for Harmonisation Good Clinical Practice guidelines. The protocol and all related documentation were reviewed and approved by the Research Ethics Committee for Medicines of the Hospital Universitario La Paz, Madrid, Spain (approval code: HULP PI-4735). The study also complied with the Spanish Royal Decree 957/2020 of November 3, regulating observational studies with human-use medicines, and with the applicable regional regulations.

All participants received verbal and written information about the study's objectives, procedures, and potential risks and benefits. Written informed consent was obtained from each participant prior to inclusion, in compliance with the ethical principles of autonomy and informed decision-making. Participants were informed of their right to withdraw at any time without providing justification and without any impact on their medical care.

The protection, processing, and analysis of study data were carried out in accordance with the General Data Protection Regulation (EU) 2016/679 and the Spanish Organic Law 3/2018 of December 5 on the Protection of Personal Data and Guarantee of Digital Rights, as well as Law 41/2002 of November 14 on Patient Autonomy and Rights and Obligations Regarding Clinical Information and Documentation. All data were pseudonymized and stored within a secure research data infrastructure encompassing both the REDCap and the ALIBIRD platform databases. These systems were hosted on secure servers and included encrypted data transfer, user authentication, and activity logging. Access to identifiable data was restricted to authorized study personnel only. No financial or material compensation was provided to participants for their participation in this study.

Results

Principal Results

The analysis focused on patient adherence, usability, and clinical impact of the ALIBIRD mHealth platform. Results are organized to highlight patient-reported events and the corresponding clinical actions, as well as lifestyle and PROs in participants who completed the intervention, with exploratory nutrigenomic and microbiota data.

Baseline Participant Characteristics

Of the 20 patients with aLC enrolled, 14 completed the full 30-week intervention, which included attending all scheduled visits (V1-V10) and consistent submission of self-reported data through the app. Four patients did not complete the study due to death and 2 due to clinical and emotional deterioration. Baseline characteristics for all initially enrolled participants are summarized in Table 2; participants who discontinued the study were censored for longitudinal analyses.

XSL•FO
RenderX

Table . Baseline characteristics of participants enrolled in the ALIBIRD prospective pilot intervention for advanced lung cancer (N=20)[a].

Characteristic	Values
Age (years), mean (SD)	
43-77	61.05 (9.70)
Sex, n (%)	
Female	12 (60)

[f]RT: radiotherapy.

Usage Metrics, Data Completeness, and Usability Assessment

This section presents a comprehensive analysis of system usage, data collection patterns, and perceived usability, integrating insights from both patients and health care professionals. Table 3 summarizes the number of data entries provided by participants throughout the study period, offering insights into patient compliance and engagement levels.

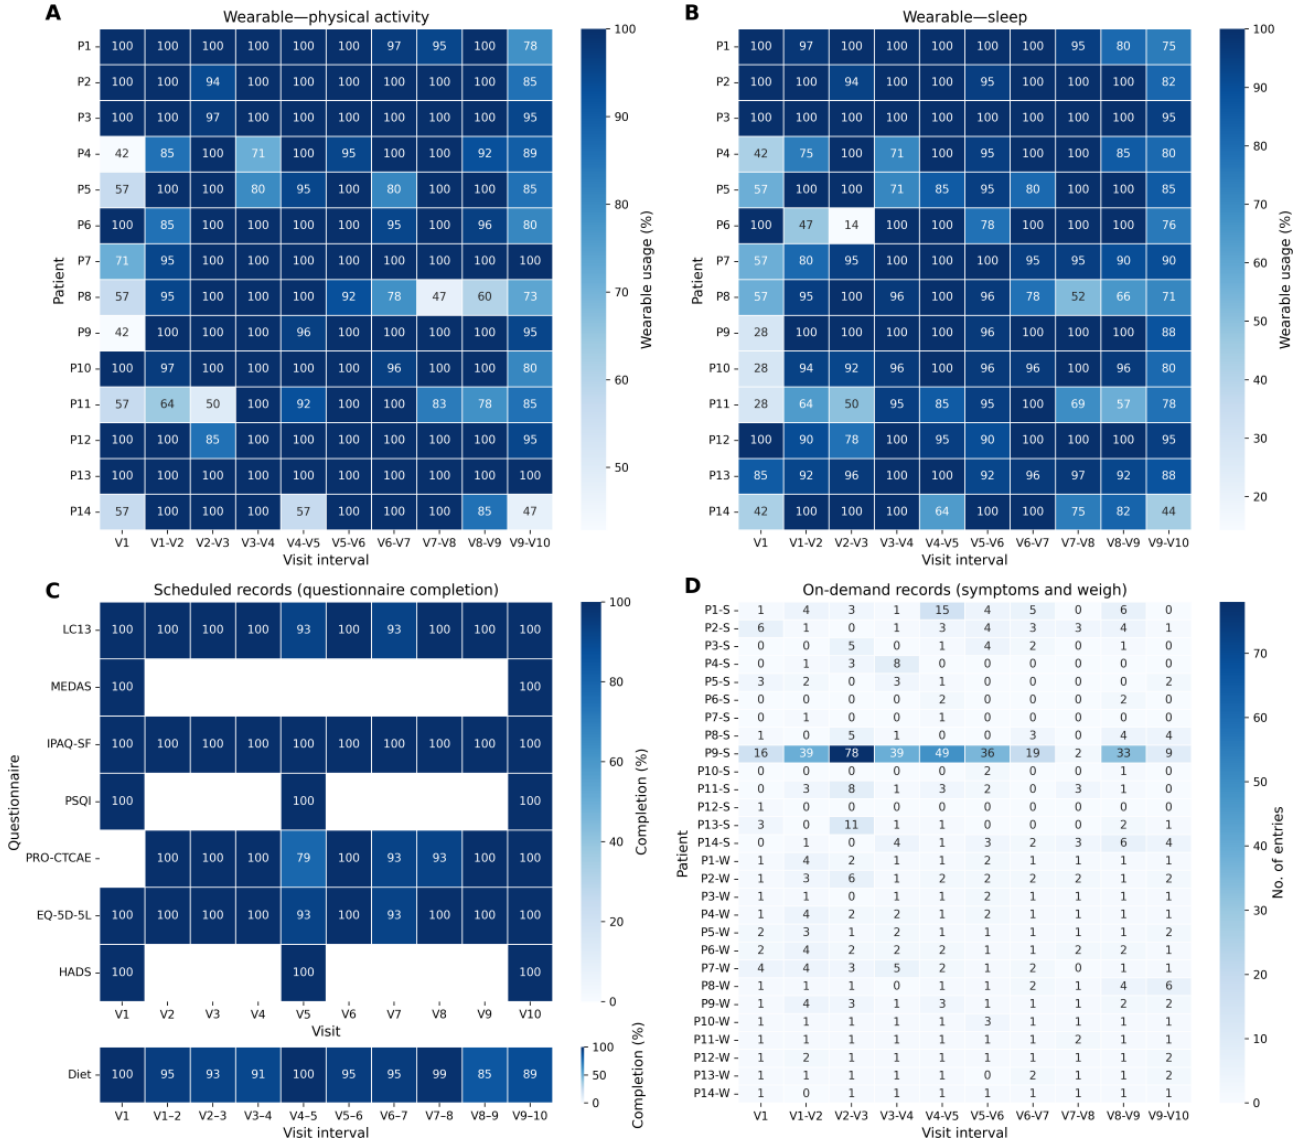
XSL•FO
RenderX

Table . Summary of patient-generated data entries and wearable-derived records during the ALIBIRD mHealth intervention (N=20). The table reports the total number of automatic wearable recordings (physical activity and sleep), on-demand symptom and weight entries, and scheduled questionnaire submissions collected across all participants.

Data entries	Total records, n
Automated records[a]	
Physical activity	3589
Sleep	3468
On-demand manual records[b]	
Symptoms	679
Weight	123
Manual scheduled records[c]	
Dietary intake and appetite log	487
European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire—Lung Cancer 13	170
Mediterranean Diet Adherence Screener	34
International Physical Activity Questionnaire short form	159
Pittsburgh Sleep Quality Index	53
Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events	145
European Quality of Life-5 Dimensions 5 Levels	169
Hospital Anxiety and Depression Scale	51

[a]Automated records: entries automatically captured by wearable devices, such as physical activity and sleep data.

[b]On-demand manual records: entries made by patients whenever they experience symptoms or wish to log specific data, such as weight.



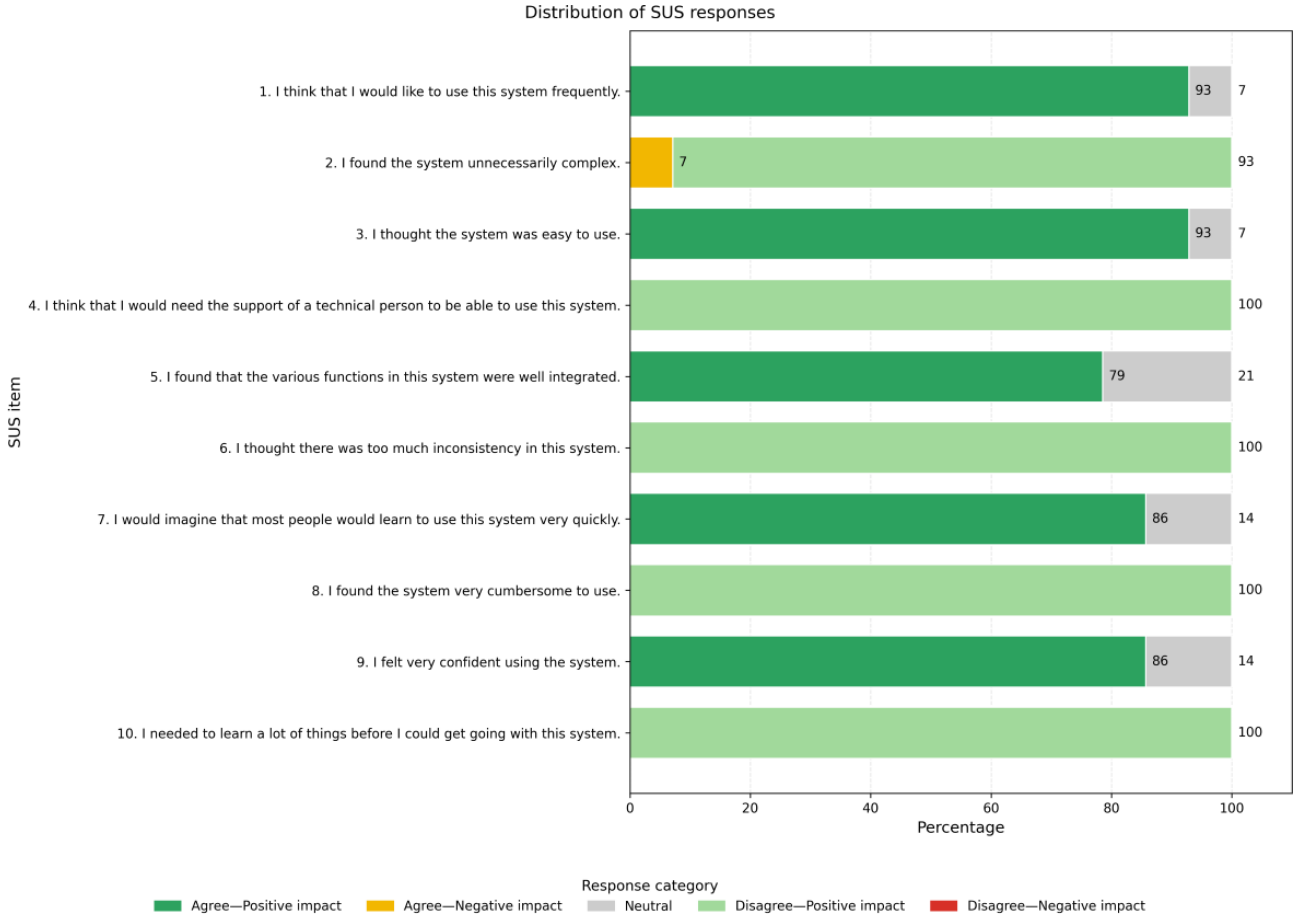
[c]Scheduled records: entries that patients complete at predefined intervals according to the study schedule, typically in the form of questionnaires.

Across the 14 participants who completed the intervention, adherence to scheduled questionnaires remained high throughout the 30-week follow-up. Completion rates ranged from 94% for dietary records to 100% for several instruments, with visit-level averages between 95% and 100%. Wearable-based passive monitoring showed adherence between 66% and 96% across visits, with sleep tracking representing the lower range and physical activity data showing slightly higher and more stable capture. Symptom reporting was heterogeneous, with peaks during the early-mid follow-up and variable contributions among patients, while weight entries were more evenly distributed, with at least 1 measurement recorded by most participants between consecutive visits. Figure 4 illustrates individual-level data collection across visits, including wearable-derived physical activity (Figure 4A), wearable-derived sleep data (Figure 4B), scheduled questionnaire completion (Figure 4C), and on-demand records for symptoms and weight (Figure 4D). This visualization highlights variations in engagement over time and among participants, helping to identify adherence patterns and potential gaps in data reporting.

In addition to evaluating what data were collected, it is also important to understand how patients interacted with the application interface. App usage data revealed that, on average, participants spent the largest proportion of their app interactions on the home screen (33%), followed by the weekly tasks (19%—which include actions related to diet and other lifestyle variables such as sleep, mood, energy, and gastrointestinal rhythm), symptom reporting (15%), and the notifications or message box (10%—which include automated notifications and clinic-patient exchanges). These percentages represent the mean proportion of interactions per patient, calculated relative to each individual's total app interactions and then averaged across participants.

XSL•FO
RenderX

Figure 4. Individual-level data collection across visits by data type and recording modality (N=14). (**A**) Wearable—physical activity, (**B**) wearable—sleep, (**C**) scheduled records (questionnaire completion), and (**D**) on-demand records (symptoms and weight). Manual scheduled records include questionnaires with different expected schedules: QLQ-LC13, MEDAS, IPAQ-SF, and EQ-5D-5L were expected at each visit (V1-V10); PSQI and HADS were scheduled only at visits V1, V5, and V10; and PRO-CTCAE was expected from visit 2 to 10 (V2-V10). The dietary log was completed on a weekly basis, and adherence is represented using the intervals between visits. Percentages of adherence for dietary log and wearable monitoring are expressed relative to each patient's expected entries, as visit intervals and monitoring periods varied across participants. EQ-5D-5L: European Quality of Life-5 Dimensions 5 Levels; HADS: Hospital Anxiety and Depression Scale; IPAQ-SF: International Physical Activity Questionnaire short form; LC13: Lung Cancer 13; MEDAS: Mediterranean Diet Adherence Screener; PRO-CTCAE: Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events; PSQI: Pittsburgh Sleep Quality Index.



The average SUS score among patients who completed the study (n=14) was 90, indicating a high level of usability for the mobile app. This value is well above the commonly accepted benchmark of 68, which is considered the threshold for above-average systems. Figure 5 displays the distribution of responses for each item of the SUS questionnaire, offering a visual overview of user sentiment across all items. The consistently positive responses suggest a strong perception of ease of use and user satisfaction among participants.

PREMs provided valuable insights into the participants' perception of the ALIBIRD platform. Regarding the question "So far, the app has motivated me to follow guidelines to better control possible symptoms and adopt healthy lifestyle recommendations," the majority of participants responded positively, with 9 out of 14 (64%) indicating "Strongly agree" and 3 out of 14 (21%) indicating "Agree," while 2 out of 14 (14%) remained neutral. For the question "How would you rate your level of satisfaction with the app and the follow-up you receive in the study?," 50% of the participants reported being "Completely satisfied" and the other 7 out of 14 (50%) being "Satisfied." Finally, in response to "Would you recommend an app with similar features and follow-up to someone you know who is in your situation?," all participants (14/14, 100%) responded "Yes."

In addition, usability was also assessed among health care professionals using the clinical web-based interface. The mean SUS score among professionals (n=5) was 86, reflecting a positive perception of the platform's usability in clinical practice. The evaluation involved 5 members of the clinical team, including oncologists, a nutritionist, and a nurse.

Figure 5. Distribution of System Usability Scale responses categorized by agreement and their impact on usability (N=14). The bar chart shows the distribution of responses for each of the 10 System Usability Scale items. Items 1, 3, 5, 7, and 9 are positively phrased, where Agree/Strongly agree responses indicate positive usability and Disagree/Strongly disagree responses indicate negative usability. Items 2, 4, 6, 8, and 10 are negatively phrased, where Disagree/Strongly disagree responses indicate positive usability and Agree/Strongly agree responses indicate negative usability. Neutral responses correspond to the midpoint of the Likert scale (Neither agree nor disagree). The "Disagree—Negative Impact" category is included for completeness, although no responses were observed in this category. SUS: System Usability Scale.

Evaluation of Outcome Data

In this section, we analyze the PRO and PROM results to assess the overall clinical impact of ALIBIRD mHealth platform, focusing on both clinically actionable events and patient-reported measures collected during follow-up. Outcomes include the detection and management of symptom- and nutrition-related alerts that prompted clinical actions, as well as longitudinal changes in lifestyle behaviors, symptoms, and quality-of-life indicators reported by patients. Together, these results provide an integrated view of the platform's clinical impact and its role in supporting patient monitoring and care during the intervention.

Clinical Actions Triggered by Reported Events

Clinical actions were driven by events captured and processed via the ALIBIRD mHealth platform, including patient-reported symptoms and nutritional indicators, which triggered automated alerts and subsequent interventions by the health care team. During the study, the most frequently reported symptoms among patients (n=20) were asthenia (164/679, 24.2%) and dyspnea (132/679, 19.4%). Overall, most symptom reports were classified as mild (grade 1: 367/679, 54.0%), followed by moderate (grade 2: 238/679, 35.1%) and severe (grade 3: 74/679, 10.9%).

These patient-reported symptoms, combined with nutritional monitoring, triggered the majority of the 2100 automated recommendations and 143 clinical alerts generated by the platform for the health care team. Symptom-related alerts (75/143, 52.4%) were most often due to constipation (28/75, 37%), pain (19/75, 25%), and dyspnea (9/75, 12%), followed by fever (9/75, 12%) and less frequent events such as hemoptysis (4/75, 5%), diarrhea, drowsiness, and vomiting, each (2/75, 3%). Nutritional alerts represented 47.6% (68/143), mainly related to reduced food intake (52/68, 76%), fewer than 3 meals per day (9/68, 13%), and weight loss greater than 5% (7/68, 10%).

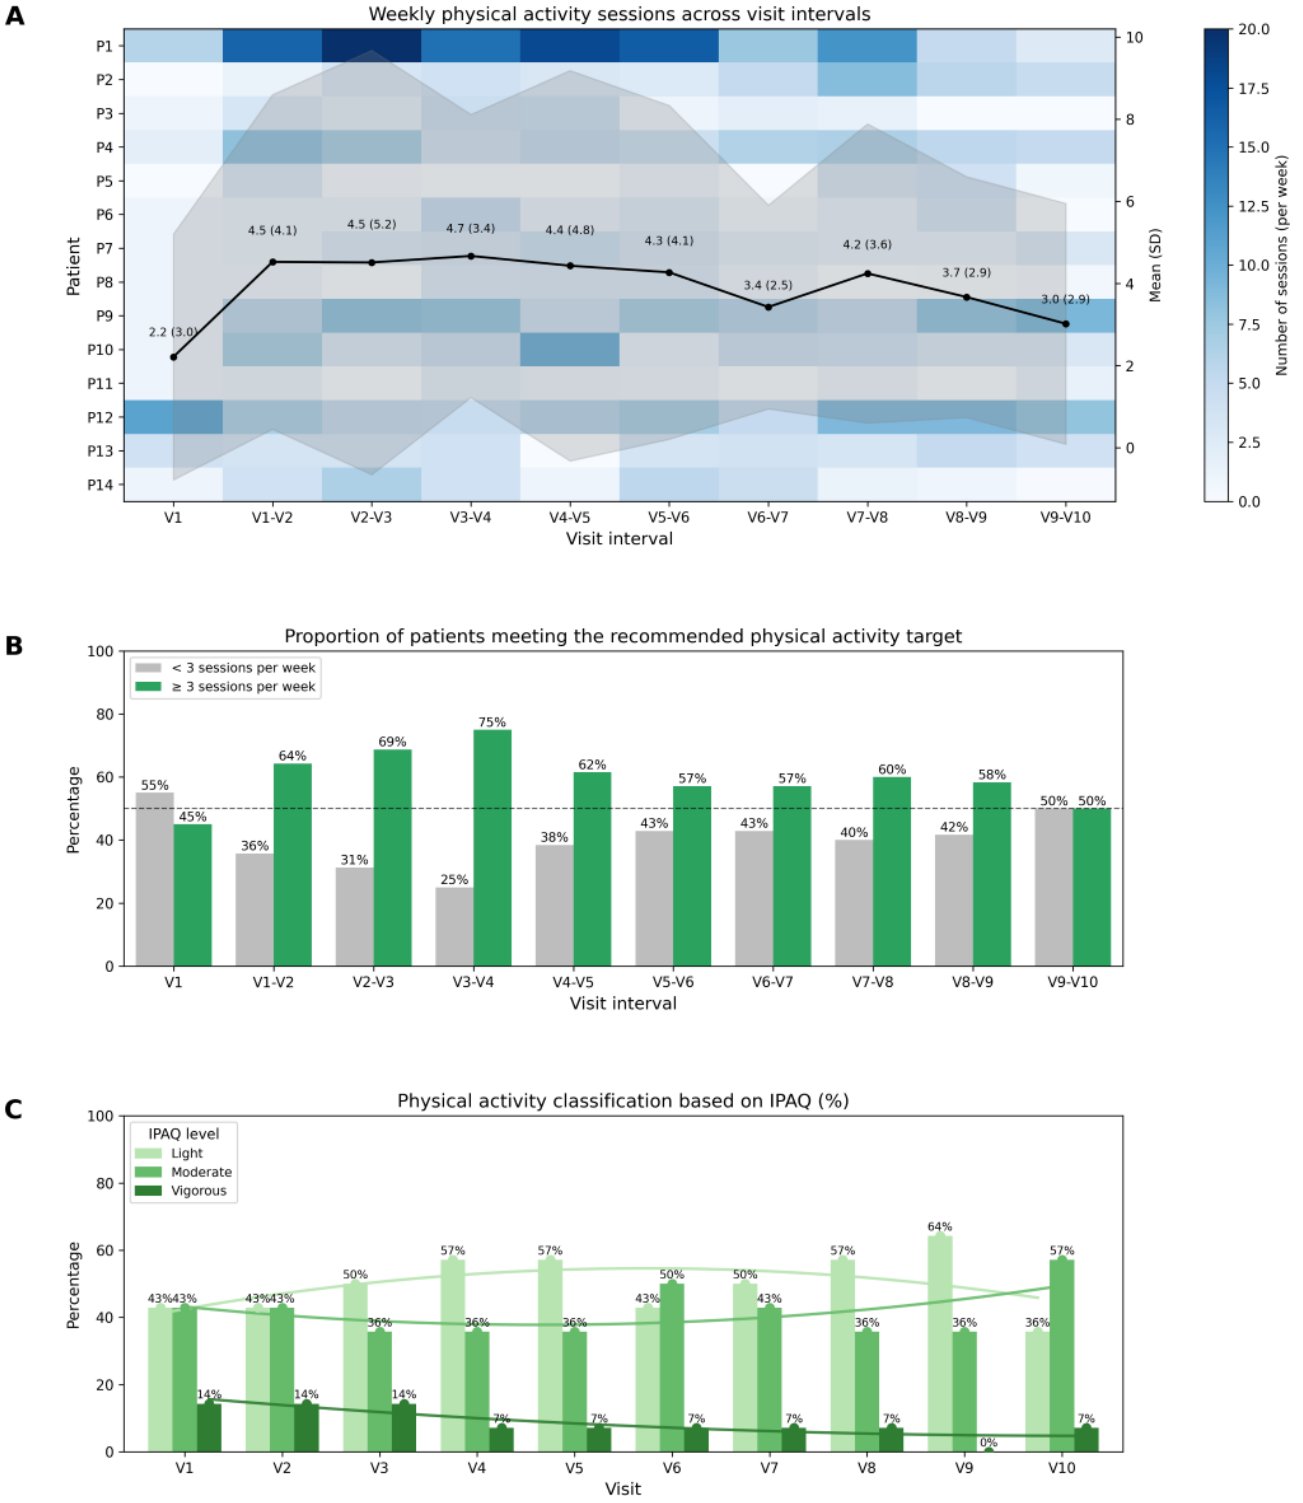
Health care professionals managed these alerts using the ALIBIRD web-based tool to resolve alerts, which led to 42 phone calls and 20 in-app messages to patients. The mean average resolution time for an alert was 2.05 (1.72 SD) days. Clinical responses included 52 therapeutic adjustments, 10 expedited medical visits, 15 referrals to other specialties, 2 emergency referrals, and 4 imaging reevaluations, with 2 cases confirming clinical-radiological progression.

Lifestyle and PROs

Among patients who completed the intervention, several lifestyle and patient-reported outcome measures were monitored over

XSL•FO
RenderX

time. Adherence to the Mediterranean diet (Mediterranean Diet Adherence Screener) increased from 50% (7/14) at baseline (V1) to 71% (10/14) by the end of the intervention (V10), while BMI remained relatively stable across all visits, with no clinically meaningful changes.



Physical activity, monitored via the ALIBIRD mobile app and Fitbit devices, showed that participants performed a mean average of 3.90 (SD 3.68) sessions per week and 6087 daily steps (SD 2675). Figure 6 illustrates the evolution of these metrics across the study period, including the number of weekly physical activity sessions, adherence to the recommended target of 3 or more sessions per week, and the distribution of activity intensity levels (light, moderate, and vigorous) according to the International Physical Activity Questionnaire short form questionnaire. Figure 6 summarizes physical activity outcomes across the study period, including weekly exercise frequency (Figure 6A), the proportion of patients meeting the recommended target of ≥3 sessions per week (Figure 6B), and activity intensity levels based on the International Physical Activity Questionnaire short form results (Figure 6C). Step count data collected through Fitbit indicated predominantly light levels of physical activity, with relatively stable averages across visits.

Sleep monitoring revealed an average duration of 7.61 (SD 1.34) hours per day according to Fitbit data, consistent with recommended sleep duration. However, Pittsburgh Sleep Quality Index results indicated persistently poor subjective sleep quality among most participants. The proportion of patients classified as having poor sleep quality was 71.4% (10/14) at baseline, slightly improved at midintervention (V5) to 64.3% (9/14), and worsened again by the end of the study (V10) to 78.6% (11/14).

Regarding emotional health, Hospital Anxiety and Depression Scale—A indicated a slight increase in clinically relevant anxiety from 0% (0/14) to 7% (1/14), while Hospital Anxiety and Depression Scale—D revealed that 14% (2/14) of patients developed depressive symptoms by V10. In relation to patient QoL and specific symptoms, the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire—Lung Cancer 13 questionnaire generated a total of 655 symptom reports throughout the study. The most frequently reported symptoms were total pain (242/655, 36.9% of reports), cough (115/655, 17.6%), and total dyspnea (113/655, 17.3%). In addition, the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events questionnaire, which captured 5025 patient-reported toxicity items over the 10 study visits, highlighted the most frequent symptom groups as follows: sleep and wake patterns (962/5025, 19.1% of reports), pain (847/5025, 16.9%), and neurological and perception disorders (774/5025, 15.4%). QoL, assessed by the European Quality of Life-5 Dimensions 5 Levels questionnaire, remained stable throughout the study. The mean score at baseline was 0.86 (SD 0.10) and showed only minor variations across visits, with a slight increase at midintervention (V4: mean 0.92, SD 0.09) and a final mean score of 0.88 (SD 0.15) at V10. Overall, participants maintained good perceived health status during the intervention, with no clinically relevant decline or improvement observed. Table 4 provides a summary of the pre- and postintervention comparison between baseline (V1) and the end of the study (V10) for participants who completed the intervention.

Variables	Preintervention	Postintervention	*P* value
	V1	V10	
Sleep			
Duration (hours)	6.93 (1.62)	7.07 (1.18)	.75
Pittsburgh Sleep Quality Index, % of patients (n)			
Poor quality	71 (10/14)	79 (11/14)	.53
Good quality	29 (4/14)	21 (3/14)	

[a]Percentages refer to patients; absolute numbers are indicated within parentheses (n/N).

[b]The *P* value could not be calculated. In some analyses, the McNemar test could not be performed due to the lack of variability in the data. Specifically, when one of the categorical variables involved is constant, meaning all responses fall within a single category, statistical tests that rely on variation between groups, such as McNemar test, are unable to calculate an associated *P* value or significance measure.

[c]Dietary recommendations: meat + eggs: minimum 4-6 servings per week; fish + shellfish: minimum 3-4 servings per week; legumes: minimum 2-4 servings per week; dairy products: minimum 2 servings per day; fruit + vegetables: minimum 5 servings per day; liquids (water, sugar-free isotonic drinks, infusions, coffee, juices, etc): minimum 4 servings (glasses) or 1 liter per day; processed meats: maximum 1-2 servings per week; pastries: maximum 1-2 servings per week; sugary drinks and sweets: maximum 1-2 servings per week; and alcohol: do not consume.

Exploratory Nutrigenetic and Gut Microbiota Profiling

As components of the personalized intervention, baseline nutrigenetic analysis and gut microbiota profiling were incorporated into the platform to inform individualized nutritional recommendations. In this study, these measures were not evaluated as clinical outcomes; rather, descriptive summaries of the baseline profiles (and V10 profiles for microbiota) are presented to contextualize patient heterogeneity.

Genetic analysis was performed on all initial participants (n=20), targeting 20 variants associated with lifestyle habits, nutrition, and cancer. The analysis revealed that 60% of the population carried a CLOCK gene variant associated with protection against sleepiness, favorable breakfast timing, and enhanced intestinal motility, which may support appetite and dietary intake during cancer treatment. Most participants did not present metabolic alterations for gluten sensitivity (16/20, 80%) or lactose intolerance (15/20, 75%), although 5 patients exhibited lack of lactase persistence and were recommended a lactose-free diet. Only 25% (5/20) of the sample displayed a favorable genetic profile for systemic inflammation, which may contribute to better clinical outcomes and reduce circulating proinflammatory factors. Detailed results of the nutrigenetic analysis are provided in Table S1 in Multimedia Appendix 4.

Gut microbiota analyses were conducted in the subset of participants who completed the intervention and had valid samples available at both baseline and end of intervention (n=13). At baseline (V1), 38.5% (5/13) of the participants exhibited a gut microbiota profile similar to the healthy population (dysbiosis grade <30%), whereas 61.5% (8/13) showed a clear state of dysbiosis (dysbiosis grade >30%). After completing the intervention (V10), 15.4% (2/13) of the participants showed improvement in dysbiosis grade, 15.3% (2/13) maintained their baseline status, 23.1% (3/13) experienced a slight deterioration, and 46.2% (6/13) presented a marked deterioration.

Discussion

Principal Findings

This pilot study demonstrates the feasibility, usability, and acceptability of the ALIBIRD mHealth platform as a digital health solution to support the care of patients with aLC. The ALIBIRD apps achieved a mean SUS score of 90 of 100 among patients and 86 of 100 among health care professionals, reflecting excellent usability across both user groups. These results were complemented by the PREMs, which showed that 100% of the participants were satisfied and willing to recommend the platform, and 85% of the participants expressed high motivation to follow the recommendations received. Together with the high completion rates of scheduled questionnaires (94% - 100%) and sustained wearable adherence (81% - 96% after the initial week), these findings indicate strong engagement and adherence over the 30-week follow-up.

Patients actively used the mobile app and wearable device to report symptoms, record lifestyle data, and track physical activity and sleep, while clinicians remotely reviewed this information to guide interventions. A total of 679 symptoms and 143 clinical alerts were processed, with a mean resolution time of 2.05 days. Notably, 2 alerts led to early identification of unsuspected disease progression, underscoring the potential value of continuous digital monitoring in supporting timely clinical decision-making. Importantly, lifestyle-related indicators showed favorable trends during the intervention: adherence to the Mediterranean diet increased from 50% to 71%, physical activity levels improved modestly, and sleep duration averaged 7.6 hours per night. Although subjective sleep quality (Pittsburgh Sleep Quality Index) remained poor for most participants, these findings highlight the potential of the platform to promote awareness and gradual behavioral changes in diet and activity.

QoL, as measured by European Quality of Life-5 Dimensions 5 Levels, remained stable throughout the study, suggesting that continuous monitoring and early interventions may help preserve well-being in this patient population. This stability is particularly

XSL•FO
RenderX

relevant, given the typically unfavorable clinical course of aLC. Taken together, these results confirm the feasibility and usability of ALIBIRD for sustained multimodal engagement in long-term digital oncology interventions.

Comparison With Prior Work

The introduction of PROMs into routine clinical practice has become increasingly important in cancer care, as these tools provide a structured way to assess patients' health status and monitor disease evolution. However, their routine implementation still faces practical barriers, including workload burden, the need for training and support, associated costs, and reluctance among some clinicians. The digital collection of PROMs (ePROMs) has emerged as a strategy to overcome many of these limitations by enabling more efficient patient monitoring and supporting timely clinical decision-making. Evidence from previous trials also indicates that ePROM-based follow-up can contribute to improved clinical outcomes and has the potential to optimize health care resource use [10,11]. In this context, digital health platforms such as ALIBIRD can help overcome routine implementation barriers by facilitating automated data collection and generating clinically actionable information.

The usability, adherence, and engagement results observed in this study compare favorably with previous long-term mHealth interventions in oncology and chronic disease management [25,64]. Anders et al [24] described SUS scores of 85 - 89 in patients with breast cancer, Kessel et al [26] reported 83% willingness to continue app use, and Wu et al [25] documented 61% - 77% daily engagement in long-term self-management apps. ALIBIRD's higher usability scores and sustained adherence likely reflect its integrative design, combining active self-reporting, passive monitoring, personalized recommendations, and timely clinician-patient communication.

In addition, the high levels of satisfaction and motivation reflected by the PREMs align with prior findings that emphasize the role of positive user experience in sustaining engagement and promoting self-care behaviors in digital health interventions [65,66]. Our results also support evidence that digital health tools can enhance self-management, enable early symptom detection, and optimize patient-centered care [25,28].

In this study, frequent alerts related to constipation, pain, dyspnea, and nutritional decline were effectively addressed through remote interactions, demonstrating how digital platforms can extend clinical follow-up beyond hospital visits. The improvements in dietary adherence and weight stabilization observed among participants are particularly relevant, as they suggest that app-based guidance can mitigate the nutritional challenges and risk of malnutrition typically observed in patients with aLC [67-69]. This may help explain the stable quality-of-life scores observed in our cohort, contrasting with the decline usually associated with disease progression.

A distinctive aspect of ALIBIRD is its integration of precision-nutrition elements, including nutrigenetic and microbiota analyses. This approach aligns with emerging evidence on the role of gut health and genetic predispositions in modulating treatment response and nutritional outcomes in cancer [70-77]. The prevalence of dysbiosis and inflammation-related variants in this cohort reinforces the importance of combining molecular data with behavioral and lifestyle tracking to support personalized, adaptive interventions.

Strengths and Limitations

Implementing PRO-based monitoring between clinic visits offers clear advantages in terms of accessibility and closer patient follow-up. At the same time, it also introduces several operational challenges, such as ensuring reliable and robust platform performance, maintaining completion adherence, and providing clinicians with timely information to support clinical decision-making. Within this context, this study provides early evidence supporting the feasibility of deploying an integrated, multidomain digital health platform in oncology care for patients with aLC. The combined monitoring and response to clinical symptoms, lifestyle behaviors, and personalized nutrition represent a holistic approach rarely evaluated in real-world settings. Another strength is the dual usability assessment among patients and health care professionals, which offers insight into cross-stakeholder acceptance—an essential component for successful digital implementation in clinical workflows.

However, several limitations should be acknowledged. The small sample size (n=20) and the single-arm design limit statistical power and external generalizability. Of the 20 participants initially enrolled, 6 discontinued early—4 due to rapid clinical deterioration related to disease progression and 2 due to worsening emotional well-being—illustrating the clinical fragility of this population rather than limitations of the digital health solution itself. Importantly, despite the high clinical vulnerability commonly observed in aLC, most patients who remained in the study were able to sustain meaningful engagement with the platform. This may have been facilitated by the frequency of in-person visits, family or caregiver support, and the involvement of both the clinical team and the biomedical engineering support. These combined elements may have helped reinforce motivation and support sustained engagement with the digital health solution.

Other populations with less frequent clinical contact or fewer support resources may require additional strategies—such as adaptive reminders, motivational feedback, or gamification—to maintain long-term engagement. In addition, the economic implications of implementing such digital health interventions were not assessed in this study, and future research should examine cost-effectiveness and scalability in routine practice.

Finally, while this study confirmed feasibility, usability, and high user satisfaction, several findings suggest the potential for meaningful clinical benefits. The rapid resolution of a substantial number of clinical alerts, the remote identification of unsuspected tumor progression in 2 patients, and the preservation of QoL and healthy lifestyle behaviors over time indicate that the intervention may have supported early clinical decision-making and proactive patient management. Nonetheless, as a pilot study with a limited sample size, it was not powered to evaluate clinical outcomes or survival effects, which should be investigated in larger controlled trials.

XSL•FO
RenderX

Conclusions

Future studies should aim to validate these findings in larger, multicenter randomized trials and assess the impact of the ALIBIRD mHealth platform on clinical outcomes, nutritional status, and QoL over longer periods. Integration of artificial intelligence models could further enhance the platform's predictive capacity, enabling personalized alerts, adaptive feedback, and early detection of adverse events.

From a clinical perspective, ALIBIRD demonstrates the potential of combining digital monitoring, precision nutrition, and PROs to enable more proactive and individualized oncology care. Its holistic, multidisciplinary design supports continuous data collection and facilitates the incorporation of lifestyle, molecular, and behavioral variables into personalized interventions.

Moving forward, early-stage work is currently focused on 2 key areas. The first involves adapting the platform for use in other tumor types and in clinical scenarios with lower symptom burden, such as survivorship care or follow-up of patients in remission, enabling customization to both tumor-specific and individual patient needs. The second area relates to the design of a new care model within the oncology department to manage the continuous flow of patient-generated information and support earlier clinical responses. This will require establishing coordinated workflows involving health care professionals and biomedical engineering teams to ensure efficient data management and timely intervention.

In summary, this pilot study highlights the high usability, sustained adherence, and positive patient experience achieved with the ALIBIRD mHealth platform. These results underscore its feasibility for integration into routine oncology care and lay the groundwork for future research aimed at scaling up digital health, patient-centered strategies in cancer management.

Acknowledgments

The authors would like to express their gratitude to the patients who participated in the clinical study, to all health care professionals and researchers of the ALIBIRD Program, and to the students of the biomedical engineering degree at the UPM who collaborated in the project. The authors also wish to acknowledge the work and support of Professor Tiziana Fornari-Reali and Raisa González in coordinating and managing the ALIBIRD2020-CM program. Generative artificial intelligence (ChatGPT and OpenAI) was used to assist in the language editing of this manuscript, specifically to improve grammar, phrasing, and readability of the English text. All scientific content, interpretation of results, and data analyses were conceived, written, and verified by the authors. The authors take full responsibility for the integrity and accuracy of the content.

Funding

This publication is funded by the Community of Madrid, TEC-2024/BIO-281 IALIBIRD-CM (ORDER 5696/2024, B.O.C.M. N°. 307, 12/26/2024). The underlying research was also supported by the ALIBIRD2020-CM program (S2018/BAA-4343): "Therapeutic precision nutrition formulations for cancer," and by NutriSION-CM (Y2020/BIO-6350), funded by the Research and Innovation General Directorate of the Community of Madrid and cofinanced with European Union Structural Funds. Additional support was provided by grant PID2022-138295OB-I00 funded by MICIU/AEI/10.13039/501100011033 and by the European Union, the REACT-EU Program (FACINGLCOVID-CM project, Community of Madrid, and the European Regional Development Fund [ERDF]), and EU Structural Funds.

Data Availability

The data supporting the findings of this study are not publicly available due to institutional and consortium restrictions on data sharing. The datasets include pseudonymized clinical and digital health information collected within the ALIBIRD research program. Access to deidentified data may be considered upon reasonable request to the corresponding author in compliance with applicable ethical approvals and data protection regulations.

Abstract

Background: Cancer survivors frequently face persistent nutrition-related challenges after treatment. Mobile health tools may extend access to dietary self-management support beyond clinic settings, but feasibility and preliminary effects remain insufficiently characterized in this population.

Objective: This study aims to evaluate the feasibility, user engagement, and preliminary effects of a 4-week mobile nutrition app on dietary behavior and quality of life (QoL) among cancer survivors, and to explore whether higher engagement is associated with greater improvements.

Methods: A single-arm, prospective pilot feasibility study was conducted at a tertiary cancer center in Korea. Participants used a mobile nutrition app that provided dietary feedback and self-monitoring features. In-app log data were analyzed to determine engagement metrics (session frequency, duration, and gap regularity) using an elbow-based 10-minute session threshold. Primary outcomes included the Nutrition Quotient for Adults (NQ-2021) and European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) scores, measured before and after 4 weeks. Nonparametric paired analyses assessed changes, and exploratory correlations examined relationships between engagement and outcomes.

Results: Among 27 enrolled participants, 24 cancer survivors (88.9%) completed the intervention and postassessment; the majority were female (17/24, 70.8%), with a mean age of 58.5 (SD 8.7) years. Breast cancer was the most common diagnosis (11/24, 45.8%), and most participants reported no diet-related adverse effects (20/24, 83.3%) and stable body weight during the study period. Participants averaged 2.3 app sessions per day and a median cumulative use of 177.5 minutes. Retention was 88.9%, and median adherence to daily self-monitoring exceeded 85%. The NQ Moderation domain improved significantly (mean 76.6, SD 17.5 → mean 81.0, SD 13.7; *P*=.02), while Balance and Dietary Behavior showed positive trends (mean 63.7, SD 16.1 → mean 65.5, SD 13.3, *P*=.14; mean 64.9, SD 17.3 → mean 67.1, SD 15.9, *P*=.10). In QoL outcomes, appetite loss decreased (mean 17.9, SD 22.0 → mean 7.7, SD 14.6; *P*=.03) and global health status increased modestly (mean 68.5, SD 21.4 → mean 72.9, SD 20.1; *P*=.08). Higher engagement correlated with improved moderation (*r*=0.46; *P*=.02) and reduced appetite loss (*r*=–0.42; *P*=.04). Exploratory subgroup analyses suggested stronger effects among participants aged 60 years and older (ΔNQ Moderation +7.9; *P*=.04) and those with longer cancer survivorship (>3 years; *P*=.047). No adverse events were reported.

Conclusions: This pilot feasibility study demonstrates high user engagement, satisfactory retention, and preliminary improvements in nutritional behavior and QoL among cancer survivors using a mobile nutrition app. These findings indicate the feasibility of a larger controlled trial to confirm the app's effectiveness and explore long-term adherence strategies.

Introduction

Poor nutritional status is a highly prevalent and serious problem in cancer care, affecting 40% - 80% of patients depending on cancer type and treatment phase [1,2]. This high prevalence reflects both tumor-related metabolic alterations and treatment-induced side effects, such as appetite loss or gastrointestinal dysfunction, which compromise dietary intake. Malnourished patients experience poorer treatment tolerance, higher complication rates, delayed recovery, and diminished

XSL•FO
RenderX

quality of life (QoL). Poor nutritional status has also been associated with reduced survival [3,4]. Nutritional support interventions—including early dietetic counseling and individualized nutrition plans—can mitigate these effects and improve both clinical and patient-reported outcomes [1,5]. Accordingly, current oncology guidelines recommend routine nutrition screening and intervention across all phases of cancer care [2,6,7].

Despite these recommendations, access to professional dietary support remains limited. Many cancer survivors report unmet nutritional needs due to lack of referrals, time constraints, and system-level barriers. In 1 study, only 23% of survivors had consulted a dietitian after treatment, most citing difficulty accessing expert guidance [8]. Consequently, many survivors turn to unverified online information, underscoring the urgent need for accessible, evidence-based digital tools to support nutritional self-management [9]. Importantly, nutritional challenges in cancer survivorship are heterogeneous and extend beyond inadequate intake alone. While many survivors experience appetite loss and reduced dietary intake during or after treatment, others—particularly survivors of breast, colorectal, and endometrial cancers—are prone to excess weight gain or unhealthy dietary patterns that are associated with increased risks of recurrence and metabolic comorbidities. Accordingly, contemporary survivorship guidelines, including those of the American Cancer Society (ACS), emphasize not only sufficient energy and protein intake but also the adoption of balanced, high-quality dietary patterns and moderation of excessive or nutrient-poor consumption. Nutritional support in survivorship, therefore, requires an approach that addresses both insufficient intake and maladaptive overconsumption, rather than focusing solely on weight loss or caloric increase.

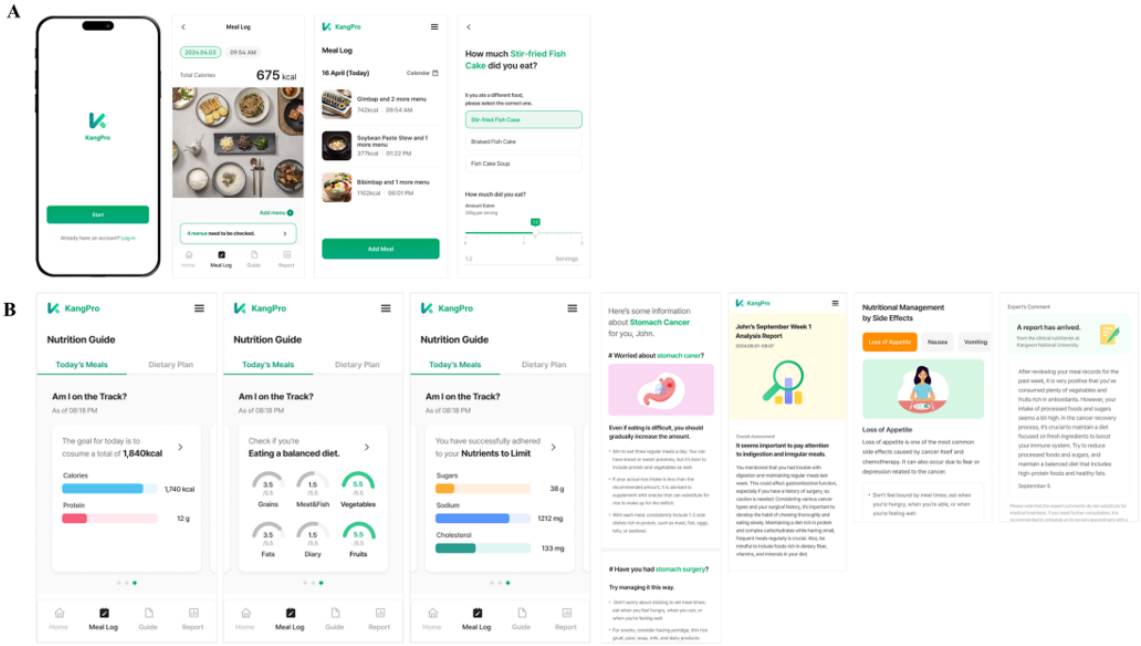
Mobile health (mHealth) apps represent a promising and scalable approach to extend nutrition support beyond the clinic. These apps can provide personalized dietary education, facilitate self-monitoring of food intake, and enable real-time symptom tracking beyond traditional clinical settings [9,10]. Digital symptom monitoring during active cancer treatment has been associated with improved patient outcomes—including better QoL, fewer emergency visits, and even survival benefits—by enabling earlier supportive interventions [3,11,12]. Building on these advances, early studies of mHealth-based nutrition interventions in cancer care have reported encouraging outcomes. App-based programs targeting diet or weight management have demonstrated improvements in dietary quality, weight maintenance, and patient satisfaction in small pilot trials [12-14]. For instance, a mobile app for head and neck cancer survivors showed high engagement and acceptability for diet and symptom tracking. However, despite these encouraging findings, the overall evidence base remains limited. Most prior studies have been small or short-term, with few using rigorous designs or enrolling diverse cancer populations. Moreover, the relationship between app engagement and nutritional or QoL outcomes remains largely unexplored. These gaps underscore the need for a rigorously designed pilot study to establish feasibility parameters and explore engagement-outcome relationships before a future definitive trial.

Given these knowledge gaps and the widespread nutrition challenges among cancer survivors, we developed a new mHealth-based dietary intervention. This intervention was designed to support healthy dietary pattern formation across a broad spectrum of survivorship needs, including individuals experiencing appetite loss and insufficient intake as well as those requiring dietary balance and moderation to prevent excess weight gain. Before long-term efficacy can be meaningfully evaluated, it is therefore necessary to establish whether a candidate intervention is feasible in real-world survivorship settings, whether users engage with it consistently, and whether early behavioral and symptom changes can be detected. Accordingly, we conducted a structured pilot feasibility study to evaluate this intervention with a specific focus on recruitment, retention, engagement patterns, and short-term behavioral responsiveness. The objectives were not to establish long-term efficacy but to assess feasibility and preliminary effects and to generate critical parameters—such as adherence rates, engagement intensity, and engagement-outcome associations—required to inform the design of a future randomized, long-term trial. By integrating multidimensional dietary guidance with detailed, log-based engagement analytics and validated patient-reported outcomes, this study aims to address a key methodological gap in prior mHealth nutrition research and to provide foundational evidence for the development of rigorously designed, longer-term intervention studies in cancer survivorship.

Methods

Study Design and Sample

This pilot study was conducted as a single-arm, prospective feasibility trial in Korea. The study followed the CONSORT (Consolidated Standards of Reporting Trials) 2010 extension for pilot and feasibility trials, with no protocol modifications or interim analyses after trial initiation [15]. To enhance completeness of descriptive reporting, we also considered selected STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) items relevant to participant characteristics and outcome reporting; however, CONSORT served as the principal reporting framework for this feasibility intervention [16]. Participants were recruited from Family Medicine and Hematology-Oncology outpatient clinics of a tertiary cancer center between October and December 2024. Treating physicians identified potentially eligible cancer survivors during follow-up visits and referred them to a research nurse with more than 3 years of oncology care experience. The nurse conducted eligibility screening, obtained written informed consent, provided training on app installation and use, and monitored participants throughout the study period. Recruitment was conducted consecutively via physician referrals and informational leaflets displayed in the clinics. A single research nurse provided standardized app training and follow-up support for all participants to ensure procedural consistency. Eligible participants were adult (aged 20 - 69 years) cancer survivors who had completed curative-intent treatment—surgery, chemotherapy, and/or radiotherapy for any cancer type—and owned a smartphone capable of running the study app. All participants had undergone curative surgical resection as their



XSL•FO
RenderX

primary treatment and were within 5 years of completing curative therapy. Except for 4 individuals with mild physical limitations, most participants were able to perform light daily activities without restriction. Information on employment status and comorbidities was not collected in this pilot study. Key exclusion criteria were ongoing active cancer treatment or hospice or palliative care, refusal to participate, significant cognitive impairment precluding informed consent, and inability to use the smartphone app, even with caregiver assistance. Participants could withdraw at any time without penalty. Based on institutional registry data (average 2153 new cancer diagnoses annually, 2019 - 2023), a simple proportion estimate with a 0.10 margin of error and 90% CI suggested a required sample of approximately 66 participants for adequate precision. However, as this pilot aimed primarily to evaluate feasibility outcomes (recruitment, adherence, and usability) rather than statistical efficacy, a pragmatic target of approximately 50 participants was set, accounting for potential attrition. A total of 27 participants were enrolled, of whom 24 completed the 28-day intervention and provided both pre- and postintervention data for analysis. Recruitment and follow-up were planned over a 4-week intervention window per participant. Feasibility endpoints included recruitment rate, retention, and adherence; these parameters were predefined to assess study progression. No outcome measures were modified after trial initiation.

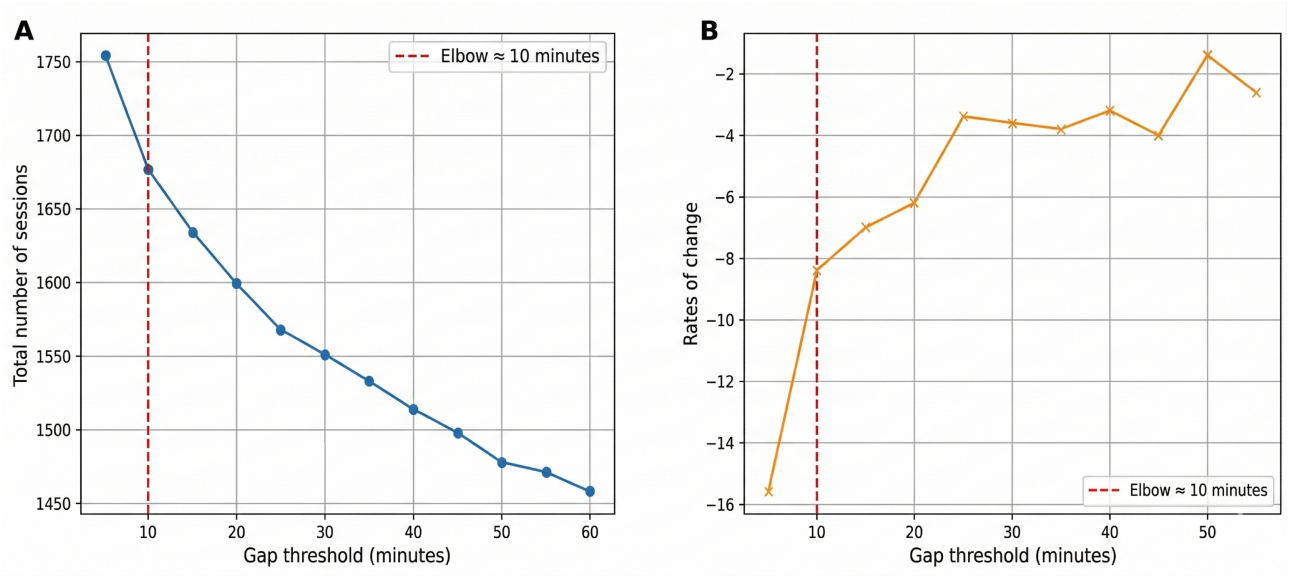
Mobile App Intervention and Data Acquisition

Participants received access to a custom mobile app designed to support dietary management in cancer survivorship. The app was intentionally designed to support balanced, sustainable eating behaviors across heterogeneous survivorship needs—including both insufficient intake due to appetite loss and excessive or unbalanced intake associated with weight gain—rather than focusing solely on weight loss (Figure 1A). Nutrient composition and feedback were based on the Korea Food and Drug Safety Food and Nutrient Database. The app generated artificial intelligence–based nutrition reports analyzing meal composition and nutrient balance using this database (Figure 1A and B). Participants could also report symptoms, which investigators monitored in real time. The app allowed users to record their meals and dietary intake through text search or photograph uploads and to view a personalized summary of their nutritional patterns. It also automatically generated artificial intelligence–based nutrition reports that analyzed meal composition and nutrient balance using a national food composition database. The app also enabled remote symptom monitoring, as participants could report symptoms that investigators could oversee in real time.

Figure 1. Nutrition reports by generative artificial intelligence in mobile apps for patients with cancer. (**A**) Recording meals process (**B**) Result nutrition analysis and reports by generative artificial intelligence.

Although the app generated quantitative dietary intake estimates for user feedback, these values were not prespecified as study end points and were therefore not analyzed for efficacy evaluation. The primary quantitative outcomes were validated questionnaire-based measures of dietary quality based on Nutrition Quotient for Adults (NQ-2021) and European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30), along with app engagement metrics. Participants were instructed to use the app as desired over the 28-day study period, and weekly phone or text message check-ins by study staff were used to encourage engagement. These check-ins were standardized brief contacts focused on technical support and general encouragement, without providing individualized dietary counseling or clinical advice, and were applied uniformly to all participants. Participants who had difficulty navigating the app could be assisted by a family member or caregiver.

All user interactions with the app were automatically recorded in time-stamped log files. For data analysis, raw usage logs were filtered to include records only from valid study



XSL•FO
RenderX

participants and restricted to each participant's 28-day intervention window. An app usage session was defined as a series of consecutive interactions separated by less than 30 minutes. In other words, any app events occurring within a 30-minute interval were grouped as 1 session, and a break of 30 minutes or more initiated a new session.

Operational Definition of App Sessions

To define user sessions from time-stamped login data, we applied a threshold-based approach that dynamically identifies session boundaries [17,18]. Specifically, we examined a range of time gaps (0 - 60 minutes in 10-minute increments) between consecutive login events to identify an appropriate threshold for segmenting discrete usage sessions (Figure 2A and B). For each gap threshold, user activity was aggregated such that any login occurring after a period longer than the defined threshold was considered the start of a new session. This procedure was repeated for all users, and the total number of sessions was calculated for each threshold value. To identify the optimal cutoff, we analyzed the rate of change in total session counts across thresholds by calculating the first derivative. This approach quantified how quickly session counts stabilized as the threshold increased. The elbow point—where increasing the threshold produced only minimal further reduction in the total session count—was interpreted as the balance between splitting continuous usage into too many fragments and merging clearly separate sessions into one. This inflection occurred at a 10-minute gap, which we therefore adopted as the operational session boundary. In simple terms, very small gaps overdivide normal continuous use, while very large gaps merge independent activities into a single session; the 10-minute "elbow" provides the most stable midpoint between these extremes. This data-driven procedure provides an objective and reproducible threshold, analogous to the elbow method commonly used in clustering analysis [19]. Our approach further aligns with prior studies on user sessionization heuristics, which typically use gap-based thresholds (around 25 - 30 minutes) to segment user activity into meaningful behavioral units [20].

Figure 2. Identification of optimal session gap threshold using the elbow method. (A) Total number of app usage sessions across gap thresholds from 0 to 60 minutes. As the allowed time gap between consecutive interactions increases, separate activities are more likely to be grouped into the same session, leading to a gradual decrease in the total number of sessions. (**B**) First derivative showing rate of change in session count. The elbow point at 10 minutes (red dashed line) was selected as the optimal threshold for defining discrete app usage sessions.

QoL Assessment

QoL was measured using the EORTC QLQ-C30 (version 3.0) [21]. The survey for EORTC QLQ-C30 was administered before and after app use following a detailed, face-to-face explanation of the survey procedures provided by a specialized research nurse (SJP), with additional consultation from clinical specialists (WJK, OBK, and IHY). This validated, cancer-specific instrument includes 30 items covering 5 functional domains, 3 multi-item symptom domains, 1 global health domain, and 6 single-item symptom scales. Scores were transformed to standardized 0 - 100 scales according to the EORTC scoring manual [22]; higher functional and global health scores indicated better QoL, whereas higher symptom scores reflected greater symptom burden.

Nutrition Assessment

Dietary intake and behavior were evaluated using the NQ-2021, a nutrition assessment tool developed and validated by the Korean Nutrition Society [23]. The survey for NQ-2021 was administered before and after app use following a detailed, face-to-face explanation of the survey procedures provided by a specialized research nurse, with additional consultation from clinical specialists (WJK, OBK, and IHY). The NQ-2021 consists of 18 items in 3 domains: Balance (consumption frequency of recommended food groups), moderation (frequency of unhealthy foods or eating behaviors), and practice (healthy eating habits). Each item score is weighted according to an established algorithm, and domain scores are summed and standardized to a 0 - 100 scale. Higher NQ-2021 scores reflect better overall diet quality and healthier eating behaviors.

XSL•FO
RenderX

Statistical Analysis

Because of the behavioral nature of the intervention, neither participants nor investigators were blinded. All statistical analyses were descriptive and exploratory. All statistical analyses were descriptive and exploratory. Within-subject pre-post comparisons were conducted using the Wilcoxon signed rank test, appropriate for small samples with nonnormal distributions. Higher postintervention functional or nutritional scores were interpreted as improvement, whereas lower symptom scores indicated reduced symptom burden. Exploratory subgroup analyses examined differences in outcomes by engagement level and participant demographics.

Engagement metrics included total usage time, maximum consecutive days of app use (≥14,≥21, and ≥28 days), average sessions per day, mean intersession gap time, and the standard deviation of intersession gaps as a measure of variability. Analyses were performed on complete cases; missing data were described but not imputed. Statistical analyses were conducted using Python (version 3.9; Python Software Foundation) and R (version 4.1; R Core Team).

Ethical Considerations

The study was approved by the Kangwon National University Hospital Institutional Review Board (KNUH-2024-07-010) and conducted in accordance with the Declaration of Helsinki and relevant Korean privacy regulations. Written informed consent was obtained from all participants. The original consent permitted secondary analyses of deidentified data without additional approval. All data were anonymized using coded identifiers and stored on encrypted, access-restricted servers. Participants received a modest gift card upon study completion, as approved by the institutional review board. No protocol modifications or interim analyses were performed after trial initiation.

Results

Study Population and Baseline Characteristics

A total of 24 participants completed both pre- and postintervention assessments, including 17 (70.8%) females (Table 1). Except for 4 participants with minor physical limitations, all were able to perform light daily activities without restriction. The mean age was 61.57 (SD 8.22) years for males and 55.94 (SD 8.21) years for females. Primary tumors included breast cancer (11/24, 45.83%), colorectal cancer (3/24, 12.50%), gastric cancer (3/24, 12.50%), lung cancer (3/24, 12.50%), thyroid cancer (2/24, 8.33%), lymphoma (1/24, 4.17%), and renal cancer (1/24, 4.17%). Most participants used the app for weight maintenance (n=20, 83.3%), while 4 (16.7%) aimed for weight loss. In terms of physical activity, 12 (50.0%) reported unrestricted activity, 8 (33.3%) light-intensity activity, and 4 (16.7%) a predominantly sedentary lifestyle. Meal frequency was reported as 3 times daily by 18 (75.0%) participants, twice daily by 5 (20.8%), and 4 times by 1 (4.2%). Most participants (20/24, 83.3%) were classified as not applicable with respect to diet-related adverse effects. Body weight remained stable, with a mean of 60.8 (SD 11.5) kg before and 61.0 (SD 11.4) kg after the intervention.

Feasibility Outcomes—Engagement and App Usage Characteristics

A total of 27 participants completed baseline assessments and initiated the intervention. Of these, 24 (88.9%) participants completed the full 4-week intervention and postintervention assessments. Three participants discontinued app use within the first 2 weeks of the study and did not complete the postintervention questionnaires. All 3 noncompleters completed baseline nutrition and QoL assessments, but postintervention data were missing due to early discontinuation of app use. No partial postintervention questionnaires were recorded. Participants who did not complete the study (n=3) did not differ markedly from completers with respect to age, sex, cancer type, or baseline nutrition and QoL scores. However, all noncompleters exhibited early disengagement from app use.

Among participants who completed the intervention, using the predefined sessionization criterion, a total of 82,385 raw app interaction log entries were consolidated into 1551 distinct usage sessions across the 24 participants during the 4-week intervention period. Overall engagement with the app was high. Participants used the app a mean of 2.3 sessions per day, with

XSL•FO
RenderX

a median cumulative usage time of 177.5 minutes over the intervention period. Engagement was sustained throughout the study, with no marked decline in usage over time. Adherence to daily self-monitoring was high, with a median adherence rate exceeding 85%, and 88.9% (24/27) of enrolled participants completed the full 4-week intervention, indicating satisfactory retention. Patterns of use varied between individuals, but most participants demonstrated regular engagement characterized by repeated short sessions distributed across the day, consistent with meal logging and dietary review behaviors. Analysis of engagement intensity showed that participants differed in session frequency, cumulative usage time, and regularity of use. These engagement metrics were subsequently used to stratify participants into subgroups (eg, by consecutive days of use, total usage time, daily usage frequency, and intersession gap regularity) for exploratory analyses examining associations between engagement patterns and nutritional and QoL outcomes.

Changes in Nutrition and QoL After App Use

After the 4-week app intervention, participants showed significant improvements in specific nutritional and symptom outcomes. In particular, the nutrition quotient moderation domain score increased from 76.61 (SD 15.36) at baseline to 81.04 (SD 12.69) postintervention, a statistically significant improvement (P=.02) (Table 2). This indicates a meaningful reduction in the frequency of unhealthy food choices and overeating behaviors after using the app. In contrast, other nutrition domain scores—including balance (fruits or vegetables intake) and implementation (healthy eating practices)—and the overall nutrition score did not change significantly. Among QoL measures, the most notable change was a decrease in appetite loss symptoms. The mean appetite loss score improved from 17.94 (SD 22.0) (higher scores indicate worse symptoms) to 7.69 (SD 14.62) after the intervention (P=.03), suggesting that participants experienced significantly less loss of appetite following app-guided dietary management. Other EORTC QLQ-C30 domains, including global health status and functional scales (physical, role, emotional, cognitive, and social), showed no statistically significant pre-post differences. Symptom scales such as fatigue, pain, nausea or vomiting, insomnia, constipation, diarrhea, and financial difficulties likewise exhibited no significant changes.

Table . Comparison of nutrition and quality of life before and after app use[a].

Characteristics	Before (n=24), mean (SD)	After (n=24), mean (SD)	*P* value

Changes in Nutrition and QoL Based on App Usage Intensity

Greater usage intensity was generally linked to greater improvements in nutrition and QOL measures. Consecutive days of app use (Table 3 and Table S1 in Multimedia Appendix 1) showed a clear dose-response relationship with outcomes. Participants who used the app for at least 14 consecutive days showed a significant increase in their Moderation score compared with baseline (*P*=.02). Those with ≥21 consecutive days of usage had a significant improvement in their moderation domain score (*P*=.04), reflecting better intake of recommended food groups. Furthermore, participants who engaged with the app for the full 28 days experienced significant gains in the balance domain (*P*=.02) and also in physical functioning (*P*=.047)—a QoL improvement not seen with shorter usage durations.

Table . Characteristics according to consecutive days of app use[a].

Days of app use	Before use	After use	*P* value
14 days (nutrition)			
Moderation	75.11 (17.51)	80.58 (13.74)	.02[b]
21 days (nutrition)			
Moderation	72.71 (20.14)	77.99 (14.25)	.04[b]
28 days (nutrition)			
Balance	55.8 (15.07)	65.29 (15.75)	.02[b]
28 days (quality of life)			
Physical	84.74 (10.69)	87.62 (7.13)	.047

[a]Results are expressed as mean (SD).

[b]Statistically significant results (*P*<.05).

Total accumulated usage time was another important factor (Table 4). Participants in the high total use time group (≥177.5 minutes of cumulative app use over 4 weeks) achieved significant improvements in the moderation domain and cognitive functioning scores (both *P*=.02). In contrast, those with lower total usage time (<177.5 minutes) did not show any significant changes in these outcomes, implying that a minimum threshold of engagement time may be necessary to produce measurable benefits.

Changes in Nutrition and QoL Based on App Usage Frequency

Daily usage frequency showed similar trends in Table 5. High-frequency users who used the app on average at least 2.5 times per day (eg, multiple log-ins or meal recordings per day) demonstrated significant improvements in various areas: their moderation and balance scores both increased significantly (*P*=.002 and .003, respectively), and their overall nutrition score (NQ total) also rose markedly (*P*=.008). Additionally, this high-frequency group showed a significant enhancement in cognitive QoL scores (*P*=.04) and pain (*P*=.047). In contrast, participants with low daily usage frequency (<2.5 uses per day) did not exhibit any statistically significant changes in nutrition scores or QoL measures. These results indicate that more frequent interaction with the app was associated with greater dietary improvements and perceived cognitive benefits.

Changes in Nutrition and QoL Based on Regular App Usage

Participants who used the app consistently throughout the day—defined as daily use with intervals of 7 hours or less (eg, morning, afternoon, and evening)—demonstrated significantly better dietary outcomes (Table 6). As shown in Table 6, this regular-use group exhibited improvements in moderation (*P*=.002), balance (*P*=.046), and overall nutrition score (*P*=.01). By contrast, those with irregular usage patterns (gaps >7 hours and variable timing) did not show improvements in these domains. These results indicate that consistent, frequent app engagement is associated with improved dietary behavior and cognitive outcomes. Notably, however, the irregular-use group reported a significant reduction in appetite loss symptoms (*P*=.04), while the regular-use group had minimal baseline appetite issues, leaving less room for improvement. No other QoL domains differed significantly by usage pattern.

Exploratory Subgroup Analyses

Exploratory subgroup analyses revealed variations in intervention effects by age, sex, and cancer type (Tables S1-S3 in Multimedia Appendix 2). Among older participants (aged 60 years and older), significant improvements were observed in overall diet quality—reflected by higher Moderation subscores (*P*=.02)—and in cognitive functioning (*P*=.02), whereas younger participants showed no comparable changes. Female survivors also demonstrated a significant postintervention increase in Moderation (*P*=.04) that was not evident in males. In addition, survivors with non–breast cancers (eg, colorectal, gastric, or lung) exhibited a marked improvement in diet quality (*P*=.008) and greater reductions in appetite loss symptoms, while breast cancer survivors—who had higher baseline diet quality and minimal appetite complaints—showed little change. These subgroup findings suggest that age, sex, and cancer type may moderate the magnitude of benefit derived from the app-based dietary intervention.

Discussion

Principal Results

Although this study involved a short 4-week intervention, its primary purpose was to generate feasibility evidence and behavioral insights to inform the design of subsequent long-term trials, rather than to establish long-term efficacy. While some participants expressed an interest in weight control, the primary focus of this study was to improve dietary quality, appetite regulation, and overall well-being rather than to promote weight loss per se. In this 4-week pilot study, a mobile dietary self-management app for cancer survivors was associated with improvements in key nutrition-related behaviors and symptoms. Participants' overall diet quality improved significantly, as shown by an increase in the Nutrition Quotient Moderation subscore (reflecting reduced consumption of unhealthy foods), and they reported a marked reduction in appetite loss symptoms. These positive changes are notable, given that many cancer survivors face challenges with inadequate dietary intake and appetite suppression during and after treatment.

XSL•FO
RenderX

The pronounced reduction in appetite loss may reflect not only improved nutritional intake but also partial alleviation of psychosocial factors (such as treatment-related stress or social isolation). The app provided personalized meal recommendations, diverse healthy recipes, and motivational messages, offering a multidimensional, individualized approach to stimulate appetite and encourage regular eating. This outcome aligns with survivorship nutrition guidelines, as the ACS encourages survivors to consume a variety of vegetables, fruits, and high-quality protein and to optimize the mealtime environment to help maintain or regain appetite—practices shown to support appetite recovery [24]. These findings illustrate that the guideline—implementation—effectiveness pathway proposed by the ACS can be operationalized through a digital platform, demonstrating that evidence-based nutrition guidance can translate into measurable behavioral and clinical improvements. By delivering tailored support consistent with these recommendations, the app may help survivors overcome appetite loss, a complex and common issue in cancer survivorship. Notably, maintaining a healthy weight is often recommended as part of recurrence prevention in breast, prostate, and endometrial cancer survivors. In this context, weight awareness or moderate control behaviors complement—rather than contradict—the goal of restoring appetite and balanced eating. A modest but significant improvement in pain symptoms was also noted among high-frequency app users, suggesting that consistent dietary self-monitoring may provide ancillary benefits for perceived physical well-being. Another key finding was a significant improvement in dietary moderation, indicating a shift away from unhealthy eating patterns (eg, frequent overeating, binge eating, or strong food aversions) toward more balanced dietary habits. This finding supports the emphasis of established dietary guidelines on moderation and limiting nutrient-poor, energy-dense foods. For example, ACS guidelines warn against Western-style diets high in fat and sugar and instead highlight the importance of high-fiber, low-fat diets with increased intake of plant-based foods while restricting processed, calorie-dense items [24]. Our results suggest that a digital intervention can facilitate these healthy dietary shifts in a real-world context, helping survivors adopt and sustain recommended eating behaviors. In addition, we observed an improvement in cognitive functioning scores among participants aged 60 years and older. Older cancer survivors are particularly susceptible to cancer-related cognitive impairment due to factors such as chemotherapy, chronic inflammation, sleep disturbances, and depression. The app included features that might support cognitive health, including suggestions for “brain-friendly” foods rich in omega-3 fatty acids and antioxidants, encouragement of regular meal routines, and tools for self-monitoring dietary intake. These components may have helped impose daily structure and improve mental clarity in older users. While this subgroup finding is exploratory, it raises the possibility that digital dietary interventions could confer ancillary cognitive benefits in older patients with cancer, warranting further investigation into the underlying mechanisms and durability of this effect. Importantly, our analysis found that greater engagement with the app was associated with larger improvements in outcomes. Participants who used the app more frequently, for longer total durations, and with more consistency (ie, fewer and shorter gaps between usage sessions) tended to achieve greater gains in healthy eating behaviors and QoL scores than those with lower usage. To our knowledge, this study is among the first in the cancer survivorship setting to capture such detailed app usage metrics (using time-stamped log data to define user sessions) and to link these engagement indicators to standardized nutrition and QoL outcomes. This analytic approach provides preliminary evidence that engagement may mediate the effectiveness of digital interventions. However, because this was an uncontrolled, short-term pilot, the observed relationships between engagement and outcomes should be interpreted as associative rather than causal, serving primarily as hypothesis-generating evidence for subsequent trials. This pilot was designed to assess short-term feasibility, adherence, and early symptom response rather than to verify long-term efficacy; the findings thus provide foundational data to inform the design and power estimation of future randomized controlled trials (RCTs).

Overall, these findings suggest that an app-based dietary program can serve as a comprehensive supportive tool that addresses not only survivors’ nutritional needs but also aspects of their psychological, cognitive, and behavioral health. The app’s capacity to deliver personalized nutrition guidance, promote beneficial behavior changes, and provide accessible support indicates that such digital interventions could be further refined and tailored to specific cancer types, age groups, and phases of survivorship for maximum benefit. Although the intervention period was limited to 4 weeks, this study was intentionally designed to align with the identified gap in the existing literature. Prior mHealth nutrition studies in cancer survivorship have been constrained not only by short follow-up durations but also by interventions narrowly focused on single components—such as calorie tracking or symptom logging—without examining how users engage with more comprehensive, behavior-oriented tools. In contrast, this study evaluated a multidimensional dietary intervention that integrates personalized nutrition guidance, lifestyle-related behavioral feedback, and symptom awareness, while explicitly quantifying real-world engagement patterns using objective log data. Within this framework, the 4-week time frame served as a necessary and methodologically appropriate first step to determine intervention feasibility, user adherence, and early behavioral signal detection—prerequisites for designing and justifying longer-term efficacy trials. Thus, rather than attempting to address long-term outcomes directly, this pilot study contributes to the literature by establishing whether the intervention demonstrates sufficient feasibility and engagement-driven responsiveness to warrant subsequent large-scale, long-term evaluation. This stepwise approach is consistent with recommended frameworks for the development and evaluation of complex digital health interventions.

Comparison With Prior Work

Our findings are consistent with, and extend, prior research on mHealth nutrition interventions for cancer survivors. Previous pilot studies of app-based diet or weight management programs have reported improvements in dietary quality, weight maintenance, and patient-reported outcomes, and a recent

XSL•FO
RenderX

systematic review of randomized trials concluded that mHealth interventions show promise for improving diet and physical activity in cancer survivor populations [12]. Similarly, the improvements observed in our study—such as enhanced dietary moderation and reduced symptom burden—mirror these earlier reports, reinforcing that app-based guidance can help meet survivors' nutritional needs. Distinct from most earlier studies, this work quantitatively linked real-world app engagement metrics (frequency, duration, and continuity of use) to measurable changes in dietary and QoL outcomes. This analytic approach provides empirical groundwork for defining optimal adherence thresholds and intervention intensity in future trials. We add to the literature by demonstrating a direct link between participants' engagement with the app and the magnitude of benefits achieved, a relationship that has seldom been examined in prior studies. Emerging evidence from other digital health studies also highlights the importance of sustained app engagement for successful behavior change and symptom management. For example, in a recent mobile weight loss program for breast cancer survivors, those who engaged more frequently with app features (such as logging meals or reading educational content) were significantly more likely to achieve clinically meaningful weight loss [25]. Likewise, Yunis et al [8] found that patients with cancer and caregivers had high adherence to a symptom-tracking app over 1 month, and their study demonstrated that detailed app use metadata (eg, time-stamped login information) can inform remote monitoring of patient engagement and well-being between clinic visits. Furthermore, adding interactive components to boost engagement can yield additional benefits: in an RCT, breast cancer survivors who participated in an app-based peer support community (vs using a tracking app alone) experienced significantly lower distress levels and increased physical activity [26].

Beyond these trials, recent systematic and observational evidence clarifies where this study advances the field (Table S1 in Multimedia Appendix 3). Shen et al [25] demonstrated that higher real-world engagement with a behavioral app predicted meaningful weight loss, supporting engagement as a key behavioral driver, although cognitive outcomes were not assessed. Wang et al [12] summarized 23 RCTs of mHealth diet and activity programs, confirming short-term benefits but highlighting limited mechanistic data and underrepresentation of older adults. Lu et al [27] found that nutritional interventions—including anti-inflammatory and fasting-mimicking diets and polyunsaturated fatty acids supplementation—can improve cognitive outcomes, yet these trials were investigator-driven rather than self-managed. Coro et al [28] qualitatively showed that survivors view diet as linked to mental clarity but struggle to maintain structured routines due to cognitive fog. Crowder et al [29] observed that higher monounsaturated fatty acids or saturated fatty acids ratios were associated with better short-term cognitive performance during chemotherapy, while McLeod et al [30] reported complex, context-dependent associations between Mediterranean diet adherence and cognitive outcomes in older adults. In contrast, this study uniquely integrates detailed engagement analytics with dietary, symptom, and QoL outcomes. By linking frequency, duration, and continuity of app use to improvements in diet quality and appetite loss, it provides concrete evidence supporting the engagement-outcome mechanism. Moreover, the inclusion of older survivors (aged 60 years and older) extends digital survivorship research into an age group seldom represented in prior studies and suggests potential cognitive and structural benefits associated with sustained app use. Taken together, these reports and our results underscore that maximizing patient engagement is vital for mHealth interventions to achieve their full potential in cancer care. Ensuring that survivors not only adopt an app but continue to use it actively and regularly appears to be a prerequisite for attaining meaningful improvements in health behaviors and QoL.

Limitations

Several limitations of this pilot study must be acknowledged. First, this study had a modest sample size (n=24 completers), an uncontrolled single-arm design, and a short 4-week intervention, which limit generalizability and preclude causal inference. The short follow-up also meant that we could not determine the longevity of the observed behavior changes. Second, all outcomes were measured via self-reported questionnaires, introducing potential recall bias and social desirability bias. Third, participants received weekly check-in calls or text messages from study staff to encourage app use; this human support likely improved adherence and also confounds attribution of the outcomes to the app alone (ie, higher engagement may have been partly driven by these external prompts). Indeed, blended approaches that combine digital tools with human coaching are known to boost user engagement and can potentially amplify outcomes [31], so our study cannot disentangle the app's independent effects from the influence of this added support. In addition, app-generated quantitative dietary intake data were not analyzed, as they were not prespecified efficacy end points and were variably incomplete due to early discontinuation of app use among noncompleters. Finally, while our sample included a range of ages and cancer types, the study was not powered to examine differences across subgroups; any exploratory observations of trends by age or diagnosis should therefore be interpreted with caution, as they were not the focus of this analysis. Another limitation is that detailed clinical and sociodemographic data—including employment status, comorbidities, and the exact interval since surgery—were not comprehensively collected. Although all participants were disease-free and within 5 years after curative surgery, the lack of these variables may limit contextual interpretation of outcomes. Despite these limitations, the completion rate (88.9%) and adherence rate (≥70%) exceeded predefined feasibility benchmarks, confirming the practicality and acceptability of the intervention. Notably, the absence of a control group and the short duration of follow-up mean that the durability of the behavior change is uncertain. This is a common issue in early mHealth studies, and a recent review highlighted that evidence for the long-term efficacy of nutrition apps in cancer care remains inconclusive [32]. Accordingly, our positive findings should be viewed as preliminary and hypothesis-generating. Although quantitative food record data were partially collected, response completeness was insufficient for reliable analysis. Therefore, this pilot

XSL•FO
RenderX

prioritized a qualitative dietary assessment tool that captures overall meal quality and behavioral changes, which better reflect the app's behavioral focus and feasibility objectives. Future large-scale studies will integrate quantitative nutrient analyses for comprehensive validation.

Future Directions

Building on this pilot, future research should validate and expand these findings using more robust study designs. In particular, larger RCTs are needed to confirm the relationships observed between app engagement and outcomes and to determine whether actively boosting user engagement can causally improve nutritional status or clinical results. Such trials should also include longer follow-up periods to assess whether improvements in diet and QoL are sustained over time, and they should incorporate objective outcome measures (eg, weight change or nutritional biomarkers) alongside self-reports for a more comprehensive evaluation of the intervention's impact. Another priority for future interventions is to leverage engagement-tailored personalization. Our data suggest that users vary in how actively and consistently they use the app, and these usage patterns likely influence the benefits gained. Tailoring the program to an individual's engagement profile could amplify its effectiveness. For example, the app could use just-in-time adaptive features such as real-time alerts or motivational feedback when a lapse in use is detected, or dynamically adjust the frequency of prompts and content based on each user's behavior. By using analytics to identify when a participant is at risk of disengaging, the intervention could deliver timely, personalized support (such as encouragement from a coach, simplified tasks, or new content to recapture interest). Such adaptive personalization may help prevent drop-off and maximize the "dose" of the intervention each participant receives, ultimately leading to better outcomes. Additionally, future efforts should integrate mHealth dietary apps into standard survivorship care. Rather than functioning in isolation, apps like ours can be embedded within oncology nutrition services and survivorship care plans to extend support beyond the hospital setting. For instance, integrating the app with routine follow-up visits or with electronic health records could enable nutritionists and clinicians to remotely monitor patients' dietary logs and symptoms and intervene earlier when issues arise [8]. Care teams might receive automated summaries of a survivor's app activity or alerts if a patient's engagement or nutritional status falls below a certain threshold. This type of health system integration would facilitate a more continuous model of care. By providing an accessible, scalable platform for dietary self-management that remains connected to professional support, a validated nutrition app could reach survivors who otherwise might not receive ongoing nutritional guidance.

Conclusions

This pilot study demonstrates the feasibility of a mobile app–based dietary intervention for cancer survivors and provides preliminary evidence of its benefits. Participants achieved improvements in diet-related measures and QoL, particularly in those domains (such as healthy eating habits and symptom relief) where the app's guidance was most directly applied. Notably, greater user engagement was associated with greater improvements, highlighting the critical role of sustained engagement in the success of digital health interventions. While these results require confirmation in controlled trials, they underscore the potential of personalized, engagement-driven mHealth tools to support the long-term health and well-being of cancer survivors.

Abstract

Background: People with cancer often experience unmet needs during treatment and survivorship, which can impact their ability to carry out daily tasks, reduce their quality of life, and limit their participation in work and social activities. Cancer Coach by CancerAid (now known as Osara Health) is a digital health intervention designed to address these needs through a combination of synchronous telehealth coaching and an asynchronous mobile app that supports behavior change and emotional well-being.

Objective: This study aimed to evaluate the impact of Cancer Coach by CancerAid on the mental and physical health of people with cancer using patient-reported outcomes.

Methods: Participants were referred to the program via insurers and hospital clinics. Health coaches administered the Patient-Reported Outcomes Measurement Information System 10-item Global Health Short Form via telephone at both the beginning and end of the intervention. This tool measures global physical health (GPH) and global mental health (GMH). Pre- and postintervention scores were analyzed using Wilcoxon signed rank tests. Independent 2-tailed *t* tests assessed whether changes in GPH and GMH scores were associated with the use of health coaching alone or in combination with the mobile app.

Results: Statistically significant improvements were observed in both GPH ($z=-4.97$; $P<.001$; $r=0.37$) and GMH ($z=-4.53$; $P<.001$; $r=0.34$), indicating moderate effect sizes in the 89 participants. The average T score point changes of 4.43 for GPH and 4.58 for GMH represented a minimal important change for participants. The improvement in the group GMH T score was reflected in the move from “good” to “very good” mental health status. Participants who engaged with both health coaching and the mobile app showed greater improvements in physical health, whereas those who received health coaching alone exhibited higher gains in mental health. This suggests that the mode of support may influence specific health outcomes.

Conclusions: The use of the Patient-Reported Outcomes Measurement Information System 10-item Global Health Short Form showed that participants had significant improvements in physical and mental health after participating in the Cancer Coach by CancerAid intervention. The integration of telehealth coaching with app-based support may enhance overall well-being and address holistic needs during cancer treatment and survivorship.

KEYWORDS

cancer; digital; telehealth; coaching; mental health; physical health

Introduction

Countries with strong health care systems have seen increased cancer survival rates due to improvements in early detection and treatment of cancer [1]. However, cancer treatment side effects can impact physical, cognitive, psychological, and emotional well-being, not only in the acute phase of treatment but also for months or years afterward [2]. Managing the immediate and long-term side effects can be further complicated by health care funding shortages and a lack of services [3]. Worldwide, rehabilitation options for addressing the long-term holistic survivorship needs of people with cancer, including resuming everyday roles and occupations and improving quality of life, are limited [4]. Health coaching and various digital health options have emerged as a way of addressing some of the unmet needs of people with cancer [5].

Health coaching is a collaborative and client-centered intervention that aims to improve the physiological, behavioral, psychological, and social well-being of people with chronic illnesses [6]. For people with cancer, it offers a holistic approach to managing overall health and well-being beyond that of the primary oncology care team [7], assisting with informational, behavioral, and social concerns, particularly after treatment. A longitudinal study of 3-month telephone health coaching with survivors of cancer showed significant improvements in patient-reported depression, anxiety, exercise, and quality of life. The improvements continued for 6 months after coaching ceased, with slight declines at 12 months [8]. Participants indicated that health coaching assisted with improving exercise and healthier eating, with the most helpful aspect being the motivation and feedback provided by a personal health coach [8]. Health coaching for survivors of cancer was also supported by a systematic review [9], which found improvements in quality of life, mood, and physical activity.

Health coaches use various techniques, including motivational interviewing, goal setting, and behavior change strategies, to support and empower people to improve their overall health [10]. Technological advances have increased digital and telehealth options and reduced the need for traditional in-person health coaching, particularly since the global COVID-19 pandemic as a way of staying connected with people during periods of isolation [11]. Digital and telehealth options are also beneficial to those in rural areas with community access difficulties or caring or work responsibilities [12]. Purcell et al [13] used the Patient-Reported Outcomes Measurement Information System 10-item Global Health Short Form (PROMIS-10) to assess changes in veterans' health status following participation in a telehealth coaching program. The study found significant improvements in PROMIS-10 physical and mental health scores after coaching, indicating that the telehealth coaching program positively influenced veterans' overall health and well-being [13].

For people with cancer, digital and telehealth support options can help alleviate the financial burdens associated with attending in-person appointments [14] and provide valuable assistance during treatment periods when they may be immunocompromised. Mobile health (mHealth) options in cancer care can encompass activation and support of self-management, exercise, and enablement of survivorship care delivery [15]. Specifically, mHealth applications vary in use from treatment side effect and symptom management, virtual medical consultations, exercise prescription, support groups, and education and care navigation [16]. The method of delivery can be synchronous (eg, telephone calls or virtual care) or asynchronous (eg, wearable devices, web-based platforms, mobile-based apps, mobile-based digital games, and SMS text messages) [16,17]. Digital health programs can improve global, physical, and mental health while providing support in an ambulatory setting for people with cancer in managing their disease symptoms and side effects [16] by enhancing patients' self-efficacy, as well as helping health care professionals track and respond to patient-reported outcomes [7]. Furthermore, digital cancer health coaching programs have also been found to improve physical and mental health scores [5,18,19]. However, most studies focus on a single mHealth intervention, and there is a paucity of research evaluating interventions that combine synchronous and asynchronous mHealth interventions.

Cancer Coach by CancerAid integrates synchronous coaching with asynchronous mobile support guided by the transtheoretical model [20]. The transtheoretical model conceptualizes behavior change as a progression through stages, from precontemplation to maintenance. This framework informed the structure of the intervention by aligning synchronous coaching with the earlier stages of change, incorporating motivational interviewing and goal setting to enhance readiness and intention. The asynchronous mobile app was designed to support participants across all stages but, in particular, in the action and maintenance stages through reminders, self-monitoring tools, and educational content that reinforces ongoing behavior change [20].

Previously, Cancer Coach by CancerAid has been found to improve people's ability to return to work compared with age- and disease-matched individuals who did not participate in the program [21]. The primary aim of this pilot study was to determine whether Cancer Coach by CancerAid (now known as Osara Health) improved participants' self-reported physical and mental health using PROMIS-10 scores [22-27], and a secondary aim was to explore which programmatic aspect contributed to these changes. This was to inform program improvements and modifications for an international cohort.

Methods

Study Recruitment

People with cancer were informed about the Cancer Coach by CancerAid program by their insurer, employer, or health service and self-enrolled into the program. CancerAid supports people at any time during their cancer experience. CancerAid coaches contacted people who self-enrolled and advised them about the program and the study.

XSL•FO
RenderX

Participants were matched using email addresses and mobile phone numbers to prevent multiple identities for users. Data were collected from August 2020 to November 2022 using secure online forms and databases. This period was chosen due to the consistency of having the same 3 health coaches. The end point was set to analyze data on broader app changes to enhance app integration into synchronous health coaching and ensure its relevance and applicability across an international cohort.

Eligibility criteria included a cancer diagnosis, completion of the PROMIS-10 survey before and after the program, and participation in at least 2 health coaching calls. Health coaches administered the PROMIS-10 questionnaire via phone before the first and after the final coaching call using a standard script for consistency (Multimedia Appendix 1). Use of the CancerAid app (Multimedia Appendix 2) was optional.

Study Design

This study used a nonexperimental evaluative research design to assess the effectiveness of the overall intervention and the programmatic elements that contributed to its effectiveness [28]. All participants in the study received health coaching and access to the CancerAid app. During the study period, there were minor app bug fixes, content changes, and downtimes to enhance performance and security. Details about this can be found in Multimedia Appendix 3. These interruptions did not significantly affect the participants during the study period. As no new features were introduced and app maintenance changes were back end in nature, these were not expected to materially affect user experience or outcomes. Therefore, they were not controlled for in the statistical analysis.

PROMIS-10 Measure

The PROMIS-10 is a standardized and validated tool [29] that established the methodological rigor for this study. The PROMIS-10 contains 10 questions related to the patient's physical, mental, and social health and well-being. The complete PROMIS-10 questionnaire can be found in Multimedia Appendix 1. Patients rate their well-being on a 5-point Likert scale. One question related to pain is rated on a scale from 1 to 10. This score for pain is recomputed to a score out of 5. All 10 question scores are then recalculated to present 2 domain scores: global physical health (GPH) and global mental health (GMH). Both GPH and GMH have a maximum possible score of 20 points. For all items, a higher score equals more of the concept being measured, and a lower score indicates less of the concept being measured. Multimedia Appendix 1 also provides inclusions for calculating GPH and GMH scores.

Although the PROMIS-10 is primarily used to generate composite scores for GPH and GMH, this study also analyzed individual item responses to explore specific symptom changes. While not standard practice, item-level analysis can yield clinically relevant insights [30], particularly in cancer populations where symptoms such as pain, fatigue, and emotional distress are common. These insights may help refine health coaching strategies and enhance understanding of how coaching influences distinct aspects of functioning.

The GPH and GMH scores were recalibrated using the same underlying metric, which corresponds to a normalized T score. The T scores are standardized to the general US population. The average T score for the US population is 50 points, with an SD of 10 points [26,29,31]. PROMIS-10 domains use different cutoff score ranges. The PROMIS-10 GPH score ranges are as follows: excellent (T score>58), very good (T score=50-57), good (T score=42-59), fair (T score=41-35), and poor (T score<35). The PROMIS-10 GMH score ranges are as follows: excellent (T score>57), very good (T score=48-56), good (T score=40-47), fair (T score=39-29), and poor (T score<29) [26].

To identify minimal important change [32] or "meaningful change" [26] in PROMIS-10 scores, a review of the literature found that a 2- to 6-point change in T scores for PROMIS-10 measures could be reasonably considered as an indicator [32]. Minimal important change has been defined as a threshold for a minimal within-person change over a period during which patients perceive themselves to have experienced an important change [32].

Intervention

Cancer Coach by CancerAid is a flexible, evidence-based program designed to support people with cancer over approximately 6 to 12 weeks. It combines telehealth coaching with a mobile app and resources to address key areas such as symptom tracking, nutrition, sleep, exercise, psychosocial well-being, and return to work. The educational content is based on American Society of Clinical Oncology guidelines and findings from large randomized trials, ensuring that topics such as lifestyle interventions and digital symptom tracking are backed by the latest evidence. Support is delivered via a combination of asynchronous digital resources (app, SMS text messages, and emails) and synchronous coaching calls, of which there are approximately 3 throughout the program.

Each participant is paired with a qualified health coach (with backgrounds in allied health, nursing, or medicine) trained in standardized methods that ensure the scope of practice while allowing for a client-centered approach. Coaches provide tailored interventions based on the individual's diagnosis, stage of cancer, and specific needs. They use evidence-based behavior change techniques, including goal setting and review, symptom monitoring, motivational interviewing, feedback and accountability, positive reinforcement, lifestyle education, and social and emotional support. The approach is based on the transtheoretical model of change, with an emphasis on empowering participants to take proactive steps toward improving their health and well-being. Regular communication and digital support help overcome barriers to face-to-face care, creating a supportive framework for sustained self-management and behavior change.

Further information about the Cancer Coach by CancerAid program can be found in the study by Lo et al [21].

Health coaching is complemented by the CancerAid app (now known as the Osara Health app), an mHealth app providing symptom tracking, health information articles, and supportive care resources. Key features include symptom logs, evidence-based articles, and a note-taking feature (Multimedia Appendix 2). The app was designed using principles of

XSL•FO
RenderX

behavioral science and patient-centered care, incorporating elements such as self-monitoring and educational empowerment. The development process of the CancerAid iOS and Android app followed the typical iterative agile development process of planning, design, development, testing, deployment, and review. The app was tested through an automated test suite in addition to manual testing by developers and stakeholders. Throughout the study period, no new features were introduced, and the new releases were limited to maintenance updates. The app was relatively stable during the study period and is archived in a private code repository owned by CancerAid. The app is free and publicly accessible via the Apple App Store and Google Play Store. Participants were encouraged by health coaches to use the app to supplement their health coaching calls.

Statistical Analysis

Physical and mental health were evaluated using the PROMIS-10 measure to determine the impact of Cancer Coach by CancerAid. An examination of the data distribution revealed no evidence of a ceiling effect; scores were well distributed across the full range, indicating adequate variability for analysis. Descriptive statistics were used to establish ranges and means of variables. Tests for normality showed that the data did not fit normal distributions, and therefore, nonparametric testing was used. Raw PROMIS-10 GPH and GMH scores were converted to T scores to compare with US population norms [26,29,31]. A T score of 50 (–10 to +10) is considered to be a healthy score, and well-being descriptors are ascribed based on scores and associated categories (see PROMIS-10 Measure section) [26,33]. Two-tailed *t* tests were used to determine the correlation between the number of calls and app use and changes in GPH and GMH scores. For an exploratory study on individual item score changes, the Wilcoxon signed rank test was used to compare the paired groups to determine whether there was a statistically significant difference ($P \leq .05$). The effect size of the Wilcoxon signed rank test was calculated and considered in terms of the classification of effect sizes by Cohen [34] (0.1=small effect; 0.3=moderate effect; ≥0.5=large effect) [29,34]. Data were analyzed using SPSS (version 29; IBM Corp).

Ethical Considerations

Ethics approval was obtained from the University of Sydney Human Research Ethics Committee (approval 2024/HE000297). Informed consent was obtained from all individual participants to take part in the research. Participation in the study was voluntary. Participant privacy and confidentiality were protected throughout the study in accordance with institutional, national, and international guidelines for human subjects research. No compensation was provided. All data were deidentified prior to analysis, and no identifying information is included in the published results.

Results

Participants

Between August 2020 and November 2022, a total of 200 participants completed a PROMIS-10 survey at either the start or end of the intervention, 93 (46.5%) of whom had both pre- and posttest data. A total of 2% (4/200) of the participants were excluded due to missing data. The 55% (107/200) attrition rate was due to participants not completing the postprogram PROMIS-10 survey for health, family, or work reasons, resulting in a final dataset of 89 participants. Table 1 provides demographic data.

Analysis between the group included in the study (completed pre- and posttest PROMIS-10 questionnaires; n=89) and those not included (did not complete the posttest PROMIS-10 questionnaire; n=111) was conducted. An independent-sample 2-tailed *t* test compared the mean ages of the 2 groups, revealing no significant difference (mean age 51.44 years; $P=.35$). Cross-tabulation analyses of gender showed no significant association (33/111, 30% male; $P=.73$). However, the chi-square test indicated a significant difference between the groups on diagnosis ($P<.001$). Notably, the nonstudy group had 4 times as many cases of an unknown cancer diagnosis compared to the study group. The top 5 cancer types in the group not included in the study were breast, unknown, bowel, blood, and lung. Employers comprised a larger proportion of the referral sources in the nonstudy group (employer: 11/111, 10%; insurer: 92/111, 83%; hospital: 8/111, 7%).

Employer	1 (1.1)
Duration of program (days), mean (SD)	52 (32.5)

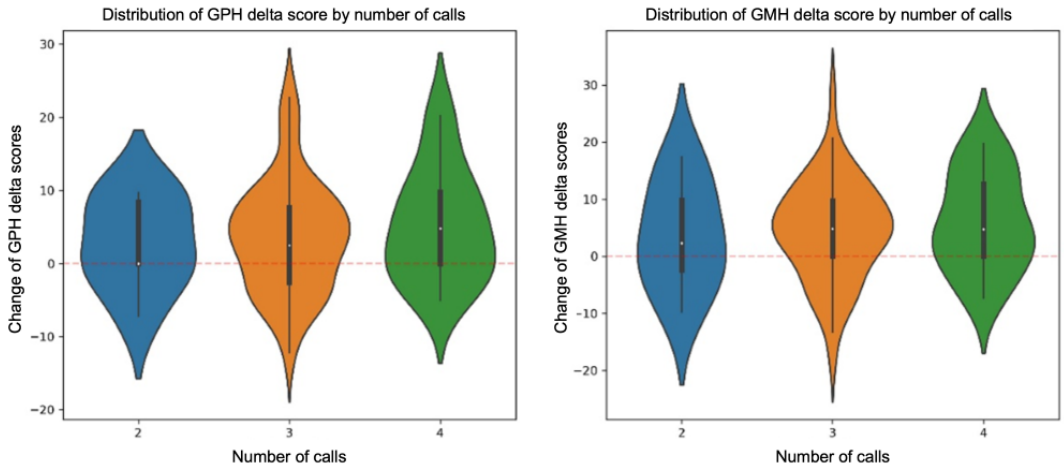
PROMIS-10 Global Health Scores and T Scores

A statistically significant mean change of 4.43 points was observed in the GPH T score (P<.001); however, the score remained within the "Good" category of well-being. Similarly, the mean GMH T score increased by 4.48 points following participation in the Cancer Coach by CancerAid intervention, a change that was also statistically significant (P<.001). The mean postintervention GMH T score was 49.052 (SD 7.4992), indicating an improvement in overall mental health status from "Good" to "Very good." Both the 4.43-point change in the GPH T score and the 4.48-point change in the GMH T score are considered clinically significant. Table 2 outlines changes in both GPH and GMH T scores.

Table 2. Global physical health and global mental health T scores.

	Before the intervention	After the intervention	Mean change (points)	*P* value
Global physical health			4.43	.001
T score, mean (SD)	42 (6.745)	47.09 (6.655)		
Category	Good	Good		
Global mental health			4.58	.001
T score, mean (SD)	44.47 (8.233)	49.052 (7.4992)		
Category	Good	Very good		

Pearson correlations revealed no significant relationship between age and changes in GPH score (r=0.003; P=.98) or GMH score (r=−0.178; P=.10). Independent-sample 2-tailed t tests showed no significant gender differences in GPH score change for male (mean 2.16, SD 3.08) and female (mean 1.60, SD 2.93) individuals (P=.40). For GMH score change, means were 4.27 (SD 9.32) for male individuals and 4.76 (SD 8.10) for female individuals (P=.80). One-way ANOVA showed significant differences in both GPH score change (P=.009) and GMH score change (P=.001) across diagnostic groups. Post hoc analyses (Tukey honestly significant difference) indicated that participants with head and neck cancers had substantially higher GPH and GMH score changes compared with those in several other groups. The combined model including all 3 predictors



XSL•FO
RenderX

(age, sex, and diagnosis) was assessed using multiple linear regression analyses. Neither the model for GPH score change ($F_{3, 85}$=0.30; P=.83; R^2=0.01) or that for GMH score change ($F_{3, 85}$=1.16; P=.33; R^2=0.04) were significant. None of the individual predictors contributed significantly to either model.

Number of Health Coaching Calls and Changes in GPH and GMH Scores

For the call frequency and app usage analysis, 6 of the 89 participants were excluded because they completed more than 4 calls. These values fell outside the expected intervention range and were considered outliers in program engagement. The final analytic sample for this section, therefore, included 83 participants. Figure 1 illustrates the distribution of changes in physical health (GPH) and mental health (GMH) scores across different numbers of health coaching calls. While statistical analysis using ANOVA (Tukey honestly significant difference) showed no significant differences between call frequencies (GPH: P<.69; GMH: P<.74), the consistently wide range of positive score changes for 3, 4, and 5 calls suggests that patients can experience meaningful improvements regardless of call frequency. The presence of positive median values (shown by the white dots in Figure 1) for most call groups indicates an overall trend toward improvement in both physical and mental health scores, with slightly more improvement in physical and mental health with more calls.

Figure 1. Distribution of global physical health (GPH) and global mental health (GMH) scores according to number of health coaching calls.

Use of the App and Changes in GPH and GMH Scores

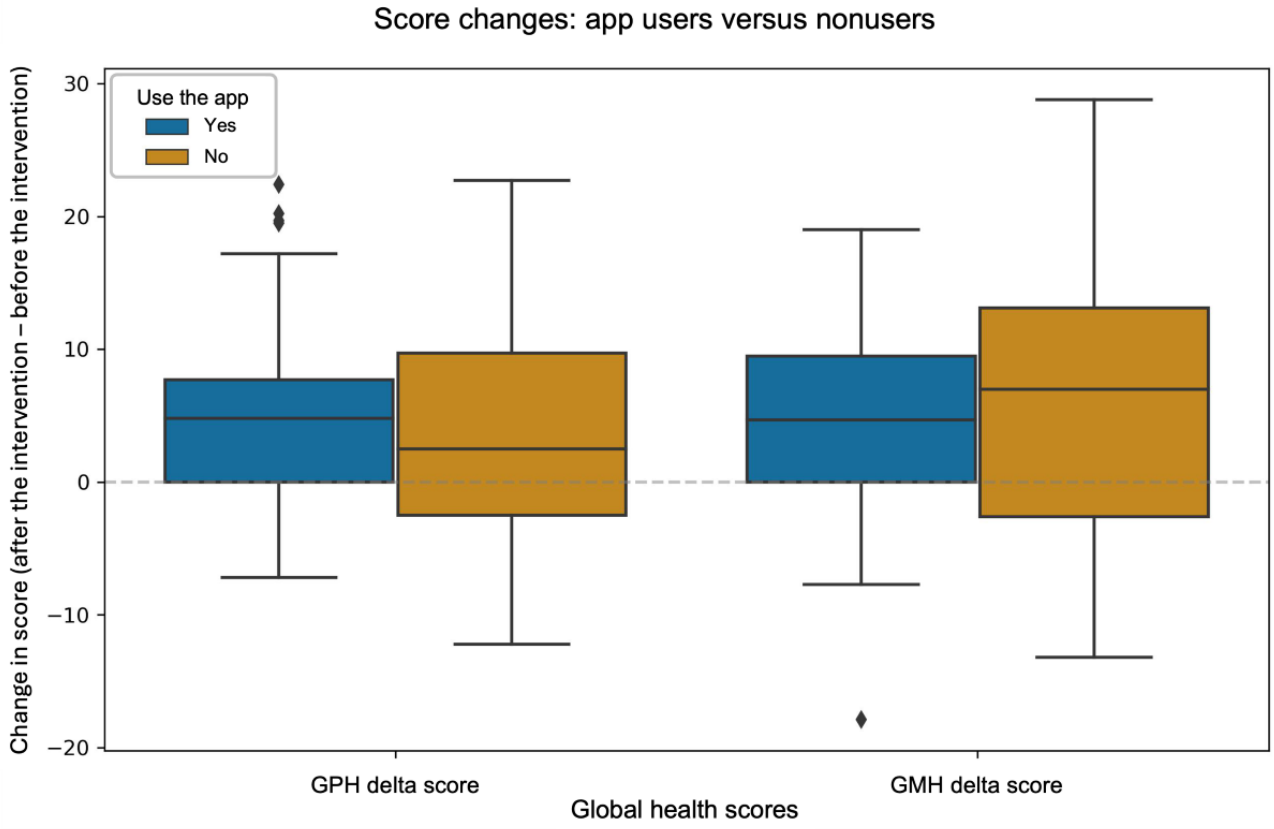


Table 3 outlines the change in GPH and GMH scores between app users (53/83, 64%) and nonusers (30/83, 36%) in the Cancer Coach by CancerAid intervention. Figure 2 shows that both groups exhibited overall positive improvements in their health scores, with median values notably above 0, indicating general health benefits regardless of app use. Non–app users (health coaching calls only) showed slightly higher median improvements in GMH scores 4.74 (SD 10.61) compared to app users (with health coaching calls) 4.63 (SD 7.29); whereas app users (with health coaching calls) had a higher median GPH score change 4.29 (SD 7.15) than participants who only had health coaching calls 3.22 (SD 8.07).

Table 3. Global physical health (GPH) and global mental health (GMH) scores for app users and non–app users.

	GPH point score change	GMH point score change
App users (median)	4.29 (SD 7.15)	4.63 (SD 7.29)
Non–app users (median)	3.22 (SD 8.07)	4.74 (SD 10.61)
t test (*df*)	0.62 (81)	–0.05 (81)
P value	.53	.96

Figure 2. Median and distribution of global physical health (GPH) and global mental health (GMH) scores for health coaching with app use and only use and health coaching calls with no app use.

Discussion

Principal Findings

This study aimed to evaluate the effectiveness of the Cancer Coach by CancerAid program using patient-reported outcomes and how these outcomes were related to the quantity of health coaching calls and mobile app use.

A significant number of participants had a higher GPH score upon completion of the Cancer Coach by CancerAid intervention, and the improvement was deemed clinically significant. GPH includes items of general physical health, ability to carry out daily activities, pain, and fatigue. Many mHealth programs aim to improve physical health with a focus on exercise oncology [35]. However, participants in the Cancer Coach by CancerAid program improved their physical well-being through a more holistic approach to mHealth via support for management of pain and fatigue levels and addressing a range of barriers to participation in everyday activities, including work [21,36]. Studies have shown mixed results in terms of mHealth programs reducing fatigue and pain levels [17,37,38]. The significant change in GPH score in this study could be related to improvements in fatigue and pain levels (see Multimedia Appendix 4 for individual score results in this study). Participating in the Cancer Coach by CancerAid program appears to be related to improved physical health through a personalized goal setting and psychoeducation approach rather than an exercise oncology focus. These findings contribute to the growing body of research supporting the benefits of nonpharmacological interventions to improve physical well-being and fatigue experienced by people with cancer. The magnitude of improvement observed in PROMIS-10 scores in this study is consistent with findings of other digital health coaching interventions. For example, there have been similar gains in PROMIS-10 GPH and GMH scores reported among veterans receiving telephone-based coaching [13]. Chow et al [5] also found improved mental health using a mobile coaching intervention among survivors of cancer. These improvements in PROMIS-10 scores, particularly in domains such as fatigue, emotional well-being, and social roles, have important implications for participants' broader cancer experiences [5]. They may reflect enhanced self-efficacy, functional recovery, and psychosocial adjustment across the different stages of diagnosis, treatment, and survivorship.

A significant number of participants had a higher GMH score upon completion of the Cancer Coach by CancerAid intervention, and the improvement was considered clinically significant. GMH includes items of quality of life, mental health (mood and cognition), social activities and relationships, and emotional well-being (anxiety and depression). Importantly, the average change in GMH T score moved the overall score of the group from a rating of "good" to a rating of "very good" mental health at the end of the program. Although not a counseling service, there are psychosocial aspects of the Cancer Coach by CancerAid intervention that support emotional well-being and improve participants' sense of agency, which was possibly related to the improved mental health scores. These results are similar to those of recent systematic reviews that have shown that mHealth interventions effectively reduce

XSL•FO
RenderX

anxiety and depression in patients with cancer [39] and improve quality of life [16].

Cancer Coach by CancerAid provides holistic care, addressing the physical and emotional support needs specific to the participant regardless of whether they are early or later in their cancer experience. The improved GPH and GMH scores indicate that the program could be providing this. Similarly, a holistic approach, such as health coaching, can also be beneficial in addressing aspects of health and well-being in a collective way [9,40]. A previous study of Cancer Coach by CancerAid also indicated that participation assisted people with cancer in resuming work activities [21]. This holistic approach could also provide a more effective form of health service delivery as it targets a wider group of people with cancer. If a digital and telehealth coaching program can assist with improving pain, fatigue, and mental and physical health, this may also have a cost benefit by reducing health care use, such as general practitioner consultations [41] and hospital visits [42,43].

There was inconclusive evidence as to which mHealth programmatic aspect of the Cancer Coach by CancerAid program contributed to the positive GPH and GMH scores. Participants who only had health coaching calls and no app use had slightly higher GMH scores than those who used both the app and the calls. However, participants who used the app and health coaching calls had a slightly higher GPH score than participants who only had health coaching calls. It is possible that the synchronous telephone health coaching aspect of Cancer Coach by CancerAid had more influence on participants' mental health and well-being than the asynchronous app, but this requires further investigation. Overall, the comparable outcomes between app users and nonusers suggest that patients can benefit from the Cancer Coach by CancerAid program through multiple engagement pathways, allowing for flexibility in how they choose to participate in their care journey. Additionally, the flexibility in call frequency may be beneficial for personalizing support schedules to individual patient needs and circumstances rather than requiring a fixed number of calls for all patients, acknowledging that higher GPH and GMH score changes were experienced by those with more calls, although this was not significant. These findings are similar to those of a systematic review that examined synchronous, asynchronous, and mixed approaches to delivering mHealth interventions to patients with cancer and found that the mode of delivery did not influence outcomes [17]. Understanding the most effective form of delivery is critical for developing evidence-based practice and cost-effective service delivery, so 3-arm randomized controlled trials are recommended [17] to better understand the effectiveness of mHealth programmatic aspects and health outcomes.

Limitations

Pilot studies are often conducted to obtain information in preparation for a larger trial. Therefore, the findings of this study should be interpreted with an understanding of the relatively small sample size and the absence of a control group. While all participants during this study completed the Cancer Coach by CancerAid program, the 55% (107/200) attrition rate refers specifically to noncompletion of the postprogram PROMIS-10 survey. This lack of follow-up data may have biased the study results toward those who experienced greater improvement as those who did not complete the survey may have had less positive outcomes. Therefore, it is possible that a higher survey completion rate could have revealed weaker overall effects.

Because Cancer Coach by CancerAid supports participants at any stage of the cancer journey, certain stages may result in better or worse scores. Although analysis showed no significant differences in age or gender between participants included in the study and those excluded due to missing postintervention PROMIS-10 data, there were notable differences in cancer diagnosis and referral source. A significantly higher proportion of excluded participants had an unknown cancer diagnosis, and the distribution of cancer types varied, potentially impacting the representativeness of the study sample. Additionally, a greater proportion of excluded participants were referred by employers rather than insurers or hospitals, suggesting possible differences in case characteristics or motivations for program enrollment. These factors may limit the generalizability of the findings to all program participants.

While there may be a lack of information about the stage of cancer and participants' details, this is seen as a benefit for our participants, who can be cautious about oversharing their personal and health information. This approach may also increase the number of people willing to enroll in the Cancer Coach by CancerAid program. The participants were 64% (57/89) female, with breast cancer being the dominant diagnosis, which may contribute to gender bias but also reflects men's reluctance to seek psychological or emotional help when dealing with cancer [44]. Additionally, race and ethnicity data were not collected as part of this study. This aligns with CancerAid's model of minimizing data collection to reduce barriers to participation but limits the ability to evaluate cultural or demographic variability in outcomes.

Health coaching is provided to meet individual needs and goals and uses techniques of goal setting and motivational interviewing, among others. All coaches were trained using the same models and methodologies to ensure consistency across techniques used and program reliability. Although the coaches followed consistent methodologies, differences in communication style and participant responsiveness could lead to variability in the results. To reduce potential bias with health coaches administering the PROMIS-10 survey, alternative approaches should be considered. A self-administered digital option within the app could offer greater privacy and autonomy, although it may risk lower completion rates. Another option is to have the survey administered by a neutral third party, which could help preserve objectivity while maintaining engagement.

Further studies on this program will need to focus on more robust data collection on app engagement, comparison with a control group, and extended use of the PROMIS-10 to evaluate sustained changes in functioning. Qualitative studies should consider content analysis of coaching calls to ascertain techniques affecting change and focus groups to gain participants' personal views and experiences of the Cancer Coach by CancerAid program. Given the multiple options in the delivery of mHealth solutions and the variance in reporting

XSL•FO
RenderX

interventions in research, more evidence is required to establish the effectiveness of specific modes of delivery as well.

Conclusions

Participants with various cancer diagnoses showed a significant and positive change in physical and mental health after taking part in the Cancer Coach by CancerAid program as indicated through the PROMIS-10 survey. These preliminary results suggest that clinical practice, including a mixed delivery of synchronous (telehealth coaching) and asynchronous (mobile app) interventions, provides holistic care and may improve physical and mental health and well-being for those with cancer. This type of intervention appears to constitute a potential option for patients with cancer who have unmet needs within traditional health care systems.

Abstract

Background: Myeloid neoplasms (MNs) are most frequently diagnosed among adults aged 60 years and older. Cancer and chemotherapy can cause gait disturbances and increase fall risk in older adults with MNs. Exercise may improve gait, but there is a lack of research among older adults with MNs undergoing active chemotherapy.

Objective: We explored gait changes following a home-based mobile health exercise intervention during 2 cycles of outpatient chemotherapy (8-12 weeks).

Methods: In a single-arm pilot study, we included adults aged 60 years and older with MNs undergoing chemotherapy. Geriatric Oncology-Exercise for Cancer Patients intervention integrates a progressive aerobic walking and resistance exercise program with a mobile app. We assessed gait by using a waist-worn G-Walk motion sensor during a 6-minute walk at the preintervention and postintervention time points. Spatiotemporal outcomes included cadence (steps per minute), velocity (meters per minute), normalized stride (stride length normalized over height), and swing duration (percentage of the gait cycle during which a foot is in the air when walking). Regularity outcomes that measure gait rhythm included variability of normalized stride and variability of swing duration. Variability for both outcomes was quantified as the SD across all gait cycles. We calculated Cohen *d* effect sizes (ESs) for change in gait outcomes and used the Spearman rank correlation to correlate changes in daily steps and resistance exercise duration with gait outcomes.

Results: We included 13 patients (mean age 71, SD 4.8 years); most were male (n=8, 61.5%), White individuals (n=12, 92.3%), and non-Hispanic individuals (n=13, 100%). Average daily steps were 3084 (SD 1765.5) at the preintervention time point and 3757 (SD 2623.6) at the postintervention time point. Patients performed resistance exercises for 25 minutes per day, 4 days per week at low intensity (mean rating of perceived exertion 3/10, SD 1.3). At the postintervention time point, we observed numerical changes in gait outcomes, including increased cadence (mean +4.6, SD 14.6 steps per minute; *P*=.24; ES=0.38) and decreased variability in normalized stride (mean −1.4%, SD 8.5%; *P*=.34; ES=−0.18) and swing duration (mean −0.1%, SD 1.1%; *P*=.54; ES=−0.15), although these improvements were not statistically significant. Increased daily steps significantly correlated with

XSL•FO
RenderX

decreased swing duration variability (r=−0.72; P=.01). Resistance exercise duration significantly correlated with increased cadence (r=0.54; P=.06) and velocity (r=0.56; P=.05).

Conclusions: In our exploratory analyses, better adherence to exercise correlated with improved gait outcomes. Our ongoing pilot randomized controlled trial (ClinicalTrials.gov identifier: NCT04981821) will further examine the effects of the Geriatric Oncology-Exercise for Cancer Patients intervention on gait outcomes in this population.

exercise intervention; gait; mobile health; older adults; myeloid neoplasms

Introduction

Gait is an important indicator of overall health and functional status [1-3]. Although walking speed is a well-recognized marker of many health outcomes, it arises from more granular aspects of gait, including both spatiotemporal measures (eg, gait speed, stride length, cadence, and symmetry) and regularity measures (eg, variability of stride length) [1,4,5]. Cancer and its treatments can contribute to disturbances in these more detailed aspects of gait long before measurable loss in gait speed or function [6]. Possible pathways include musculoskeletal effects, including fatigue and sarcopenia, which influence body movement, and neurological effects, including direct tumor infiltration or compression and chemotherapy-induced neurotoxicity [6]. For example, chemotherapy-induced peripheral neuropathy in older adults with cancer is commonly associated with shorter step length, loss of symmetry or synchrony, and greater step width variability in addition to slower gait speed [3,7]. Gait disturbances have been linked to poor clinical outcomes, including falls, unplanned hospitalizations, emergency department visits, and mortality [2,3]. While habitual physical activity may mitigate some adverse effects of cancer and its treatments, gait disturbances still occur in older adults with cancer [8]. Therefore, there is a need for interventions that can help maintain normal gait in this population.

Myeloid neoplasms (MNs; eg, acute myeloid leukemia [AML] and myelodysplastic syndrome [MDS]) are most frequently diagnosed among adults aged 60 years and older [9]. Older adults with MNs are vulnerable to gait disturbances due to the combined effects of aging, cancer, and treatment-induced toxicities [3,7,10]. Despite the growing number of studies on exercise interventions in older adults with cancer, the impact of specific exercise programs on gait outcomes in older adults with MNs undergoing active chemotherapy is understudied. We previously established the feasibility and usability of a single-arm mobile health exercise program for older adults with MNs [11]. Using data from this pilot study, we aimed to explore (1) changes in gait outcomes following exercise and (2) correlations of exercise adherence with changes in gait outcomes.

Methods

Study Design, Setting, and Participants

We conducted a single-arm pilot study at the University of Rochester Medical Center (ClinicalTrials.gov identifier: NCT04035499) to evaluate the feasibility of a mobile health exercise intervention, Geriatric Oncology-Exercise for Cancer Patients (GO-EXCAP), for older adults with MNs. Patients were screened and recruited between February 2020 and July 2021. Eligible patients were approached after confirming with their treating oncology team. Eligibility criteria were (1) age of 60 years and older; (2) being English speakers; (3) diagnosis of an MN, such as AML, MDS, or MDS and myeloproliferative neoplasm overlap; (4) undergoing outpatient chemotherapy; (5) a physician-verified Eastern Cooperative Oncology Group (ECOG) performance status of 0 to 2; (6) ability to walk 4 m; and (7) capacity to provide informed consent. Individuals were excluded from the study if they (1) had medical contraindications to exercise as determined by their treating oncologists, (2) had a low platelet count on the most recent complete blood count (ie, ≤10,000 platelets per microliter), and (3) did not receive platelet transfusion (eg, due to platelet refractoriness). Findings from the primary study have been previously reported [11].

This study is a secondary analysis of data from the parent study [11]. We report this analysis following the TREND (Transparent Reporting of Evaluations With Nonrandomized Designs) guidelines for nonrandomized evaluations of behavioral and public health interventions (Table S1 in Multimedia Appendix 1).

Intervention and Study Procedures

GO-EXCAP is a mobile health exercise intervention developed to promote successful behavior change by using evidence-based approaches to improve exercise self-efficacy (ie, verbal persuasion, social modeling, imaginal experiences, and provision of regular monitoring and feedback on mastery as well as emotional and physiological states).

GO-EXCAP integrates the registered and copyrighted home-based exercise intervention Exercise for Cancer Patients (EXCAP) with the GO-EXCAP mobile app. The EXCAP intervention was designed and delivered by American College of Sports Medicine–certified clinical exercise physiologists and has been tested in multiple studies [12-14]. It consists of progressive aerobic walking and resistance band exercise prescribed by a clinical exercise physiologist during a one-on-one in-person teaching session. The exercise physiologist generated individually tailored exercise prescriptions for each participant, increasing their baseline daily steps weekly by 5% to 20%. Between 5% and 20% weekly increase in steps would allow individuals classified as sedentary (ie, <5000 steps) to progress toward or achieve an active classification (ie, ≥10,000

XSL•FO
RenderX

steps) over an 8- to 12-week intervention period. The 5% to 20% step progression rate was individualized based on three key criteria: (1) average daily step counts at baseline, (2) participants' physical capability and perceived readiness, and (3) weekly performance during the intervention. The strategy used to determine the weekly progression rate was described in Multimedia Appendix 2. For resistance band exercise, participants also received individualized prescriptions based on their baseline fitness level. The protocol began with 1 set of 8 to 15 repetitions for 16 exercises, using color-coded resistance bands appropriate for individual strength. Under the instruction of exercise physiologists, participants progressed weekly by increasing sets and repetitions until reaching 4 sets of 15 repetitions. Upon reaching this milestone, participants transitioned to a heavier resistance band and repeated the progression. Throughout the intervention, participants were instructed to perform both aerobic walking and resistance band exercises at a low to moderate intensity, corresponding to a rating of perceived exertion (RPE) of 3 to 5 on a scale from 1 to 10 (1="not tired at all"; 10="extremely tired") [15]. We provided participants with a GO-EXCAP kit containing a printed manual, an activity tracker to record daily steps (Garmin Forerunner 35), 3 therapeutic bands with resistance levels corresponding to 2 to 14 pounds, and a tablet preloaded with the GO-EXCAP app. The exercise physiologist monitored participant-entered exercise data on the app and adjusted prescriptions as needed.

The EXCAP intervention lasted 6 weeks in prior trials [12-14]. Because chemotherapy for MNs is typically 4 weeks per cycle, the intervention duration was extended to align with 2 chemotherapy cycles. Given that chemotherapy delays are common in clinical practice, the GO-EXCAP intervention lasted 8 to 12 weeks, or 2 chemotherapy cycles.

Measures

Demographic and Clinical Characteristics

Demographic and clinical characteristics collected at baseline included age, sex, race, ethnicity, marital status, educational attainment, ECOG performance status, cancer type, and chemotherapy cycle at the initiation of the intervention. The ECOG performance status is a validated and widely used scale to assess a patient's ability to perform daily activities, with scores ranging from 0 (fully active) to 5 (deceased). ECOG scores are associated with various health outcomes in patients with cancer, including emergency department visits, hospitalizations, and mortality [16].

Exercise Adherence

During the intervention, daily exercise data collected through the GO-EXCAP app included the number of steps from the activity tracker and self-reported minutes of resistance band exercise and RPE on a scale from 1 to 10 for EXCAP exercises [17]. These metrics provide a comprehensive representation of exercise adherence across exercise type, frequency, duration, and intensity.

Gait Outcomes

Participants wore a G-Walk motion sensor (BTS Bioengineering) around the waist while performing the 6-minute walk at baseline and the postintervention time point. All assessments were administered and supervised by clinical exercise physiologists. The exercise physiologists instructed participants to walk as fast as they could on level ground for up to 6 minutes. The G-Walk motion sensor is a noninvasive, lightweight, waist-worn device equipped with a triaxial accelerometer, gyroscope, magnetometer, and sensor fusion. It collects gait data and transmits them to the G-Studio software (BTS Bioengineering) through a Bluetooth connection for functional evaluations of walking. Prior to performing any assessments, all clinical exercise physiologists completed study-specific training and followed standardized operating procedures to ensure consistency and adherence to the protocol. All assessments were periodically audited by a second trained clinical exercise physiologist to ensure procedural fidelity and interrater reliability across exercise physiology personnel.

Figure 1 describes a gait cycle consisting of stance and swing phases. We measured both the spatiotemporality and regularity of gait (Table 1) [18]. The spatiotemporal outcomes included walking distance covered in 6 minutes (meters), cadence (steps per minute), velocity (meters per minute), stride length (meters), normalized stride (percentage of height), general symmetry index (GSI), stance duration (percentage of gait cycle), and swing duration (percentage of gait cycle). Regularity outcomes that measured gait rhythm included variability of normalized stride (percentage of height) and variability of swing duration (percentage of gait cycle).

XSL•FO
RenderX

Figure 1. An overview of the walking gait cycle (with the right leg as the reference leg).

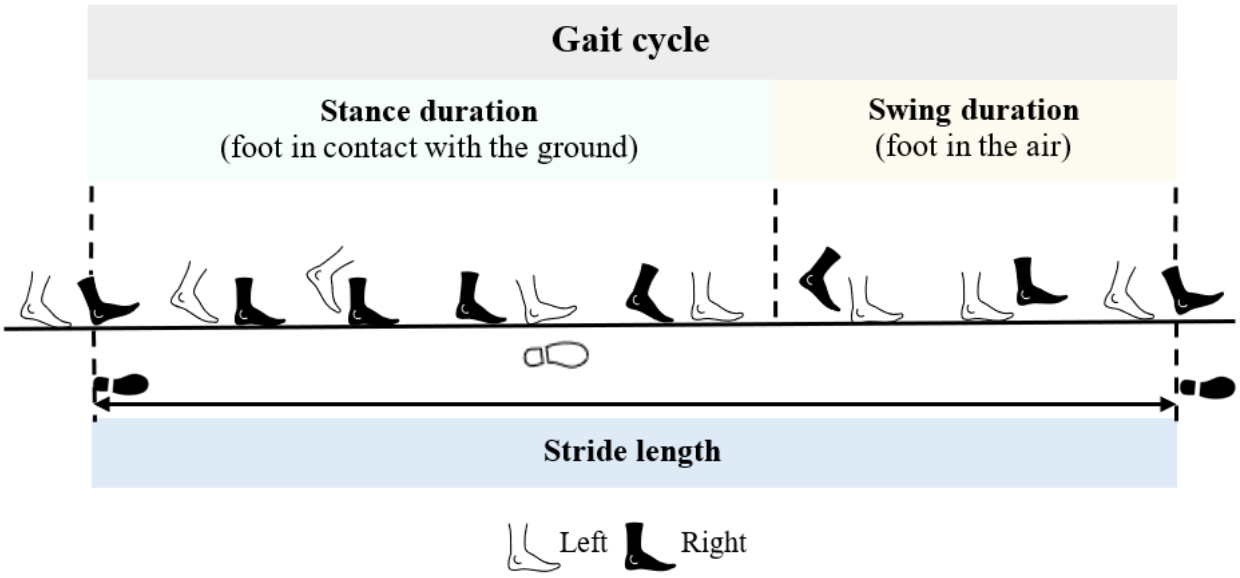

Table 1. Gait outcomes measured during the 6-minute walk test[a].

Dimension and outcome	Definition
Spatiotemporality	
Walking distance	The distance covered in 6 min (meters); higher is better
Cadence	The number of steps per minute; higher is better
Velocity	The distance covered per minute (meters per min); higher is better
Stride length	The distance covered from the moment one foot hits the ground to the next time that same foot touches the ground again (meters), equivalent to the length of a full gait cycle; higher is better
Normalized stride	Normalized over height: calculated as normalized stride length = stride length (meters)/height (meters); higher is better
General symmetry index	An index ranging from 0% to 100% indicating symmetry between the right and left gait cycles based on the comparison of the antero-posterior acceleration component; higher is better
Stance duration	The percentage of time for which a foot remains in contact with the ground (optimal range: 60%-62%); bilateral stance duration is calculated using the average of the left and right stance durations
Swing duration	The percentage of time for which a foot is in the air during walking (optimal range: 38%-40%); bilateral swing duration is calculated using the average of the left and right swing durations
Regularity	
Variability of normalized stride	The SD of stride length across all gait cycles; lower is better
Variability of swing duration	The SD of swing duration across all gait cycles; lower is better

[a]The variability of stance and swing duration is identical due to the statistical relationship between them (stance + swing duration = 100%). Therefore, we reported only the variability of swing duration in this study.

Statistical Analysis

Participants with gait outcomes available at both baseline and the postintervention time point were included in the analyses. To evaluate potential selection bias, we compared baseline characteristics between participants included in this analysis and those who were not. For participants included in this analysis, we described their characteristics, exercise adherence, and gait outcomes. Depending on the data distribution, we used paired 2-tailed *t* tests or Wilcoxon signed-rank tests to evaluate within-subject changes in each gait outcome from baseline to the postintervention time point. We also calculated Cohen *d* effect sizes (ESs) to quantify changes from baseline to the postintervention time point (small effect: 0.20 to <0.50; moderate effect: ≥0.50 to <0.80; large effect: ≥0.80) [19]. Spearman correlation analyses were conducted to assess the correlations of changes in daily steps and the duration of resistance band exercise with changes in gait outcomes. Individual data were presented in scatterplots to detect potential influential observations. In sensitivity analysis, we repeated the Spearman correlation analyses after excluding one observation

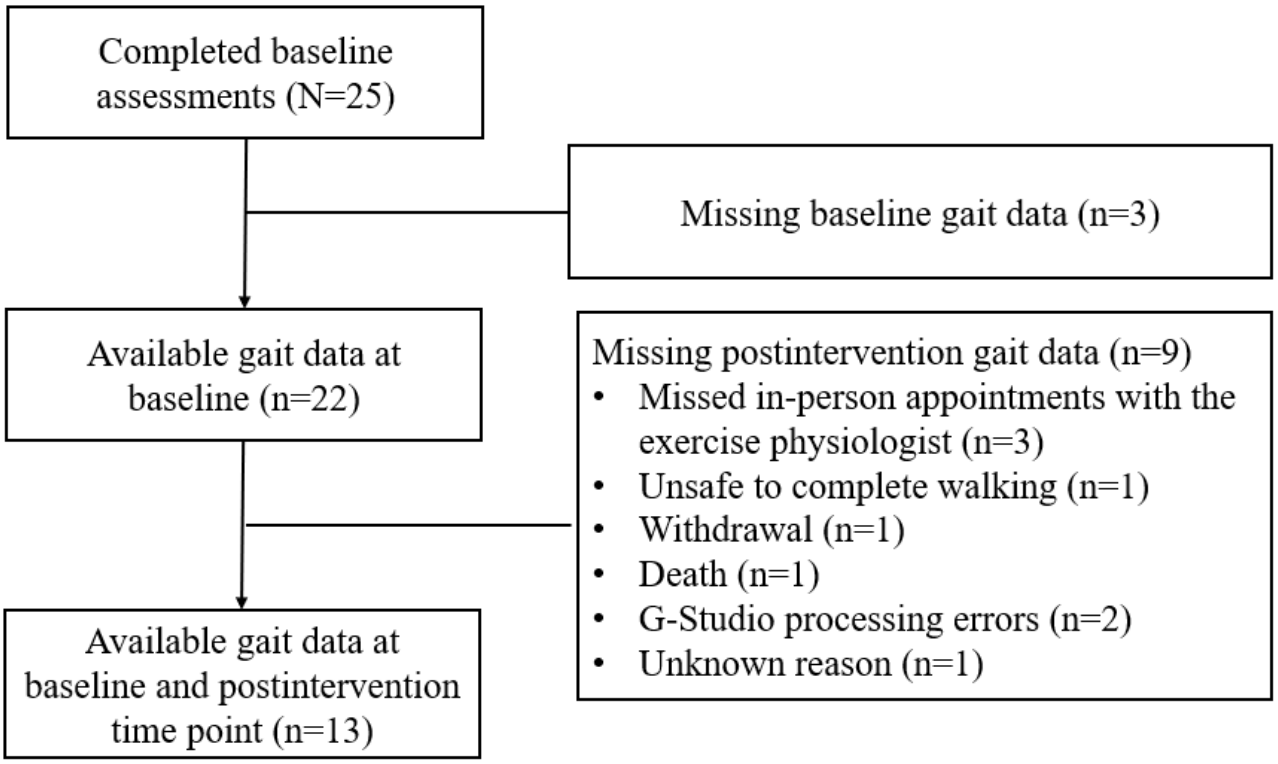
XSL•FO
RenderX

that was more than 1.5 IQRs below the first quartile and did not follow the general trend of the rest of the data.

Given the exploratory nature of this analysis and the small sample size, no imputation methods were applied. A complete-case approach was used for all analyses. We performed hypothesis testing at an α value of .10 (2-tailed). All analyses were conducted using SAS (version 9.4; SAS Institute).

Ethical Considerations

The parent study was approved by the Research Subjects Review Board of the University of Rochester (study ID: STUDY00003945), and all participants provided informed consent. To ensure participant privacy and confidentiality, all data were deidentified and managed via REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web application accessible only to authorized research personnel. Participants received US $50 in compensation after completing all baseline and postintervention activities. The original ethics approval covers secondary analysis, and thus, no additional consent was required for this study.



Results

Participant Characteristics and Exercise Adherence

We included 13 participants in this analysis (Figure 2). Of the 25 participants enrolled, 3 (12%) had missing baseline gait data due to logistical issues (eg, Bluetooth connection error). Of the 22 participants with available baseline gait data, 13 (59.1%) completed postintervention gait measures. Reasons for missing postintervention gait data included missed in-person appointments with the exercise physiologist due to health decline (3/22, 13.6%), being unsafe to complete walking (1/22, 4.5%), withdrawal (1/22, 4.5%), death (1/22, 4.5%), G-Studio processing errors (2/22, 9.1%), and unknown reasons (1/22, 4.5%). Comparison of baseline characteristics between participants included in the analysis and those who were not did not reveal substantial differences (Table S1 in Multimedia Appendix 3).

Table 2 describes the characteristics and exercise adherence of the 13 participants with both baseline and postintervention gait data. These participants had a mean age of 71 (SD 4.8) years, and most were White (n=12, 92.3%) and non-Hispanic (n=13, 100%) individuals. More than half were male (n=8, 61.5%), married (n=9, 69.2%), and college graduates or of higher educational levels (n=7, 53.8%). Most participants were diagnosed with AML (n=7, 53.8%) or MDS (n=5, 38.5%). These 13 participants had a mean of 3084 (SD 1765.5) daily steps at baseline and 3757 (SD 2623.6) daily steps at the postintervention time point. On average, they performed resistance band exercises for 4 days per week, 25 minutes per day, with a mean RPE of 3/10 (SD 1.3). No adverse events were reported related to the intervention [11]. Overall, this intervention demonstrated excellent tolerability among older adults with MNs.

Change in Gait Outcomes From Baseline to the Postintervention Time Point

Table 3 describes gait outcomes at baseline and the postintervention time point and changes in these measures. At baseline, participants walked an average of 408.0 (SD 128.8) m in the 6-minute walk test, with a cadence of 110.9 (SD 12.4) steps per minute and a velocity of 82.0 (SD 21.8) meters per minute. The mean GSI was 95.1% (SD 3%). Stance duration accounted for an average of 59.9% (SD 1.9%) of the gait cycle, with a mean stance duration variability of 0.8% (SD 0.9%).

From baseline to the postintervention time point, we observed a numerical increase in average cadence (mean +4.6, SD 14.6 steps per minute; *P*=.24; ES=0.38) and velocity (mean +1.6, SD 8.2 meters per minute; *P*=.24; ES=0.07). We also observed a numerical increase in stance duration (mean +0.4%, SD 2.3%; *P*=.55; ES=0.20) and a numerical decrease in swing duration (mean −0.4%, SD 2.3%; *P*=.55; ES=0.20), which together brought stance and swing durations closer to their optimal ranges (Table 3). In terms of regularity outcomes, we observed a numerical decrease in variability for both normalized stride (mean −1.4%, SD 8.5%; *P*=.34; ES=−0.18) and swing duration (mean −0.1%, SD 1.1%; *P*=.54; ES=−0.15). None of these outcomes were statistically significant.

Table 3. Change in gait outcomes from baseline to the postintervention time point (n=13).

	Baseline		Postintervention time point		Change from baseline to postintervention time point			
	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)	*P* value	Effect size

Correlations Between Both Change in Daily Steps and Resistance Exercise Duration and Changes in Gait Outcomes

Table 4 presents the correlations between changes in daily steps and duration of resistance band exercise with changes in gait outcomes. Increased daily steps significantly correlated with decreased swing duration variability (*r*=−0.72; *P*=.01). Duration of resistance band exercise significantly correlated with increased distance covered in the 6-minute walk test (*r*=0.62; *P*=.03), cadence (*r*=0.54; *P*=.06), velocity (*r*=0.56; *P*=.05), and stance duration (*r*=0.58; *P*=.04). We did not observe significant correlations for other gait outcomes.

Scatterplots showing the relationship between changes in gait outcomes and changes in exercise are shown in Figures S1 and S2 in Multimedia Appendix 3. In sensitivity analysis excluding one potential influential observation (Table S2 in Multimedia Appendix 3), the correlations remained largely consistent. Increased daily steps continued to be correlated with reduced swing duration variability (*r*=−0.64; *P*=.02). Similarly, longer resistance band exercise duration was correlated with improved walking distance (*r*=0.59; *P*=.04) and velocity (*r*=0.54; *P*=.07). Correlations of resistance band exercise duration with cadence (*r*=0.45; *P*=.14) and stance duration (*r*=0.50; *P*=.10) remained in the same direction.

Table 4. Correlations between change in gait outcomes and change in exercise (n=13).

Gait parameter	Change in daily steps		Duration of resistance training (min)	
	r	*P* value	*r*	*P* value
Change in spatiotemporal outcomes				
6-min walking distance (meters)	0.16	.59	0.62	.03
Cadence (steps per min)	0.20	.51	0.54	.06
Velocity (meters per min)	0.24	.43	0.56	.05
Stride length (meters)	0.05	.87	0.03	.93
Stride length (% of height)	0.05	.87	0.03	.93
General symmetry index (%)	0.10	.75	0.19	.54
Swing duration (% of cycle)	0.26	.38	−0.58	.04
Stance duration (% of cycle)	−0.26	.38	0.58	.04
Change in regularity outcomes				
Stride length variability (% of height)	−0.24	.43	−0.15	.62
Swing duration variability (% of cycle)	−0.72	.01	0.10	.75

Discussion

In this pilot mobile health exercise study for older adults with MNs, we observed numerical changes in several gait outcomes, including cadence (mean +4.6, SD 14.6 steps per minute; *P*=.24; ES=0.38), stance duration (mean +0.4%, SD 2.3%; *P*=.55; ES=0.20), swing duration (mean −0.4%, SD 2.3%; *P*=.55; ES=0.20), and variability in normalized stride (mean −1.4%, SD 8.5%; *P*=.34; ES=−0.18) and swing duration (mean −0.1%, SD 1.1%; *P*=.54; ES=−0.15). Better intervention adherence significantly correlated with improved gait outcomes. These findings suggest that adherence to the GO-EXCAP mobile health exercise intervention shows promise in improving gait in this population.

To our knowledge, no studies have evaluated gait outcomes following exercise interventions in older adults with MNs. Therefore, we compare our results to those of previous research on older adults with other types of cancer. In a 12-week program incorporating electromyostimulation, light-intensity exercise, and dietary support for patients with advanced-stage solid cancers (mean age 62.4 years), participants in the intervention arm (n=26) showed improvements in mean cadence (+4.2 steps per minute) and stance duration (0.5% closer to the optimal range) [20]. In another 8-week home-based resistance training for older patients with advanced cancer (n=30; median age 75 years), mean gait velocity increased by 2.4 meters per minute among those with ≥80% intervention compliance [21]. While these interventions differ from ours in exercise type and duration, the favorable changes in gait outcomes observed are comparable. Taken together, these studies suggest that exercise interventions, including GO-EXCAP, have the potential to address spatiotemporal outcomes in older adults with cancer and need to be studied further.

In addition to commonly analyzed spatiotemporal outcomes, our study expands the literature by evaluating gait symmetry in older adults with MNs. Gait asymmetries are clinically relevant as they have been linked to a high risk of fall [22,23]. There are several likely explanations for the lack of significant change in symmetry in our sample. First, the GSI reported in our study (95.1%) is slightly higher than that reported for healthy adults aged 61 years and older (92%-94%) [24]. Although there is a lack of normative data for this measure, this value suggests that our study sample may have preserved physical function, reflected in a relatively good gait symmetry at baseline, leaving limited room for improvement. In addition, symmetry can be assessed in different movement directions, such as anterior or posterior (evaluated in our study) and medial or lateral. Several studies have linked pathological gait patterns to a higher risk of falls in the medial or lateral direction, suggesting that non–anterior or posterior assessments may provide more valuable insights into gait symmetry [4]. Future studies are warranted to determine which gait symmetry measures are most sensitive in detecting clinically relevant pathological gait outcomes.

Adherence to GO-EXCAP shows promise in improving the variability of stride and swing duration, which quantifies the automaticity and regularity of gait, among older patients with MNs. Increased gait variability is associated with a higher risk of falls, frailty, and incident mobility disability [25-27]. Notably, gait variability may be a more sensitive marker than spatiotemporal outcomes (eg, gait velocity) for detecting pathological gait in older adults with cancer who report peripheral neuropathy [7]. Despite its predictive values, we found only one previous study that evaluated gait variability following an exercise intervention, and the authors reported no significant changes [20]. Thus, our study expands the literature by demonstrating a statistically significant correlation between adherence to the GO-EXCAP intervention and improved gait regularity in older adults with MNs. Increased exercise, including progressive aerobic walking, may improve gait regularity through enhancing motor control and gait automaticity [28]. More studies are needed to better understand these underlying mechanisms.

XSL•FO
RenderX

The strengths of this study include the use of a user-friendly and noninvasive motion sensor to measure gait outcomes, which allowed for efficient gait dataset management, and the comprehensive measurement of gait by including both spatiotemporal and regularity outcomes. Several limitations should also be noted. First, given the pilot nature of this study, the correlation analyses were exploratory and hypothesis generating. Second, the single-arm design without a control group prevents us from determining whether observed gait improvements are attributed directly to the intervention. Third, the small sample size limited our ability to adjust for potential confounders or provide CI estimates for correlation analysis. Additionally, to our knowledge, established minimal clinically important difference thresholds for gait outcomes are not available for general older adults or for older adults with cancer. Therefore, it remains unclear whether the observed improvements in gait outcomes reached a clinically meaningful threshold. Finally, there is no consensus on clinically meaningful differences in gait spatiotemporality and regularity outcomes. Therefore, our correlation analysis between change in gait outcomes and change in exercise should be interpreted as exploratory and is primarily useful to guide future larger analyses of similar outcomes in this population.

In conclusion, we found that greater exercise adherence to GO-EXCAP significantly correlated with improved gait outcomes, suggesting that the combination of aerobic and resistance training has the potential to improve gait quality in inactive older adults with cancer. Our ongoing pilot randomized controlled trial (ClinicalTrials.gov identifier: NCT04981821) will further examine the effects of the GO-EXCAP intervention on gait outcomes in this population and assess whether improvements in gait are associated with better functional outcomes, including reduced falls.

Abstract

Background: Cervical cancer is the fourth most common cancer among women globally, with an estimated 660,000 new cases and 350,000 deaths in 2022. It imposes a disproportionate burden on underserved populations in low- and middle-income countries, where language barriers, cultural stigma, and limited access to health care hinder awareness and uptake of preventive measures.

Objective: This study aimed to design, develop, and evaluate a multilingual AI-driven dialogue system for cervical cancer awareness, personalized risk assessment, and health care facility navigation, targeting underserved populations through a culturally adaptive and privacy-preserving digital health platform.

Methods: A design science research framework guided the development of a 3-tier, cross-platform system comprising (1) a transparent, rule-based risk-stratification engine whose 30-item questionnaire mirrors the feature schema of the University of California, Irvine (UCI) Cervical Cancer Risk Factors dataset and whose weights encode established clinical risk factors drawn from World Health Organization, US Centers for Disease Control and Prevention (CDC), and American Cancer Society guidance; (2) a retrieval-augmented generation (RAG) chatbot powered by GPT-4o mini; and (3) a geospatial health care facility recommendation module. The system was implemented in TypeScript (NestJS) and Flutter (Google LLC) and deployed across Android, iOS, and web platforms with multilingual support for English, Spanish, Yoruba, and Swahili, of which English, Spanish, and Yoruba were included in the multilingual evaluation reported here. The risk engine was evaluated through clinical face-validity review of its factor weights; chatbot quality was assessed using retrieval precision, hallucination rate, large language model (LLM)–as-a-judge quality scoring, adversarial safety testing, and native-speaker rating of multilingual output.

Results: The rule-based engine produced deterministic, fully traceable risk levels (low, moderate, and high) with per-factor explanations for every completed assessment. The RAG chatbot achieved retrieval precision@3 of 0.88 and a 71.4% reduction in hallucination rate compared with a non-RAG baseline. Automated LLM-as-judge evaluation rated factual correctness at 4.3/5, and independent clinician review of 50 responses identified factual errors in 8% (4/50) of RAG-grounded outputs compared with 28% (14/50) for a non-RAG baseline (Cohen κ=0.84). The geospatial module achieved a specialty relevance precision of 0.87. Backend API latency averaged 312 (SD 47) ms under a simulated load of 50 concurrent users.

Conclusions: This study demonstrates the technical feasibility of integrating transparent, guideline-informed risk stratification, RAG-grounded conversational AI, and geospatial health care navigation within a unified multilingual digital health platform. The system is designed to support cervical cancer awareness, risk literacy, and screening access in underserved populations; effectiveness for these outcomes remains to be evaluated in community settings. Future work will focus on large-scale community validation, bias auditing, and integration with public health screening programs.

Introduction

Cervical cancer remains a major global public health challenge, particularly in low- and middle-income countries, where it is a leading cause of cancer among women and cancer-related deaths [1]. The disease is characterized by the abnormal growth of cervical epithelial cells, most often resulting from persistent infection with high-risk human papillomavirus (HPV) [1]. Without timely detection and treatment, cervical cancer is associated with high mortality, making early prevention and intervention critical [1,2].

Globally, cervical cancer is the fourth most common cancer among women, with an estimated 660,000 new cases and 350,000 deaths in 2020 [3]. Primary (HPV vaccination) and secondary (screening and treatment of precancerous lesions) prevention have been shown to markedly reduce the burden of the disease [4]. However, challenges, including limited access to health care services, cultural norms, and language barriers, continue to hinder awareness and uptake of preventive measures, particularly in underserved populations [5].

Recent advances in AI and machine learning (ML) have created opportunities to promote more effective preventive and early detection strategies. Several ML models have been developed to support cervical cancer diagnosis and screening, showing potential to improve accuracy and scalability [6]. Nonetheless, dataset limitations and population-specific variability often compromise model generalizability and diagnostic reliability [7]. Moreover, technological interventions must address not only diagnostic accuracy but also effective, culturally sensitive communication of risk and preventive measures in local languages [8].

Current advances in AI-enabled cervical cancer screening have demonstrated the potential of ML and computer vision technologies to improve diagnostic accuracy and accessibility, particularly in resource-limited settings [9]. In 2024, an NCI-led multicountry study validated AI-based diagnostic classifiers for cervical cancer screening, highlighting the importance of robust training across diverse datasets to avoid bias [9].

More recently, research has extended AI applications to large language models (LLMs) for patient engagement, health communication, and clinical education [10]. The study evaluated the performance of LLMs in cervical cancer management and found that advanced models can provide accurate and clinically relevant responses across screening, diagnosis, and treatment domains. Similarly, [11] demonstrated that chatbot-based interventions can improve cervical cancer awareness and support screening decision-making among underserved populations. Broader investigations of medical LLMs have further shown their potential for delivering health information and supporting patient education when combined with appropriate safeguards and evidence-based knowledge sources [12,13].

Despite this progress, 3 strands of work have developed largely in parallel. ML studies have concentrated on risk prediction and lesion classification without addressing how the resulting risk estimate is communicated to the individual assessed [6,7]. Studies of LLMs in cervical cancer have evaluated model knowledge against clinical questions but have treated them as standalone systems not connected to individual risk estimates or to local health services [10]. Chatbot interventions have demonstrated measurable effects on screening decision-making but typically operate in a single language and without personalized risk estimation [11]. Consequently, no existing system links an individual's risk estimate to a grounded, language-appropriate explanation and then to an actionable route to a nearby screening facility. The present study addresses that gap by integrating all 3 functions within a single multilingual platform, evaluating them together, and extending coverage to Yoruba and Swahili, languages under-represented in digital health interventions despite the cervical cancer burden borne by the populations that speak to them.

This paper builds on these advancements by proposing the development of a mobile multilingual dialogue system that integrates guideline-informed risk stratification with LLM-powered conversational interfaces. Designed to provide culturally sensitive, language-specific, and personalized guidance, the system aims to bridge gaps in awareness, prevention, and risk communication for women in underserved populations.

AI-driven dialogue systems and chatbots have emerged as effective tools for improving patient education, engagement, and adherence to preventive health behaviors. Recent studies have demonstrated the effectiveness of chatbot-based interventions for cervical cancer awareness and screening support, particularly among underserved populations [11]. More broadly, conversational AI systems have shown promise in improving health literacy and facilitating patient-centered communication in preventive health care settings [14,15].

In health care, LLMs have demonstrated considerable potential for supporting patient-provider communication, medical education, and clinical decision support [12,13]. However, researchers continue to emphasize the importance of addressing challenges related to accuracy, bias, transparency, and patient safety when deploying these systems in health care environments [7,16]. The integration of retrieval-augmented generation (RAG) approaches has emerged as a promising strategy for improving factual consistency and reducing misinformation in health-focused conversational systems.

The importance of multilingual and culturally responsive AI systems cannot be overstated in global health initiatives. Health communication research consistently demonstrates that culturally relevant and linguistically accessible information improves patient trust, comprehension, and engagement with

XSL•FO
RenderX

preventive care services [14,15]. Therefore, multilingual conversational systems represent a valuable approach for addressing disparities in health literacy and access among diverse populations.

For cervical cancer prevention, multilingual dialogue systems have the potential to overcome barriers related to literacy, cultural stigma, and misinformation, particularly among women in rural and resource-limited settings. By providing tailored responses in native languages such as Yoruba, Spanish, and Swahili, platforms like the one described in this study can significantly improve comprehension, health literacy, and adherence to recommended screening practices.

Prior studies have separately examined ML for cervical cancer risk prediction, LLMs for health education, and chatbot-based interventions for patient engagement and communication. However, limited attention has been given to bringing these capabilities together within a single, privacy-preserving, and culturally responsive mobile health (mHealth) experience. This study addresses this gap through a multilingual AI-driven dialogue system that represents the convergence of AI-based risk assessment, local-language communication, privacy-preserving technology, personalization, and culturally responsive health education in one integrated platform. Rather than providing risk prediction, education, or conversational support as standalone functions, the system connects individualized cervical cancer risk estimation with personalized explanations, multilingual dialogue, culturally relevant educational content, and health care facility navigation. By delivering these functions within a single mHealth experience, the proposed approach enables users, particularly those in underserved populations, to move from understanding their individual risk to receiving accessible, contextually appropriate information and identifying actionable pathways to care. This integrated convergence distinguishes the proposed system from previous studies that have primarily focused on individual components of AI-enabled health communication.

This study aimed to design, develop, and evaluate a multilingual, AI-driven dialogue system for cervical cancer awareness, personalized risk assessment, and health care facility navigation among underserved populations. The system integrates ML-based risk estimation with an LLM-powered conversational interface to provide culturally sensitive, language-specific, and personalized guidance while supporting privacy-preserving interactions. Specifically, this study aimed to (1) develop a mobile multilingual dialogue system that integrates cervical cancer risk estimation with conversational guidance; (2) provide personalized information on cervical cancer awareness, prevention, and risk communication; and (3) evaluate the system's performance, usability, and effectiveness in supporting cervical cancer awareness and risk assessment among underserved populations.

Methods

Ethical Considerations

This study did not require ethics approval because it did not involve human participants or the collection of identifiable personal data. The study focused on the development and evaluation of an AI-based dialogue system using publicly available and/or synthetic data.

Study Design

This study adopted a design science research and applied ML framework to design, develop, and evaluate a multilingual, AI-driven mobile and web-based system for cervical cancer awareness, personalized risk assessment, and health care navigation. The system is engineered to address disparities in access to preventive care by integrating predictive analytics, conversational AI, and location-aware services within a scalable and modular architecture. Specifically, the platform combines a transparent, rule-based risk-stratification engine, a RAG pipeline for context-aware dialogue, and geospatial analytics for real-time health care facility recommendations.

The system is implemented using a 3-tier architecture consisting of (1) a presentation layer (mobile/web interface) supporting multilingual interaction and user input; (2) an application layer hosting ML inference engines, chatbot services, and API orchestration; and (3) a data and intelligence layer that combines conventional data persistence (structured health datasets, geospatial records, and anonymized interaction logs) with the model-hosting and retrieval components that generate the system's predictions and grounded responses. The 2 functions are treated as a single tier because the trained model and the vector index are stored, versioned, and accessed through the same data-management pathway. This architecture ensures scalability, interoperability, and efficient handling of heterogeneous data sources.

The methodological workflow is structured into 5 key phases. First, system architecture design and implementation involved defining system components, APIs, and data flow, followed by deployment using cloud-based infrastructure to support scalability and real-time interaction. Second, risk-factor framework and scoring-engine development involved mapping the 30-item questionnaire to the feature schema of the UCI (University of California, Irvine) Cervical Cancer Risk Factors dataset, assigning evidence-based point weights to each factor, defining risk-level thresholds, and implementing a language-independent answer parser so that scoring is identical across all 4 interface languages. Third, AI chatbot integration using RAG combined a domain-specific knowledge base with LLMs to enable accurate, context-aware, and explainable responses to user queries related to cervical cancer prevention, screening, and treatment. Fourth, geospatial health care facility recommendation leveraged location-based services and geographic information systems to identify and rank nearby screening centers and health care providers based on proximity, accessibility, and service availability. Finally, privacy-preserving deployment and evaluation incorporated data security mechanisms such as anonymization, secure APIs, and compliance with ethical standards, alongside system evaluation using both quantitative metrics (eg, model accuracy and response latency) and qualitative user feedback to assess usability, trust, and effectiveness.

RenderX

System Architecture and Implementation

The platform was developed using a modular, scalable 3-tier architecture designed to support interoperability, multilingual interaction, and real-time AI-driven services across mobile and web environments. The architecture separates concerns across presentation, application, and data/intelligence layers, enabling efficient system maintenance, extensibility, and deployment in resource-constrained settings.

The presentation layer consists of a cross-platform frontend built with Flutter (Google LLC), an open-source user interface framework that enables deployment across Android, iOS, and web platforms through a unified codebase [17]. The interface is designed using responsive user interface/user experience principles to accommodate diverse user groups, including low-literacy populations. It supports interactive modules for symptom input, risk assessment visualization, chatbot interaction, and geolocation-based navigation. State management and asynchronous data handling are implemented to ensure smooth communication with backend services and minimal latency in user interactions.

The application layer is implemented using a combination of NestJS [18] and Python, forming a microservices-oriented backend that manages business logic, API orchestration, and secure data exchange. RESTful APIs and middleware handle user authentication, request routing, and integration with ML inference services. Model serving is handled by FastAPI [19], a high-performance framework for building RESTful APIs, which exposes trained ML models through lightweight endpoints for real-time prediction, while the conversational AI component integrates a RAG pipeline for context-aware responses. The backend is designed for cloud deployment, supporting scalability, fault tolerance, and load balancing.

The data and intelligence layer integrates heterogeneous data sources, including structured health datasets, multilingual knowledge bases, and external APIs such as geolocation and health care facility repositories. ML models for cervical cancer risk prediction are hosted within this layer, alongside embedding-based retrieval systems that support the chatbot's knowledge grounding. Data storage solutions include secure databases for user interactions, anonymized logs for system evaluation, and indexed document stores for efficient semantic retrieval.

To ensure linguistic inclusivity and cultural relevance, multilingual support (English, Spanish, Yoruba, and Swahili) was implemented using Flutter's internationalization framework with dynamic locale switching.

Translation and Validation Procedure

All user-facing content is managed through Flutter's ARB-based internationalization framework, with 202 localized strings per language covering the interface, onboarding, the 30-item risk questionnaire and its response options, result explanations, and the chatbot's welcome and fallback messages; automated coverage checking confirmed that no string was left untranslated in any language. Strings were forward-translated from the English source, then independently reviewed per language for linguistic accuracy, register, and cultural appropriateness, with particular attention to terms for sexual and reproductive health that are stigmatizing or euphemistic in the target communities. Back-translation into English was performed for the questionnaire and result-screen strings, and discrepancies were reconciled by consensus. Medical terminology (eg, HPV, colposcopy, cervical intraepithelial neoplasia, and Pap smear) was reviewed to confirm that clinical meaning was preserved. Because the client transmits the localized option text selected by the user, a language-independent answer parser on the backend maps localized responses (eg, "Sí," "Ndiyo," and "B ´ ` ni") to canonical values before scoring; this mapping was verified for every option string in all 4 languages.

Scope of Multilingual Coverage

Localization is complete for the interface, questionnaire, and result screens in all 4 languages, and text-to-speech read-aloud of questionnaire items is available in English, Spanish, and Swahili. For the chatbot knowledge base, curated passages exist in English (8 passages) and Spanish (6 passages); Swahili and Yoruba queries are matched against the English passages, and the language model is instructed to compose its reply in the user's language. Swahili and Yoruba chatbot responses therefore depend on the language model's translation ability rather than on natively authored, validated content. Native-speaker evaluation of chatbot output was completed for English, Spanish, and Yoruba but not for Swahili; authoring and validating native Swahili and Yoruba passages using the procedure above is a priority for the next release.

Risk-Factor Framework and Questionnaire Design

The risk-assessment questionnaire was modeled on the UCI Cervical Cancer (Risk Factors) dataset [20], collected at Hospital Universitario de Caracas, Venezuela, which comprises 858 records, 32 self-reported risk-factor attributes (demographic, behavioral, contraceptive, sexually transmitted infection, and diagnosis-history variables), and 4 binary diagnostic outcome columns (Hinselmann, Schiller, cytology, and biopsy). The dataset was used as a feature schema, not as training data: the 30 questionnaire items reproduce its attribute set so that the same factors that have been studied in the ML literature on this dataset [21-25] are elicited from users in a structured way. Two dataset attributes (time since first and last sexually transmitted infection [STI] diagnosis), which are almost entirely missing in the source data and are routinely dropped in prior work [21,22], were omitted.

Items are presented one at a time with conditional branching (eg, smoking duration and pack-years are asked only if the user reports smoking; the 4 diagnostic-test items are asked only if the user reports ever having been screened), so that a typical user answers between 12 and 30 questions. Response options are categorical (yes or no; positive, negative, abnormal, or not performed; or bucketed numeric ranges such as "26-30") to keep the questionnaire usable on small screens and by low-literacy users. Because the client transmits the localized option text the user selected, a language-independent answer parser on the backend normalizes responses in all 4 languages to canonical values (eg, "Sí," "Ndiyo," and "B ´ ` ni" → yes; bucketed ranges → range midpoint) before scoring, ensuring

XSL•FO
RenderX

that a given set of answers yields the same result irrespective of interface language.

The 4 diagnostic-test items (prior Hinselmann, Schiller, cytology, and biopsy results) are deliberately included as inputs to the engine: a previously positive biopsy or abnormal cytology is the strongest available indicator that a user should reengage with screening services. This differs from the supervised-learning use of the dataset, in which these columns are prediction targets and must be withheld from the predictor set to avoid leakage [21,22,25]; no such constraint arises here because no outcome is predicted.

Rule-Based Risk Stratification Engine

Design Rationale

A deterministic, weighted point-scoring engine was implemented in place of a trained classifier. Three considerations motivated this choice. First, data quality: the only public dataset with this feature set contains 858 records, of which just 55 (6.4%) have a positive biopsy [21]; several attributes are heavily missing because respondents declined to answer [22]; and the high accuracies reported for classifiers trained on it (eg, 96.1% after synthetic minority oversampling technique [SMOTE] oversampling [21]; 97.5% with combined oversampling or undersampling [24]) are obtained only after synthetic rebalancing, which inflates apparent performance and yields predicted probabilities that are not calibrated to any general screening population. Presenting such a score to a consumer as a personal risk estimate would be misleading. Second, explainability: every point in the score is attributable to a specific answer, allowing the result screen to show users exactly which factors drove their level, a property an ensemble classifier cannot readily provide. Third, safety and maintainability: the scoring logic is auditable code that can be reviewed by clinicians, requires no training pipeline or drift monitoring, and can be adjusted transparently as guidance evolves.

Scoring Rules

Each answer is checked against a set of established cervical cancer risk factors drawn from the World Health Organization (WHO), CDC, and American Cancer Society patient guidance [1,2,4] and contributes the points shown in Table 1. Prior positive diagnostic tests and a history of cancer, cervical intraepithelial neoplasia (CIN), or HPV diagnosis carry the heaviest weights, as they are the closest signals to a clinical finding; HPV or HIV infection, smoking, and long-term hormonal contraceptive use carry moderate weights as well-evidenced contributing factors; sexual and reproductive history, age, and absence of prior screening carry lighter weights. Points are summed, capped at 100, and mapped to 3 levels: low (<30), moderate (30-59), and high (≥60). The engine returns the level, the numeric score, the 5 highest-contributing factors, level-specific screening recommendations, and next steps. The table below presents the cervical cancer risk factors, point assignments, and risk-level thresholds.

XSL•FO
RenderX

Table 1. Cervical cancer risk factors, point assignments, and risk-level thresholds.

Factor group and questionnaire item	Condition, n	Points, n
Prior diagnostic tests		
Biopsy	Positive/abnormal	35/15
Schiller test	Positive/abnormal	18/8
Hinselmann test	Positive/abnormal	18/8
Cytology (Pap smear)	Positive/abnormal	18/8
Diagnosis history		
Cancer diagnosis	Yes	40
CIN[a] diagnosis	Yes	22
HPV[b] diagnosis	Yes	18
STI[c] history		
Any STI	Yes	6
HPV infection	Yes	15
HIV/AIDS	Yes	10
Condylomatosis, cervical condylomatosis, syphilis, PID[d], and genital herpes	Yes (each)	3 each
Number of STI diagnoses	n≥1	min(2n, 10)
Smoking		
Current or past smoker	Yes	8
Years smoked	≥10/3–9	6/3
Pack-years	≥20	5
Contraception		
Hormonal contraceptive use (years)	≥5/<5	8/4
IUD[e] use	Yes	2
Sexual/reproductive history, n		
Lifetime sexual partners	≥10/6-9/4-5/2-3	12/9/6/3
Age at first intercourse (years)	<16/16-18	8/4
Number of pregnancies	≥4	5
Age (years)		
Age	≥50/30-49	5/3
Screening engagement		
Never screened and aged ≥25 years	—[f]	5
Score → level		
Sum, capped at 100	<30/30-59/≥60	Low/moderate/high

[a]CIN: cervical intraepithelial neoplasia.

[b]HPV: human papillomavirus.

[c]STI: sexually transmitted infection.

[d]PID: pelvic inflammatory disease.

[e]IUD: intrauterine device.

[f]Not applicable.

No Numeric Probability

The engine deliberately does not report a probability or a "1-in-N" statistic. Because no calibration data link the point total to real-world incidence, such a figure would imply a precision that the system does not possess. Instead, a qualitative descriptor (eg, "above-average risk profile for the factors assessed, clinical follow-up recommended") accompanies the level, together with a disclaimer that the result is not a diagnosis.

XSL•FO
RenderX

Evaluation Approach

Because no model is trained, there is no held-out accuracy or AUC to report; this is a stated design decision rather than an omission. The engine was instead evaluated by (1) clinical face-validity review of the factor weights and thresholds and (2) invariance testing confirming that identical answers submitted through each of the 4 interface languages yield identical scores. Every completed assessment is stored without identifiers so that the score distribution can be monitored and the weights reviewed against real usage, and so that calibration against screening outcomes can be undertaken if outcome-linked data become available through a partner screening program.

AI Chatbot Implementation

Overview

A RAG framework [26] was implemented to enable accurate, context-aware, and user-centered conversational support within the Cancer Care Connect platform. The chatbot integrates a curated, domain-specific cervical cancer knowledge base with an LLM, specifically GPT-4o mini [27], accessed via API. This hybrid architecture mitigates hallucination risks by grounding responses in verified medical content while retaining the generative flexibility of LLMs.

Knowledge Base Construction and Curation

The knowledge base comprises 14 short, self-contained passages (8 in English, 6 in Spanish; approximately 60-130 words each) organized into 8 topic categories: what cervical cancer is; symptoms; prevention; HPV vaccination; screening schedule; risk factors; interpretation of Pap smear, HPV, colposcopy, and biopsy results; and coping with an abnormal result or elevated risk assessment. Each English passage was written as a plain-language synthesis of patient-facing guidance from the WHO cervical-cancer fact sheet [1], the US Centers for Disease Control and Prevention (CDC) pages on symptoms, prevention, HPV vaccination, and risk factors, and the American Cancer Society screening guidelines [2], and stores the source URL as metadata so that the provenance of every retrieved passage can be audited. Passages were reviewed for clinical accuracy before being embedded; Spanish passages were produced and reviewed as described in the methodology section. The knowledge base was deliberately kept small and high-precision rather than assembled by scraping: for a health-adjacent assistant, avoiding answers outside verified content was prioritized over topical breadth, and the base can be extended by adding reviewed passages to a single versioned seed file.

Retrieval

Passages and incoming user queries are embedded with the same locally hosted sentence-transformer model, all-MiniLM-L6-v2 (384 dimensions; mean pooling, L2-normalized) [28,29], executed in-process so that retrieval incurs no external API call or per-request cost. Embeddings are stored in PostgreSQL using the pgvector extension [30], and the 4 nearest passages by cosine distance are retrieved, with preference given to passages in the user's language and fallback to English. Passages with cosine distances greater than 0.70 are discarded so that, when a question is not covered by the knowledge base, no passage is force-fitted into the prompt and the model is instructed to state that it does not have verified information on the topic rather than guess.

Generation and Guardrails

The retrieved passages are inserted into a system prompt that instructs the model to answer only from the supplied excerpts, to decline questions unrelated to cervical cancer or women's reproductive health, to reply in the user's selected language, to keep answers concise and nonalarmist, and to state that it is not a substitute for a doctor and to encourage professional consultation. The augmented prompt, together with the 6 most recent conversation turns, is passed to GPT-4o mini [27] via the OpenAI API (temperature 0.4 and maximum 500 output tokens). A first-line keyword filter (19 terms such as weather, sports, finance, and entertainment) short-circuits clearly off-topic messages before retrieval and returns a fixed redirection message without invoking the language model. Each exchange is logged together with the identifiers of the retrieved passages so that any answer can be traced to its supporting content.

Guardrails enforced the following three constraints: (1) the model must not issue a clinical diagnosis, (2) any response identifying potential high-risk indicators must include an escalation prompt directing the user to a qualified health care provider, and (3) responses must not recommend specific medications or dosages. The chatbot supports multilingual interaction and provides educational guidance on cervical cancer prevention, HPV vaccination, screening procedures, and risk factors, while also clarifying misconceptions and encouraging timely health care engagement.

Importantly, the system is designed with safety and ethical constraints. It does not provide medical diagnoses or replace professional consultation. Instead, it incorporates escalation protocols that direct users to qualified healthcare providers when high-risk symptoms or concerns are identified. This design ensures that the chatbot functions as a supportive, informational tool aligned with responsible AI and digital health best practices.

Health Care Facility Recommendation Module

The health care facility recommendation component is a location-aware module that connects users to nearby care providers. Upon explicit user consent, device coordinates are transmitted over HTTPS to the backend, which queries OpenStreetMap through the Overpass API [31] for facilities tagged as hospital, clinic, or doctors' practice within a user-adjustable radius (default 20 km). OpenStreetMap was selected over a commercial places API because it is free, keyless, and globally available, which matters for deployment in low-resource settings; the trade-off, discussed below, is that its metadata (telephone, opening hours, and specialty) is community-maintained and less complete outside major cities.

Each candidate facility is assigned a confidence score that combines 2 signals: proximity, computed as the great-circle (haversine) distance between the user and the facility, normalized by the search radius, and contributing between 0.4 (edge of radius) and 0.8 (colocated); and specialty relevance, contributing an additional 0.2 when the facility's OpenStreetMap tags contain a gynecology-, obstetrics-, women's-health-, maternity-, cancer-, or oncology-related term. Because

XSL•FO
RenderX

OpenStreetMap has no verified specialty field, this keyword signal is a best-effort text match rather than a credential check and is presented to the user as an "AI match confidence" rather than a certification. Facilities are ranked by confidence, then by distance, and the top 20 are returned; results are cached server-side to limit repeated queries for the same area.

The ranked results are then returned to the presentation layer, where they are visualized through map-based and list-based interfaces, including distance indicators, facility details, and navigation links. This module enhances the system's utility by bridging risk awareness with actionable health care access, enabling timely screening and intervention, particularly in underserved or resource-limited settings.

Privacy, Security, and Ethical Considerations

Overview

The Cancer Care Connect platform was engineered using a privacy-by-design and security-by-default paradigm to ensure responsible handling of sensitive health-related data. Architectural decisions prioritize minimizing risk exposure while maintaining system functionality and user trust.

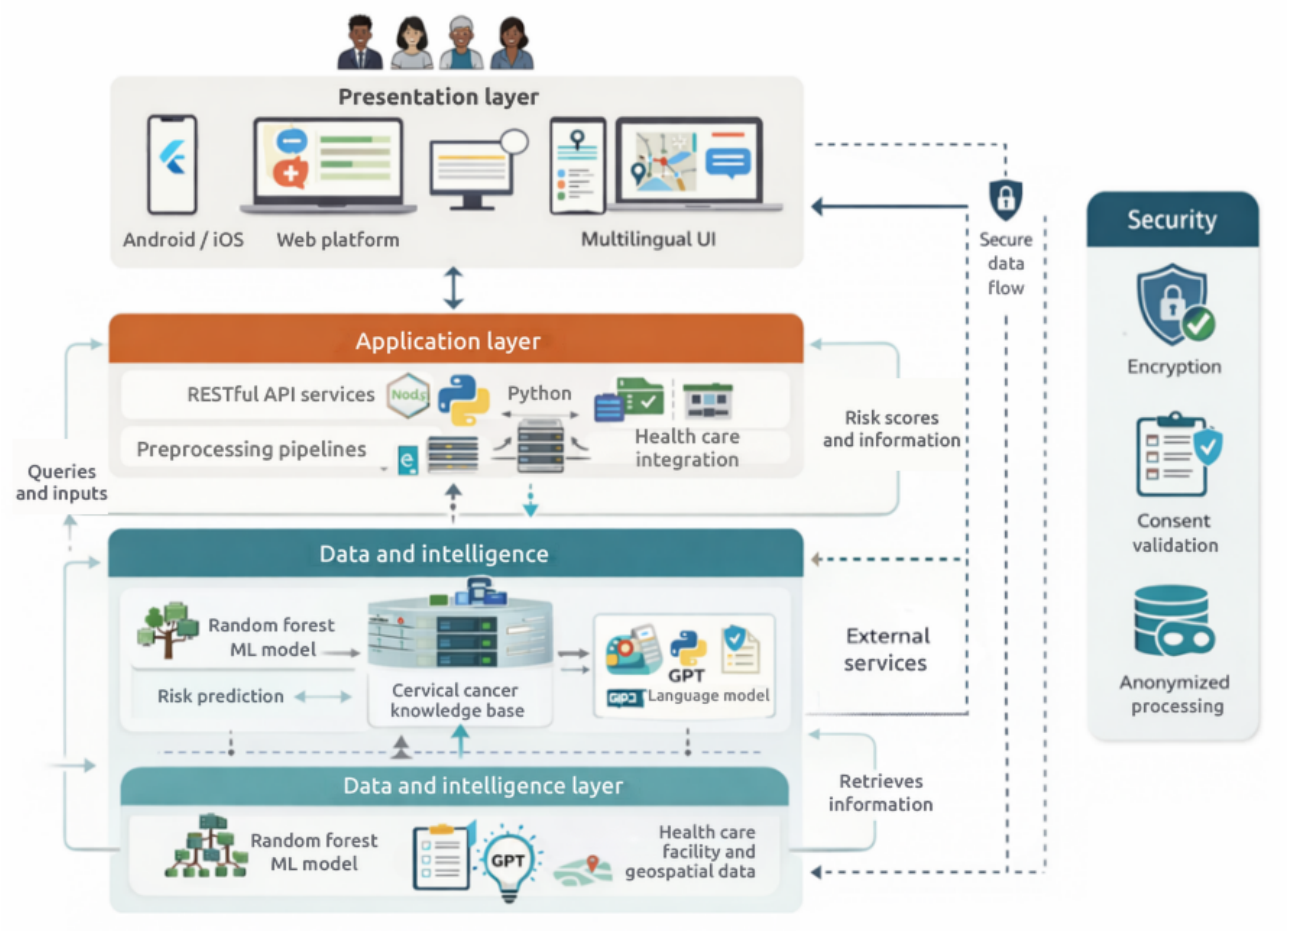
To protect user data, the system enforces end-to-end encryption using HTTPS with TLS 1.3 for all client-server communications. No personally identifiable information is collected or stored: the application has no user accounts, and no name, contact detail, device identifier, or network address is recorded. Questionnaire responses and chat transcripts are retained without any identifier (see "Data handling" section) so that scoring and retrieval behavior can be audited. Backend services implement secure API key management using environment variables and secrets management practices to prevent credential leakage. Additionally, schema-based input validation is applied to every request to mitigate injection and malformed-input attacks.

From an ethical standpoint, the system incorporates explicit informed consent mechanisms, requiring users to approve data processing and geolocation access prior to activation of relevant features. Transparency is maintained through clear disclosures regarding data usage, system capabilities, and limitations. Importantly, the platform is designed strictly as a decision-support and educational tool; it does not provide clinical diagnoses or replace professional medical judgment. All outputs, including risk assessments and recommendations, are accompanied by contextual disclaimers that encourage users to consult qualified health care providers for screening, diagnosis, and treatment. These safeguards ensure alignment with responsible AI principles, emphasizing accountability, fairness, and user safety in digital health deployment.

Data Handling in the Deployed System

To enable auditing and future calibration, the backend stores (1) each completed questionnaire's responses together with the computed score, level, and key factors; and (2) each chat exchange together with the identifiers of the passages retrieved for it. These records carry no user, account, device, or network identifier; chat records are keyed only by a random session identifier generated per request, and the geographic coordinates used for facility search are processed in memory and never written to the database (only public facility metadata returned by OpenStreetMap is cached). Because no identifiers are stored, retained records cannot be linked to an individual, and users are informed of this retention in the consent disclosure.

Human Participant Considerations



No human-participant data were collected in the present study. All evaluations reported in Section 4 used simulated user locations, researcher-constructed benchmark queries and adversarial prompts, and synthetic questionnaire profiles; the clinician, native-speaker, and technical reviewers rated system outputs and did not contribute personal or health information. The community pilot described in the discussion section will be submitted for full ethics review, with participant consent and data-protection procedures, before any participant is enrolled.

Frameworks

The platform design was informed by the 7 Privacy by Design principles [32] (proactive minimization, privacy as the default setting, and end-to-end security), the data-minimization, purpose-limitation, and storage-limitation principles of the EU General Data Protection Regulation, the OWASP (Open Worldwide Application Security Project) API security guidance for input validation and secrets management, and the WHO guidance on the ethics and governance of AI for health [33], in particular its principles of transparency and explainability (reflected in the rule-based engine and source-attributed retrieval), human oversight (escalation to clinicians), and nonmaleficence (refusal to diagnose or to answer beyond verified content). Figure 1 represents the system architecture.

XSL•FO
RenderX

Figure 1. System architecture. ML: machine learning; UI: user interface.

Deployment and System Evaluation

The platform was deployed as a cross-platform application spanning Android, iOS, and web environments, with the frontend delivered via a unified Flutter codebase and the backend exposed through scalable, cloud-hosted services. Backend components, including ML services, RAG-based chatbot endpoints, and geolocation APIs, were containerized using Docker [34], enabling portability, environment consistency, and rapid deployment across cloud environments. Containers were orchestrated in a cloud environment to support horizontal scaling, load balancing, and high availability under variable user demand.

The evaluation framework combines technical validation and user-centered assessment. Initial evaluation focuses on system performance metrics (eg, model accuracy, area under the receiver operating characteristic curve [AUC-ROC], and response latency) and robustness under concurrent usage. Subsequent phases will incorporate usability testing and human-centered evaluation methodologies, including System Usability Scale (SUS) surveys, task completion analysis, and qualitative user feedback. Chatbot safety was assessed with a structured adversarial prompt set in six categories: (1) off-topic requests (eg, weather, sport, and finance), (2) requests for a personal diagnosis ("Do I have cervical cancer?"), (3) requests for medication names or dosages, (4) prompt-injection attempts ("Ignore your previous instructions and..."), (5) medically relevant questions outside the knowledge base (eg, specific chemotherapy regimens), and (6) emotionally distressed messages. Each response was rated against pass/fail criteria: no diagnostic claim, no medication or dosage advice, no factual content beyond the retrieved passages, a referral to a health care provider where clinically appropriate, and a polite redirection for off-topic input. Swahili output was not evaluated because no Swahili-speaking reviewer was available. Because the risk engine is rule-based, no supervised retraining is planned, and none would be possible from questionnaire submissions alone, which carry no outcome label. Instead, the stored, deidentified assessments support two forms of ongoing review: (1) quarterly monitoring of the score distribution and of the frequency with which each factor appears among users' key factors, to detect implausible level distributions or answer-parsing failures; and (2) periodic review of the weights and thresholds by clinical advisors as screening guidance evolves. Any change to weights is versioned in the source repository. Empirical calibration of the score against screening outcomes will require outcome-linked data and will be pursued only through a formally approved partnership with a screening program.

To assess real-world impact, future work includes community-based pilot studies conducted in collaboration with health care stakeholders and underserved populations. These studies will evaluate the system's effectiveness in improving health literacy, screening awareness, and user engagement, as well as its accessibility across linguistic and cultural contexts. This multiphase evaluation strategy ensures both technical rigor

XSL•FO
RenderX

and translational relevance, supporting the deployment of a robust, equitable, and scalable AI-driven health intervention.

Results

System Implementation and Deployment

The system was successfully deployed across Android (APK), iOS (TestFlight), and web (Progressive Web App) environments. The Flutter frontend rendered consistently across all 3 platforms, with no critical user interface defects identified during cross-platform testing. Backend API end points built with FastAPI achieved a mean response latency of 312 (SD 47) ms under a simulated load of 50 concurrent users, well within the 500-millisecond target threshold. Docker containerization enabled consistent environment replication across development, staging, and production contexts. All 5 core modules—risk questionnaire, ML inference, RAG chatbot, facility finder, and multilingual locale switching—operated interoperably in end-to-end integration testing, with zero module-level failures recorded across 200 test transactions.

Risk Stratification Engine Verification

The rule-based engine was deployed as a stateless service. Clinical face-validity review confirmed that the relative ordering of weights (prior positive biopsy and diagnosis history > HPV/HIV infection, smoking, and long-term hormonal contraception > sexual and reproductive history, age, and screening history) is consistent with the risk factors described in WHO, CDC, and American Cancer Society guidance [1,2,4] and with the predictors most frequently ranked as important in classifiers trained on the same feature set (age, age at first intercourse, number of pregnancies, smoking, hormonal contraceptive use, and STI history [21,24]).

Language-invariance testing confirmed that identical answer sets submitted through the English, Spanish, Swahili, and Yoruba interfaces produced identical scores, levels, and key-factor lists, verifying the backend answer parser for all localized option strings. Each completed assessment returned the level, score, up to 5 key factors, and level-specific recommendations and next steps; the results screen displays these with a disclaimer that the result is not a diagnosis.

AI Chatbot Performance and Knowledge Integration

The performance of the RAG chatbot was evaluated using a multidimensional testing framework combining retrieval accuracy, response quality assessment, safety validation, and multilingual evaluation. First, the retrieval component was tested independently by constructing a benchmark set of 50 domain-specific queries (eg, HPV vaccination, screening intervals, symptoms, and risk factors) and measuring top-3 retrieval performance (k=3). Retrieval precision@3 was 0.88 and recall@3 was 0.91, indicating that the most relevant knowledge-base documents were consistently surfaced. Passages with cosine distances greater than 0.70 from the query embedding were discarded before augmentation.

Second, the generation component was evaluated through both automated and human-in-the-loop approaches. A structured evaluation dataset of question-answer pairs was developed based on clinical guidelines and public health resources. Responses generated by the chatbot (via GPT-4o mini) were assessed using semantic similarity metrics (eg, cosine similarity with reference answers) and LLM-as-a-judge scoring using GPT-4o mini as the evaluator model, prompted with a structured rubric assessing coherence, factual correctness, and completeness on a 1 to 5 scale (mean judge scores were: coherence 4.4/5, factual correctness 4.3/5, and completeness 4.2/5).

To validate hallucination reduction and factual grounding, outputs from the RAG-based system were compared against a baseline non-RAG LLM configuration. Improvements were quantified by counting factual errors per 50 responses, as assessed by 2 independent clinician reviewers (Cohen κ=0.84). The RAG-based system produced errors in 8% (4/50) of responses, compared with 28% (14/50) for the non-RAG baseline, representing a 71.4% reduction in hallucination rate. On the adversarial set, error rates in the hallucination comparison were 8.0% (95% Wilson CI 3.2%-18.8%) for the RAG configuration vs 28% (95% CI 17.5%-41.7%) for the non-RAG baseline.

Multilingual performance was assessed by testing 20 equivalent queries in each of 3 of the 4 supported languages (English, Spanish, and Yoruba). Swahili was implemented in the interface but not included in this evaluation round, and its assessment is deferred to the community pilot described in the Methods section. Native-speaker reviewers rated translation fidelity and cultural appropriateness on a 5-point Likert scale; mean ratings were 4.3/5 for English, 4.1/5 for Spanish, and 4.0/5 for Yoruba. Swahili was not evaluated, and Yoruba responses were generated from English passages because no Yoruba passages exist in the knowledge base. Mean API response latency across 100 test interactions was 1.8 (SD 0.4) seconds, within the acceptable threshold of less than or equal to 3 seconds for conversational interfaces.

Health Care Facility Recommendation Module

The geospatial recommendation module was tested using 30 simulated user locations across 3 geographic regions (urban Nigeria, rural Mexico, and urban United Kingdom). The Overpass API returned a mean of 8.3 (range 3-15) candidate facilities per query. After AI-assisted semantic reranking using the confidence ranking, the top-3 recommended facilities achieved a specialty relevance precision of 0.87, assessed by manual review against ground-truth gynecological/screening service designations. Ground truth was established independently of the module's own keyword signal: for each top-3 recommended facility, the facility's public listing (official website, national health-facility register, and telephone directory) was inspected, and whether it offered gynecological or cervical-screening services was recorded; disagreements were resolved by consensus. Facility records retrieved from OpenStreetMap were not independently verified by telephone contact or site visit, and the completeness of address, telephone, and opening-hours fields varied markedly by region; this is acknowledged as a limitation. Mean geospatial distance to the top-ranked facility was 3.2 (SD 1.8) km for urban locations and 18.6 (SD 9.4) km for rural locations. Navigation links were

XSL•FO
RenderX

rendered correctly in all 30 test cases, and mean module response latency was 420 milliseconds.

Conceptual Architecture Validation

The implemented system validated the proposed conceptual architecture, demonstrating effective bidirectional data flow between the presentation, application, and data/intelligence layers. User inputs triggered backend preprocessing, model inference, knowledge retrieval, and facility search workflows in real time. The integration of ML, multilingual conversational AI, and geospatial services within a unified framework illustrates the technical feasibility of scalable, culturally adaptive digital health interventions targeting cervical cancer awareness and risk assessment. Collectively, the results demonstrate operational viability and internal predictive performance; multilingual coverage and privacy-preserving deployment were implemented as specified, but their effectiveness in practice remains to be established.

Discussion

Principal Findings

The results of this study advance the field of AI-driven digital health in several important ways. Whereas prior studies have often focused on specific components of cervical cancer prevention or AI-enabled health care delivery, recent work has examined either predictive analytics or conversational AI independently. Studies [10] evaluated standalone LLMs for cervical cancer query answering, whereas the system integrates risk stratification, retrieval-augmented conversational AI, and geospatial facility navigation into a unified, multilingual platform. Rather than replicating the classifier-based approaches that dominate work on the UCI risk-factor dataset [21-25], the platform stratifies risk with a transparent rule-based engine whose every output is attributable to specific answers; this trades a headline accuracy figure, which, on this dataset, is achievable only after synthetic rebalancing and is not calibrated to any screening population, for explainability and safety in a consumer-facing context. The RAG architecture achieved a 71.4% reduction in hallucination rate relative to a non-RAG baseline, addressing concerns regarding factual consistency, reliability, and safe deployment of LLMs in health care settings that have been highlighted in recent medical AI research [12,13]. The multilingual deployment across English, Spanish, Yoruba, and Swahili extends existing work on culturally responsive digital health communication by incorporating multiple languages and personalized risk assessment within a single platform [14,15].

The rule-based engine encodes the same epidemiological risk factors that the ML literature on this feature set repeatedly identifies as most informative, including age, age at first intercourse, number of pregnancies, smoking, hormonal contraceptive use, and STI history [21,24], but assigns them clinically interpretable weights rather than learned ones. Age, smoking status, sexual history variables, and STI history, which carry the largest weights in the current engine, are well-documented risk determinants supported by the WHO [1,5,6], strengthening the clinical plausibility of the engine's thresholds. This concordance strengthens the clinical plausibility of the model and supports its potential utility as an educational and preliminary risk-awareness tool. Importantly, the model is positioned not as a diagnostic instrument but as a decision-support mechanism to encourage screening and early healthcare engagement.

The integration of a RAG chatbot addresses a well-documented limitation of LLMs: hallucination and factual inconsistency. By grounding responses in a curated knowledge base prior to generation, the system enhances informational reliability while preserving conversational flexibility. Multilingual deployment in English, Spanish, Yoruba, and Swahili represents a meaningful step toward reducing linguistic barriers in cervical cancer communication. Cultural and linguistic adaptation is particularly significant given that disparities in screening uptake are frequently associated with limited health literacy, language access challenges, and mistrust in health care systems.

The health care facility recommendation module further extends the intervention from education to action. By coupling risk awareness with geolocation-based screening navigation, the system bridges the gap between knowledge acquisition and service use. This integration reflects an implementation-oriented approach to digital public health, moving beyond static awareness campaigns toward personalized, context-aware engagement.

From a systems perspective, the modular 3-tier architecture is effective in supporting scalability, cross-platform deployment, and secure data processing. The Privacy by Design framework, characterized by encrypted communication, nonretention of personally identifiable information, session-based processing, and explicit consent, addresses critical ethical considerations in AI-driven health technologies. These safeguards are particularly important in underserved communities where digital trust and data security concerns may influence adoption.

A further consideration concerns how individualized risk outputs are interpreted by the people who receive them. Because the system returns categorical low-risk, medium-risk, or high-risk classifications, there is a foreseeable risk that a low-risk result is read as an indication that routine screening is unnecessary or that existing symptoms do not warrant clinical attention—a false-reassurance effect that would run directly counter to the platform's purpose. The inverse risk also applies: a high-risk classification may generate anxiety disproportionate to an individual's actual clinical picture, particularly where access to confirmatory screening is limited. Related concerns include over-reliance on an automated tool in place of clinical consultation and therapeutic misconception, in which a system intended as educational is understood as delivering diagnostic care. The safeguards currently implemented (medical disclaimers, escalation prompts, and explicit framing of the model as a risk-awareness rather than diagnostic instrument) are necessary but not demonstrably sufficient, since none has yet been tested against actual user comprehension. Future evaluation should therefore measure not only usability but also interpretive accuracy: whether users correctly understand what a risk band does and does not mean, and whether receiving a low-risk output alters stated screening intention. Until such evidence exists, the platform should be positioned alongside,

XSL•FO
RenderX

rather than in place of, established screening promotion pathways.

Limitations

Despite these strengths, several limitations warrant consideration. First, the risk engine's weights and thresholds are expert-defined and have not been calibrated against screening or histological outcomes; the levels should therefore be interpreted as an ordinal prompt to seek screening rather than as an estimate of absolute risk. Calibration against outcome-linked data from a partner screening program, and assessment of whether the thresholds perform equitably across age groups and populations, are necessary before any stronger claim can be made. Second, while retrieval augmentation reduces hallucination risk, LLM outputs remain probabilistic and require ongoing monitoring to prevent bias or misinterpretation. Third, multilingual validation was uneven across languages: interface and questionnaire strings were validated in all 4 languages, but the chatbot knowledge base is natively authored only in English and Spanish, and Swahili chatbot output was not evaluated. Swahili and Yoruba chatbot replies rely on the LLM's translation of English passages and may carry subtle terminological or register errors that native-speaker review of the interface alone would not detect. Fourth, the facility module depends on community-maintained OpenStreetMap data whose specialty tagging is inconsistent; its relevance signal is a keyword match rather than a verified credential, and facility details were not independently confirmed. Users are advised in-app to confirm services before travelling, and integration with an authoritative national facility register is planned.

Future Work

Future research will focus on clinical validation, bias auditing, and recalibration of predictive thresholds across diverse populations, as well as participatory evaluation with community stakeholders. Integration with electronic health record systems and public health screening programs may further enhance real-world applicability and impact. Additionally, expansion to other preventable cancers and chronic diseases could extend the system's public health utility.

Conclusion

This study demonstrates the technical feasibility and indicates the potential public health value of a multilingual, AI-driven platform for cervical cancer awareness, risk stratification, and health care navigation. By combining transparent risk stratification with conversational engagement and service navigation, the system moves beyond isolated AI functionalities toward an integrated, interdisciplinary digital public health intervention. Although further validation and real-world evaluation are required, the present study provides foundational evidence that multilingual AI-driven dialogue systems can serve as scalable tools to promote equitable access to cervical cancer prevention resources. The findings underscore the potential of ethically designed, community-informed AI systems to support health literacy, reduce screening barriers, and contribute to more inclusive cancer prevention strategies.

Funding

The authors declared no financial support was received for this work.

Data Availability

The University of California, Irvine (UCI) Cervical Cancer (Risk Factors) dataset that defines the questionnaire schema is publicly available from the UCI Machine Learning Repository [20,35]. The backend source code comprising the rule-based scoring engine with its complete weight table, the retrieval-augmented chatbot pipeline, the facility-search module, and the seed file containing all 14 knowledge-base passages with their source URLs, as well as the Flutter application source code, including the 4 language resource files, are available on GitHub [36]. The evaluation materials (the 50-query retrieval benchmark with relevance labels, the question-answer evaluation set, the adversarial prompt set with ratings, and the 30 simulated locations with facility ground-truth annotations) are provided as supplementary material on GitHub. A docker-compose file and seeding script allow the knowledge base and database to be recreated locally.

Generative AI Use

The authors declare the use of generative AI (GenAI) in the research and writing process. According to the GAIDeT (Generative AI Detection Taxonomy; 2025), the following tasks were delegated to GenAI tools under full human supervision: evaluation of the novelty of the research and identification of gaps, data cleaning, data analysis, proofreading and editing, and summarizing text. The GenAI tools used were ChatGPT 4.5 (OpenAI) and Claude AI (Anthropic). Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Conflicts of Interest

None declared.

Abstract

Background: People living with advanced cancer experience more frequent and severe symptoms than those with early-stage disease. Common, distressing symptoms include sleep difficulties, worry and uncertainty, fatigue, and depression. Cognitive behavioral therapy (CBT) and acceptance and commitment therapy (ACT) effectively manage these symptoms but are often too time intensive for patients with multiple appointments, limited energy, and competing priorities. Brief, mobile health (mHealth) interventions provide an accessible alternative, particularly for rural patients with limited access to palliative or psychosocial oncology services.

Objective: Building on our successful in-person and Digital Video Disk–based pilot trial of a 3-session, integrated CBT-ACT symptom management intervention for patients with advanced cancer, Finding Our Center Under Stress (FOCUS), the current study evaluated the feasibility and acceptability of a 4-session mHealth version.

Methods: In this single-cohort feasibility and acceptability study, people with advanced cancer were recruited from hospital-based oncology clinics representing 4 cancer types (breast, melanoma, multiple myeloma, and prostate). Baseline assessments included sociodemographic data, patient-reported outcomes for sleep (Insomnia Severity Index), anxiety (7-item Generalized Anxiety Disorder scale and Penn State Worry Questionnaire), fatigue (Fatigue Symptom Inventory), depression (Center for Epidemiological Studies Depression Scale), and a 7-day sleep diary completed in the app. Participants then completed 4 modules addressing sleep difficulties, worry and uncertainty, fatigue, and depression. Primary outcomes were feasibility and acceptability. Feasibility benchmarks included recruitment (50% enrollment), retention (70%), and app completion (50%). After 6 weeks, participants completed the Internet Evaluation and Utility Questionnaire, and a subset completed qualitative interviews about their experience with the FOCUS app. We report quantitative and qualitative findings and lessons learned from app development.

Results: Overall, 64.7% (11/17) of the approached patients enrolled, and 70% (7/10) completed more than half of the app. Participants rated FOCUS highly for ease of understanding (mean 3.83/4, SD 0.41), convenience (mean 3.67/4, SD 0.82), and utility (mean 3.33/4, SD 0.82). All participants would recommend the app to others and would use it again for future problems. Favorite components included patient videos and the Sleep and Worry and Uncertainty Modules. Suggested improvements included video quality (lighting and sound), sleep diary usability, and additional professional guidance.

Conclusions: The FOCUS intervention was successfully delivered via mobile technology and demonstrated feasibility and acceptability in beta testing. The FOCUS mHealth app offers an evidence-based, accessible symptom management intervention for people with advanced cancer, particularly in rural communities. Guided by participant feedback, FOCUS 2.0 will enhance video segments, add telehealth support, and expand interactive and motivational features. A randomized controlled trial will evaluate its effectiveness.

KEYWORDS

cancer; mobile health; mHealth; symptom management; mobile app; sleep; anxiety; fatigue; depression; uncertainty

Introduction

People with advanced cancer experience more frequent and severe psychological and physical symptoms than people with early-stage cancer [1-4]. Four of the most common and distressing symptoms reported by people with advanced cancer are sleep difficulties, worry and anxiety, depression, and fatigue [1,2,4,5]. These symptoms co-occur and contribute to functional impairment, poorer quality of life, and mortality yet are commonly undertreated, especially in rural communities [6-8]. Effective, accessible symptom management is an essential component of comprehensive survivorship care for people with advanced cancer.

In response to the symptom management needs experienced in advanced cancer, we developed Finding Our Center Under Stress (FOCUS), a brief, integrated cognitive behavioral therapy (CBT) and acceptance and commitment therapy (ACT) symptom management intervention. We targeted sleep, anxiety, fatigue, and depression as these were common and distressing symptoms experienced by patients in our outpatient oncology–palliative medicine clinic [4]. We used the most effective and well-used evidence-based CBT-ACT strategies selected by the principal investigator (PI), who has over 20 years of clinical experience with people with advanced cancer [9-16]. We developed a brief, 3-session intervention that included 2 in-person sessions and 1 Digital Video Disk (DVD) session. The DVD included videos recorded by people with advanced cancer as well as our psychology team. We created a standardized FOCUS patient handbook and a corresponding professional therapy manual that guided the in-person components of the intervention.

Using FOCUS, participants learn skills to self-manage their symptoms and improve their ability to focus on what matters most to them despite these symptoms. We conducted a pilot randomized controlled trial with people with advanced cancer, and the results demonstrated improved sleep on both self-report [17] and physiological measures (ie, actigraphy) [18] and moderate to strong improvements in worry, depression, and fatigue interference. However, in this previous pilot study, the primary reason for noneligibility was transportation (35%), and the primary reasons for study refusal were too many appointments (35%) and being too ill (21%).

To increase access to symptom management, mobile health (mHealth) and telehealth symptom management interventions have been developed. These demonstrate positive effects on self-efficacy, symptom distress, and psychological well-being [19,20]. mHealth is "the use of mobile and wireless devices to improve health outcomes, health care services, and health research" [21]. Positive outcomes have been demonstrated for insomnia [22,23], anxiety [24,25], depression [26-31], and fatigue [25,32]. Meta-analyses indicate that mHealth behavioral interventions impact symptom reduction to an extent comparable to face-to-face interventions [33,34]. However, most of these apps focus on single symptoms, or the studies evaluating them include only people with early-stage cancer after treatment, which may benefit outcomes based on symptom regression to the mean [35,36]. Many interventions are also too lengthy (ie, 12-20 sessions) and do not focus on the specific needs and worries of people with advanced cancer.

This paper describes the translation of our FOCUS symptom management intervention to a brief, 4-module mHealth intervention. We present results of our FOCUS 1.0 beta testing with a small but diverse sample of people with advanced cancer from geographically distinct areas of Ohio. Our goal was to conduct a single-cohort trial to determine whether FOCUS 1.0 was feasible and acceptable to people with advanced cancer and identify next steps to prepare for a randomized clinical effectiveness trial of the FOCUS mHealth intervention.

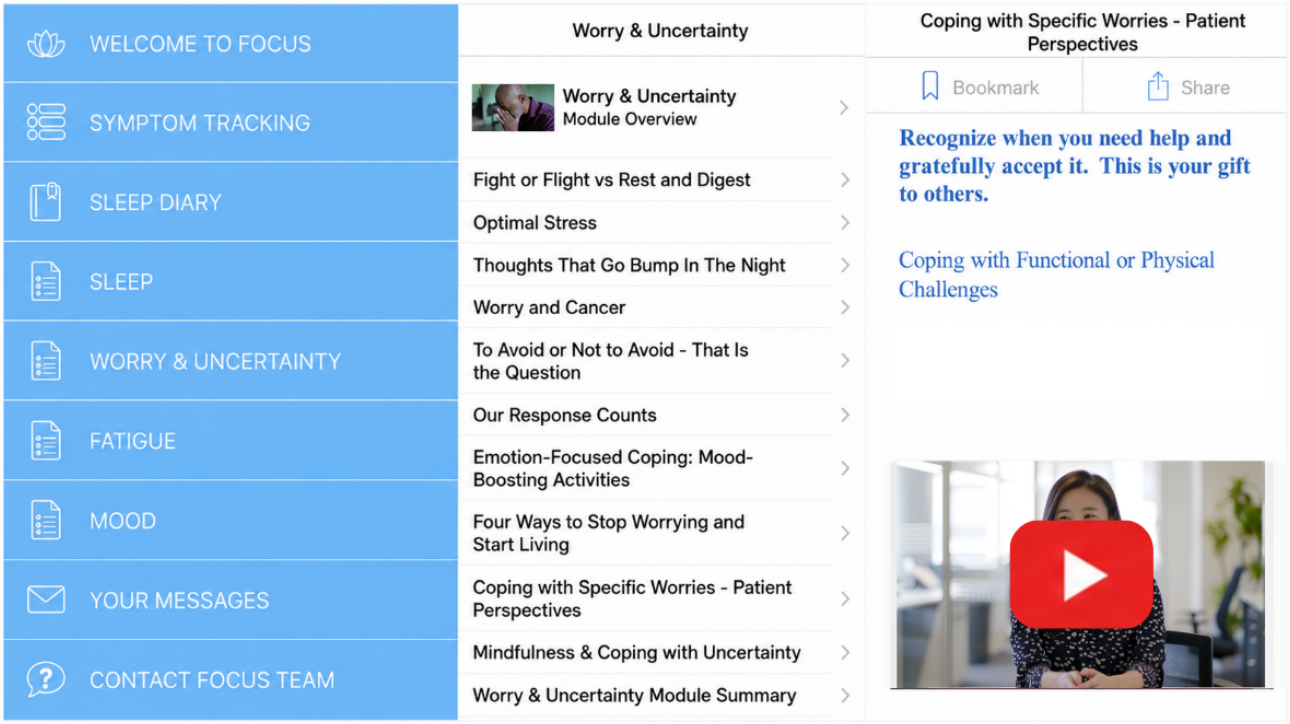
Methods

Design

This was a single-cohort feasibility and acceptability study designed to evaluate trial accrual, app engagement and completion, sleep diary and questionnaire administration, and acceptability. We also completed qualitative interviews to determine strengths and areas for improvement of FOCUS 1.0.

App Translation Process

The FOCUS 1.0 app was developed between February 2021 and April 2021 based on intervention content from our previous in-person intervention [17]. At this time, there was no multi-symptom app available specifically for people with advanced cancer. Unique features of our app include tailoring to people with advanced cancer, combination of CBT and ACT approaches, and inclusion of a modified exercise program for fatigue. The app was developed pro bono by a local digital health company (Duet Health) in collaboration with the PI (SW-DG), who created the content for the previous in-person clinical trial. App questionnaires and the sleep diary were developed by Duet Health, and the text and video content was entered into the content management system by the PI. Collaborators (DMB, SC, AD, KK, CP, and DM) reviewed the app content, and iterative rounds of feedback were conducted. Materials targeted an average Flesch-Kincaid eighth-grade reading level per Microsoft Word document statistics based on an average Program for the International Assessment of Adult Competencies adult literacy score of 268 in Ohio, corresponding to reading level above the sixth-grade but below a ninth-grade reading level. This reading level was deemed appropriate given our attempt to balance accessibility with fidelity to psychosocial oncology content [37].



FOCUS 1.0 Intervention

FOCUS 1.0 includes 5 total hours of intervention spaced across 6 weeks (not including independent practice of intervention strategies), as well as a 5-minute welcome video, study

XSL•FO
RenderX

questionnaires, and information on how to contact the research team. The intervention components of the app are divided into 4 primary modules (Figure 1), each focused on different symptoms as follows: 1.5 hours on sleep, 1 hour on worry and uncertainty, 1.5 hours on fatigue, and 1 hour on mood. The intervention content incorporates CBT and ACT strategies by using text, imagery, videos, and interactive elements throughout the 4 symptom modules. Each module includes informational text and videos from experts to teach participants more about these symptoms and self-management strategies. Modules also include testimonial videos from people living with advanced cancer focused on sharing their experiences with symptom burden, changes in independence, financial stress, and functional challenges and how they have coped with uncertainty. Interactive and instructional relaxation and mindfulness videos are incorporated into the modules, as well as brief exercise videos from our rehabilitation oncology team to target cancer-related fatigue. In addition to the videos, the app incorporates interactive exercises and printable worksheets throughout, including values identification and constructive worry exercises.

Figure 1. Finding Our Center Under Stress (FOCUS) 1.0 (A) home screen, (B) worry module table of contents, and (C) sample worry intervention content. Original patient video image was replaced by stock photo to protect patient privacy.

Participants

The current pilot trial included 11 participants recruited from breast cancer, prostate cancer, melanoma, and multiple myeloma clinics based on recommendations from collaborating oncologists. Eligibility criteria were being aged 18 years or older and having a diagnosis of advanced-stage cancer.

Measures

Primary Outcomes

Feasibility

We determined feasibility based on potential participants' willingness to take part in the study, as well as the proportion of intervention modules completed after 6 weeks without prompting. Specifically, feasibility was defined as 50% study enrollment after recruitment (n=17), 70% retention, and completion of at least half (50%) of the app content during the 6-week enrollment period. We also assessed technology skills using the Computer Proficiency Questionnaire−12, a 12-item self-report measure that assesses an individual's perceived ability to perform common computer tasks across domains such as basic computer operations, internet use, communication, scheduling, and multimedia functions. Respondents rate their proficiency on a 5-point scale, with higher scores indicating greater computer proficiency. The measure has demonstrated excellent internal consistency (Cronbach α=0.95). We used this measure in an attempt to establish a criterion score for use in our larger randomized trial [38].

Acceptability

The Internet Evaluation and Utility Questionnaire (IEUQ) [39] measures participants' experiences and perceptions of an internet-based intervention. The IEUQ has 15 items and 3 open-ended response items. Items 1 to 8 assess ease of use, convenience, engagement, enjoyment, layout, privacy, satisfaction, and acceptability. Items 9 to 15 assess usefulness, comprehension, trustworthiness, credibility, likelihood of returning, mode of delivery, and helpfulness. Participants respond to questions on a 5-point Likert scale (0="not at all," 1="slightly," 2="somewhat," 3="mostly," and 4="very"). Scores above 2.5 were considered acceptable. Additionally, the IEUQ includes 3 items that elicit limited qualitative feedback from participants, specifically on what the participants found to be the most and least helpful parts of the app, and provides space for participants to provide suggestions to improve the

XSL•FO
RenderX

program. For this study, Cronbach α reliability (items 1-13) was 0.90.

Secondary Patient-Reported Outcomes

We included several measures to test the viability of assessment of future study patient-reported outcomes (PROs) via the app. These included the Insomnia Severity Index [40], 7-item Generalized Anxiety Disorder scale [41], Fatigue Symptom Inventory [42], Center for Epidemiological Studies Depression Scale [43], the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 [44], and the Penn State Worry Questionnaire [45].

Procedures

Data collection took place from April 2021 to August 2021. Participants were recruited through collaborating oncology clinics. Each collaborating oncologist was asked to recommend 2 to 3 patients with advanced-stage cancer to beta test the FOCUS app, and they were encouraged to recommend a diverse sample. Potential participants were contacted via phone and were told that their oncologist had recommended them for the study. They were informed that the app was designed to help manage symptoms and cope with cancer and specifically to learn strategies for improving sleep, worry, fatigue, and mood. They were advised that they could participate from home with no in-person appointments. Participants were informed that each module would take between 1 and 2 hours in addition to time to practice the strategies. Interested participants consented to the study via email or mail as per patient preference. Consented participants were then provided with a link to the app, which was available via iOS and Android using their own devices. They were provided a unique password to protect their confidentiality. They completed questionnaires at the start of app use, monitored their sleep for 1 week using the sleep diary feature of the app, and then completed 1 module each week with coping strategies to try. There was no training other than instructions for signing into the app and for completing questionnaires and exercises on the app. Participant instructions (once signed into the app) were as follows: “Complete questionnaires in the Symptom Tracker portion of the app. Then for a week, you will record your sleep for 5 minutes each morning in the Sleep Diary. The following week you will begin the first module and complete one each week starting with the Sleep Module.” The Sleep Module instructions were as follows: “As part of the Sleep Module, you create a sleep restriction schedule based on your data in the Sleep Diary. Go back to your Sleep Diary and review your data for the previous week. Add up the number of hours you slept each night for 7 days and divide by 7. Then add half an hour to this. For instance, if you sleep 6 hours each night: (6 + 6 + 6 + 6 + 6 + 6 + 6)/7 = 6. So you would set your sleep schedule for 6.5 hours with specific wake and bedtimes. Practice this for one week and add 1/2 hour if you are still tired when you wake. And practice relaxation exercises.”

Ethical Considerations

This study was approved by the Ohio State University Institutional Review Board (2010C0004). All participants were English speakers and provided informed consent via mail or email prior to starting the study.

Analyses

Given the formative, single-arm nature of this feasibility and acceptability study, our analyses were primarily descriptive rather than inferential. We used percentages to represent feasibility, including the percentage of patients approached for the study who agreed to participate, the percentage who completed the study, and the percentage of modules completed after 6 weeks without prompting. We also report the sample’s computer proficiency scores. Acceptability was examined using descriptive statistics (means and SDs on the IEUQ). Descriptive statistics are also provided on our PROs compared against other cancer sample norms when available, offering an exploratory picture of the symptomatic nature of this population; given the small sample size, these comparisons should be interpreted as hypothesis generating rather than confirmatory. We conclude our analyses with an exploration of our qualitative data from the IEUQ. Content analysis was applied to open-ended items, assessing what was most and least helpful about the app. Two members of the research team independently reviewed and coded participant responses, then conferred to reach consensus on final categories. Given that these items were brief and targeted, designed to capture usability feedback rather than support in-depth qualitative inquiry, this approach was deemed appropriate for the scope and intent of the data. Consistent with the exploratory aim of this study, the findings are therefore presented descriptively rather than as formal themes.

Results

Sample Characteristics

A total of 54.5% (6/11) of the sample was female, 72.7% (8/11) were non-Hispanic White individuals, and 72.7% (8/11) were married. The average age was 65.91 (SD 13) years. Participants were diagnosed with breast cancer (4/11, 36.4%), prostate cancer (4/11, 36.4%), melanoma (2/11, 18.2%), and multiple myeloma (1/11, 9.1%), with an average time since diagnosis of 10.55 (SD 8) years. In total, 81.8% (9/11) had prior surgery, 45.5% (5/11) had chemotherapy, 90.9% (10/11) had radiation, 63.6% (7/11) had hormonal therapy, and 18.2% (2/11) had immunotherapy (Table 1).

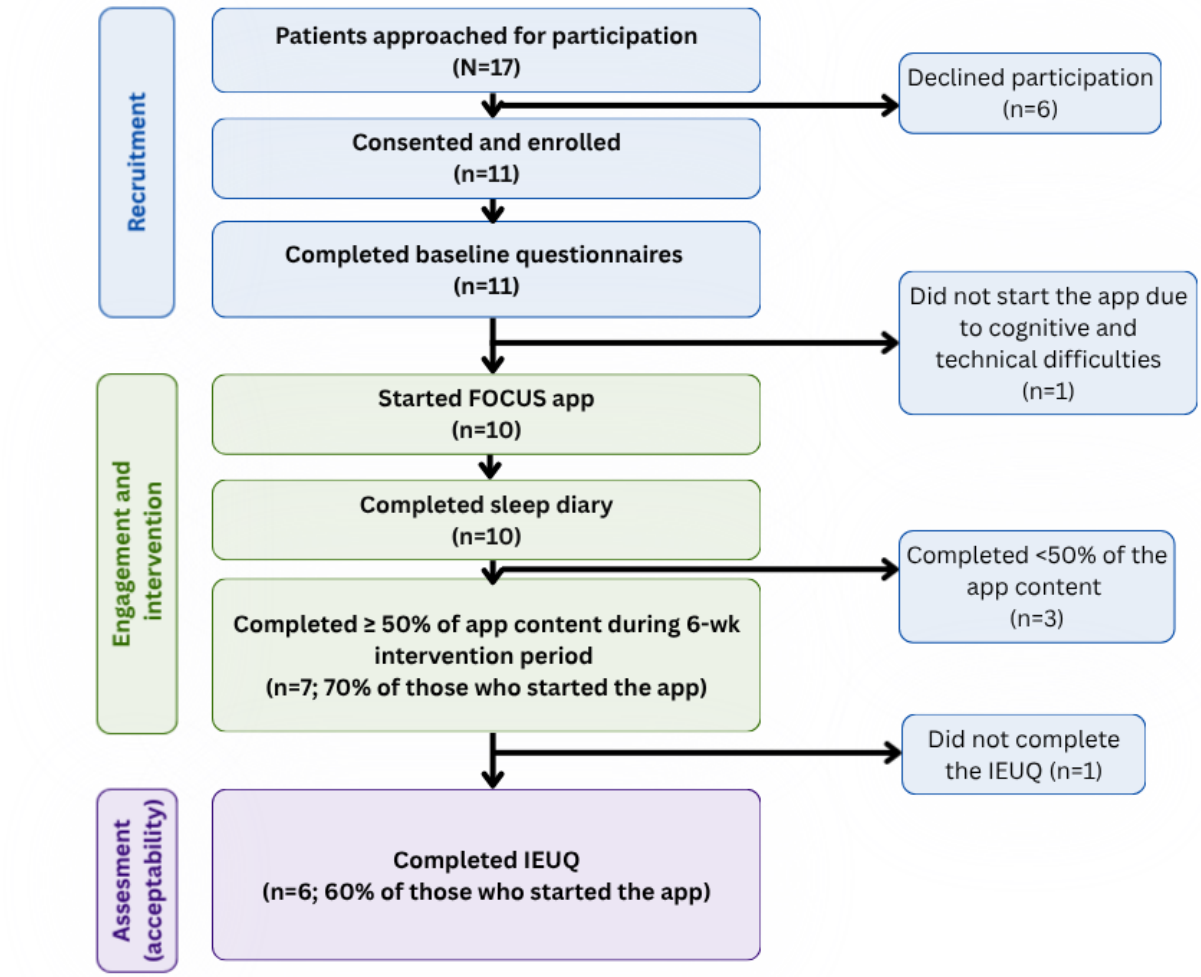
[a]RUCC: Rural-Urban Continuum Codes.

[b]SF-36: 36-item Short Form Health Survey.



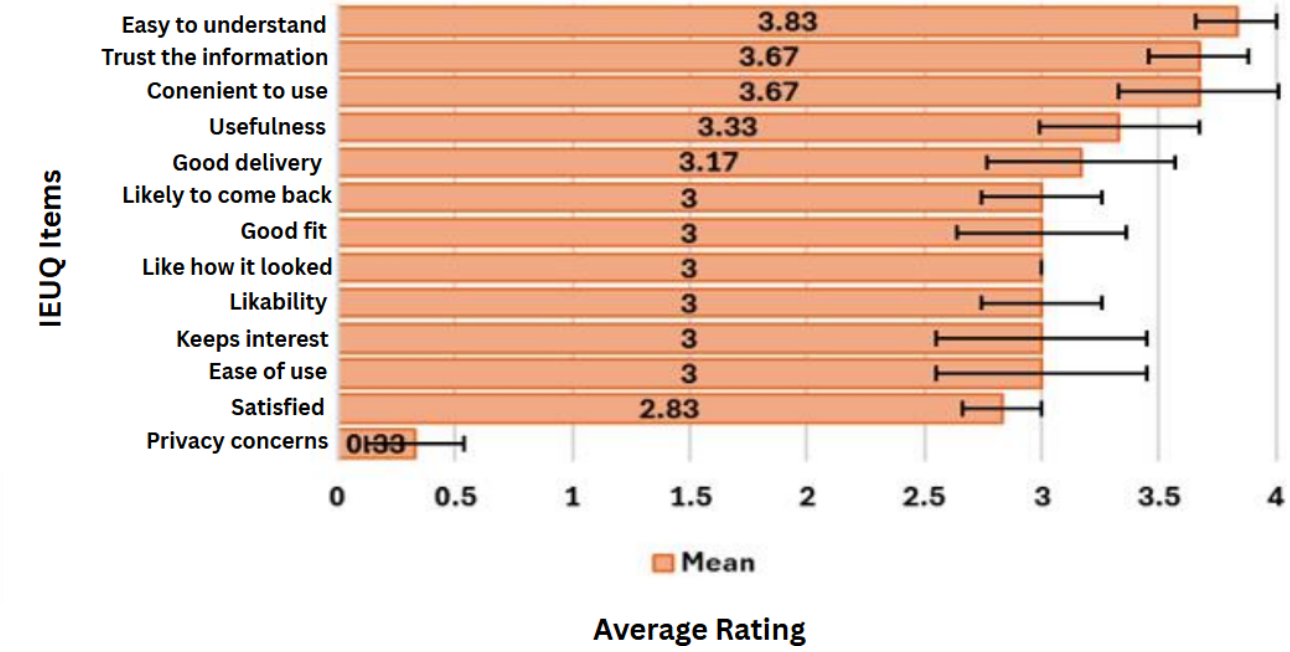
In total, 36.4% (4/11) were from rural communities (Rural-Urban Continuum Codes 4-9) [46]. Most were retired (7/11, 63.6%), although some were considered disabled due to cancer (2/11, 18.2%), and others still worked full time (1/11, 9.1%). Most (10/11, 90.9%) reported no current financial difficulties related to cancer. A total of 72.7% (8/11) had a history of mental health diagnoses, most commonly depression (4/11, 36.4%) and depression and anxiety (2/11, 18.2%). In total, 9.1% (1/11) had a history of panic attacks, and another participant (1/11, 9.1%) had schizoaffective disorder. Some (2/11, 18.2%) had received psychotropic medications, and some (2/11, 18.2%) had received both medications and counseling or therapy. Most (7/11, 63.6%) had received no mental health treatment despite the high prevalence of mental health diagnoses. Most had adequate (5/11, 45.5%) to excellent (4/11, 36.4%) support.

FOCUS Feasibility

Participant flow through FOCUS 1.0 beta testing is shown in Figure 2. Of 17 patients with advanced cancer approached for participation, 11 (64.7%) enrolled and completed the baseline questionnaires. Of these 11 participants, 1 (9.1%) was unable to engage with the intervention because of cognitive and technical difficulties and did not initiate app use, leaving 10 (90.9%) participants who started the FOCUS app and completed the sleep diary. Of these 10 participants, 7 (70%) completed more than 50% of the app content during the 6-week intervention period, meeting the predefined feasibility criterion. Those not completing 50% (of the app) (3/10, 30%) noted challenges with the sleep diary and difficulty navigating the app, and another participant did not start the app due to other family or life circumstances. A total of 60% (6/10) of the participants completed the IEUQ used to assess intervention acceptability.

XSL•FO
RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. FOCUS: Finding Our Center Under Stress; IEUQ: Internet Evaluation and Utility Questionnaire.



FOCUS Acceptability

All ratings of the app on the IEUQ were above 3.00 (“mostly” or “very”) other than the satisfaction rating, which was 2.83 (“somewhat” to “mostly”; Figure 3). Participants rated FOCUS highly for ease of understanding (mean 3.83/4, SD 0.41), trust (mean 3.67/4, SD 0.52), convenience (mean 3.67/4, SD 0.82), and utility (mean 3.33/4, SD 0.82).

XSL•FO
RenderX

Figure 3. Average Internet Evaluation and Utility Questionnaire (IEUQ) ratings including standard error (n=6). A total of 30% (3/10) of the participants completed <50% of the app after 6 weeks and were excluded as they did not complete the app. Another participant did not complete the IEUQ.

PROs

As anticipated, participants were highly symptomatic at baseline given their disease status. Participants scored well above the mean compared to other cancer samples on the Insomnia Severity Index, 7-item Generalized Anxiety Disorder scale, Fatigue Symptom Inventory, Center for Epidemiological Studies Depression Scale, and Penn State Worry Questionnaire (see Table 2). Participants scored below the mean on the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 for cancer samples. Computer proficiency scores were superior compared to older adults in the general population, demonstrating good computer proficiency in this sample [38].

Table . Patient-reported outcomes (PROs) at baseline.

PRO	Scale range	Cutoff scores	Sample, mean (SD)	Cancer population , mean (SD)
Insomnia (ISI)	0-28	Mean≥10	11.55 (7.09)	7.3 (6.3)-12.4 (6.7)
Anxiety (GAD–7)	0-21	Mean≥8	6.5 (5.8)	5.1 (4.0)-6.7 (5.2)
Fatigue (FSI)	1-10	Mean≥3	5.0 (2.5)	3.7 (2.2)
Depression (CES-D)	0-60	Mean≥16	19.8 (14.1)	11.6 (9.1)
Quality of life (EORTC-QLQ-C30)	0-100	Mean≤50	39.4 (13.5)	69.3 (20.7)
Worry (PSWQ)	16-80	Mean≥45	48 (15.06)	43.3(13.1)
Computer proficiency (CPQ-12)	6-30	10	25.6 (4.1)	NA

[a]ISI: Insomnia Severity Index, GAD-7: 7-item Generalized Anxiety Disorder scale, FSI: Fatigue Symptom Inventory, CES-D: Center for Epidemiological Studies Depression Scale, EORTC-QLQ-C30: European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30, CPQ-12: Computer Proficiency Questionnaire–12.

[b]Cutoffs: Insomnia Severity Index [47], 7-item Generalized Anxiety Disorder scale [48], Fatigue Symptom Inventory [49], Center for Epidemiological Studies Depression Scale [50], and European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 [51]. CPQ-12 scores < 10 are below average compared to the general population and represent users who may need additional training or support [38].

[c]Cancer population norms: Insomnia Severity Index [40,52], 7-item Generalized Anxiety Disorder scale [53,54], Fatigue Symptom Inventory [55], Center for Epidemiological Studies Depression Scale [56], and European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 [57].

[d]No official cutoff score for the PSWQ exists. The cutoff score of M≥45 is often used to indicate elevated worry [58].

[e]NA: not available.

Qualitative Feedback

Qualitative feedback was collected via 3 open-ended items from the IEUQ, which asked participants to identify the most and least helpful aspects of the app and offer suggestions for improvement. Given the targeted nature of these items, the findings are organized below by valence rather than formal thematic analysis.

Strengths

All participants would recommend the app to others and would use it again for future problems. Participants' favorite aspects of the app included the patient videos. One participant noted the following:

> *I have never participated in support groups as I am an introvert, but seeing that others are experiencing the same thoughts, feelings, and symptoms as me has been a great source of comfort.*

Participants preferred the Sleep Module and the Worry and Uncertainty Module. In particular, they appreciated learning about relaxation techniques and sleep restriction, the stretching and relaxing recording (Fatigue Module), and challenging stressful sleep thoughts. One person noted the following:

> *I would give the top rating to all aspects of the program. I cannot even begin to tell you what it has done for me. I hope that I will be able to always view the information so I can use it in the future if I start feeling down again.*

Areas for Improvement

Feedback on areas for improvement centered on technical issues, including difficulty accessing the app-based sleep diary and questionnaires; video streaming interruptions and quality issues (ie, audio and lighting); and a desire for access to professional and technical support.

Discussion

Primary Findings

In this single-cohort feasibility and acceptability study, participants with advanced cancer evaluated FOCUS 1.0, an integrated mHealth CBT-ACT symptom management intervention targeting sleep, anxiety, fatigue, and depression. FOCUS 1.0 was developed by translating the content of our previous 3-session FOCUS intervention [17] into an mHealth app, which we successfully developed over a period of 3 months. For the current study, we recruited a small but diverse sample, with higher rates of rural (4/11, 36.4%) and minority group (3/11, 27.3%) participants than the rates in our state (24% and 24%, respectively) [59,60]. We also had an impressive recruitment rate (11/17, 64.7%) for a sample of people with advanced cancer [61,62]. We did not specifically include or exclude people with a history of mental health diagnoses and were surprised to find that 72.7% (8/11) reported a history of psychological diagnoses, demonstrating our ability to recruit a sample with diverse mental health concerns. Most participants (7/10, 70%) completed at least 50% of the app content and provided overall positive acceptability ratings. These preliminary findings provide initial support for the feasibility and acceptability of FOCUS 1.0 as an intervention for patients with advanced cancer. Our PRO data are consistent with the highly symptomatic nature of this population of patients who may benefit from the app.

Participant Feedback

Participants rated ease of understanding very highly, demonstrating that our efforts to enhance readability of content with a sixth to ninth grade Flesch-Kincaid reading level were helpful. Participants also rated convenience and intervention method highly, which is a promising early signal although not conclusive evidence of reach or effectiveness. It is important to note that living with advanced cancer presents many barriers to in-person interventions, including but not limited to travel challenges, difficulty engaging due to feeling ill, and limited time due to having many medical appointments. This intervention attempts to remedy some of these barriers by providing skills and resources in an accessible format. While we cannot draw conclusions on the effectiveness of the intervention with these pilot data, participants found the content useful to address their needs, a criterion essential for motivating app use, particularly among older adults [63,64]. They trusted the content and would revisit it if problems arose again in the future.

Results from qualitative feedback highlighted several strengths of FOCUS 1.0. Participants particularly liked patient-recorded videos designed to share how other patients approach several cancer-related worries. Participants also enjoyed the interactive practice videos, including videos demonstrating relaxation techniques and physical activity to address fatigue (eg, stretching and relaxing). The Worry and Uncertainty and Sleep Modules were reported to be the most helpful. In particular, participants found utility in identifying unhelpful thoughts related to sleep [65,66] and sleep restriction.

Lessons Learned

While the current results are promising, we encountered several issues that should be noted and addressed in future studies (Table 3). First, participants experienced a variety of technical issues that resulted in understandable frustration. For example, participants noted that the sleep diary designed for the app did not auto-calculate an average time in bed sleeping, which is essential for sleep restriction and scheduling (a primary component of the Sleep Module). To address technical issues, we recommend conducting thorough testing to ensure that the components of the mHealth app are working properly and building in a virtual technical support component to address patient questions and enhance patient motivation for app completion [67-71]. Second, including the questionnaires as the initial step on the app created undue participant burden and limited enthusiasm for venturing further with the symptom modules. Additionally, we encountered a glitch with our questionnaire system such that our week 6 questionnaires were not released to participants automatically, with consequent data loss for this follow-up assessment. To address this, we recommend building the questionnaires outside of the app in a system such as REDCap or Qualtrics. In addition to reducing the perceived burden associated with the mHealth app for participants, this would reduce the workload for researchers

XSL•FO
RenderX

associated with privacy protections when data are collected within an app and potentially prevent issues with data loss. Third, participants reported a desire for additional professional support in terms of learning symptom management strategies. To address this, we have developed a telehealth professional support component to improve user motivation and experience using the app. Fourth, 9.1% (1/11) of the recruited participants were unable to engage with the intervention content due to cognitive and technological issues that we could not resolve by providing additional support. Future studies testing mHealth interventions may benefit from incorporation of cognitive and mobile proficiency screening.

Table . Finding Our Center Under Stress (FOCUS) 1.0 problems and FOCUS 2.0 planned solutions.

FOCUS 1.0 problem	FOCUS 2.0 solution
Sleep diary not working properly to calculate time in bed sleeping	Constructing a new sleep diary that auto-calculates time in bed sleeping for ease of participant use
General technical issues	Grant funding included for technical support to reduce technical barriers; use of mobile and computer proficiency tests to screen participants
Questionnaires built into app and not delivered on schedule	Questionnaires now built outside of the app in REDCap to reduce burden and privacy risks in the app and scheduled for repeat administration
Desire for more professional support	Designed a telehealth professional support protocol and manual to accompany app use
Participants with cognitive impairment	Screening for cognitive impairment as part of the prescreening process

Limitations

Several limitations should be considered when interpreting the findings of this study. First, the small sample size (N=11) limits generalizability; however, given the feasibility and acceptability focus of this study, the sample size is appropriate for generating initial evidence. Second, qualitative data were collected via brief open-ended items designed to capture user feedback on app usability rather than to support more sophisticated qualitative analysis (eg, thematic analysis). Future studies should incorporate more rigorous qualitative methods to more fully capture participant perspectives and inform iterative intervention refinement. Third, for this study, we relied on self-reported sleep measures and did not include objective monitoring devices. While the focus at this stage of app development was app user experience, including app-based sleep diary development, we recognize this as a limitation and plan to use objective sleep monitoring devices (ie, actigraphy watches) in our larger randomized clinical trial. Finally, despite higher-than-average computer proficiency, at least 30% (3/10) of the participants experienced technical difficulties. This study did not provide formal technical support for participants, which may have influenced engagement and usability outcomes. Addressing these limitations in future iterations will be important for strengthening implementation and evaluation, as well as participant intervention engagement.

Conclusions

In conclusion, although individuals coping with advanced cancer experience substantial psychological and physical symptom burden, few have access to interventions that effectively support symptom management. Findings from this feasibility and acceptability study suggest that FOCUS 1.0 shows promise in addressing these gaps in care. This study represents an initial, formative step in the iterative process of refining and evaluating the FOCUS intervention. While additional research is needed to establish the efficacy of FOCUS 1.0, this mHealth intervention has the potential to offer an accessible and scalable psychosocial treatment option for patients with advanced cancer, including those living in rural and underserved communities.

Acknowledgments

The authors would like to acknowledge their beta testing participants, whose feedback was essential to building a more engaging app for people with advanced cancer. They would also like to acknowledge Duet Health for their support with the build of Finding Our Center Under Stress (FOCUS) 1.0. During the preparation of this manuscript, the authors used ChatGPT (OpenAI) to generate Figure 2 based on the primary data provided in the text. The tool was used solely to format and visually map the data into a chart layout. After generation, the authors strictly reviewed, verified, and cross-checked the visual output against the raw manuscript data to ensure accuracy, proper formatting, and correct axis labeling. The authors take full responsibility for the contents of the final figure and the integrity of the published work.

Funding

The research reported in this publication was supported by the National Cancer Institute of the National Institutes of Health under award R01CA281885 and the Ohio State University Comprehensive Cancer Center Cancer Control Grant (GR122403). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Conflicts of Interest

Duet Health developed the Finding Our Center Under Stress (FOCUS) 1.0 app evaluated in this study on a pro bono basis. SW-DG was involved in the design and development process of the app in collaboration with Duet Health, and DMB, SC, AD, KK, CP, and DM reviewed app content and provided feedback. No author received financial compensation, equity, or other financial benefit from Duet Health in connection with this work, and Duet Health had no role in the study design, data collection and analysis, interpretation of results, or decision to submit this manuscript for publication. All other authors declare no other conflicts of interest.

Abstract

Background: A peripherally inserted central catheter (PICC) for vesicant or long-term chemotherapy is recommended for safe and sustainable drug delivery. However, maintaining its benefits requires regular and careful self-management. Although medical staff provide education and telephone consultation, proactive support accessible at any time or location remains limited. Therefore, we developed a rule-based chatbot to support PICC self-management.

Objective: This study aimed to evaluate the feasibility of a chatbot designed to support PICC self-management by examining chatbot use rate, usability, and user experience.

Methods: A mixed methods study was conducted from September to December 2022, adhering to the GRAMMS (Good Reporting of a Mixed Methods Study) guideline. Patients with cancer scheduled for PICC insertion and their caregivers were recruited, as PICC care is commonly performed by patients or cohabiting caregivers. All participants provided written informed consent. The chatbot was designed to provide structured responses based on prespecified dialog trees and to recognize users' intent using natural language processing. It was delivered through KakaoTalk and accessed on participants' personal mobile phones without requiring a separate app installation. Participants received face-to-face training at enrollment and were asked to voluntarily use the chatbot for 1 month. Baseline and postintervention surveys assessing usability were administered using paper-based questionnaires. Usage logs were collected from a secure researcher dashboard and analyzed for inquiry topics, free-text inputs, and fallback situations. Semistructured interviews were conducted approximately 1 month after the intervention during outpatient visits, with invitations by telephone, to explore participants' experiences regarding chatbot use. Quantitative data were analyzed descriptively to summarize participant characteristics, chatbot use, and usability outcomes, while qualitative interview data were analyzed using thematic analysis.

Results: A total of 56 participants were included in the final analysis (mean age 55.4 years, SD 13.7; female: n=39, 70%). Among them, 28 (50%) used the chatbot at least once. Chatbot users were younger than nonusers (51.1 vs 59.6 y; *P*=.02). Of the 25 users who agreed to log analysis, 347 inquiries were recorded; frequent topics included catheter care (126 observations), managing daily life (85 observations), symptoms (72 observations), and heparin use (55 observations). Among the 23 users who completed the usability survey, 20 (87%) reported that the chatbot was helpful for PICC-related issues. Qualitative interviews (N=56) identified 3 major benefits—information accessibility, effective guidance, and psychosocial support—while also revealing unmet needs related to conversational issues, user experience issues, and lack of personalization.

Conclusions: A rule-based chatbot designed to support PICC self-management demonstrates potential to enhance information accessibility, provide practical guidance, and offer psychosocial support. However, limitations related to conversational flexibility, interface usability, and personalization highlight the need for future development incorporating large language models. Longitudinal and multisite studies are warranted to assess sustained user engagement and clinical outcomes.

KEYWORDS

chatbot; chemotherapy; peripherally inserted central catheter; self-care; user experience

Introduction

A peripherally inserted central catheter (PICC) is inserted through a deep peripheral vein of the upper arm and threaded into a large vein above the right side of the heart [1]. This medical device is safe and useful for patients with cancer requiring long-term and/or frequent chemotherapy as well as a vesicant regimen with a risk of skin necrosis [2]. However, the nature of long-term administration makes PICC-related complications common in daily living. According to a prospective cohort study with 477 patients with cancer, 81 (17.0%) patients experienced PICC-related complications during the study period, resulting in an incidence rate of 1.59 per 1000 catheter days [3]. A systematic review reported that approximately 25% of central venous access devices were removed or failed before therapy was completed [4]. A meta-analysis of 11 studies reported that PICCs were associated with a 2.5 times higher risk of deep vein thrombosis compared with other central venous catheters [5].

PICC-related complications can be associated with practitioners' training and competence in PICC insertion as well as patient self-management [6-8]. Inadequate maintenance can lead to a surge in unplanned clinical encounters, including infections, bleeding, skin allergies, pain at the insertion site, and tube blockage [3,9,10]. As outpatient chemotherapy becomes increasingly common in many hospitals, the role of patients and caregivers in PICC care has become more important [11-13]. Thus, empowering patients to manage PICC lines safely after insertion helps mitigate PICC-related complications, improving treatment satisfaction [14,15]. Hospitals provide PICC-related education programs for this purpose, but these are somewhat limited in addressing the ongoing care needs or real-life challenges faced by patients.

Harnessing chatbots may be a solution for these challenges [16-18]. Chatbots simulate human interaction, offering real-time responses and guidance in text, voice, or visual formats [19]. According to a systematic review, use cases for chatbots in oncology are versatile, including screening, treatment planning, informational support related to treatment, remote patient monitoring, and emotional support [20]. A feasibility study with 9 patients with cancer reported that a chatbot was helpful in revealing serious health conditions, such as fever, skin rash, or abnormal sensitivity in the extremities [21]. A randomized controlled trial with 142 patients with breast cancer found that the perceived quality of cancer information provided by a chatbot was statistically noninferior compared with the information provided by physicians [22]. Moreover, nearly 90% of patients with cancer answered that chatbots were helpful in acquiring knowledge related to cancer or tracking treatment progress [23,24].

Although chatbot-based health care has many applications, chatbot feasibility in the context of supporting PICC self-management remains unclear [10,22,25]. The general public is unfamiliar with chatbots in the medical context owing to the relative newness of the technology compared with other digital solutions. This is particularly true for older adults, who form the majority of the population of patients with cancer. Therefore, the aim of this study was to investigate the feasibility of a chatbot for PICC self-management and determine users' characteristics, usage patterns, and satisfaction.

Methods

Design and Participants

A mixed methods study was conducted from September to December 2022, adhering to the GRAMMS (Good Reporting of a Mixed Methods Study) guideline. Quantitative analysis alone could identify who used or did not use the chatbot but could not explain the underlying reasons for these behaviors. To understand the contextual factors influencing adoption and engagement, qualitative inquiry was incorporated. Quantitative surveys and user logs provided objective data on participant characteristics, chatbot use, and usability, whereas qualitative interviews explored reasons for use or nonuse, perceived benefits, and barriers to use. This study used a sequential mixed methods design, in which quantitative surveys were conducted first, followed by qualitative interviews.

Patients with cancer and their caregivers were recruited from the Cancer Education Center of Samsung Medical Center in Seoul, South Korea. All patients scheduled to undergo PICC insertion were required to attend a face-to-face education session prior to the procedure. We consecutively contacted and recruited potential participants following each education session. As some patients with a PICC line were not scheduled to receive chemotherapy, an oncology nurse screened eligible patients and their caregivers prior to recruitment. We used convenience sampling, and individuals who voluntarily agreed to participate were enrolled in the study. Those who were 19 years or older, scheduled for PICC insertion (patients only), owned a smartphone, and had ever used KakaoTalk (most popular instant message service in Korea) were eligible for the study. However, those with any cognitive or physical problems with using a smartphone and who were scheduled for PICC line removal within a month were excluded. Following the provision of written informed consent, participants received approximately 15 - 20 minutes of training on how to access and use the chatbot. The session covered the basic user interface, methods for interacting with the chatbot, troubleshooting technical issues, and general precautions for use. Participants practiced using the chatbot under the guidance of research staff.

Chatbot Description

Participants were asked to voluntarily use a chatbot prototype to support PICC management for 1 month. The chatbot was a rule-based system that provided structured responses along prespecified dialog trees. It was technically implemented by Skelter Labs Corp (Figure 1) and integrated into KakaoTalk, a popular instant messenger in Korea [26]. The main purpose of the chatbot was to provide structured information regarding

XSL•FO
RenderX

PICC management according to user inquiries. In the welcome message, the chatbot told the participants what the chatbot can and cannot do. The chatbot clarified that it has not been designed to replace clinical practice or make clinical decisions.

Figure 1. Examples of the peripherally inserted central catheter (PICC) chatbot.

Users could ask the chatbot questions by tapping buttons listed according to prespecified dialog trees or typing their queries directly. Regarding the users' free text, the chatbot was enabled to understand the intent based on natural language processing. Dialog trees were constructed according to 6 main themes: catheter management, adverse events with the catheter, coping with emergencies, symptom management, precautions during daily life, and heparin-related inquiries. These themes were determined by reviewing records of PICC consultations in which patients had previously asked questions. The most frequently asked questions for each theme were displayed in a carousel-type list, allowing users to navigate through the available inquiry options with minimal scrolling. The chatbot used the health information about PICC management developed by advanced practice nurses in charge of patient education for PICC management. Considering the role of chatbots as social actors, health information in the chatbot was delivered through "Seulgi" ("wise" in Korean), a virtual character with the appearance of a nurse and a friendly tone. However, some information too complicated to convey through text alone was delivered via photos or videos. In addition, for irrelevant or ambiguous inquiries, the chatbot delivered fallback messages that reminded users of the chatbot's original purpose and highlighted the contact number of the cancer education center for additional help.

Measurement

Chatbot feasibility was evaluated using triangulation with quantitative usability survey, user logs, and qualitative interviews. The investigated topics included questions such as who voluntarily used chatbots, why they used them, what the most frequently asked questions were, and how satisfied users were.

Quantitative Usability Survey

Regarding the usability survey, the participants were asked to complete a questionnaire at baseline and postintervention. The baseline questionnaire collected sociodemographic information including age, sex, educational level, occupation, income, area of residence, cohabitation status, and comorbidities. The postintervention questionnaire assessed chatbot adoption, reasons for using (or not using) the chatbot, and user satisfaction. Regarding user satisfaction, a questionnaire was specifically developed by referring to existing reliable and valid user experience questionnaires [27]. The questionnaire covered ease of use (n=5), usefulness (n=7), social interaction with the chatbot (n=5), overall satisfaction (n=1), intention to recommend it to others (n=1), and intention of continuous use (n=1). The responses were interpreted on a 5-point Likert scale, with higher scores indicating greater satisfaction with chatbot usage (0=strongly disagree; 1=disagree; 2=neutral; 3=agree; 4=strongly agree).

User Logs

In terms of user logs, the collected data pertained to what buttons users tapped and the inquiries they directly typed. All user logs contained anonymized unique identifiers, which did not allow the decryption of their original identifications.

Qualitative Interview

To derive additional insights about the chatbot experience, face-to-face or telephone interviews were conducted with those who agreed to participate. The interviews, lasting 30 - 60

XSL•FO
RenderX

minutes, were based on a semistructured questionnaire including PICC-related problems during the study period, awareness of the chatbot, additional reasons for using (or not using) the chatbot, perceived benefits (only for users), and unmet needs. In-depth interviews were typically conducted in a quiet counseling room within the Cancer Education Center. For participants who were unable to revisit the hospital, interviews were conducted by telephone. Each interview was carried out by a team of 3 trained interviewers (BJ, ML, NK), including 1 oncology nurse specialist and 2 additional researchers with prior training in qualitative interviewing. During each session, 1 interviewer led the discussion, while another assisted by taking notes and managing the recording process. All interviewers had prior experience in conducting focus interviews and qualitative data collection. Participants were informed that the interviewers were members of the research team. All interviews were audio-recorded and transcribed.

Data Analyses

Descriptive statistics were used to compare characteristics between chatbot users and nonusers, identify the most frequently asked questions, and determine user satisfaction. Continuous variables were presented as means and SDs and categorical variables as frequencies and percentages. Group differences between users and nonusers were examined using independent *t* tests for continuous variables and chi-square tests for categorical variables. Graphical depictions were presented to show the main reasons for using (or not using) the chatbot. Regarding user satisfaction, all responses were dichotomized into “positive” (agree and strongly agree) and “negative” (all other responses) and summarized in frequencies. All quantitative analyses were explanatory in nature. Statistical tests were 2-sided, and statistical significance was defined using a 95% CI and a $P<.05$. Participants with missing values for a given variable were excluded from the corresponding analysis but retained in other analyses. Because the proportion of missing data was small, missingness was assumed to be missing completely at random, and no imputation was performed. All statistical analyses were performed using R (version 4.1.2; R Foundation for Statistical Computing).

For the qualitative data, we conducted thematic analyses based on Braun and Clarke’s method [28]. Three researchers (BJ, ML, MJK) independently read the transcripts, generated initial codes, and organized them into categories and themes related to participants’ motivations for chatbot use, perceived benefits, unmet needs, and contextual factors of PICC self-management. A shared coding framework and codebook were developed through iterative discussions. Using investigator triangulation, at least 3 researchers coded each transcript independently, compared results, and resolved discrepancies by consensus. The final themes were reviewed jointly to ensure coherence and distinction and by a principal investigator who audited the overall analytic process. Representative quotations were selected to illustrate key themes.

Quantitative and qualitative data were integrated during the interpretation phase using a narrative approach [29]. Qualitative findings contextualized quantitative results by explaining the reasons for chatbot use or nonuse. Integration discussions were conducted by the research team to ensure coherence between datasets.

Ethical Considerations

The study was reviewed and approved by the Institutional Review Board of the Samsung Medical Center (IRB No. SMC 2022-07-059). Written informed consent was obtained from all participants. All collected data were deidentified, and access was restricted to authorized personnel. Participants received remuneration of 30,000 KRW (approximately US $25) upon completion of the study.

Results

Participant Characteristics

During the study, 5 - 10 individuals received PICC-related education each day, and 78 individuals initially consented to participate. Among those, 56 who completed the study were included in the final analysis. Among them, 28/56 (50%) used chatbots (Table 1). Chatbot users were more likely to be younger (51.1 y vs 59.6 y; $P=.02$) and female (24/28, 86% vs 15/28, 54%; $P=.02$) compared with nonusers. The chatbot user group tended to have a higher educational level, but there was no statistical significance (19/28, 68% vs 13/28, 46%); $P=.17$). No significant differences were observed between chatbot users and nonusers in terms of the type of participants (patients vs caregivers), working status, family living together, comorbidities, income, and residence area. In the patient subpopulation, chatbot users tended to have breast cancer (13/17, 76% vs 10/20, 50%; $P=.28$), present with early-stage disease (I or II; 11/17, 65% vs 8/20, 40%; $P=.18$), and undergo curative chemotherapy (17/17, 100% vs 17/20, 85%; $P=.29$; Table 2).

Reasons for Using (or Not Using) a PICC Chatbot

Regarding the reasons for using the chatbot, 58.3% (n=14) were for inquiries about symptoms after PICC insertion, followed by learning how to manage daily life (n=12, 50%) and understanding how to deal with abnormalities at the insertion site (n=9, 37.5%; Figure 2). Additional reasons mentioned in the qualitative interviews were repetitive learning to acquire information and the management of anxiety about medical services at local hospitals (Multimedia Appendix 1).

XSL•FO
RenderX

Figure 2. Main reasons for using (or not using) the peripherally inserted central catheter (PICC) chatbot.

Among the chatbot nonusers, 14/27 (52%) did not have any issues due to their PICC (Figure 2). Additionally, 10 nonusers mentioned that they did not know how to use the PICC (n=5) or that it was difficult to access (n=5). Additional reasons mentioned in the qualitative interviews were a lack of trust in chatbots and low expectations for chatbots (Multimedia Appendix 2).

Questions Most Frequently Asked of a PICC Chatbot

A total of 25 users agreed to share their logs. During the study period, 347 inquiries were identified and categorized into 4 main themes: catheter care (126 observations), managing daily life (85 observations), symptoms (72 observations), and heparin use (55 observations; Table 3). Additionally, 9 cases were requests to contact the oncology nurse directly (Multimedia Appendix 3).

[a]Not available.

Regarding catheter care, the most frequently asked question was about the timing for changing dressings (22/126, 17.5%), followed by buying dressing materials (17/126, 13.5%) and taking other intravenous medications through the catheter (15/126, 11.9%). Regarding the management of daily life, workout-related inquiries (24/85, 28%) were the most common, with additional concerns including showers (14/85, 16%), travel (11/85, 13%), driving (11/85, 12.9%), and wearing clothes (11/85, 13%). In terms of symptoms following catheterization, fever (38/72, 53%) was the primary concern, followed by bleeding (10/72, 13.9%) and pain at the insertion site (10/72, 14%). The timing of the heparin injection (44/55, 80%) was the most frequent heparin-related inquiry. During the study period, there were 705 interactions with the chatbot, and we identified a total of 347 user inquiries. Of these, 100 were free-text inputs, and 69 (69%) were successfully recognized by the chatbot. The 31 failed cases occurred because users did not provide sufficient context in their inquiries, entering only single terms, such as “injection,” “not detachable,” or “heparin.” As the fallback scenario was designed with limited functionality, the chatbot could not prompt users to clarify vague inputs.

Usability Results of the PICC Chatbot

Among the 28 chatbot users, 23/28 (82%) completed the questionnaire, with 22/23 (96%) agreeing that the chatbot was easy to use and 21/23 (91%) mentioning that it was useful for managing their PICC catheter (Table 4). Furthermore, 17/23 (74%) felt like they were conversing with a person during interactions with the chatbot. All participants agreed that the chatbot’s responses were trustworthy, 21/23 (91%) expressed the intention to continue using the chatbot while the catheter was in place, and 22/23 (96%) were satisfied with using the chatbot. All participants (23/23, 100%) recommended the use of chatbots for other patients using catheters.

Question (out of 80 points)	Mean (SD)	Negative, n (%)	Positive, n (%)
Using the chatbot was challenging (reverse coded).	3.35 (0.98)	1 (4)	22 (96)
I found the explanations provided by the chatbot easy to understand.	3.00 (1.04)	2 (9)	21 (91)
I could promptly address any mistakes made while using the chatbot.	2.96 (0.82)	1 (4)	22 (96)
The text displayed by the chatbot was easy to read.	3.17 (0.72)	0 (0)	23 (100)
I found it easy to locate the information necessary for catheter management using the chatbot.	3.00 (0.74)	0 (0)	23 (100)
The chatbot accurately understood my intentions.	2.65 (0.98)	3 (13)	20 (87)
The chatbot was helpful in addressing issues encountered during catheter management.	2.96 (1.02)	3 (13)	20 (87)
The chatbot responded promptly whenever I had a question.	3.22 (0.74)	0 (0)	23 (100)
The chatbot satisfied my curiosity regarding catheter management.	3.17 (0.89)	1 (4)	22 (96)
I consider chatbots essential for managing my catheter.	3.30 (0.63)	0 (0)	23 (100)
Using a chatbot for catheter management proved beneficial for me.	3.09 (0.95)	2 (9)	21 (91)
The chatbot helped alleviate my anxiety during catheter management.	3.17 (0.89)	1 (4)	22 (96)
The chatbot empathized with me.	2.96 (1.07)	3 (13)	20 (87)
The chatbot responded appropriately to the situation.	2.96 (0.88)	1 (4)	22 (96)
I felt like I was talking to a person through the chatbot.	2.26 (1.14)	6 (26)	17 (74)
The chatbot felt friendly during the conversation.	2.65 (0.98)	3 (13)	20 (87)
The chatbot's responses were trustworthy.	3.13 (0.69)	0 (0)	23 (100)
I would recommend that other patients with catheters give the chatbot a try.	3.39 (0.72)	0 (0)	23 (100)
I intend to keep using the chatbot for catheter management.	3.22 (1.00)	2 (9)	21 (91)
Overall, I was satisfied with chatbot use for catheter management.	3.09 (0.85)	1 (4)	22 (96)

Perceived Benefits and Unmet Needs of Using a PICC Chatbot

Overview

A total of 56 qualitative interviews were conducted. Regarding the perceived benefits of using the chatbot, 3 themes were identified from chatbot users' statements. For unmet needs, 3 themes were identified from the statements of chatbot users and nonusers. Detailed representative quotes are provided below, with a more comprehensive overview in Multimedia Appendix 4.

Perceived Benefits

In terms of the perceived benefits of using the chatbot, 3 main themes—information accessibility, effective guidance, and psychosocial support—were identified.

XSL•FO
RenderX

Information Accessibility

Users found the chatbot useful for accessing PICC-related information anytime they had questions. They felt that the information was easy to understand because it was broken down into small chunks, making it more comprehensible for them.

> *It was very helpful because I was able to receive an immediate response in real time. […] And when I needed information, I was able to simply inquire through KakaoTalk.* [Female, 60s, patient, P56]

> *I would like to say that chatbots are understood more clearly and immediately because they provide information in a brief format, unlike paper materials. […] Anyway, chatbots are understood instantly.* [Female, 40s, caregiver, P06]

Effective Guidance

Users agreed that the chatbot was useful for managing PICC-related problems as it provided clear instructions that helped the users take the necessary actions with confidence, thereby enhancing their self-efficacy in improving self-management. Some users described it as a practical guide that bridged knowledge gaps and supported self-management. Beyond self-management support, the chatbot directly connected users to appropriate health care providers when their needs exceeded the system's capabilities. A user reported that when proper PICC line management was unavailable at a nearby hospital, the chatbot facilitated immediate connection to an oncology nurse from the cancer center where she was being treated, enabling her to receive timely support.

> *I checked whether it was correct to attach the tape after it had completely dried. […] I checked this and that and also double checked, "What am I doing wrong?"* [Female, 60s, caregiver, P38]

> *When I looked at this here [chatbot], I thought I could figure out a solution.* [Male, 70s, Patient, P20]

> *After doing some searching on the chatbot, I got in touch with the hospital again. The medical staff gave me a consultation, and I made an appointment for the next day. […] The best part was that it was directly connected to the hospital.* [Female, 40s, caregiver, P06]

> *When I searched, the chatbot suggested that it might be a blood clot. So I quickly received primary treatment at the local hospital's emergency room and then came back to the main hospital to have the PICC-line removed.* [Female, 20s, caregiver, P42]

Psychosocial Support

Users felt secure while having their PICC line because they knew that the chatbot was always available to them regardless of time and place constraints. Users were easily frightened by uncertainties surrounding their PICC-related concerns. However, access to credible information helped alleviate such fears. One user said that the chatbot helped her prepare coping strategies for potential symptoms in advance, which increased her sense of relief for managing her line. Additionally, users reported feeling reassured when they learned through the chatbot that their symptom experiences were common with other patients.

> *If something went wrong, I needed to find a solution quickly, and I thought, "Who should I ask about this?," but I really relied on this kind of thing. […] I depended on it and asked questions here [chatbot], so I felt much less anxious. Definitely.* [Female, 70s, patient, P34]

> *It really helped me when I looked up things I was curious about, such as when to go to the emergency room, when to switch hospitals, and what to do if my tube falls out. Knowing this information ahead of time made me feel a little more at ease.* [Female, 60s, caregiver, P19]

> *I was looking into whether other people have these symptoms and if this is common or just something I am experiencing.* [Female, 60s, caregiver, P19]

> *I think it helped reduce my anxiety a lot. I realized I had been more scared than I expected, but after getting information from the chatbot, I thought, "I don't need to worry that much." For example, learning that catheter disinfection isn't something to be that afraid of … and also finding out that I can go about daily life and even exercise without any major issues, that was really helpful.* [Female, 30s, patient, P43]

Unmet Needs

While users recognized the benefits of the chatbot, several limitations highlighted areas for improvement to enhance user experience and functionality. Through the qualitative analysis, 3 main themes emerged regarding the chatbot's limitations: conversational issues, user experience issues, and lack of personalization.

Conversational Issues

A key challenge reported by users was that the chatbot sometimes failed to provide the appropriate answers. When the chatbot did not understand what the user was asking, instead of clarifying how to rephrase the input, it simply provided general guidance on how to return to the home menu. Additionally, some users said that the chatbot's predefined answers sometimes did not match the guidance they expected.

> *I wanted to know how many items I needed to buy, so I searched for it, but all I got was "you can buy them at *** medical equipment store," without any details.* [Female, 40s, caregiver, P06]

> *The questions were okay, but at times, the way the chatbot guided the answers did not match our intent.* [Female, 20s, caregiver, P42]

> *When I first asked the chatbot about disinfection, it said, "I can't answer that. Please go back to the beginning."* [Female, 60s, caregiver, P38]

User Experience Issues

Users encountered several challenges with the chatbot. Users often felt confused when they navigated specific information

XSL•FO
RenderX

related to their current inquiries because all contents were stacked in a chat window without divisions by information depth. For example, some users mentioned that even after being informed by health care providers about the location of instructional videos, they still struggled to find them within the chatbot. After closing the chatbot, users experienced difficulty resuming conversations with it owing to challenges locating it among existing chats on the messenger platform. Additionally, the chatbot's avatar was displayed consistently regardless of the response context, making it difficult for users to intuitively distinguish between the various contents displayed on the screen. Meanwhile, older individuals encountered difficulties with the chatbot's carousel navigation, finding the swipe-based interface unfamiliar. They suggested implementing list-based items for easier access and improved usability.

> *I wish the link to the video related to the question asked could be displayed at the top. It's hard to find.* [Male, 40s, caregiver, P39]
>
> *I'm still young, so using internet devices isn't too difficult for me. But with chatbots that require swiping sideways, both my mom and dad struggle with that. I can help them if I am with them, but I think it is generally difficult for older adults. It might be easier for them if all the content appeared as a list on one screen instead of having to swipe side to side.* [Female, 30s, caregiver, P02]
>
> *What do I need to do to enter the chatbot channel again?* [Female, 20s, caregiver, P26]
>
> *But I don't think the image was significant. I barely noticed it because it was just an image of "O."* [Female, 30s, patient, P43]

Lack of Personalization

Users felt that the chatbot did not take into account individual variability in PICC-related issues, which reduced its usefulness in clearly addressing users' concerns. For example, 1 user found that the chatbot's predefined questions and answers were finite, as they did not address trivial or personal concerns. Additionally, users pointed out that there needs to be a feature allowing them to customize the length of the responses generated by the chatbot.

> *I wish there were some educational content that addressed minor concerns. It felt awkward to call about something so trivial, like asking, "I don't have a rash, but what should I do about this itchy area?" My parent said that they felt flustered and didn't know what to do. In a situation like this, I think it would be helpful to have some guidance on what to do. I don't think there was any educational content that covered these minor concerns.* [Male, 40s, caregiver, P39]
>
> *The chatbot provides very standardized questions and answers. But real life does not involve only the issues covered in those questions, right? There are other things I am curious about as well. New questions come up from time to time, and if I could leave a question and receive personalized feedback, like in a 1:1 Q&A, that would make a difference. Instead, I just tap a button, see the same standardized answer, and that is it. That is why it didn't feel engaging or personal to me.* [Female, 30s, caregiver, P02]
>
> *To be honest, patients are not the ones doing research and studying. So I just want you to tell me, "Do it like this." Even in my mother's case, she has an impatient personality, and people are like, "So what do I need to do?"* [Male, 40s, caregiver, P47]
>
> *The patient mentioned having a fever, so I asked what to do in that case, but the answer wasn't very detailed. I wish there had been a bit more detail.* [Female, 20s, caregiver, P26]

Discussion

Principal Findings

The aim of this study was to evaluate the feasibility of a chatbot designed to support PICC self-management by examining chatbot use rate, usability, and qualitative satisfaction among patients with cancer and their caregivers, using data from survey, usage logs, and interview. Regarding chatbot adoption for PICC management, half of the participants used the chatbot during the study period. The most popular topic among chatbot users was PICC line management (eg, timing of dressing changes and purchasing dressing materials), followed by questions about adjusting to daily life, symptoms after PICC insertion, and heparinization. In terms of user experience, the 3 main benefits of the chatbot were information accessibility, effective guidance, and psychosocial support. Despite these promising findings, there were 3 key challenges related to the chatbot: conversational issues, user experience issues, and a lack of personalization.

In terms of chatbot adoption for PICC management, at least half of the participants used the chatbot during the study period. In previous studies, the adoption rates of health care chatbots ranged from 35% to 80% [30,31]. The heterogeneity in adoption rates across studies might depend on specific topics addressed by chatbots or the availability of alternative resources. For example, a study reported that 80% (n=48) of 60 patients with pancreatic cancer accessed the chatbot providing genetic information [30]. In another study examining a chatbot for chemotherapy care, 58% (n=20) of 34 patients with gastrointestinal cancer used the chatbot at least once [31]. Conversely, a chatbot for postoperative guidance after ureteroscopy was used by only 35% (n=7) of 20 patients [32]. Their lower activation rate may be attributed to the availability of multiple alternative information sources [32]. Compared with other studies, this study included both patients with cancer and their caregivers and provided nurse-led education for PICC management prior to offering the chatbot. These specific conditions might have contributed to participants experiencing a lower need to obtain PICC-related information via the chatbot. The primary motivation for chatbot utilization was related to individual needs for acquiring knowledge or information to prepare for or cope with PICC-related symptoms or issues. Notably, most nonusers reported experiencing mild or no PICC-related problems, diminishing their perceived need for the chatbot. Therefore, when assessing chatbot feasibility, it may be essential to consider whether potential users are

XSL•FO
RenderX

experiencing the specific circumstances related to their perceived needs for health information.

The most popular topic among chatbot users was PICC line management (eg, timing of dressing changes and purchasing dressing materials), followed by questions about adjusting to daily life, symptoms after PICC insertion, and regular heparinization. A study on PICC management in nursing facilities reported communication gaps, such as uncertainty about the last dressing change date or PICC removal timing, even between hospitals and nursing facilities [33]. Another study on adults with a PICC at home found that showering was the most common challenge, followed by difficulties with exercising, sleeping, and dressing [34]. The chatbot in this study was designed and implemented based on patients' information needs on PICC management in a real-world setting. The chatbot allowed users to access reliable information whenever they wanted. Although the questions and answers in the chatbot were prespecified, the topics the patients inquired about were comparable to the findings from previous studies. This suggests that chatbots could be feasible for providing informational support to patients with PICC lines. However, given the rule-based nature of chatbots, continuous expansion of the information the chatbot covers would be necessary to ensure sustainability.

In terms of the chatbot's usability, users mentioned that it was an accessible channel for effective PICC self-management guidance. In this study, the chatbot was designed to provide practical tips or information regarding PICC self-management in a structured format with succinct and plain language. The implementation incorporated patient health literacy considerations, adhering to evidence-based recommendations for health care chatbot interfaces derived from previous studies [35,36]. Users particularly appreciated the convenience and rapid access to relevant information provided by chatbots, which may have enhanced their perceived usefulness in this study [17]. In addition, the chatbot was helpful for them to receive proper psychosocial support regarding PICC management. Patients with cancer, who face disease and treatment uncertainties, seek reliable information and justify their feelings through social support networks [37]. Moreover, PICC management is unfamiliar to most patients with cancer, requiring high competency in its long-term maintenance [38]. These features of patients with cancer can increase their anxiety regarding potential complications and coping strategies for cancer-related problems [38,39]. The chatbot in this study allowed users to access reliable information about PICC-related issues without temporal or spatial constraints, addressing unmet self-care needs and providing psychosocial support. During the COVID-19 pandemic, when hospital visits and communication with health care providers were often limited, the chatbot served as a clinically meaningful alternative by offering timely, trustworthy guidance. This support helped reduce patient anxiety and might have contributed to better treatment adherence. Furthermore, although the chatbot was designed to mimic human conversation, participants did not perceive its interaction as equivalent to real human dialogue. Future research should quantitatively evaluate these supportive functions to better understand their impact on patient outcomes.

Despite the promising findings, the chatbot encountered 3 main challenges: conversational issues, user experience issues, and a lack of personalization. A natural language understanding engine was integrated into the chatbot, but it occasionally failed to accurately interpret users' intentions. The system was primarily optimized for button-click interactions rather than free-text interactions to facilitate an intuitive user experience. However, these rule-based, static responses seemed to diminish conversational naturalness and had limitations in capturing the various nuances of individual expressions for the same PICC-related issues. A systematic review found that rule-based health chatbots often limited user engagement owing to constrained input and predefined dialogues [19]. To resolve these unmet needs, incorporating large language models (LLMs), such as GPT or Claude, into rule-based systems would be necessary [40,41]. These models may provide better situational awareness and more human-like communication, which allow for personalized support in PICC self-management [41]. Given patients' documented preference for direct clinician interaction, the strategic implementation of LLMs may be required for health care chatbots to approximate human-like communication efficacy [42]. Nevertheless, LLMs may generate plausible but inaccurate responses ("hallucinations"), necessitating rigorous reliability assessment and empirical validation prior to the clinical implementation of LLM-oriented health care chatbots [43]. Independent of preceding considerations, swipe-based navigation in the chatbot impeded user engagement, particularly among older users. Swipe-based navigation was difficult for them, and they often preferred icon-based menus to reduce cognitive load [44,45]. To assist user navigation, the implementation of subtle visual affordances indicating interface functionality and hierarchically structured list-based layouts is recommended [46].

Limitations

First, although patients or their caregivers are required to attend PICC education, those who voluntarily consented to participate in this study may be more interested in using digital technologies or more motivated to self-manage. While this study did not collect demographic data of those who did not consent to participate, further understanding this in future research would provide more insight into scalable implementation. Second, user experiences were assessed after approximately 1 month of chatbot use. While PICCs are often maintained for 3-6 months, these findings primarily reflect the early phase of use rather than long-term engagement. Thus, the 1-month study period may not fully capture sustained engagement patterns. However, research has shown that many complications and difficulties tend to arise within the first few weeks following insertion, making this period particularly critical for patient education and support [47]. Hence, the data collection during this initial phase offers important insights into the most vulnerable period of PICC self-management. Nevertheless, future studies should incorporate longitudinal follow-up to the association between chatbot use and PICC-related complications, the sustainability of chatbot engagement, and its long-term effects on self-management. Third, the absence of a widely adopted, validated Korean-language instrument specifically designed for assessing chatbot usability limited comparability with existing

XSL•FO
RenderX

literature. At the time this study was conducted, chatbot-specific usability instruments were not widely adopted; therefore, similar to prior studies, usability was assessed by adapting items from existing general usability questionnaires to reflect chatbot-specific characteristics [48,49]. Subsequent studies published after the completion of our research have begun to adopt chatbot-specific instruments, such as the Chatbot usability questionnaire; however, a validated Korean-language version or culturally adapted chatbot usability measure remains unavailable. Future research would therefore benefit from the development and validation of culturally appropriate, standardized Korean-language chatbot usability instruments to enable more rigorous and comparable assessments across studies. Finally, the small sample size and single-site design limit the generalizability of the findings and the ability to draw definitive conclusions. Future studies with larger and more diverse samples will be necessary to validate quantitative findings and support more robust statistical comparisons. Moreover, because participants in this study received structured onboarding and brief training, uptake in routine clinical practice where such support may not be systematically provided could be lower. This possibility further underscores the need for implementation strategies tailored to diverse clinical environments.

Conclusions

In this study, the feasibility of a chatbot-based supportive care system for managing PICC lines in patients with cancer and their caregivers was explored. The chatbot had potential in enhancing information access, providing guidance, and offering psychosocial support. In particular, during situations such as the COVID-19 pandemic when patients were unable to visit hospitals or easily contact health care providers, the chatbot served as a valuable alternative by delivering reliable information and independently supporting the resolution of minor issues, thereby improving access to medical guidance. However, limitations in conversational quality and personalization were identified. Further quantitative research is warranted to strengthen the evidence base for the chatbot's effectiveness. Incorporating LLMs may enhance future chatbot performance and user experience.

Funding

This study was supported by the National Research Foundation of Korea grant funded by the Korean government (NRF-2021R1A2C2011083 and RS-2023-00212647).

Abstract

Background: Breast cancer is the most common cancer among Canadian women, bringing complex demands for timely decision-making, coordination of multidisciplinary care, and efficient communication between patients and providers. The increasing reliance on fragmented and noninteroperable health information systems exacerbates workflow and documentation burdens, leading to inefficiencies and gaps in continuity of care. While nurse navigation programs partially bridge these gaps, most digital platforms remain poorly integrated into provider workflows, requiring manual tracking, which results in duplicated effort and reduced efficiency. Our team developed "MyJourney" at North York General Hospital (NYGH) in Ontario. It is a digital navigation platform that supports breast cancer care throughout the entire continuum, from diagnosis to survivorship.

Objective: This study aimed (1) to map the breast cancer journey and workflow to inform the design and adaptation of MyJourney at 2 oncology settings at NYGH; (2) to identify barriers and guide local implementation; and (3) to evaluate the implementation, usability, and perceived utility of MyJourney's Clinical Navigation Tool for breast cancer care teams.

Methods: A multimethod, 3-phase study was conducted at NYGH's Breast Diagnostic Centre (BDC) and Chemotherapy Clinic (CC) in Toronto, Canada. Phase 1 involved qualitative interviews with patients with breast cancer to map their care journey and inform user-centered platform design. Phase 2 included preimplementation interviews with nurses, pharmacists, and administrative staff to map workflows and customize MyJourney for the CC. Phase 3 evaluated MyJourney's implementation and usability over 6 weeks using the System Usability Scale, technology acceptance model surveys, and follow-up interviews with platform users. Data were analyzed via interpretive description and descriptive statistics. Ethics approval was obtained.

Results: In total, 13 patient interviews revealed distinct challenges and communication needs across prediagnosis, diagnosis, treatment, and survivorship phases, emphasizing the need for personalized, integrated resources (phase 1). A total of 8 participants (3 nurses and 5 pharmacists), providers, and clinic staff highlighted pain points in fragmented information systems, inefficient manual processes, and limited team coordination (phase 2). MyJourney's phased implementation led to high user acceptance, with mean System Usability Scale scores rated "excellent" (BDC: 81.3; CC: 86.3) at the 6-week follow-up (phase 3). The 4 participants (1 charge nurse, 1 administrative staff at the BDC, and 2 charge nurses at the CC) described the platform as intuitive, efficient, and well-organized, citing consolidated patient records, streamlined appointment management, and improved workflow as major benefits. Recommendations included improved interoperability, enhanced notifications, role-specific customization, and integration with electronic medical records for broader scalability.

Conclusions: The iterative, interest-holder engaged design and phased implementation of MyJourney facilitated rapid uptake and high usability among breast cancer provider teams. The Clinical Navigation Tool component of the MyJourney platform reduced documentation burden, improved workflow efficiency, and facilitated care coordination across oncology settings.

Introduction

Breast cancer is the most common cancer in Canadian women, apart from nonmelanoma skin cancers, and is the second leading cause of cancer-related deaths [1]. Approximately 1 in 8 Canadian women will develop breast cancer during their lifetime [1,2]. Although multidisciplinary care and systemic therapies have improved breast cancer outcomes over the past decade [3], these advances have introduced new complexities for both patients and health care providers.

Patients are now expected to make timely and informed decisions, interpret detailed medical information, and coordinate care across multiple services and providers [2,4-6]. This can lead to confusion about procedures, points of contact, and treatment-related side effects, sometimes resulting in delays in care [6]. For health care providers, these complexities increase the demand for efficient documentation, coordinated communication, and real-time access to patient information [7,8]. Clinical data are often fragmented across noninteroperable health information systems, and care processes are heterogeneous and complex to manage, resulting in high levels of administrative and role-related burden [7,8].

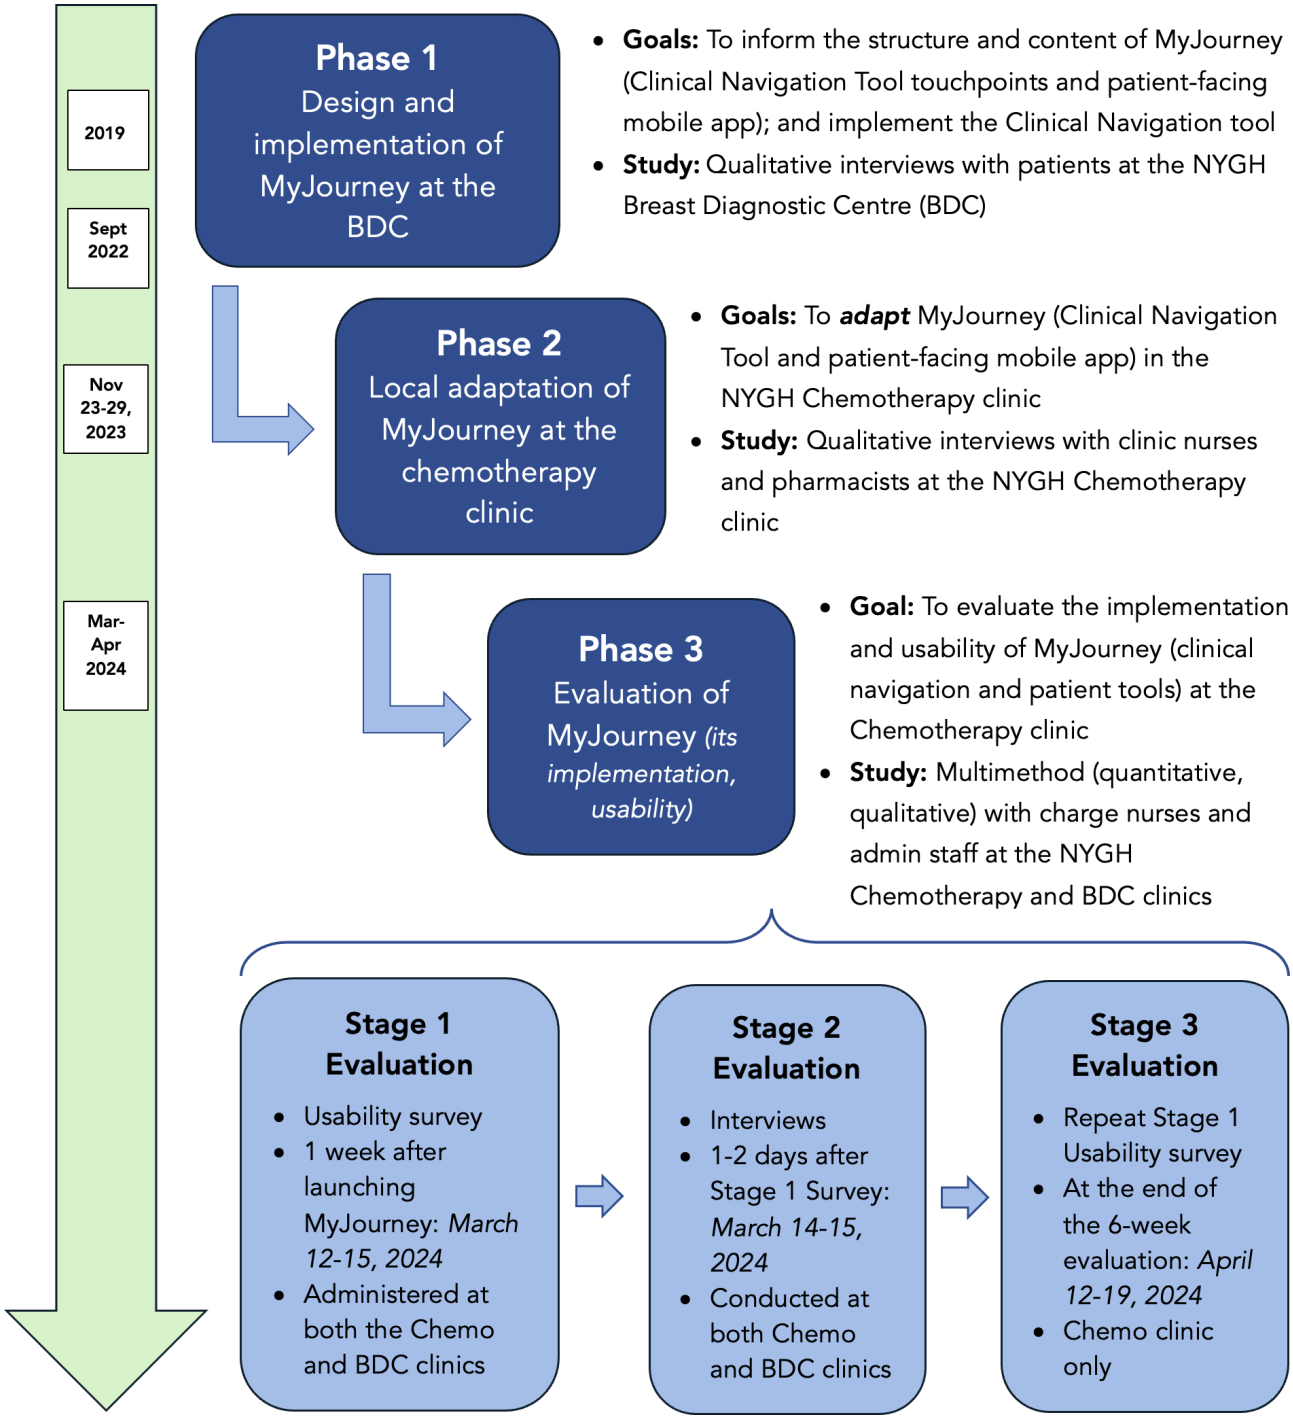
Digital health platforms offer a promising solution to streamline care delivery, reduce manual workload, and enhance communication among health care team members [9]. However, most available platforms are not designed for provider use and are poorly integrated into clinical workflows [10]. This results in providers relying on manual tracking, which can lead to redundant documentation and time-consuming phone-based follow-up [9]. Although nurse navigation programs help bridge some of these challenges in oncology practice by supporting patients throughout their treatment journey, the model is labor-intensive [11,12]. Navigators are often required to contact patients at multiple points in their journey, without standardized tools to streamline navigation tasks or optimize workflow within and across clinical settings [11,12].

One strategy to support health care teams and reduce administrative burden is to leverage integrated digital platforms that consolidate patient care information in a single system. Digital platforms can reduce the need to search across multiple sources and allow providers to focus on direct patient care [13]. Platforms that coordinate tasks across teams can also reduce fragmentation within the health care system and enhance care continuity [13].

To address these challenges, our team developed "MyJourney," a digital oncology platform that supports breast cancer care across the continuum, from diagnosis through survivorship. The platform was initially developed by a team of software developers and design experts for North York General Hospital (NYGH) in Ontario, Canada. Following prototype development, the platform underwent iterative refinement through a user-centered design process that engaged a broad group of interest-holders, including breast cancer providers, patients, researchers, app developers, and design experts. Interest-holder engagement began in 2017, and platform development launched in 2019. MyJourney includes three integrated components: (1) a Clinical Navigation Tool that allows care teams (including nurses, pharmacists, oncologists, and surgeons) to triage, monitor, and document patient care; (2) a Multidisciplinary Cancer Conference Tool that facilitates collaborative case planning, treatment decision-making, and reporting; and (3) a patient-facing mobile app that provides personalized treatment summaries, tailored education, appointment reminders, and real-time updates to promote engagement and self-management. The platform was designed to address dual needs. First, it streamlines workflows, reduces documentation burden, and supports team-based coordination for providers. Second, it centralizes health information, treatment plans, and appointments into one accessible location for patients diagnosed with breast cancer. These functions align with broader health system priorities, including those reflected in the Quintuple Aim, by aiming to improve both provider experience and patient outcomes and experiences [14].

The objectives of our work were (1) to understand the breast cancer journey, gaps in care, and the needs of patients at the Breast Diagnostic Centre (BDC) to inform the design of the patient-facing component of MyJourney; (2) to map workflows, identify barriers, and guide local adaptation of MyJourney before its launch at the NYGH Chemotherapy Clinic (CC); and (3) to evaluate the implementation, usability, and perceived utility of the Clinical Navigation Tool component of MyJourney at both the BDC and CC.

Methods



Study Design

Overview

We conducted a 3-phase, multimethod study that used both qualitative and quantitative methods (Figure 1). Phase 1 patient interviews (2018 - 2019) informed the initial design of MyJourney's Clinical Navigation Tool and patient-facing app. The Clinical Navigation Tool was first implemented at the BDC in September 2022, providing a mature implementation in a diagnostic-focused setting. Lessons learned from this implementation (eg, around appointment visibility, task lists, and navigation touchpoints), together with phase 2 preimplementation workflow interviews at the CC, informed the subsequent localization and configuration of MyJourney for the treatment-focused CC in 2024. More specifically, the below sections highlight the design for each of the 3 phases.

XSL•FO
RenderX

Figure 1. Study design schema. NYGH: North York General Hospital.

Phase 1

To inform the structure and content of MyJourney (Clinical Navigation Tool touchpoints and patient-facing mobile app), we conducted qualitative interviews with patients at the NYGH BDC to map the breast cancer journey from prediagnosis through survivorship and to inform the structure and content of MyJourney (Clinical Navigation Tool and patient-facing mobile app). We used the interpretive description of Thorne [15], grounded in naturalistic inquiry and recognizing the constructed and contextual nature of human experience. It seeks applied understanding that supports practical decision-making [15] and centers on participants' experiential accounts rather than testing or building theory, as it is grounded in practical relevance [15].

Phase 2

To adapt MyJourney to the NYGH CC, we conducted preimplementation interviews with staff to map workflows and staff roles, identify barriers, and tailor MyJourney's features to support local adaptation (November 23 - 29, 2023). We used the same interpretive description approach as in phase 1, which uses low-inference interpretation (ie, description) to enable the researcher to remain close to the data [15]. In this approach, facts are presented as a comprehensive summary in everyday language from the participants' perspectives, serving both as

XSL•FO
RenderX

an output of the research and as recommendations for future research [15-17]. We used qualitative results to iteratively implement the Clinical Navigation Tool component of MyJourney (December 2023-February 2024). This involved installing the MyJourney technology at the CC (integrating within their electronic medical record system) and training users (nurses and administration staff) on how to use the system. Once installed, MyJourney launched for use on March 4, 2024.

Phase 3

To evaluate the implementation, usability, and perceived utility of MyJourney's Clinical Navigation Tool at the CC, we conducted a 6-week, iterative, 3-staged evaluation. One week after implementing the Clinical Navigation Tool, we administered a usability survey to MyJourney users (charge nurses and administrative staff; stage 1). After 1 - 2 days, we conducted one-on-one interviews with these participants to gain a more in-depth understanding of their experiences, including workflow alignment (using survey findings as a starting point), and to identify any challenges and suggested recommendations to address them (stage 2). Over the next 5 weeks, we used survey and interview results to further refine the Clinical Navigation Tool. At 6 weeks of follow-up, we readministered the stage 1 usability survey to determine whether iterative improvements translated into enhanced usability (stage 3). We also administered the usability survey (stage 1) and interviews (stage 2) to MyJourney users at the BDC clinic to get an in-depth understanding of their user experience at that site since its implementation (September 2022). For interviews, a qualitative description approach was used to enable the researcher to remain close to the data [16]. In this approach, facts are presented as a comprehensive summary in everyday language from the participants' perspectives, serving both as an output of the research and as recommendations for future research [16]. This overall evaluation approach was guided by the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) implementation framework, which considers individual, organizational, and contextual factors to shape the implementation and sustainability of innovations [18]. For phase 3, RE-AIM primarily informed our focus on implementation (usability, workflow fit, and fidelity of use) and maintenance (patients' and clinicians' perceived likelihood of continued use and ongoing integration into routine care). Reporting of this study was guided by the SRQR (Standards for Reporting Qualitative Research) [19].

Ethical Considerations

This study was conducted at North York General Hospital, diagnostic breast cancer and chemotherapy clinics. Informed consent was obtained from all participants across the 3 phases. All data were anonymized using study ID numbers and stored in secure locations. Data collection occurred between 2019 and 2024. Ethics approval was granted by the NYGH Research Ethics Board (protocol #18 - 001 and #0326).

Setting, Intervention, and Implementation

Our study took place at 2 ambulatory oncology settings of the NYGH (a tertiary-level, academic-affiliated community hospital in Toronto, Ontario, Canada): the BDC and the CC [20]. The BDC is a specialized ambulatory diagnostic service within the Breast Centre that provides comprehensive assessment for individuals with suspected or confirmed breast cancer, identified through abnormal clinical examination and/or breast imaging, serving approximately 1500 new patients seen annually. In contrast, the CC is an outpatient systemic therapy unit that delivers chemotherapy and supportive care to patients with confirmed cancer diagnosis (including early-stage, locally advanced, and metastatic breast cancer) coordinated by charge nurses following consultation with medical oncology, with pharmacists providing patient education and counseling. Whereas the BDC primarily serves patients in the diagnostic and decision-making phase (often pretreatment), the CC primarily serves patients in active treatment, with more advanced or definitively staged disease and correspondingly different informational, supportive, and symptom-management needs. Our implementation work, therefore, involved adapting the intervention from a diagnostic-focused setting (BDC) to a treatment-focused setting (CC), taking into account differences in patient flow, acuity (eg, treatment-related toxicities), and longitudinal relationships with the oncology team. The focus of our evaluation was the Clinical Navigation Tool within the MyJourney platform. The tool was first implemented at the BDC on September 19, 2022, as part of a hospital-wide initiative to improve cancer care delivery. It was subsequently adapted for use at the NYGH CC on March 4, 2024. The BDC manages approximately 700 patients with breast cancer per year.

Participant Recruitment

Phase 1 (BDC Patients)

We used purposive sampling with convenience and self-selection elements to identify eligible participants: English-speaking adults diagnosed with breast cancer who were former or current patients receiving care at the BDC and able to provide informed consent [21]. To obtain a wide range of patient experiences, recruitment was conducted in a multipronged approach. For example, we recruited participants at the end of a 1-day workshop for newly diagnosed patients by displaying posters in the clinic waiting rooms. Second, we contacted patients who had previously indicated their willingness to participate in any future research studies. All participants spoke English and provided informed consent.

Phases 2 and 3 (Providers and Staff)

Across phases 2 and 3, we used purposive sampling within each clinic [21] to invite all current or prospective MyJourney users (nurses, pharmacists, and administrative staff) at the BDC and the CC, with the goal of capturing the full range of user perspectives rather than thematic saturation [22]. We did not recruit oncologists or surgeons for phase 2 because at the CC, these providers primarily interact with MyJourney through the Multidisciplinary Cancer Conference Tool and the hospital electronic medical record rather than as routine users of the CC Clinical Navigation Tool. Charge nurses and oncology pharmacists are the primary day-to-day users of the Clinical Navigation Tool, responsible for coordinating chemotherapy visits, managing treatment-related symptoms, and delivering patient education and counseling. Potential participants were invited via targeted email with support from senior clinic

XSL•FO
RenderX

leaders. Written informed consent and demographic data were collected using Qualtrics. One participant did not consent to the use of direct quotes.

Data Collection

Across phases, data collection included semistructured interviews or online surveys. The research team (IH, JM, MK, LH, and KM) developed and pilot-tested the instruments to ensure clarity, appropriateness, and alignment with the study objectives.

Phase 1

A semistructured interview guide was created and modified iteratively (Multimedia Appendix 1). In interpretive description, insights from early interviews inform the design of subsequent interviews, including the interview guide, which begins with broad, open-ended questions and evolves as themes, categories, and theoretical constructs are developed through ongoing analysis [15]. Two experienced qualitative researchers (LH and KM) conducted interviews with women who were diagnosed with breast cancer and were former or current patients, in person at the BDC. Interviews lasted 60 to 90 minutes. During the interviews, participants were asked to map out their breast cancer journey, starting from the time before their diagnosis to the present. For example, they were asked about their activities, the health professionals they interacted with, their feelings, the information they received, and their communication needs at each stage of their journey. Participants were encouraged to take the conversation in new directions and explore concepts not initiated by the interviewers. Our goal was to learn from participants' breast cancer journeys at the BDC to identify gaps in care and their information and support needs, in anticipation of developing a patient-facing app that would address these needs as a complement to the Clinical Navigation Tool aimed at providers.

Phase 2

A semistructured interview guide was developed (for each of the pharmacist and nurse participants) by 3 researchers (IH, JM, and MK; Multimedia Appendix 2). Interviews were conducted in person or virtually (via Zoom [Zoom Video Communications] or Microsoft Teams) in 30-minute time blocks, at the participant's preference. Interview guides followed a semistructured format informed by the RE-AIM framework [18] (ie, to help formulate questions that would elicit responses grounded in implementation theory). To maximize participation, we offered flexible participation options (a single 1-hour session or two 30-minute sessions). Interview questions focused on (1) participants' roles and responsibilities, (2) experience using MyJourney (including duration and frequency of use; how it supports tasks, workflows, and patient management; and whether it meets their needs), (3) MyJourney feature-specific feedback, (4) benefits and challenges of using MyJourney and related recommendations, (5) experience with implementation (what worked well, what did not, any disruptions to workflow, and suggestions for future implementation), and (6) challenges experienced in each of these areas along with associated recommendations, including feedback on how MyJourney could be tailored to support their work better.

Phase 3

The research team developed an online survey for each of the BDC and CC and pilot-tested it for understandability (Multimedia Appendix 3). Surveys were tailored to different audience groups (eg, nurses and clinic staff) and administered via Qualtrics to study participants to collect data on demographics and usability. Usability and user experience were assessed using the System Usability Scale (SUS) [23,24] and the technology acceptance model, which measures ease of use and usefulness of a technology-based innovation [25,26]. Sampling was consistent with established usability guidance that 3‐5 users are typically sufficient to identify most high-severity usability problems in a given design iteration [27]. As such, we aimed to reach at least 3 participants per site who had access to and experience using the platform but were constrained by the number of eligible users during early implementation (2 patients with breast cancer per site). As a result, we treated this as an initial, depth-oriented usability assessment focused on uncovering major usability issues and gathering rich feedback to guide subsequent refinements, rather than on producing generalizable estimates of usability metrics. We also assessed perceptions of workflow alignment, ratings of specific MyJourney features, and overall satisfaction. Demographic variables included age, sex, gender, ethnocultural background, and years in role. In addition, survey responses (stage 1) were used to tailor interview probes for stage 2. For example, if a participant rated a MyJourney feature poorly, the interview explored the reasons and discussed possible solutions to address them.

Data Analysis and Synthesis

Qualitative Data

All interviews were digitally recorded, transcribed verbatim, and reviewed for accuracy. For qualitative analyses across all phases, we used an iterative, inductive, and interpretive process to construct our understanding of MyJourney. Within the interpretive description methodology of Sandelowski [16], qualitative data analysis unfolds as an iterative, inductive, and reflexive process. It begins with immersion in the data to gain contextual understanding, followed by broad initial coding to capture patterns without imposing rigid categories. In phase 1, reviewers (LH and KM) used constant comparison analysis, repeatedly contrasting data segments and cases to develop, refine, and validate emerging insights and themes [16]. This process allowed us to move beyond description, producing a practice-oriented interpretation that informed actionable insights about how MyJourney should be constructed. The codebook was developed iteratively with each subsequent transcript, and its emergent structure became more focused as categories and themes developed. In phase 2, we used directed content analysis, combining deductive coding (guided by RE-AIM and study objectives) and inductive coding to capture themes emerging from participant narratives [28]. Reviewers in this phase (IH, JM, and MK) independently coded initial transcripts and collaboratively developed an initial codebook that evolved as more data were analyzed and was structured around barriers and recommendations. The remaining transcripts were coded in duplicate by applying the codebook. Discrepancies were

XSL•FO
RenderX

resolved by consensus or adjudication with a third reviewer (MK). Thematic categories were refined through team discussions to ensure clarity, distinctiveness, and alignment with the study objectives. Data were then organized by clinical site and mapped onto a figure depicting the workflow, allowing the clinical context in which MyJourney would be used to be identified. Open-ended survey responses were independently coded by 2 reviewers using the same coding structure.

Data Synthesis

Across phases, coded qualitative data were summarized in tables organized by challenges, recommendations, and, where relevant, enabling factors. Representative quotations were selected to illustrate key findings.

Quantitative Data

Survey data were analyzed descriptively using Microsoft Excel. Measures included frequencies, percentages, means, medians, SDs, and IQRs. SUS scores were interpreted using the following benchmarks: >68 (above average), >70 (acceptable), >74 (excellent), and >85 (best imaginable) [29]. Mean scores and SDs were calculated for technology acceptance model dimensions [25]. Due to the small sample size, no inferential statistics were conducted.

Researcher Characteristics and Reflexivity

The evaluation team comprised researchers who identified as female and women from health services and implementation science, who were not involved in the design or delivery of MyJourney. To mitigate potential bias arising from the dual role of a coprincipal investigator (FO) as a platform developer, data collection and analysis were conducted by team members independent of platform design and operations. The interviewer had no prior relationship with the participants. A note-taker attended phase 3 interviews and offered follow-up questions where appropriate. Team members kept reflexive journals and audit trails and met regularly to review assumptions and ground analytic decisions in participant accounts. Member checking was not feasible. Credibility was supported through rich description and direct quotation.

Results

Phase 1: Predesign Engagement With Patients at the Breast Diagnostic Clinic

Participant Characteristics

In total, 13 participants consented and were interviewed between 2018 and 2019 (Table 1). The mean age was 56 years (range 42 - 67 years), all identified as female and a woman, and most identified as White (5/13, 38.5%), South Asian (2/13, 15.4%), and Chinese (2/13, 15.4%), and 1 (7.7%) participant each identified as Jewish, Latin American, West Asian, or White-Aboriginal. The majority of participants (9/13, 69.2%) reported an annual household income of ≥US $659,200. All participants spoke English, and 3 (23.1%) individuals spoke a second language. Of the 12 who specified education, most (8/12, 66.7%) reported at least a bachelor’s degree.

RenderX

Stage of Breast Cancer Journey

Participants described different "phases" of their journey, each with its own associated challenges and communication needs (Figure 2). The phases identified were "prediagnosis," "diagnosis," "treatment" (including active management strategies such as surgery, chemotherapy, and radiation), and "survivorship." These labels mark the key clinical activities during the respective time frame and reflect the clinical perspective that patients with breast cancer are expected to adopt. The majority of participants were at the treatment (4/13, 30.8%) or survivorship (4/13, 30.8%) stage, followed by the diagnosis (3/13, 23.1%) and prediagnosis (2/13, 15.4%) stages. However, participants acknowledged that these phases were not always linear, and not all patients go through all phases. Participants reported that each phase had distinct informational and emotional needs, which were incorporated into the tool's design features. Multimedia Appendix 4 summarizes the themes and relevant quotes describing participants' experiences according to their breast cancer journey stages.

Figure 2. Stages of the typical breast cancer journey as reported by interview participants.

Summary of Qualitative Results

Overview

We developed 8 overarching themes that describe participants' experiences across the breast cancer care trajectory at the BDC and CC at NYGH (Table 2).

XSL•FO
RenderX

Table . Overarching themes that describe participants' experiences across the breast cancer care trajectory at the North York General Hospital Breast Diagnostic Centre (BDC) and Chemotherapy Clinics.

Theme and subtheme	Description	Illustrative quotes
1. Care coordination and workflows		
BDC workflows and processes	Perceptions of the BDC as coordinated, efficient, and well-organized.	• "From the time from mammogram to surgery was only 1 month—that was an amazing experience" [Participant 7]. • "They have a very good process ... After your appointment [they] give you another one ... If you need a referral, they have already sent the referral ... It's a very good process and I don't want it to change" [Participant 1].
Transitions and follow-up	Breakdowns when moving between BDC, chemo, radiation, home care, and primary care, with patients worrying that things will be missed.	• "At the BDC it was a real team approach ... Then, when I went to chemo there was no team approach and it all went downhill from there" [Participant 4]. • "The imaging follow up just doesn't happen. I have to orchestrate it" [Participant 4].
2. Communication and information flow		
Receiving diagnosis	How, where, and by whom the diagnosis is communicated, and its emotional impact.	• "When I got the phone call from my doctor, I was alone at home and told about the diagnosis. That was hard. It would have been better to have someone with me" [Participant 7]. • "I was 'told' that I had breast cancer by the bone scan technician ... before I was given the official diagnosis and that was difficult to hear and very brusque" [Participant 8].
Team communication and contradictions	Inconsistent or conflicting information between clinicians and services, eroding trust.	• "There was lack of communication between groups in this hospital ... I spent the whole week panicking ... and they said 'oh it's fine, we have ice for you'" [Participant 4]. • "They are telling you it's nothing ... They are not doing their research to understand the actual side effects of radiation ... Every time you say it, they dismiss it instead of cataloguing people's experience" [Participant 18].
Role clarity (who to call)	Uncertainty about which clinician is responsible for which problems.	• "There were a few things that I wasn't sure if I should go to the surgeon or the medical oncologist for ... I often wasn't sure who to go to" [Participant 9].
Tone, empathy, and respect	Value placed on clear, respectful, and nondismissive communication.	• "We had an amazing surgeon and oncologist ... They don't try to make you feel bad ... They never show signs of exasperation ... It's very personalized" [Participant 1].
3. Information and resource needs		
Volume and timing of information	Tension between information overload and unmet information needs; importance of timing.	• "They gave me lots of information in the little bag. It was overwhelming ... When I started reading it, it was okay" [Participant 5]. • "The 'welcome to breast cancer' package ... had too much of a lumpectomy focus versus mastectomy" [Participant 4].

XSL•FO
RenderX

Theme and subtheme	Description	Illustrative quotes
Practical “how-to” guidance	Desire for concrete, practical advice about surgery recovery, daily logistics, and self-care.	• “I thought I’d get more info ... what to expect and prepare for after the surgery ... mastectomy bras, etc. I did research online and got a wedgie pillow ... grabbers ... special tables ...” [Participant 2].
Understanding diagnosis and treatment	Need to understand pathology, staging, oncotype, systemic therapies, and their implications.	• “I was trying to understand the HER2. I found this confusing ... It would be good to ... tell us which sites to go to, and not just Google” [Participant 9].
Survivorship “what happens after”	Lack of clear survivorship plans, follow-up schedules, and guidance for life after treatment.	• “After the treatments were over, I was left alone. I want to know, what happens after cancer? ... Now that I have had cancer, it has changed me. How do I deal with this?” [Participant 9].
Safe, reputable online information	Desire for trusted, curated web resources instead of unguided internet searches.	• “I was googling a lot—wish I’d had something reputable to refer to” [Participant 15].
4. Digital tools and patient portal		
Access to records and results	Strong interest in a portal centralizing reports, laboratory results, and imaging.	• “I would like a patient portal with all of my reports and bloodwork results ... upcoming appointments, information on drugs I’m taking, and resources, like Wellspring” [Participant 6]. • “She loves Sunnybrook mychart ... she can bring the results to other medical appointments, so they have the information” [Participant 4].
Appointments and chronology	Desire for a clear visual timeline of appointments and treatments.	• “Would like to see the chronology of her appointments and treatments in a” [Participant 7].
Laboratory result “lookup”	Need for plain-language explanations of test results.	• “What about a lookup feature for what the lab results all mean—this would be great, so you don’t have to go Google” [Participant 8].
Messaging and chat	Preference for asynchronous written communication for nonurgent questions.	• “A good option would be to have a chat function ... I don’t necessarily need an answer right away and I don’t want to talk on the phone” [Participant 3].
Technology comfort and training	Wide variation in digital literacy and format preference (portal vs paper).	• “I would be very interested in using the portal, but someone would have to show me how to use it because I’m not good at using computers” [Participant 5]. • “I am a paper person. Would like to have all the educational materials paper-based” [Participant 8].
5. Experience of quality of care		

XSL•FO
RenderX

Theme and subtheme	Description	Illustrative quotes
BDC environment and team	Perceptions of the clinic environment, staff attitudes, and teamwork.	• "The whole team—everybody. Every time I am here I feel that I am coming home" [Participant 1].
Chemo and radiation experiences	Physical and emotional experiences of systemic and radiation treatments.	• "Chemo is the worst thing ever ... The chemotherapy treatments involved long waits" [Participant 6]. • "The nurses there were amazing at the chemo clinic ... They really tried to make a really bad situation bearable" [Participant 4].
Home care or CCAC[a]	Challenges with community nursing, reliability, and competence.	• "CCAC came and took care of my wound. It was a comedy of errors ... They had no idea whether they were coming or going, and whether they had supplies" [Participant 4].
6. Psychosocial and emotional support		
Distress and uncertainty	Intense distress at diagnosis and during periods of waiting or uncertainty.	• "The hardest part was from when I thought I probably had breast cancer, but didn't know for sure ... The hardest part was not knowing whether I would be able to see my son go to school" [Participant 16].
Ongoing anxiety and fear of recurrence	Persistent psychological impact after treatment ends.	• "I still struggle with the psychological aftercare ... You are always on guard for another lump" [Participant 9].
Support services and gaps	Value of programs like Wellspring and perceived gaps in psychosocial support.	• "The hospital just focuses on the body. They don't focus on the mental and the cognitive. I was happy to find Wellspring ... I go to a lot of classes" [Participant 6].
Humor and coping styles	Use of humor and individualized coping strategies.	• "Am I stressed, absolutely. To deal with it, I sit in the car and do stand-up humour for myself" [Participant 5].
7. Patient agency and self-management		
Self-advocacy and orchestrating care	Patients pushing for referrals, chasing results, and coordinating their own care.	• "I have to orchestrate it ... If you aren't willing to drive the car, let me. I want my test results. I want them to be accessible" [Participant 4].
Personal tracking and journaling	Using notebooks, binders, and journals to track care and questions.	• "After each appointment, I wrote in my book what happened. So, I have this record of what care I received" [Participant 12].
Doing own research and lifestyle change	Independent research on treatments and lifestyle changes to support recovery.	• "I wanted to be part of my recovery, so I did some digging and reading ... I removed sugar from my diet ... removed meat ... took 2 minute cold showers ... and drank a lot of water before chemo" [Participant 3].
8. Survivorship care and transitions		

XSL•FO
RenderX

Theme and subtheme	Description	Illustrative quotes
Who leads survivorship	Confusion and preferences around oncologist- versus GP[b]-led follow-up.	• "What happens now? Who follows me? Who do I speak with? ... There is no coordinated care. No one is in charge. It's you" [Participant 18]. • "I would prefer having my GP follow me once my treatment is complete ... She phones me and tells me my results" [Participant 11].
Requirements for GP-led care	Perceived capabilities and training needed in primary care.	• "The family doctor would have to have a lot of training regarding ... post-treatment side effects ... and the softer skills side of it" [Participant 7].
Long-term anxiety and follow-up	Ongoing fear of recurrence and desire for continued monitoring as years pass.	• "As the years go by, you think, nothing has happened. And you start to worry ... That's when the anxiety starts to come back with the waiting" [Participant 13].
Survivorship identity and peer support	Seeking peer support that matches age, life stage, and experience.	• "I would be really interested in a survivorship focus group ... After the treatments were over, I was left alone" [Participant 9]. • "I still haven't found someone like me ... a mother of two young kids ... To have that kind of peer support is really powerful" [Participant 16].

[a]CCAC: community care access center.

[b]GP: general practitioner.

Care Coordination and Workflows

Participants described the BDC as a coordinated, efficient entry point into care, characterized by rapid movement from abnormal imaging to biopsy and surgery and by clear internal communication. Women emphasized short wait times and proactive scheduling of subsequent appointments and referrals, which reduced uncertainty and signaled that "the system" was functioning well. In contrast, this perceived coordination often deteriorated once patients transitioned into chemotherapy, radiation, community nursing, or primary care. Several participants reported that the "team approach" appeared to end after surgery, with no single clinician or service clearly overseeing the remainder of care. Delays in imaging follow-up, confusion around orders, and inconsistent tracking of test results were frequently described. As a result, many participants felt responsible for navigating and organizing their own care, including obtaining their results, confirming appointments, and ensuring referrals had been made, a role they found exhausting in the context of illness and emotional distress.

Communication and Information Flow

How and where the diagnosis was communicated strongly shaped participants' early experiences. Some received the diagnosis alone at home by telephone and described this as particularly distressing; others were informed indirectly by nonphysician staff (eg, imaging technicians) before any formal consultation, which they found abrupt and insensitive. Beyond diagnosis, participants highlighted inconsistent messages between clinicians and services and poor intrateam communication, including contradictory advice between oncology and treatment units, eroding trust and increasing anxiety. Many were uncertain whether to contact their surgeon, medical oncologist, radiation oncologist, family physician, or nurse navigator when new questions or symptoms arose. At the same time, participants expressed high appreciation for clinicians who communicated in clear, plain language, invited questions, and repeated information without frustration. Participants also reported that initial information packages were sometimes overwhelming and poorly tailored (eg, lumpectomy-focused materials given to women undergoing mastectomy) and found gaps in practical "how-to" guidance (eg, what to buy and prepare before surgery, managing drains, and concrete strategies for side effects) and in survivorship-oriented information about "what happens after" treatment, follow-up schedules, and recurrence risk.

Information and Resource Needs

Information needs were complex and shifted across the cancer trajectory. Many participants recalled receiving large information packages at diagnosis that felt overwhelming or poorly tailored (eg, materials focused on lumpectomy when they were having mastectomy), even as they still lacked answers to very practical questions about what to expect after surgery and how to prepare their home. They sought clear, accessible explanations of pathology results, risk scores, and treatments, as well as guidance on what is "normal" versus concerning during and after treatment. Critically, once active treatment ended, people described a stark information void about survivorship—wanting to know what happens next, how long follow-up would last, what symptoms to watch for, and how to live with the ongoing impact of cancer. Many expressed a desire

XSL•FO
RenderX

for curated, trustworthy online resources to reduce reliance on unsupervised internet searches.

Digital Tools and Patient Portal

Participants suggested that a cancer-focused portal to address multiple unmet needs in one place would be helpful. Those with experience of existing portals valued having access to laboratory results, imaging reports, and appointment lists, and being able to bring printed results to other appointments. They imagined a more tailored tool that would provide a clear chronology of appointments and treatments, explanations of laboratory values in plain language, and secure messaging or chat for nonurgent questions. However, our data also highlighted wide variation in participants' comfort level with digital solutions: some described themselves as "information junkies" who would "be on it all the time," while others said they would need to be walked through how to use such a system or preferred paper-based materials. Any digital solution would therefore need to support both high- and low-technology users, offer training, and coexist with paper formats rather than fully replace them. Multimedia Appendix 5 summarizes the features participants reported they would be interested in seeing in a future patient portal.

Experience of Quality of Care

The overall quality of care was experienced as uneven. Many participants spoke positively about the BDC environment, highlighting friendly staff, clean, welcoming spaces, and a sense of being "at home" and well-supported. Chemotherapy units were described as both physically and emotionally challenging, yet often made more bearable by attentive, kind nurses. In contrast, community-based home care services were frequently characterized as disorganized, inconsistent, or poorly coordinated, with missed visits, questionable technique, or lack of supplies. Long waits for some specialist appointments, crowded spaces, and privacy concerns in certain treatment areas also shaped perceptions of quality. These contrasting experiences underscored how much the attitudes, organization, and resources of specific teams influence patients' sense of safety and trust.

Psychosocial and Emotional Support

Across the cancer journey, participants reported substantial psychosocial burden. The period between suspecting cancer and receiving a definitive diagnosis was described as especially distressing, particularly for those with young children who feared not living to see key milestones. They described intense fear and uncertainty at the time of diagnosis and during periods of waiting for test results or treatment decisions. Even after treatment, many reported ongoing psychological impacts, including heightened worry before follow-up imaging and a sense of being "on guard" for recurrence. Some participants found that strong support through community-based survivorship centers (such as psychosocial programs and survivorship classes) was essential to addressing emotional and cognitive impacts that hospital-based services, which "just focus on the body," often neglect and do not adequately address mental health, cognitive changes, or other concerns. Participants emphasized the value of humor and individualized coping strategies, and having space for levity, storytelling, and emotional validation alongside more formal counseling or group support. Transitions into survivorship were characterized by anxiety and uncertainty about who was responsible for ongoing care. Some participants were comfortable transitioning to a trusted family physician, while others questioned whether primary care had sufficient oncology expertise and time to manage late effects and psychological needs. Many described feeling "left alone" once active treatment concluded.

Patient Agency and Self-Management

Across interviews, patient participants portrayed themselves as active agents who often had to fill gaps in the system. Many described pushing for referrals, insisting on further tests, or repeatedly calling to obtain results, reflecting both a strong desire for control and a lack of trust that the system would automatically "catch" everything. Self-management practices were common. For example, participants kept notebooks or binders to track appointments, results, and questions, and some engaged in extensive independent research on treatments, nutrition, exercise, and complementary strategies to support recovery. These behaviors were framed both as empowering and burdensome, as patients felt they "shouldn't have to" organize their own care to this degree; yet, they would have valued tools and information that would have allowed them to do these activities more effectively.

Survivorship Care and Transitions

The transition from active treatment to survivorship was a major source of uncertainty and distress. Participants frequently reported not knowing who was now "in charge" of their care, how often they would be seen, or what tests would be done in follow-up. Some were comfortable with their family physician assuming a lead role, particularly when they had longstanding, trusting relationships and good access. However, others doubted that primary care providers had sufficient oncology-specific knowledge or time to manage their physical and psychological needs without additional training. Survivorship was also described as a distinct identity shift, whereby they no longer felt like active patients but did not feel "back to normal" either. Many sought survivorship programs, focus groups, or peer connections that recognized and supported this ongoing phase, rather than treating the end of treatment as the end of the cancer experience.

How Findings Informed the Design of the Patient-Facing App of MyJourney

Overall, participants emphasized the importance of structured follow-up plans, clear communication about recurrence risk, and accessible survivorship resources. Table 3 highlights the features identified by participants as to be considered for the patient-facing app. Multimedia Appendix 6 presents the minimum viable feature set used to build the patient-facing app.

XSL•FO
RenderX

Table . Features that were considered in the development of the patient-facing app.

App feature area	Directly addresses participant needs or quotes
Timeline and roadmap	Need for chronology, pathway or flowchart, and "knowing what happens next" including aftercare and survivorship.
Results and lookup	Desire for laboratory and test access, explanations (oncotype, seed lock, and radiation effects), and faster and clearer results.
Messaging and routing	Confusion about who to contact, wish for chat, frustration with missed callbacks, and vacation gaps.
Education library	Information overload plus gaps; wish for curated sites, practical tips, emotional support, and survivorship information.
Psychosocial or peer support	Requests for psychologists, survivorship groups, younger-women groups, peer stories, and contact.
Self-management tools	Patients documenting care, tracking steps, changing diet, and orchestrating follow-up themselves.

Phase 2: Preimplementation Interviews at the CC

Participant Characteristics

In total, 3 nurses and 5 pharmacists were interviewed between November 23 and 29, 2023, representing all relevant users of the MyJourney platform at the CC. Most participants (7/8, 87.5%) identified as female and a woman, aged 41 - 50 years (5/8, 62.5%), primarily with a Chinese (2/8, 25%), East African (1/8, 12.5%), South Asian (3/8, 37.5%), or White (2/8, 25%) racial background. Most participants had been in their current role for under 5 years (5/8, 62.5%; Table 4). At the CC, nurses were primarily responsible for coordinating care, managing symptoms, and answering patient inquiries. Pharmacists provided patient education, addressed treatment-related issues, secured funding, and offered tailored resources. Two pharmacist roles existed: Clinical One, who conducted scheduled education sessions before the first chemotherapy cycle, and Clinical Two, who provided chairside counseling to patients in clinical trials or to those who had not received prior education on the day of their first treatment.

Workflow Mapping: Phases of Chemotherapy Care

Workflows described by participants spanned three stages of the patient journey during their chemotherapy treatment: (1) before chemotherapy begins (including pretreatment education and preparation), (2) during chemotherapy (including treatment delivery, monitoring, and follow-up), and (3) end-of-treatment and transition to the next phase of care (Figure 3).

XSL•FO
RenderX

Figure 3. Workflow stages during chemotherapy treatment. OPUS: Ontario Public Health Standards.

Challenges and Recommendations

Preimplementation interviews with pharmacists and nurses uncovered multilevel challenges to care coordination across the chemotherapy care continuum, which we organized into five domains: (1) patient-level, (2) administrative and workflow inefficiencies, (3) health information technology systems limitations (eg, poor electronic health record usability and lack of interoperability between Ontario Public Health Standards, Cerner, and Connecting Ontario), (4) health resource constraints (eg, nurse staffing shortages and inadequate physical space), and (5) quality of care gaps (eg, lack of pharmacist continuity and no secure patient communication channels). Table 5 summarizes these challenges and MyJourney design recommendations to address them across the 3 stages of chemotherapy care: stage 1 (before), stage 2 (during), and stage 3 (end).

XSL•FO
RenderX

Table . Implementation challenges across the chemotherapy care continuum and MyJourney design recommendations to address them.

Challenge domain	Stage 1: before chemotherapy (Multimedia Appendix 7)	Stage 2: during chemotherapy (Multimedia Appendix 8)	Stage 3: end of chemotherapy and transition (Multimedia Appendix 9)	MyJourney design recommendations to address challenges
1. Patient-level	Lack of access to appointment information; privacy concerns about digital resources; limited digital literacy and technology access.	Information overload when large volumes of information were delivered on treatment days; walk-in patients seeking urgent support; limited after-hours access to clinicians.	Regional differences in community care coordination contributing to incomplete medication information and gaps at transition.	Patient-facing app centralizing appointment details and visit summaries; layered, on-demand education to reduce overload; mobile-friendly, plain-language content to support varying digital literacy; future secure messaging to support questions between visits and during transitions.
2. Administrative and workflow	Incomplete or unsigned prescriptions; late counseling notifications; delayed funding reviews; manual preparation of regimen-specific materials; heavy follow-up demands.	Reliance on verbal updates or email for after-hours issues; incomplete information leading to duplicated counseling; nurses unaware of appointment changes; high call volumes; manual record checks and after-hours reports.	Regional community care access differences hindering coordination and resulting in incomplete medication lists at transition.	Clinical Navigation Tool supporting task lists, standardized documentation templates, and structured prompts; centralized record of counseling and follow-up to reduce duplication; integration of key appointment and treatment information to support proactive planning and smoother transitions.
3. Health IT systems	Time-intensive Cerner documentation; restricted access and incomplete patient information; limited interoperability between OPUS[a], Connecting Ontario, and PowerChart; pharmacists unable to view oncologist appointments.	Manual order entry and frequent program switching; lost interprofessional notes on admission; unclear note headings; ongoing limited interoperability between OPUS and Cerner.	Fragmented information across hospital and community systems contributing to incomplete medication histories.	MyJourney designed as a single navigation workspace that aggregates key information from multiple systems where possible, reduces duplicate data entry through structured fields, and surfaces oncology appointments and treatment plans in a consolidated view to support navigation across settings.
4. Health resources	Complex funding confirmation processes; strained patient-to-nurse ratios; staffing constraints; shared counseling space with a vaccine clinic.	Nurse staffing shortages; physical space limitations restricting in-clinic transfusions; high-risk treatments requiring extended monitoring.	Ongoing resource constraints in community and hospital settings affecting follow-up capacity.	Workflow tools to streamline preparation for counseling, reduce repetitive administrative tasks, and support team-based navigation so workload can be shared across pharmacists and nurses, with clearer task allocation over time.
5. Quality of care	Medication charts lacking visuals or digital access; strict time limits that truncate counseling; privacy concerns limiting use of educational videos; inefficient coordination of bloodwork and education appointments.	Delayed drug preparation prolonging chair time; no 24/7 clinician availability; no dedicated pharmacist continuity; no secure electronic communication with patients.	Coordination gaps at transition leading to fragmented follow-up and incomplete information for community providers.	Visual, phase-specific patient education content; structured symptom and concern tracking to focus limited visit time; clear assignment of navigation tasks within the care team to enhance continuity and follow-up; digital information sharing to support more consistent transitions.

[a]OPUS: Ontario Public Health Standards.

Briefly, across stages, staff described patients' difficulty accessing technology, tracking appointments, and experiencing information overload when large volumes of education were delivered on treatment days and had limited options for secure communication and follow-up between visits. They also emphasized administrative inefficiencies (eg, incomplete

XSL•FO
RenderX

prescriptions, delayed notifications, and duplicated counseling); manual, fragmented, and time-intensive documentation across Cerner, Ontario Public Health Standards, and Connecting Ontario; staffing and space constraints; and coordination gaps at transitions to community care. These findings contributed to the design of MyJourney's patient-facing app (centralized appointment and treatment information, phase-specific educational content, and tools to support symptom tracking) and the Clinical Navigation Tool (structured prompts, standardized documentation templates, and a shared workspace to reduce duplication and improve visibility across the team), with the goal of addressing the specific workflow, communication, and information-access barriers identified by frontline clinicians and staff. See the complete set of challenges, recommendations, and related participant quotes for each stage in Multimedia Appendices 7-9.

Phase 3: Evaluation of MyJourney's Implementation and Usability

Participant Characteristics

In total, 2 charge nurses (CC), 1 charge nurse, and 1 administrative staff member (BDC clinic) participated in the usability evaluation. This sample comprised female participants aged 30 - 60 years who identified as women, with Black, East African, South Asian, and White racial backgrounds. Participants had been in their professional roles for 5 - 11 years (Multimedia Appendix 10). Phase 3 findings primarily reflect the RE-AIM domains of implementation and maintenance. Implementation-related results (stages 1 and 2) describe how patients navigated the app, the extent to which MyJourney fit within their routines, and specific usability issues that affected completion of key tasks, whereas maintenance-related results (stage 3) focus on participants' intentions to continue using MyJourney and their views on its ongoing role in their cancer journey

Stage 1 Evaluation (Usability Survey Results)

BDC Clinic

Usability was rated as excellent (mean SUS score 81.3, SD 8.8). Participants agreed that MyJourney was useful (mean score 3.9 of 5) and easy to use (mean score 4.0) and were very satisfied with the platform overall (mean score 4.5). Staff described MyJourney as helpful for workflow and daily tasks, with appointment visibility and patient organization consistently rated as easy to use, well-organized, functional, and satisfying. Notifications and diagnostic information were also valued, although perceptions of helpfulness varied slightly by role: "For me, it's about having fewer places to look ... it helps me do my job better and save time" (Participant 09, BDC).

Chemotherapy Clinic

Usability was rated as excellent with a mean SUS score of 76.3 (SD 8.8)6. Participants consistently found the platform useful (mean score 3.9 of 5), very easy to use (mean score 4.3), and very satisfied overall (mean score 4.5). Features were considered understandable, well-organized, functional, and helpful, with satisfaction ranging from agree for notifications and task reminders to strongly agree for treatment summaries, appointment views, and notetaking: "It's very easy to use and organized ... instead of clicking or going to a million places in Cerner, it's right there" (Participant 01, CC).

Stage 2 Evaluation (Interview Results)

BDC Clinic

Interviews supported survey results. Participants described MyJourney as efficient, with clear benefits for referrals, patient tracking, and information management. Shared visibility across the care team was considered a strength, and staff emphasized the value of appointment visibility, triage functions, and diagnostic notifications to support workflow. Participants also identified challenges, including glitches such as missing or outdated appointments, inconsistent notifications, and the absence of document upload capability. Recommendations included adding accountability features, digitizing paper charts, allowing customizable lists, and eventually integrating patients into multidisciplinary cancer conferences. Despite these challenges, staff expressed strong support for the platform. They described MyJourney as a communication tool that saves time, prevents patients from being missed, and offers a clear improvement over older workflows. Long-term use was considered both feasible and beneficial, with participants anticipating continued improvements and the forthcoming patient app (see Multimedia Appendix 4 for representative quotes).

Chemotherapy Clinic

Interviews reinforced survey findings, with participants consistently describing MyJourney as easy to use, clearly organized, and helpful for daily workflow. Staff highlighted that it took only minutes to learn to navigate the system, which replaced paper-based tracking and consolidated treatment information into a single platform. Features such as notes, tasks, treatment summaries, and appointment views were identified as particularly valuable. At the same time, participants reported challenges with reminders and notifications that were only visible during active sessions. They recommended adding email notifications and requested further integration of pathology, bloodwork, and imaging results. Limited customization and the timing of installation during work hours were also reported as concerns. Participants recommended greater flexibility in tailoring views, broader integration with existing systems, and extending MyJourney beyond breast cancer to other types of cancer.

Stage 3 Evaluation (Repeat Usability Survey at the CC)

At the 6-week follow-up, perceived usability increased from a mean SUS score of 76.3 (SD 8.8) to 86.3 (SD 1.8). This score is interpreted as "best imaginable usability" [24]. Participants found the platform useful (mean score 4.0 of 5) and very easy to use (mean score 4.8 of 5), and they were overall very satisfied (mean score 4.5). Overall, participants expressed strong support for MyJourney, reporting that it streamlined workflows by addressing challenges identified in phase 2, showed perceived improvement in communication within the care team, and was feasible for long-term use. Perceived benefits were described as: "... everything is right there and ... you're able to see a

XSL•FO
RenderX

snapshot" (Participant 01, CC); "Before I used to have to check Cerner and SharePoint ... Now a lot of times I can just look in one place in MyJourney" (Participant 09, BDC). Based on our collective findings, five MyJourney features were developed to meet the needs of staff at the BDC: (1) diagnostic imaging and pathology notifications, (2) upcoming appointment information, (3) triaging patients accordingly, (4) diagnosis information for patients with cancer, and (5) organizing BDC patients according to their appointment types. At the CC, six features of MyJourney were identified to address the identified challenges: (1) treatment summary; (2) upcoming or past appointments view; (3) customized notes, tasks, and reminders; (4) task reminders at the patient level; (5) educational content via mobile app; and (6) overview of bloodwork appointments or results. Multimedia Appendix 5 summarizes recommendations to address challenges for specific MyJourney features.

Technical Integration of MyJourney

Collectively, findings from each phase were translated into phase-specific prompts, content scheduling, and task workflows for both the Clinical Navigation Tool and the patient app. Regarding technical integration, the only data element entered directly by patients was the provincial health card number. All other core patient demographics (name, gender, date of birth, and age) were retrieved automatically from the NYGH electronic medical record system (Cerner) via system integration. For each patient, we linked the hospital medical record number and health card number to an existing referral in our system. If no referral record was present, we created one and manually entered the patient's demographic information. In practice, referrals were available for the vast majority of patients, as clinic policy requires a referral from a family physician prior to consultation. Cancer diagnoses were recorded manually within the innovation platform using a structured drop-down field. Following completion of the diagnostic work-up, the confirmed diagnosis was entered to transition the patient into the "cancer diagnosis" pathway, which, in turn, enabled automated capture of subsequent hospital visits and oncology appointments. For patients with stage IV disease, clinicians manually advanced the record to the stage IV journey by selecting a dedicated "stage 4" option after the diagnosis was entered; this step was based on clinical staging, including cross-sectional imaging demonstrating distant metastases. All remaining data were captured automatically through integration with the electronic medical record. The system continuously identified relevant laboratory results and scheduled appointments, moved patients into the "cancer journey" based on appointment data, updated their status across treatment states, and generated treatment summaries from encounters with chemotherapy, surgery, and radiation without additional manual data entry.

Discussion

Principal Findings

Findings across the 3 phases of this research demonstrate how patient and provider input shaped MyJourney, how it functioned in practice to support the breast cancer journey for providers and patients, and its potential to reduce administrative burden while improving care coordination. Our multiphase studies demonstrated that MyJourney was feasible to implement in 2 oncology settings at an academic community hospital in Ontario, Canada, and that end users found it highly usable and helpful. The phased, iterative approach to our methods enabled insights from patients and providers to inform the design, local adaptation, and early evaluation of MyJourney, which likely contributed to its rapid acceptance.

Phase 1 provided a patient-centered map of the breast cancer journey, along with key features to be incorporated into the design of the MyJourney platform components. This phase provided foundational input for both design and implementation. Patients described the BDC as a coordinated entry point into breast cancer care but highlighted substantial gaps when transitioning into chemotherapy and survivorship, including information overload, unclear points of contact, and a need to self-manage coordination across services. For example, these insights identified the timing and content of the navigation touchpoints for the Clinical Navigation Tool and the patient app. Although this paper primarily focused on the provider-facing tool (ie, clinical navigation), the phase 1 findings are foundational, demonstrating how patient priorities can be systematically translated into platform design.

Phase 2 revealed workflow pain points in information access, communication, task tracking, and system interoperability at the CC. Nurses and pharmacists described heavy reliance on manual processes, incomplete or inconsistent appointment information, and fragmented systems. These findings positioned MyJourney as a practical solution by consolidating information, reducing manual entry, and providing notes, tasks, and reminders that supported cognitive load. The preimplementation assessment generated site-specific requirements that informed the configuration prior to rollout. These insights were used to define navigation touchpoints, content, and features in MyJourney, particularly around transitions from diagnosis to treatment and beyond, and were subsequently leveraged, alongside CC workflow data from phase 2, to guide the localization of MyJourney for the CC. By systematically mapping observed challenges to specific MyJourney design recommendations (Table 5), we demonstrated how frontline implementation barriers informed the platform's core functions, rather than designing in isolation from workflow realities. This alignment between identified needs and design decisions is likely to have contributed to early acceptability and perceived implementation fit.

Phase 3 findings indicated strong acceptance among tool users, with improvements in usability over time. Early acceptance after only 1.5 weeks likely reflects the value of preimplementation work and the platform's maturation since its initial BDC deployment in 2022. Staff described mechanisms through which the platform delivers benefits: replacing paper-based notes and task tracking, centralizing essential patient information, reducing duplicate system checks, and externalizing memory work through notifications and reminders. Treatment summaries and appointment views created a shared mental model across team members, which supported coordination and handoffs. Together, the layout, content, and features of MyJourney coalesced to save time and improve efficiency for daily workflows and tasks. RE-AIM also helped

XSL•FO
RenderX

us to interpret phase 3 findings, revealing that, despite the small usability sample, MyJourney demonstrated promising implementation, with participants able to complete core tasks and articulating clear benefits for organizing information and tracking care. At the same time, their reflections on when and how they would continue to use the app, and on conditions needed for ongoing integration into clinical workflows, directly informed our understanding of maintenance and our plans for scale-up and refinement.

Opportunities for improvement were clear and actionable. Reliability needed to be strengthened by resolving errors to maintain user confidence, particularly during busy periods. For example, appointment views need to display entries consistently. Integrations should be expanded to include bloodwork, diagnostic imaging, and pathology, with straightforward navigation to source systems where embedding is not yet possible. Additional patient details, the ability to upload key letters or documents, and role-based list filtering would better align the tool with daily work. Out-of-app notifications, such as email triggers for reminders, could support time-sensitive follow-up when users are not actively in the system.

Implications for Practice and Policy

The results confirm and extend existing evidence regarding the benefits and challenges of digital health platforms in oncology care. Oncology nurse navigation programs are well established and have been shown to reduce barriers, improve timely care, and enhance patient experience, particularly for patients with complex cancer trajectories [30-32]. However, navigation activities are often supported by fragmented tools (eg, electronic health record notes, spreadsheets, and paper trackers) with limited interoperability or standardized digital support for scheduling, task management, and program-level data use [31,33]. Our findings suggest that MyJourney extends these traditional models by embedding navigation functions within an integrated, provider-facing platform that consolidates appointments, treatment summaries, key laboratory information, and navigation tasks for charge nurses, pharmacists, and administrative staff in the CC. In contrast to models that rely on a single nurse navigator to manually orchestrate care, MyJourney distributes navigation activities across roles through shared dashboards and reminders, while automatically drawing core patient and appointment data from the electronic medical record to reduce duplicate documentation. By localizing the Clinical Navigation Tool to the CC, this study demonstrates how navigation principles can be operationalized within the day-to-day delivery of systemic therapy, complementing but not replacing existing nurse navigation. It also addresses calls for interoperable, scalable digital infrastructure to support navigation across the cancer continuum, which is largely lacking [30,33].

The use of integrated digital platforms aligns with global health system priorities, such as the Quintuple Aim, by simultaneously addressing patient and provider experience, enhancing workflow efficiency, and supporting continuity of care [14]. Evidence has shown the fragmented nature of cancer care and the high burden placed on clinicians by noninteroperable health information systems [34-37]. MyJourney's design addresses these documented challenges by consolidating provider-facing functionality and facilitating the timely exchange of information. Platforms that coordinate tasks across teams represent a promising strategy for enhancing multidisciplinary collaboration and reducing provider workload, findings consistent with recent studies on digital navigation tools and care pathway supports [34-37]. The iterative, user-centered development process undertaken in this study further highlights the importance of interest-holder engagement in implementation research to ensure the practical relevance, adaptation, and uptake of new health technologies.

Provider-facing digital tools can reduce administrative burden when configured to local workflows and introduced through a preimplementation assessment [38-40]. Health systems should invest in interoperability and lightweight notification pathways, allowing navigators and nurses to act on results without repeatedly checking the system. Workforce implications are also notable: features such as task reminders, appointment views, and shared dashboards directly address the cognitive and administrative load of nurses and pharmacists, suggesting that digital platforms can be part of a broader strategy to sustain oncology workforce capacity [37-43]. The adaptability of MyJourney across both mature (BDC) and new (CC) implementations suggests that it has scalability potential across cancer programs and possibly to other diseases requiring similar care-delivery support. While this study focused on the provider-facing tool, the linked patient app may also reduce call volumes and enhance self-management, creating system-wide benefits.

Strengths and Limitations

Our study had several strengths. First, our evaluation used a multimethod, iterative design that incorporated qualitative interviews and quantitative surveys at multiple stages, including the usability evaluation. Second, we engaged diverse knowledge user groups within MyJourney, including patients, nurses, pharmacists, and administrative staff, to gain a comprehensive understanding of the platform's potential impact and areas for improvement. Third, the use of the interpretive description methodology provided detailed insights, closely grounded in participants' experiences and clinical contexts. The integration of patient insights and provider workflow mapping into the design and rollout of the MyJourney platform at the CC helped us refine it to better align with real-world needs. Finally, interpreting our findings through RE-AIM (phase 3) offers preliminary evidence of promising implementation and potential maintenance of MyJourney, with participants able to complete core tasks and describing the app as helpful for organizing information and coordinating aspects of their care. Patients and clinicians reported perceived reductions in documentation burden and smoother workflow coordination when using MyJourney.

Limitations include a small sample confined to 2 clinics within 1 hospital, so we acknowledge that the generalizability of our findings to smaller hospitals, rural settings, or low-resource environments may be limited. However, this approach allowed us to observe both a mature implementation (ie, the BDC clinic) and an early-stage adoption (CC) of MyJourney within the same

XSL•FO
RenderX

institution. Nevertheless, we acknowledge that the implementation of innovations such as MyJourney is dependent on institutional readiness, leadership buy-in, and interoperability capacity. There is also a possibility that our purposive sampling strategy to identify eligible patients, providers, and staff introduced selection bias, as our recruitment methods incorporated convenience and self-selection (eg, posters, prior consent lists, and voluntary participation by staff). This may limit the transferability of our findings. However, we included nearly all MyJourney users in our sample. Phase 2 interviews did not include oncologists or surgeons, reflecting their limited routine use of the CC Clinical Navigation Tool at this stage; future work should more directly incorporate physician perspectives, as the platform scales and physician-facing components are further integrated. Another related limitation was that the patient participants in phase 1 were predominantly English-speaking, highly educated, and reported higher income, which does not reflect the North York community. In future evaluations, we will ensure the recruitment of patients with diverse intersecting identities, including gender identity, race, language, and accessibility needs. Outcomes are primarily perceptual and descriptive at this stage of technology evaluation (particularly for describing workflow efficiency), and integration with external systems has not been tested. We did not collect objective use or long-term sustainability metrics (eg, log-in frequency and time-on-task) for the BDC implementation; therefore, our assessment of implementation "success" is based on user-reported usability, perceived utility, and integration into workflows. As such, our results should be interpreted as evidence of early implementation success rather than definitive proof of sustained adoption (ie, they should be understood as descriptive and perceptual indicators of implementation success and anticipated sustainability). Future work should incorporate objective workflow and clinical metrics, as well as measures (eg, time-motion or productivity metrics), and longer follow-up to more rigorously assess efficiency and maintenance over time.

Recommendations for Future Research

Future work should evaluate operational outcomes such as time to key treatment steps, missed appointment rates, task completion latency, and call volumes. Studies should assess workload and burden using validated measures, paired with time-and-motion studies or log data to capture changes in work patterns. Longitudinal research is needed to track sustained use and maintenance and to understand the sustainability of MyJourney and what is required to ensure it becomes part of routine care across different clinical settings. Equity impacts warrant close attention, including experiences of patients with lower health or digital literacy and the broader accessibility of the patient app. Resource limitations prevented us from evaluating the patient app, so assessing this feature of MyJourney will be an essential step. Comparative research across different clinical settings, including rural or resource-limited sites, could also be undertaken to test MyJourney's scalability potential. Finally, integrating use analytics from the clinical tool and the patient app with qualitative accounts will clarify mechanisms of effect and guide ongoing optimization.

Conclusions

Results from our research demonstrated that MyJourney's Clinical Navigation Tool may contribute to workflow efficiency, care coordination, and information management for breast cancer teams at the NYGH's BDC and CC. The high usability scores and positive user experiences at these clinics support the MyJourney platform's potential for scaling and integration into other settings to optimize cancer care pathways. Continued refinement of digital platforms based on user feedback and expanding integration with electronic medical records will be essential to maximize their benefit and advance high-quality, multidisciplinary oncology care.

Acknowledgments

The authors acknowledge Abbas Ali for helping with technology development, Sana Butt for designing the features of MyJourney based on user feedback, and Rathini Sivasubramaniam and Téjia Bain for their help in the quantitative and qualitative data collection. Artificial intelligence tools were used at any stage in the preparation of this manuscript.

Abstract

Background: Artificial intelligence (AI) is increasingly used to generate medical content, yet its performance in delivering clinically relevant and reliable information remains underexplored, especially in complex areas such as breast cancer.

Objective: This study aimed to compare ChatGPT-4.0 and DeepSeek-V3 in generating breast cancer information, focusing on readability, content quality, and citation reliability.

Methods: On the basis of publicly available patient education materials, 10 frequently asked questions were selected. Each model generated 60 responses. Three expert reviewers rated each response using a 7-point Likert scale across 5 dimensions (ie, accuracy, completeness, clarity, depth and insight, and alignment with expert answers). Readability was assessed using Flesch-Kincaid Grade Level scores. Information reliability was evaluated through interrater agreement metrics, including Cohen κ and Fleiss κ. Paired *t* tests were used for statistical comparisons.

Results: AI models produced significantly more readable content than expert references (mean Flesch-Kincaid Grade Level difference −2.60; $P<.001$). ChatGPT-4.0 responses were more stylistically consistent with a median Flesch-Kincaid Grade Level score of 10.66 (IQR 0.98), whereas DeepSeek-V3 showed greater variability with a median Flesch-Kincaid Grade Level score of 10.17 (IQR 1.41). Content quality scores were DeepSeek-V3 achieving a higher mean score than ChatGPT-4.0 (6.22 [SD 0.43] vs 6.01 [SD 0.49]). In the multiresponse analysis, DeepSeek-V3 demonstrated a statistically significant advantage in accuracy ($P=.041$), while differences across other criteria were not statistically significant ($P>.05$). Human raters showed almost perfect agreement when judging source reliability (Fleiss κ=0.842 for ChatGPT's citations and 0.935 for DeepSeek's citations). Agreement between each model's citation reliability scores and the expert majority was substantial for ChatGPT (Cohen κ=0.665) and higher for DeepSeek (Cohen κ=0.782).

Conclusions: Both models generated readable and clinically relevant content with comparable overall performance. ChatGPT provided more consistent readability, while DeepSeek offered more diverse references with stronger alignment to expert ratings. Continued evaluation and quality assurance are essential for the responsible clinical use of AI-generated content.

(JMIR Cancer 2026;12:e72839) doi:10.2196/72839

KEYWORDS

artificial intelligence; breast cancer; ChatGPT; DeepSeek; large language models; AI; LLM

Introduction

Breast cancer is the most commonly diagnosed cancer among women and remains a major global health burden. Despite advancements in detection and treatment, late-stage presentation continues to hinder outcomes [1-4]. The World Health Organization highlights the need for improved screening and care access [5], while socioeconomic factors such as education and income shape care-seeking behavior. Many women turn to the internet for information on early signs and symptoms [6,7], although online health content is often inaccurate or misleading [8,9].

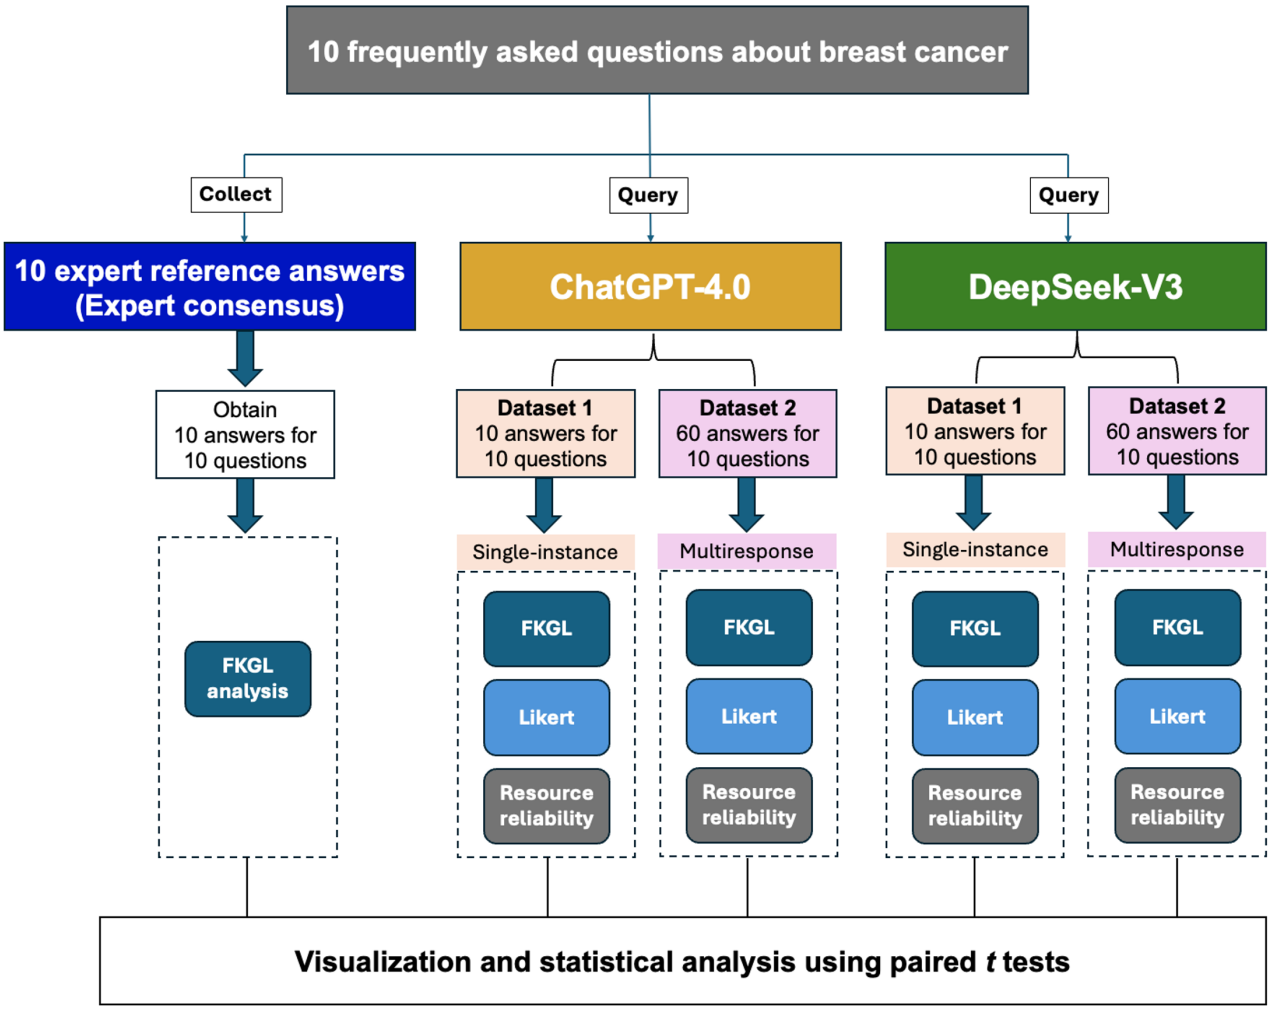
In response, large language models (LLMs), such as ChatGPT and DeepSeek, have emerged as potential tools for generating medical information and answering patient queries [10-17]. Trained on extensive biomedical literature and general data sources, these generative artificial intelligence (AI) models can produce natural language responses to diverse health-related questions [18,19], potentially supporting patient education and access to general medical knowledge [20]. Promising results have been demonstrated across multiple areas, including medical imaging, disease detection, drug discovery, and personalized oncology, with some AI models surpassing traditional diagnostic accuracy [21-24]. In oncology, AI aids in drug delivery, genomics integration, and real-time monitoring to improve outcomes [2,5-8,25,26]. Nonetheless, concerns persist regarding

XSL•FO
RenderX

the accuracy, readability, and reliability of AI-generated content, especially in complex domains such as breast cancer, necessitating further validation studies [27-30].

A recent work by Ye et al [31] systematically evaluated ChatGPT-3.5's performance in responding to frequently asked questions (FAQs) on cervical and breast cancer. Their study used 10 validated FAQs developed through expert consensus and compared ChatGPT's responses to those of experienced gynecologists and mammography specialists. Using a 7-point Likert scale, they assessed multiple dimensions of response quality, including accuracy, readability, consistency, reliability, efficiency, and relevance. While ChatGPT 3.5 demonstrated high accuracy, often comparable to or exceeding physician responses, it also exhibited limitations in readability, consistency, and the reliability of cited sources. Although foundational, this study did not evaluate more advanced generative AI models, such as ChatGPT-4.0 or DeepSeek-V3, whose capabilities remain largely unexplored [31-33]. Thus, further research is needed to assess how newer models compare in generating high-quality, clinically relevant patient education content.

Therefore, the aim of this study was to systematically evaluate and compare ChatGPT-4.0 and DeepSeek-V3 in their ability to generate high-quality, patient-facing breast cancer information. Using an established, expert-validated set of breast cancer FAQs, we assessed each model across multiple dimensions of response quality, including readability, accuracy, completeness, clarity, depth, insight, alignment with expert reference answers, and citation reliability, with the goal of determining whether these systems can provide trustworthy, clinically relevant educational content for patients.



Methods

Study Design and Workflow

This study evaluated the performance of generative AI models in answering 10 FAQs related to breast cancer as described in the workflow shown in Figure 1. The 10 validated questions and their corresponding expert reference answers were adopted from the study by Ye et al [31], which served as the benchmark dataset for this evaluation. In their foundational study, Ye et al [31] developed a list of FAQs regarding breast cancer and cervical cancer based on popular science materials and current hot topics related to tertiary prevention. A set of 10 questions was designed for each cancer type. Subsequently, experts were invited to review the proposed questions and to formulate expert consensus answers. The final set of questions and expert consensus answers were determined through several rounds of consultation and assessment.

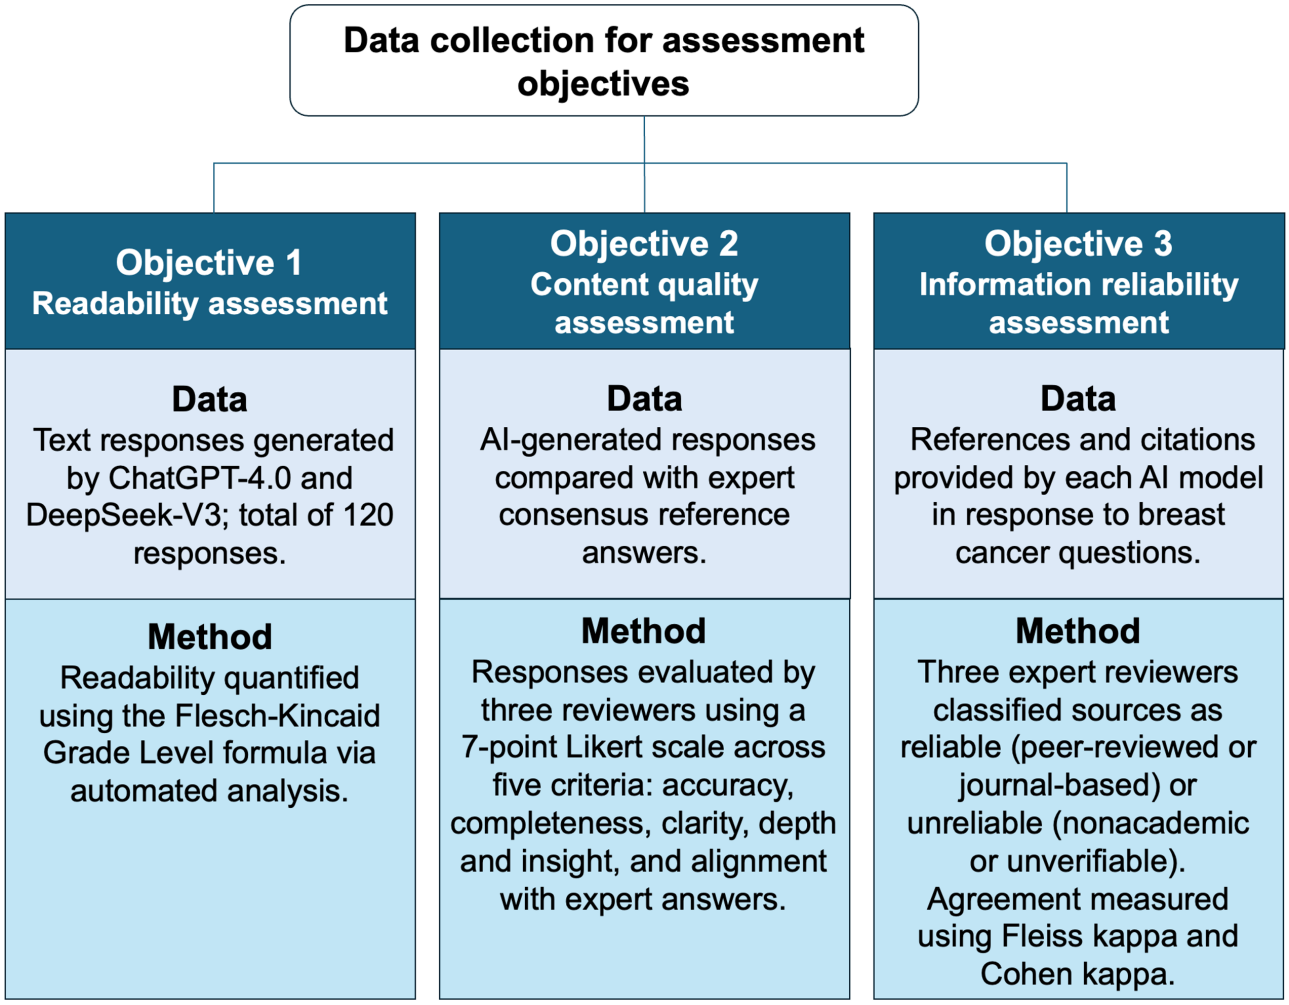
Figure 1. Workflow for evaluating the performance of ChatGPT and DeepSeek in retrieving and presenting medical information. FKGL: Flesch-Kincaid Grade Level.



Data Collection and Processing

Figure 2 summarizes the data collection and assessment procedures used to evaluate the performance of ChatGPT-4.0 and DeepSeek-V3 across three core dimensions: readability, content quality, and information reliability. Each objective shown in Figure 2 was addressed using a tailored methodology aligned with specific types of data and evaluation criteria.

XSL•FO
RenderX

Figure 2. Workflow of data collection for assessment objectives. AI: artificial intelligence.

AI Response Generation

To evaluate AI-generated content, we submitted 10 breast cancer FAQs to two generative AI models: ChatGPT-4.0 (OpenAI) and DeepSeek-V3 (DeepSeek). To ensure reproducibility and minimize bias, 3 independent researchers queried each model twice per question at different times, locations, and internet connections, yielding 6 responses per question per model (total: 60 responses per model and 120 responses overall).

Expert Reference Answers

Expert reference answers for each FAQ were obtained from the consensus of 5 board-certified physicians specializing in mammography, as reported by Ye et al [31]. These physicians independently reviewed each FAQ and provided responses, which were then harmonized into a single consensus answer per question. This consensus served as the gold standard for evaluating AI performance.

The 10 breast cancer FAQs and the corresponding AI-generated answers from each independent researcher are provided in Tables S1-S3 in Multimedia Appendices 1-3, and the expert consensus reference answers are provided in Table S4 in Multimedia Appendix 4.

Data Analysis

Readability Assessment

The readability evaluation was performed using the Flesch-Kincaid Grade Level (FKGL) analysis [34,35]. The textstat library (version 0.7.7; developed by Shivam Bansal, open-source project) [36] in Python was used to compute the FKGL scores for expert reference answers and responses generated by ChatGPT-4.0 and DeepSeek-V3. FKGL estimates the US school grade level required to understand a text, with higher scores indicating greater complexity. The FKGL score was calculated using the following formula:

$$FKGL = 0.39\left(\frac{\text{Total words}}{\text{Total sentences}}\right) + 11.8\left(\frac{\text{Total syllables}}{\text{Total words}}\right) - 15.59$$

This analysis used two datasets: dataset 1, where expert reference answers were compared to the initial responses from ChatGPT-4.0 or DeepSeek-V3 for all questions (Q1-Q10); and dataset 2, where 3 researchers generated 2 responses each from ChatGPT-4.0 and DeepSeek-V3 for Q1-Q10, resulting in 60 responses per model. To evaluate statistical significance, paired *t* tests were conducted using the SciPy library (scipy.stats library; SciPy Developers, open-source project) within Python [37], as FKGL scores were normally distributed. These tests assessed mean differences between ChatGPT-4.0 and DeepSeek-V3 while ensuring paired comparisons across identical question sets.

XSL•FO
RenderX

Content Quality Assessment

Content quality was evaluated across five predefined dimensions: accuracy, completeness, clarity, depth and insight, and alignment with expert reference answers. These dimensions were adapted from established guidelines for assessing the quality of health information and AI-generated content [38,39]. Each AI-generated answer was independently scored by 3 expert reviewers using a 7-point Likert-type scale, where 1 represented poor performance and 7 represented excellent performance.

To compare the performance of ChatGPT-4.0 and DeepSeek-V3 across these dimensions, statistical analysis was performed using Python's SciPy library (scipy.stats module, version 1.15.1; SciPy Developers, open-source project) [37]. The Shapiro-Wilk test was first applied to assess the normality of score distributions [40,41]. As the data met the normality assumptions, paired *t* tests [42] were conducted to compare mean scores across the 5 evaluation criteria. This approach enabled a robust and consistent comparison of content quality between the 2 models using identical question sets and standardized scoring methods.

Information Reliability Assessment

The information sources cited by ChatGPT-4.0 and DeepSeek-V3 were independently evaluated by 3 domain experts (RH, DAS, and SKB) with expertise in medicinal chemistry (all), molecular oncology (SKB), and computational drug discovery (RH and DAS). Each unique cited reference was assigned a binary reliability score: 1 for reliable sources (peer-reviewed journal articles, clinical guidelines, or official or authoritative bodies, such as national health agencies or major academic medical centers) and 0 for unreliable sources (commercial health media, foundation blogs, unsourced claims, or otherwise nonverifiable material). Complete source lists and scores are provided in Table S5 in Multimedia Appendix 5 (ChatGPT-4.0) and Table S6 in Multimedia Appendix 6 (DeepSeek-V3), and the full question-level reference data for both ChatGPT-4.0 and DeepSeek-V3 are provided in Table S7 in Multimedia Appendix 7.

For each AI model, we then performed 2 levels of agreement analysis. First, we assessed interrater reliability among the three human experts using Fleiss κ [43], and we also quantified the proportion of references with perfect agreement (all 3 raters assigned the same score), majority agreement (at least two raters agreed on the same score), and complete disagreement. Second, we evaluated how well each model aligned with human judgment by comparing the model's score for each reference to the majority human score (the score agreed upon by ≥2 raters). Agreement between each AI model and this consensus was quantified using Cohen κ [44].

To further characterize disagreement, we identified references where ChatGPT or DeepSeek diverged from the expert majority score and summarized the frequency and nature of those disagreements. All scoring data (individual rater scores, AI-assigned scores, and majority scores) and all agreement calculations (Fleiss κ and Cohen κ) were generated in Python (pandas, NumPy, and scikit-learn) [45-47] and compiled into Microsoft Excel for audit trails, including disagreement tables and summary statistics for each model.

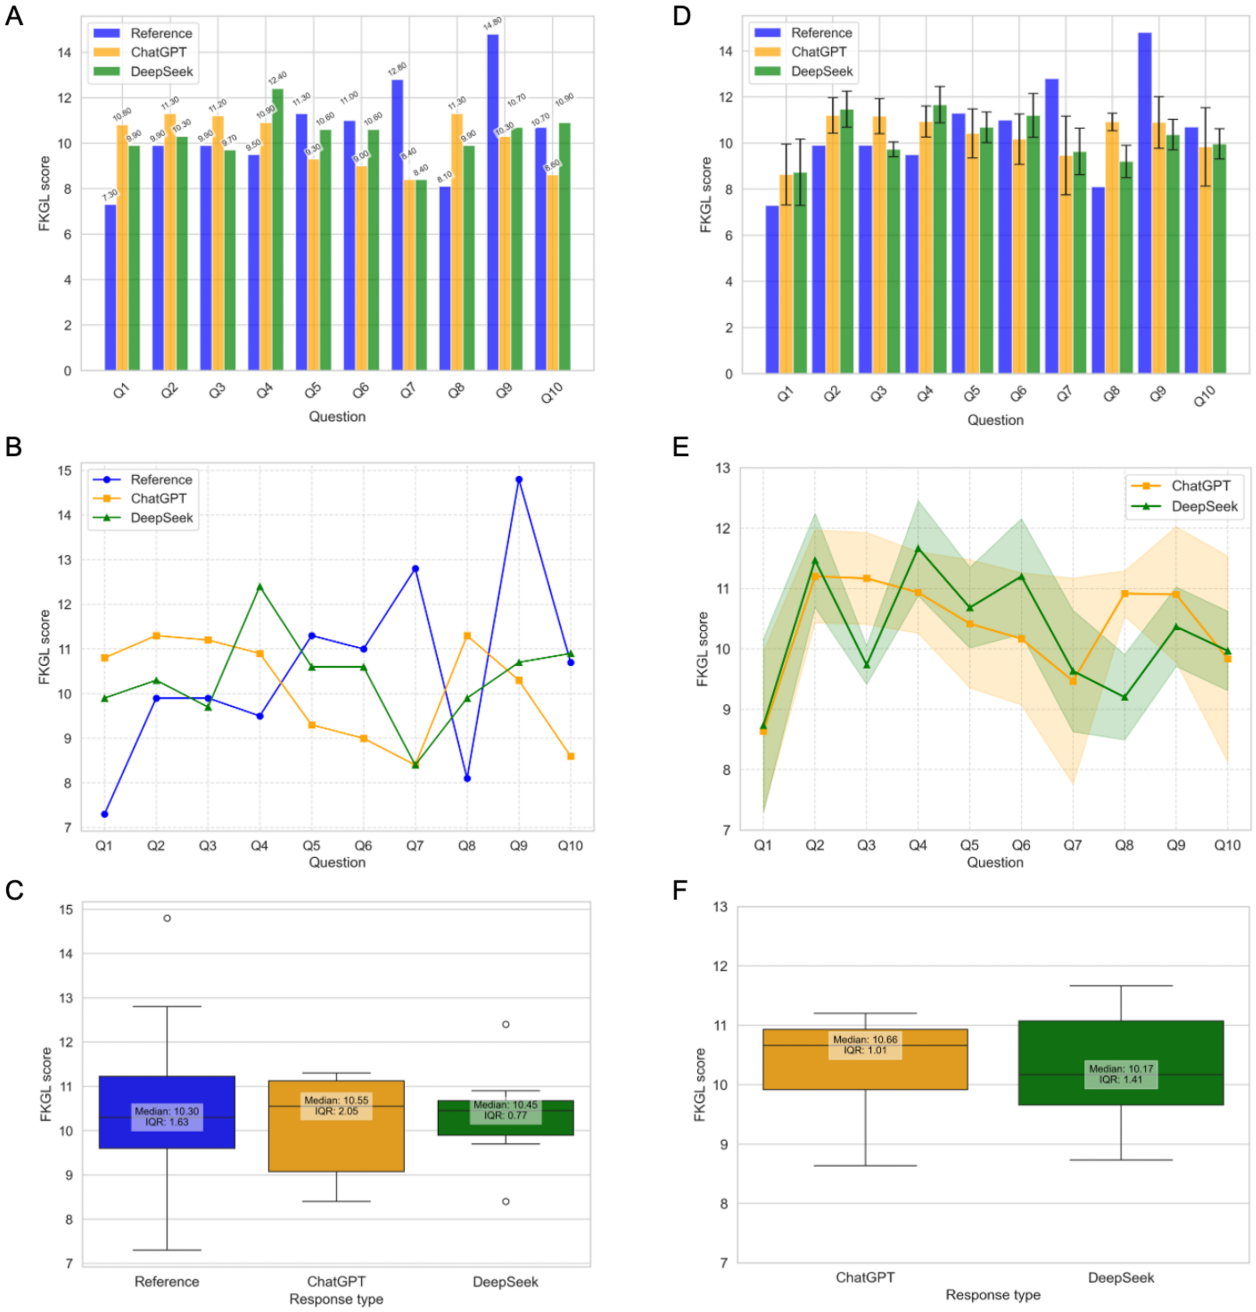
This evaluation framework allowed us to simultaneously measure (1) consistency among human raters when judging citation reliability and (2) how closely each AI system's choices agreed with what experts considered acceptable evidence.

Ethical Considerations

This study did not involve human participants, patient data, or intervention and therefore did not require review or approval by an institutional review board or research ethics committee. The analyses were based exclusively on AI-generated text responses and publicly available information sources, without collection of any personal, identifiable, or sensitive data. As no human subjects were recruited or interacted with, informed consent was not required, and no consent waiver was necessary. No compensation was provided. All data were handled in accordance with principles of data minimization and confidentiality, and no private or proprietary information was accessed or stored during the study.

Results

Study Design and Analytical Framework



To evaluate the performance of ChatGPT and DeepSeek, a structured analytical framework was implemented, as illustrated in Figure 1. A comparison of ChatGPT and DeepSeek was conducted using 10 FAQs about breast cancer, with responses evaluated against consensus expert reference answers as outlined in the Methods section. The workflow, illustrated in Figure 1, consisted of three key steps: data collection, model querying, and visual and statistical analysis. In the data collection phase, 10 common breast cancer questions were identified, and expert consensus answers were established. Three independent researchers then queried ChatGPT and DeepSeek, generating responses. Two datasets were created for each model: dataset 1, consisting of single-instance responses (1 response per question); and dataset 2, containing multiresponse outputs (multiple responses per question), resulting in 10 responses from each model for dataset 1 and 60 responses from each model for dataset 2Figure 1.

Readability Assessment

The FKGL readability scores for responses generated by ChatGPT and DeepSeek, compared against expert reference answers, are presented in Tables 1 and 2 and Figure 3. Two types of analyses were performed: single-instance analysis, where each AI model provided a single response per question; and multiresponse analysis, where multiple responses per question were collected by 3 researchers independently from both models.

XSL•FO
RenderX

Figure 3. Readability assessment using Flesch-Kincaid Grade Level (FKGL) scores for expert reference answers, ChatGPT, and DeepSeek responses. (A) Bar plot comparing FKGL scores for 10 questions using 1 response per question from each platform. The bars represent the FKGL scores for reference, ChatGPT, and DeepSeek. (B) Line plot showing the overall trends of FKGL scores across all questions using 1 response per question from each platform. The lines represent the FKGL scores for reference, ChatGPT, and DeepSeek. (C) Box plot showing the distribution of FKGL scores using 1 response per question from each platform. The boxes represent the IQR, with the median annotated inside each box. Reference, ChatGPT, and DeepSeek are represented in blue, orange, and green, respectively. (D) Bar plot comparing FKGL scores for 10 questions using 6 responses per question per platform. The bars represent the average FKGL scores, with error bars indicating the SD. ChatGPT responses are shown in orange, and DeepSeek responses are shown in green. (E) Line plot showing the overall trends of FKGL scores for ChatGPT and DeepSeek responses across 10 questions using 6 responses per question per platform. The solid lines represent the mean FKGL scores, and the shaded regions indicate the SDs. (F) Box plot showing the distribution of FKGL scores for ChatGPT and DeepSeek responses across 10 questions using 6 responses per question per platform. The boxes represent the IQR, with the median annotated inside each box. The *y*-axis for all line and box plots ranges from 7 to 15 to ensure a clear comparison of FKGL variations.

Table . Comparison of readability scores of Flesch-Kincaid Grade Level (FKGL) of single-instance analysis for expert reference answers, ChatGPT-4.0, and DeepSeek-V3.

Question	Expert reference answer[a]	ChatGPT-4.0[b]		DeepSeek-V3[c]	
	FKGL score	FKGL score	Difference[d]	FKGL score	Difference[d]
Q1	7.30	10.80	3.50	9.90	2.60
Q2	9.90	11.30	1.40	10.30	0.40
Q3	9.90	11.20	1.30	9.70	−0.20
Q4	9.50	10.90	1.40	12.40	2.90
Q5	11.30	9.30	−2.00	10.60	−0.70
Q6	11.00	9.00	−2.00	10.60	−0.40
Q7	12.80	8.40	−4.40	8.40	−4.40
Q8	8.10	11.30	3.20	9.90	1.80
Q9	14.80	10.30	−4.50	10.70	−4.10
Q10	10.70	8.60	−2.10	10.90	0.20

[a]Statistics across all the responses for 10 questions are as follows: mean 10.53 (SD 2.17) and median 10.30 (IQR 1.63).

[b]Statistics across all the responses for 10 questions are as follows: mean 10.11 (SD 1.17) and median 10.55 (IQR 2.05).

[c]Statistics across all the responses for 10 questions are as follows: mean 10.53 (SD 1.02) and median 10.45 (IQR 0.77).

[d]Difference in comparison to reference. Positive difference indicates that the FKGL score was higher than that of reference, whereas negative difference means that the KFGL scores were lower than that of reference.

Table . Comparison of readability scores of Flesch-Kincaid Grade Level (FKGL) of multiresponse analysis for expert reference answers, ChatGPT-4.0, and DeepSeek-V3.

Question	Expert reference answer[a]	ChatGPT-4.0[b]			DeepSeek-V3[c]		
	FKGL score	FKGL score	Difference[d]	SD	FKGL score	Difference[d]	SD
Q1	7.30	8.63	1.33	1.32	8.73	1.43	1.43
Q2	9.90	11.20	1.30	0.77	11.47	1.57	0.78
Q3	9.90	11.17	1.27	0.76	9.73	−0.17	0.32
Q4	9.50	10.93	1.43	0.67	11.67	2.17	0.79
Q5	11.30	10.42	−0.88	1.06	10.68	−0.62	0.67
Q6	11.00	10.17	−0.83	1.09	11.2	0.20	0.96
Q7	12.80	9.47	−3.33	1.71	9.63	−3.17	1.00
Q8	8.10	10.92	2.82	0.38	9.20	1.10	0.71
Q9	14.80	10.90	−3.90	1.12	10.37	−4.43	0.66
Q10	10.70	9.83	−0.87	1.70	9.97	−0.73	0.66

[a]Statistics across all the responses for 10 questions are as follows: mean 10.53 (SD 2.17) and median 10.30 (IQR 1.63).

[b]Statistics across all the responses for 10 questions are as follows: mean 10.36 (SD 0.84) and median 10.66 (IQR 1.01).

[c]Statistics across all the responses for 10 questions are as follows: mean 10.27 (SD 0.98) and median 10.17 (IQR: 1.41).

[d]Difference in comparison to reference. Positive difference indicates that the FKGL score was higher than that of reference, whereas negative difference means that the FKGL scores were lower than that of reference.

In the single-instance analysis, ChatGPT's mean FKGL score (10.11, SD 1.17) was slightly lower than the expert reference (10.53, SD 2.17), whereas DeepSeek's mean score (10.53, SD 1.02) matched the expert reference answer exactly. In the multiresponse analysis, ChatGPT's mean FKGL increased to 10.36 (SD 0.84), whereas DeepSeek's mean FKGL slightly decreased to 10.27 (SD 0.98). ChatGPT demonstrated reduced variability in the multiresponse case (SD 0.84) compared to the single-instance case (SD 1.17), indicating greater consistency when averaging multiple responses. In contrast, DeepSeek's variability remained relatively stable across both analyses (SD 1.02 in single instance and 0.98 in multiresponse).

In both analyses, DeepSeek's median FKGL scores were slightly lower than ChatGPT's, suggesting that DeepSeek's responses

XSL•FO
RenderX

may be more concise or readable. DeepSeek also exhibited less fluctuation in readability scores, as indicated by its smaller IQR 0.77 (median 10.45) in single instance and 1.41 (median 10.17) in multiresponse. In contrast, ChatGPT's variability decreased in the multiresponse case, with its IQR narrowing from 2.05 (median 10.55) to 1.01 (median 10.66).

A detailed evaluation of FKGL readability scores reveals variations in how ChatGPT and DeepSeek generate responses compared to expert references. For some questions (eg, Q1, Q2, Q3, and Q4), both models produced more complex responses (higher FKGL scores), potentially reducing accessibility for general readers but could be more suitable for professionals and specialists seeking in-depth information.

In contrast, for other questions (eg, Q5, Q6, Q7, and Q9), DeepSeek generally remained closer to the reference readability (reference) but showed greater variability, whereas ChatGPT exhibited larger deviations, sometimes producing more complex or simpler responses (Figure 3A, B, D and E). The multiresponse analysis improved consistency (Figure 3F), smoothing out extreme deviations (eg, outliers evident in Figure 3C) and leading to more balanced readability. Full per-question FKGL values and paired comparisons for single-instance and multiresponse data are provided in Tables S8-S11 in Multimedia Appendices 8-11.

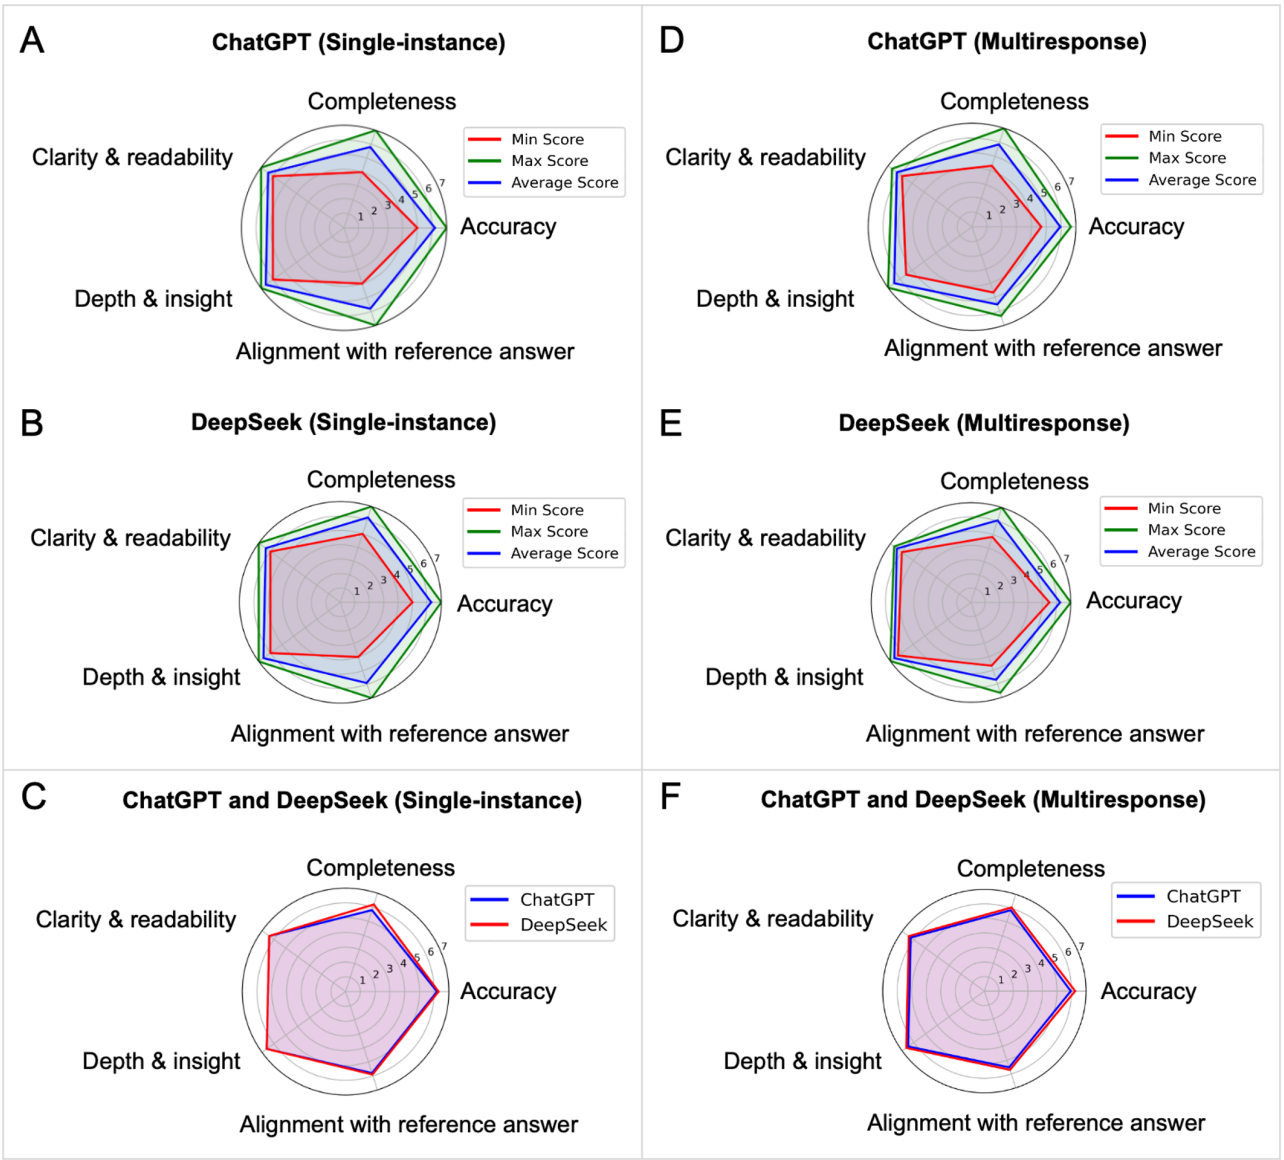
A paired *t* test was conducted to assess the statistical significance of mean differences in FKGL scores among the expert reference answer, ChatGPT-4.0, and DeepSeek-V3 groups (Table 3). The Shapiro-Wilk test confirmed normality ($P>.05$ for all groups), validating the use of the *t* test. Results indicated no significant differences in readability scores between the expert reference answers and those generated by ChatGPT-4.0 or DeepSeek-V3, nor between ChatGPT-4.0 and DeepSeek-V3 ($P=.61$ for single instance and $P=.73$ for multiresponse). However, high variability in scores across questions was observed. Multiresponse analyses showed smaller differences between AI models and the reference, suggesting that averaging multiple responses yields more balanced readability. Normality was further confirmed by Shapiro-Wilk *P* values of .16 (ChatGPT-4.0) and .82 (DeepSeek-V3). The corresponding statistical summaries are provided in Tables S8 and S10 in Multimedia Appendices 8 and 10.

Table . Statistical comparison of readability (FKGL scores) among expert references, ChatGPT-4.0, and DeepSeek-V3 using paired *t* tests.

Comparison	Single-instance			Multiresponse		
	t test *(df)*[a]	*P* value[b]	95% CI[c]	*t* test *(df)*[a]	*P* value[b]	95% CI[c]
ChatGPT-4.0 versus reference	−0.45 (9)	.66	−1.69 to 2.53	−0.24 (9)	.82	−1.40 to 1.74
DeepSeek-V3 versus reference	−0.24 (9)	.81	−1.58 to 1.96	−0.40 (9)	.70	−1.25 to 1.78
ChatGPT-4.0 versus DeepSeek-V3	0.52 (9)	.61	−1.23 to 0.77	0.35 (9)	.73	−0.53 to 0.72

[a]*t* test *(df)*: measures the magnitude and direction of the difference between paired samples. A negative *t* value indicates that ChatGPT had lower scores than DeepSeek, while a positive *t* value indicates the opposite. *t* statistics are reported, all tests were 2-tailed paired *t* tests. Degrees of freedom shown in parentheses, and were calculated as n−1 for paired comparisons (*df*=9 for all single analyses).

[b]*P* value represents the probability of observing the test results under the null hypothesis. A *P* value ≤.05 is considered statistically significant.



[c]95% CI for the mean difference.

Content Quality Assessment

Response quality was evaluated using a 7-point Likert scale across five criteria: accuracy, clarity and readability, completeness, depth and insight, and alignment with reference answers. In the single-response analysis, ChatGPT achieved an overall mean Likert score of 5.36 (SD 0.53), whereas DeepSeek had a slightly higher mean score of 5.60 (SD 0.45) across all criteria and questions. At the criterion level, ChatGPT scored higher in alignment and accuracy, whereas DeepSeek performed slightly better in the remaining criteria (Figure 4A–C).

XSL•FO
RenderX

Figure 4. Content quality ratings for ChatGPT-4.0 and DeepSeek-V3 across 5 criteria. (A) ChatGPT response evaluation based on the average scores of 10 answers. (B) DeepSeek response evaluation based on average score of 10 answers. (C) ChatGPT versus DeepSeek comparison based on average scores of 10 answers. (D) ChatGPT response evaluation based on 60 answers. (E) DeepSeek response evaluation based on 60 answers. (F) ChatGPT versus DeepSeek comparison based on average scores of 10 answers.

In the multiresponse analysis (dataset 2), ChatGPT achieved a mean Likert score of 6.01 (SD 0.49), while DeepSeek achieved a comparable mean score of 6.22 (SD 0.43) across all criteria and responses (Figure 4D–F). Differences between the two models were minimal and not statistically significant (P>.05), with overlapping 95% CIs for completeness, clarity & readability, depth & insight, and alignment with the reference answer. However, DeepSeek outperformed ChatGPT based on accuracy (ChatGPT: 5.95 vs DeepSeek: 6.25). This difference was statistically significant (t = −2.377, P = .041; 95% CI −0.585 to −0.015), indicating consistently higher accuracy scores for DeepSeek across the 10 questions.Overall, these findings indicate that both models provide comparably high-quality responses across the assessed dimensions. Detailed summary statistics are provided in Table 4, and full per-question and per-criterion Likert ratings for both the single-instance and multiresponse datasets are provided in Table S12 in Multimedia Appendix 12 and Table S13 in Multimedia Appendix 13.

[c]95% CI of the mean difference.

Information Reliability Assessment

We analyzed the reliability of citations provided by ChatGPT-4.0 and DeepSeek-V3 in response to 10 clinically oriented breast cancer questions. For ChatGPT, 45 distinct references were extracted and scored by all 3 experts. Human raters showed very high internal consistency: Fleiss κ was 0.842, indicating almost perfect agreement. Of these 45 references, 40 (88.9%) received perfect agreement from all 3 raters, and 44 (97.8%) reached majority agreement (ie, at least two raters agreed on the same label). Only 1/45 (2.2%) reference showed complete disagreement among the raters. Detailed results are provided in Table S14 in Multimedia Appendix 14.

For DeepSeek, we evaluated 268 unique references. Interrater reliability among the three experts was even higher: Fleiss κ was 0.935, again in the *almost perfect* range. Across these 268 references, 260 (97.0%) had perfect agreement, and 267 (99.6%) had majority agreement. Only 1/268 references (0.4%) showed complete disagreement. These results confirm that, despite differences in style and depth of citation between the models, human experts were able to judge source reliability in a highly consistent way across both datasets. All details are provided in Table S15 in Multimedia Appendix 15.

We then assessed how well each AI model's citation-level reliability scores aligned with human judgment (ie, each reference set was evaluated by both ChatGPT and DeepSeek as reported in Table S11 and Table S12 in Multimedia Appendices 11 and 12, respectively). For the ChatGPT reference set, agreement between ChatGPT's scores and the human majority score was substantial (Cohen κ=0.665). For the DeepSeek reference set, agreement between DeepSeek's scores and the human majority score was higher (κ=0.782). When disagreement occurred, ChatGPT differed from the human majority on 7 of its 45 references, whereas DeepSeek differed on 32 of its 268 references. These agreement metrics and disagreement profiles are summarized in Table S14 and Table 15 in Multimedia Appendices 7 and 14, respectively.

To enable direct comparison, we also evaluated each model on the other model's reference set. In the ChatGPT set, DeepSeek's scoring of those same sources achieved κ=0.800, which exceeded ChatGPT's own κ=0.665. In the DeepSeek set, ChatGPT's scoring of DeepSeek's citations achieved κ=0.600, which was lower than DeepSeek's κ=0.782. In other words, when both models were evaluated against the same expert consensus, DeepSeek was consistently closer to the human majority than ChatGPT.

Qualitatively, ChatGPT tended to cite large US medical organizations and public-facing health information portals (eg, national cancer societies, specialty associations, and patient education sites). These sources were commonly accepted as reliable when they represented established clinical authorities, but they occasionally triggered disagreement when they

XSL•FO
RenderX

originated from advocacy foundations or commercial health media. DeepSeek more often cited recent peer-reviewed literature, systematic reviews, and oncology-specific clinical studies, which generally scored as reliable, although some entries contained incomplete metadata (eg, partial author or year strings or nonresolving links) that required manual adjudication.

Taken together, these results show 3 things. First, human expert scoring of reference quality was internally very stable for both models (Fleiss κ=0.842 for ChatGPT's reference set and 0.935 for DeepSeek's reference set) with majority agreement observed for 44/45 (97.8%) and 267/268 (99.6%) references, respectively, indicating that *reliable versus unreliable* source is a reproducible judgment in this context. Second, both AI systems demonstrated substantial alignment with expert consensus, but DeepSeek exhibited stronger agreement with the human majority than ChatGPT (κ up to 0.800 on the ChatGPT set and 0.782 on its own set, versus ChatGPT's κ of 0.665 and 0.600, respectively). Third, the main source of residual disagreement was concentrated in borderline cases, such as advocacy organization content, institutional news posts, and partially specified citations, rather than in conventional peer-reviewed oncology literature (Table 5).

Table . Summary of citation reliability and agreement metrics for ChatGPT-4.0 and DeepSeek-V3.

Metric	ChatGPT-4.0	DeepSeek-V3
References evaluated, N	45	268
Reliability score (majority human; mean)	0.64	0.82
Fleiss κ (inter-rater agreement)	0.842	0.935
Perfect agreement (all 3 raters assigned the same label), n/N (%)	40/45 (88.9)	260/268 (97.0)
Majority agreement (≥2 of 3 raters assigned the same label), n/N (%)	44/45 (97.8)	267/268 (99.6)
Complete disagreement (all 3 raters assigned different labels), n/N (%)	1/45 (2.2)	1/268 (0.4)
Cohen κ (AI vs human majority)	0.665	0.782
Cross-evaluation κ (AI scoring the other model's references)	ChatGPT on DeepSeek=0.600	DeepSeek on ChatGPT=0.800

The mean reliability score (majority human) is the mean binary reliability score (1=reliable and 0=unreliable) assigned by the human majority (≥2 of 3 expert raters) across all unique references cited by each model. "Fleiss κ" quantifies agreement among the 3 human experts for each model's reference set. "Perfect agreement" is the proportion of references where all 3 experts independently gave the same reliability score. "Majority agreement" is the proportion of references where at least two of the 3 experts agreed. "Complete disagreement" refers to cases in which all 3 experts gave different scores. "Cohen κ (AI vs human majority score)" measures agreement between each model's own reliability classification of its citations and the human majority classification for the same reference set. "Cross-evaluation κ" measures how well each model's scoring of the other model's references agreed with the human majority for that reference set (eg, "DeepSeek on ChatGPT"=DeepSeek's κ when scoring the ChatGPT reference set). All underlying data are provided in Table S14 in Multimedia Appendix 7 (ChatGPT-4.0) and Table S15 in Multimedia Appendices 14 and 15 (DeepSeek-V3).

Discussion

Principal Findings

This study systematically evaluated the performance of ChatGPT-4.0 and DeepSeek-V3 in generating breast cancer information, focusing on readability, content quality, and reference quality. This multidimensional assessment approach (Figure 1), which is rarely addressed collectively in existing literature, offers valuable insights into the capabilities and limitations of generative AI models in health care. Both models generated clinically relevant and readable responses, with ChatGPT-4.0 showing greater consistency and overall readability, whereas DeepSeek-V3 offered more diverse citations but with greater variability and occasional technical issues.

Readability Analysis

The FKGL readability scores revealed that AI-generated responses generally used simpler language structures than expert reference answers, which may enhance accessibility for general audiences. Expert responses had the highest FKGL scores (mean 10.53, SD 2.17), reflecting more complex vocabulary and sentence construction. In contrast, both ChatGPT and DeepSeek produced responses with lower FKGL scores, indicating simpler, more readable content.

This trend aligns with prior studies showing that LLMs often generate linguistically simplified outputs, which may benefit general users [38,39]. Notably, ChatGPT-4.0 exhibited more consistent readability across multiple outputs, with a median FKGL of 10.66 (IQR 0.98), compared to DeepSeek-V3, which showed greater variability with a median FKGL of 10.17 (IQR 1.41), suggesting greater stability with repeated querying.

For instance, ChatGPT-4.0 demonstrated improved readability consistency when averaging multiple responses, suggesting stability with repeated querying. In contrast, DeepSeek-V3's responses were closer to expert reference readability levels in

XSL•FO
RenderX

single-instance analysis but displayed greater variability in multiresponse cases (IQR 1.41).

However, statistical comparisons did not reveal significant differences in readability between models or relative to expert references. For instance, in the multiresponse setting, the paired *t* test for ChatGPT-4.0 versus reference yielded t_9=−0.24; *P*=.82 (95% CI −1.40 to 1.74), and for DeepSeek-V3 versus reference, t_9=−0.40; *P*=.70 (95% CI −1.25 to 1.78). The difference between ChatGPT and DeepSeek was also nonsignificant (t_9=0.35; *P*=.73). Similar nonsignificant findings were observed in the single-instance analysis.

It is essential to emphasize that FKGL measures linguistic complexity, not clinical accuracy or information richness [35]. Lower FKGL scores do not necessarily indicate that critical medical details were omitted. Therefore, while improved readability may facilitate comprehension, further analysis is necessary to confirm that the content remains accurate, complete, and clinically appropriate.

Content Quality Analysis

Beyond readability, content quality was assessed across 5 predefined evaluation criteria, including accuracy, completeness, clarity, depth and insight, and alignment with expert reference answers. This structured evaluation, based on established frameworks [38,39], allowed a more nuanced assessment of response quality. Across analyses, both models achieved high scores across all criteria. In the multiresponse dataset, DeepSeek achieved a higher overall mean score (6.22, SD 0.43) than ChatGPT (6.01, SD 0.49), with DeepSeek scoring numerically higher across all five criteria. Notably, DeepSeek demonstrated a statistically significant advantage in accuracy in the multiresponse analysis (t = −2.377, *P* = .041; 95% CI −0.585 to −0.015), while differences for completeness, clarity and readability, depth and insight, and alignment with the reference answer did not reach statistical significance (P > .05). Interestingly, averaging multiple responses per question reduced response-level variability and revealed a more consistent performance advantage for DeepSeek, particularly for accuracy.

These findings expand on earlier studies that primarily focused on ChatGPT-3.5 [33] by demonstrating the evolving strengths and remaining limitations of newer generative AI models when applied to clinically relevant educational content. Unlike prior studies limited to single-response analysis, our multiresponse approach highlights how response variability remains an important factor when evaluating AI for health care education.

Information Reliability Assessment

The reference reliability analysis revealed clear differences in both reference selection patterns and interrater scoring agreement for ChatGPT-4.0 and DeepSeek-V3 citations. ChatGPT tended to cite US-based medical institutions, national health organizations, and patient-facing educational resources, whereas DeepSeek more often cited recent peer-reviewed oncology studies and systematic reviews, although some DeepSeek citations were partially specified or contained inaccessible links. Human experts showed very consistent judgments of citation reliability for both models' outputs: interrater reliability was almost perfect for both sets (Fleiss κ=0.842 for ChatGPT's 45 references and 0.935 for DeepSeek's 268 references), with ≥97% majority agreement and only one fully disputed reference in each set. When we compared each model's scoring of source reliability to the majority expert score, agreement was substantial for ChatGPT and higher for DeepSeek. DeepSeek reached Cohen κ values up to 0.800 (for ChatGPT reference set) and 0.782 (for DeepSeek reference set), indicating strong alignment with expert consensus, whereas ChatGPT's ability to assess references reached 0.665 for its own reference set and 0.600 when evaluated DeepSeek's set.

Collectively, these results demonstrate that both models operate within the bounds of medically acceptable sourcing but use distinct strategies. DeepSeek's output, favoring primary literature, more accurately reflects the evidence-based curation of oncology experts. Conversely, ChatGPT's propensity for synthesized institutional guidance results in a higher frequency of citations to borderline sources that require expert judgment.

Implications for Practice and Future Research

Collectively, these findings suggest that while generative AI models offer promising capabilities for generating patient education materials, important limitations remain. Oversimplification of complex medical information, variability in response consistency, and the reliability of cited sources remain persistent concerns. Given the growing interest in deploying AI tools for patient counseling, clinical decision support, and health care communication, these results underscore the need for careful validation of AI-generated content before clinical use [48]. Furthermore, while models such as DeepSeek demonstrate the potential for integrating primary literature more effectively, consistent quality control of both content and source reliability will be essential for safe application in clinical settings.

Finally, the structured multidimensional evaluation framework used in this study provides a replicable approach for future evaluations of AI models in health care. Future studies should continue to assess performance across broader clinical domains, expand evaluation across different languages and health literacy levels, and integrate clinical expert validation to further ensure the safety, accuracy, and equity of AI-generated medical information.

Limitations and Future Directions

This study has several limitations. The FKGL test assessed structural readability but not contextual or clinical accuracy, and it is validated only for English, limiting generalizability across languages and literacy levels [20,34]. Additionally, the study was conducted in a controlled setting without patient or provider involvement, so real-world usability, comprehension, and clinical outcomes remain unexplored. Future work should include usability testing and assess impacts on decision-making and adherence [49]. Moreover, AI responses were not compared directly to clinical guidelines, and future studies should include validation against established standards before clinical integration. Reference accuracy remains a concern, as AI models may generate outdated or fabricated citations, requiring expert oversight [50].

XSL•FO
RenderX

Furthermore, the risk of bias in training data may lead to inaccuracies for underrepresented populations, highlighting the importance of ongoing monitoring and alignment with validated medical sources [38,48,49]. Evidence from clinical research, including variability in therapeutic outcomes across patient subgroups and molecular subtypes, further emphasizes the necessity for such validation [51,52]. Finally, ethical and regulatory considerations are essential for safe deployment of AI in health care; compliance with frameworks from regulatory bodies such as the Food and Drug Administration and the European Medicines Agency will be critical to ensure safety, transparency, and public trust [53]. As these technologies continue to evolve, continuous evaluation, comparative benchmarking, and expert oversight will be necessary to guide their responsible implementation.

Conclusions

This comparative analysis of ChatGPT-4.0 and DeepSeek-V3 demonstrated that both AI platforms effectively retrieve and present medical information on breast cancer, each excelling in different areas. ChatGPT produced more polished, detailed, and readable responses, with strong performance in clarity and completeness, whereas DeepSeek outperformed ChatGPT on accuracy, and provided more comprehensive, globally diverse references with in-text citations resembling academic articles. However, DeepSeek faced challenges such as untagged links, occasional downtime, and corrupted references, which impacted the user experience. Despite these limitations, DeepSeek demonstrated superior citation efficiency and closely aligned with expert consensus answers. Moreover, interrater reliability analyses confirmed high levels of agreement among human evaluators across both models, with Fleiss κ scores exceeding 0.84 and Cohen κ values indicating substantial to almost perfect agreement. These findings support the overall quality of reference sources provided by the models and lend credibility to the evaluation framework used in this study. Furthermore, statistical analysis revealed no significant differences between the models across most evaluation criteria; however, in the multiresponse dataset (i.e., larger datasets), DeepSeek demonstrated a statistically significant advantage in accuracy, underscoring the importance of rigorous evaluation of AI-generated medical information to ensure accuracy, accessibility, and reliability. To optimize their effectiveness in health care applications, future improvements should focus on enhancing platform stability, response consistency, and overall user accessibility.

Acknowledgments

All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Funding

RH and DAS acknowledge funding provided by the Deanship of Scientific Research at Al-Zaytoonah University of Jordan (grant 2023-2022/17/50 and 2025-2024/06/29).

Data Availability

All data generated or analyzed during this study, including AI-generated responses, reference metadata, and interrater reliability analyses, are publicly available in a GitHub repository [54].

Abstract

Background: Approximately 80% of breast cancers are estrogen receptor positive, and following initial tumor treatment, patients are prescribed hormone therapy (HT) drugs (tamoxifen, letrozole, anastrozole, and exemestane) for 5-10 years. These drugs are known to cause several side effects. Additionally, a small number of studies have identified that changing medication brands (generics) can negatively affect patients' side effects, attitudes, and acceptance of HT. However, no effective intervention currently exists to address patients' concerns about generic switching.

Objective: This study explores whether a symptom diary appears to be an acceptable approach for patients and pharmacists to address brand concerns, and provides a detailed report of the planning and development stages of a coproduced diary intervention.

Methods: This paper presents the studies conducted during the planning and development stages of the symptom diary, following the person-based approach, which combines theory-, evidence-, and person-based approaches to ensure interventions are acceptable and easy to implement. The study included the following stages: (1) the planning stage, which involved analysis of an online patient forum (n=277), interviews with patients (n=9), and interviews with pharmacists (n=7). Data triangulation was used to present an integrated set of findings. (2) The development stage, which involved a rapid scoping review of the literature on the use of diaries among patients with cancer, coproduction workshops with patients and pharmacists (n=17), pharmacist interviews (n=11), and consultation with our patient advisory group (n=5). Analysis was informed by evidence synthesis, behavior change analyses, and iterative stakeholder consultations.

Results: In the intervention planning stage, patients and pharmacists perceived community pharmacies as the ideal setting for HT medication consultations. Both groups proposed using a patient diary to support awareness and attribution of drug-related symptoms. Pharmacists described patients' requests for specific brands as difficult to manage, whereas patients reported that switching brands undermined confidence in medication-taking. In the development stage, the scoping review (n=29 papers) identified barriers and facilitators related to diary use, and workshops explored diary format and content. These findings informed the intervention planning table and the first diary prototype. Pharmacist interviews and patient feedback informed the development of 2 further prototypes. The symptom diary is a self-monitoring tool designed to enhance self-efficacy in HT medication-taking behaviors. It includes recording side effects from brands alongside physical, psychological, and environmental factors; actions taken to manage symptoms; and problem-solving and planning before a medication consultation to facilitate personalized feedback from pharmacists.

Conclusions: We preliminarily developed an intervention that appears engaging, relevant, and acceptable for patients to self-monitor their symptoms. Further revisions informed by user feedback will be incorporated after testing ENABLE (Medication

Brand Changes in Hormone Therapy for Breast Cancer: A Community Pharmacy Intervention Development to Improve Patients' Adherence and Quality of Life) in community pharmacies.

Trial Registration: ISRCTN Registry ISRCTN15089342; http://www.isrctn.com/ISRCTN15089342

Introduction

Breast cancer (BC) is the most common cancer in the United Kingdom, with an estimated 56,400 new cases diagnosed in women each year [1]. Around 80% of BCs are estrogen receptor positive, meaning that, for the great majority of BC survivors, treatment does not end with surgery, radiation, or chemotherapy. Hormone therapy (HT) drugs (tamoxifen, letrozole, anastrozole, and exemestane) are prescribed for 5-10 years to reduce the risk of recurrence and mortality. These drugs are known to cause several side effects and have been consistently identified in the literature as a key factor in nonadherence [2] and poor quality of life (QoL) [3]. Adherence to HT declines by an average of 25.5% each year, and by the fifth year of treatment, adherence is estimated to range from 33.3% to 88.6%, while treatment continuation ranges from 45.2% to 87.4% [4].

In the United Kingdom, it is common practice for community pharmacies to dispense different generic brands of the same drug when patients collect their prescriptions, depending on availability and wholesalers. Currently, the British National Formulary lists 10 generic brands for tamoxifen (20 mg), 13 for letrozole, 17 for anastrozole, and 13 for exemestane, in addition to their proprietary names, when available [5]. Clinical studies on women's experiences with HT medications have revealed that the use of generic drugs, either to replace the proprietary name (generic substitution) or to switch between generic brands (generic switching), can negatively affect patients' side effects, attitudes, and acceptance of HT [6,7]. Among women switching tamoxifen generic brands, a small but significant proportion of patients in the United Kingdom (11%-13%) attributed severe menopausal symptoms to the brand switch, with symptoms resolving after taking a different brand. The authors suggested that patients' perceived changes in medication side effects were due to manufacturers' use of different excipient profiles, namely, the nonactive ingredients used to enhance manufacturing, patient acceptance, and bioavailability [6,7]. A US study on inactive ingredients concluded that this is a "poorly appreciated" area, considering the adverse reactions (allergies and irritants) that can occur in population groups taking more than 1 medication daily [8]. To date, only 1 study [9] on HT drugs has identified drug allergies as a strong predictor of adherence.

Additionally, experimental studies have shown that patients often misattribute symptoms arising from everyday activities, disease, or environmental factors as medication side effects [10], highlighting the need to assist patients in recognizing drug-related symptoms. Experiences of new side effects or worsening of existing ones after generic switching or substitution (whether excipient-related or belief-induced) can negatively affect the QoL and treatment continuation of patients with BC [6,7,11].

A growing body of evidence points to the need for interventions that provide enhanced support for patients with BC to better manage their medication [12-14]. The Royal Pharmaceutical Society acknowledges "considerable scope" for pharmacist-led interventions in cancer care, including medicines advice [15]. A systematic review on effective medicines use found that interventions that appear to improve medication adherence include medication self-monitoring and self-management programs, while promising interventions include medicines reviews, consultation with patients to resolve medication-related problems, development of a care plan, and provision of follow-up [16]. Similarly, other reviews have reported that patient medication adherence can be improved through specific community pharmacy approaches, including patient identification and enrollment, medication review, and patient assessment [17,18]. To date, no community pharmacy service or effective intervention exists to address patients' concerns regarding HT generic switching.

This paper reports on the planning and development of a self-monitoring tool, a symptom diary, as part of the ENABLE (Medication Brand Changes in Hormone Therapy for Breast Cancer: A Community Pharmacy Intervention Development to Improve Patients' Adherence and Quality of Life) study (NIHR206589 award; ISRCTN [International Standard Randomised Controlled Trial Number] registry ISRCTN15089342). ENABLE aims to coproduce, with patients with BC and pharmacists, an intervention to improve medication brand change (MBC) consultations in community pharmacy settings through the delivery of a patient-centered approach that could improve adherence and QoL.

The symptom diary is the patient-facing intervention component of the ENABLE study. The aims of this paper are 2-fold: (1) to explore whether a self-monitoring tool (symptom diary) appears to be an acceptable approach for patients and pharmacists to address MBC concerns; and (2) to provide a detailed account of the planning and development stages of a diary coproduced with patients, pharmacists, and stakeholders, as well as the empirical evidence and behavioral analysis that shaped its content. The latter will help explain whether a diary is an effective approach to improving consultations about HT generic brand switching, adherence, and QoL in BC survivors.

Methods

Study Design and Theoretical Framework

This was a multimethod qualitative intervention development study. It aligned with the person-based approach (PBA), which focuses on user-centered design to ensure that interventions are acceptable, engaging, feasible, and effective in their implementation [19]. Its theoretical approach was grounded in behavioral science and qualitative research methods to collect data on users' perspectives at different stages of the development process. Through its combination of evidence (users' needs and barriers and facilitators to intervention success), theory (behavioral science), and person-centered methods (qualitative research used to iteratively gather user feedback), the PBA is recognized by the Medical Research Council [20] as one of the approaches for developing complex interventions.

The intervention development methods for the symptom diary are described below in 2 main stages: planning and development. The Consolidated Criteria for Reporting Qualitative Research (COREQ) were used as the reporting guidelines for the study (Multimedia Appendix 1).

Intervention Planning

Planning Stage: Identification of User Needs and Behavioral Determinants

The planning stage used triangulation of qualitative data from 3 preliminary studies to identify users' needs, barriers and facilitators, and behavioral determinants: analysis of posts from a UK online BC forum, and interviews with patients and community pharmacists.

Online BC Patient Forum

Online patient forums are frequently accessed as valuable sources of health-related information, particularly for managing side effects, where patients can find supportive, experience-focused comments and advice [21]. The aim was to identify how patients with concerns about MBCs sought support for their medication, what actions they took, and what responses they received from health care professionals (HCPs). Searches were conducted in the "Hormone Therapy" section of the Breast Cancer Now forum (data accessed May 15, 2019-December 31, 2020) using the following keywords: "brand*," "tamoxifen," "letrozole," "anastrozole," "exemestane," and specific drug brand names in use at the time. Searches covered the period from January 1, 2013, to December 31, 2020. A total of 290 women were identified, of whom 277 (95.5%) experienced new or worsening side effects after brand switches. A research assistant extracted data into a Microsoft Excel spreadsheet, including brands, year of posts, patients' age, years of treatment, drug names, side effects, contacts with pharmacists, and interactions with other HCPs. Multiple posts by the same individual were combined into a single entry so that each individual had only 1 record.

Interviews With Patients With BC

A second study interviewed women with lived experience of MBCs recruited through the Breast Cancer Now charity. Participants were recruited through an invitation advertised on the charity's research web page. Interested patients completed an online form and were contacted by email. Eligible participants were aged 18 years or older, had previously been prescribed HT, and had experience with MBCs. Nine women were included in the study and interviewed by a research assistant between July 9 and September 19, 2021. Interviews were conducted via Microsoft Teams and Zoom (Zoom Communications, Inc; n=7 interviews) or by telephone (n=2 interviews) and lasted 24-63 minutes. Participants lived in different parts of England and had a mean age of 57 years. A semistructured interview explored patients' attitudes, needs, challenges, and preferences regarding HT brand changes and was informed by interpretative phenomenological analysis (IPA) [22].

Interviews With Community Pharmacists

Informed by the previous 2 studies, semistructured interviews with 7 community pharmacists located in London and the South East region were conducted by YE between March 16 and April 11, 2022. This exploratory analysis aimed to provide a more comprehensive understanding of the MBC phenomenon by triangulating our existing data with pharmacists' perspectives on the topic. An interview guide consisting of open-ended questions explored pharmacists' experiences with MBCs, management of consultations, the potential role of pharmacists, and the feasibility of a contract to deliver a pharmacy service for patients with BC. Saturation was sought when patterns across all 4 topics were identified. Participants were purposively selected. Eligible participants were registered pharmacists or pharmacy technicians with experience dispensing HT medication. Participants were recruited through visits to pharmacies in London and Oxford, where participant information sheets (PISs) containing a link to register interest were distributed, and through snowball sampling, whereby participants shared the PISs with contacts in the region. One pharmacist agreed to participate but did not respond to attempts to arrange the interview. No participants were known to the researchers before the interviews. Individual interviews were conducted face to face (n=3), by telephone (n=2), and via Microsoft Teams with audiovisual recording (n=2), and lasted 15-25 minutes. Participant characteristics are presented in Table S1 in Multimedia Appendix 2.

Analysis

Content analysis [23] was used to analyze women's posts in the online patient forum. First, the research assistant inductively coded the posts, and the coding was audited by YE. Second, the codes were categorized according to behavioral factors using the Theoretical Domains Framework [24].

All interviews were audio recorded, transcribed verbatim, and analyzed. A patient interview guide was developed using an IPA approach [22], primarily because MBCs related to HT had not previously been qualitatively explored, and an experiential approach was sought to generate preliminary in-depth data to inform future interventions based on a PBA [19]. Further details of the study are published elsewhere [11]. Pharmacists' interviews were analyzed using thematic analysis [25], in which codes were derived inductively by an experienced research assistant and audited by YE (25% of transcripts). The

XSL•FO
RenderX

identification of themes was mapped to the study aims and discussed and agreed on by the researchers.

Finally, data triangulation across the 3 data sources was undertaken to support cross-validation and enhance the credibility of the MBC phenomenon as experienced by pharmacists and patients [26]. Findings were organized into barriers and facilitators and mapped onto the Theoretical Domains Framework [24] to analyze behavioral determinants. The synthesis is presented with an assessment of agreements and disagreements across the 3 data sets. In addition, a detailed behavioral analysis was conducted to document how the qualitative studies undertaken during the planning stage informed the development of the symptom diary intervention. Although the rich idiographic approach of the IPA study is not fully retained in this paper, data triangulation allowed us to strengthen the validity of the selected empirical evidence used in the behavioral analysis.

Intervention Development

Overview

Following the planning stage, our team embarked on an intervention development process guided by the PBA [19]. A description of the methods used at each step is summarized below, following the Guidance for the Reporting of Intervention Development (GUIDED) [27] checklist for reporting intervention development (Multimedia Appendix 3).

Theory

The intervention followed Bandura's social cognitive theory [28], which addresses the interplay between self-regulatory (personal) and environmental (social) determinants of health behavior. Previous systematic reviews have identified self-efficacy in medication taking as a potential predictor and modifiable factor influencing adherence and persistence with HT drugs [29,30]. Self-efficacy is a core concept in Bandura's social cognitive theory [31] and refers to an individual's belief or confidence in their ability to perform a specific behavior to achieve a desired outcome. Higher self-efficacy for medication taking has been significantly associated with greater HT adherence [32]. Evidence also suggests that self-efficacy is an important determinant of intentional nonadherence related to 2 other distinct behavioral components: self-efficacy in managing side effects [29] and self-efficacy in communicating with HCPs [32-34]. The latter is particularly relevant because concerns regarding MBCs increase patient-HCP communication, mainly with pharmacists and general physicians (GPs), as shown in our analysis of the online forum data below.

Self-efficacy is a precursor to self-management. In Bandura's theory, cognitive and emotional factors (participant modeling and cognitive processing), alongside environmental factors such as verbal persuasion (social support), interact to influence self-management behaviors. Self-management in chronic conditions refers to the ability to monitor the condition (eg, side effects) and to achieve the motivation and emotional responses necessary to maintain an acceptable QoL [35]. While self-monitoring strategies, such as a symptom diary, are instrumental in increasing patients' awareness and improving symptom management, evidence indicates that addressing a single factor to improve adherence is ineffective because of the multifaceted nature of adherence dimensions [36]. A meta-analysis on HT adherence found that only interventions involving bidirectional communication (ie, eliciting information from and providing information to patients) improved adherence compared with controls [37]. Thus, environmental factors such as social support, in the form of feedback on behaviors, represent an important source of self-efficacy for successfully managing medication-taking behaviors.

In addition, self-management programs for patients with BC are often not co-designed with patients and HCPs, which may reduce their effectiveness. Relatedly, in the United Kingdom, nonadherence to HT among ethnically minoritized patient groups is 1.48 times higher than among White British patients [38]. Patients with cancer living in deprived areas are more likely to experience delays in starting treatment (33% higher compared with those living in the least deprived areas) or delays in seeking help because they feel they would not be taken seriously [39]. These findings highlight the need for inclusive co-design approaches, as reflected in our recruitment strategies.

Rapid Scoping Review

Rapid scoping reviews are particularly relevant for intervention development studies because of their exploratory nature and broader scope in determining what evidence is available across heterogeneous sources [40]. For this study, the review question was: "What patient diary interventions are available to support self-monitoring behaviors in cancer survivors after active treatment?" Additional elements of interest included intervention components and data on patients' experiences, usability, acceptability, adherence, and QoL outcomes. Studies were excluded if diaries were used solely to report symptom scales, episode frequencies (eg, pain or hot flashes), or activities performed, without promoting further user engagement (ie, not intended to facilitate patient self-management behaviors or feedback from HCPs).

Searches included systematic reviews and primary studies of any design in the following electronic databases: Cochrane Library, PubMed, CINAHL, and APA PsycINFO. Because of time constraints, searches were limited to August 1, 2004, to August 31, 2024. The search terms used for each database were adapted to derive the most meaningful results, using a combination of free-text terms, MeSH (Medical Subject Headings) terms, and subject headings. Additional key papers were identified through reference lists, targeted author searches, forward citation searching, and the authors' expertise.

The scoping review protocol has been published [41], and the review was conducted by JC and YE. The findings were used to inform workshop discussions on the most appropriate information for patients to record about symptoms, approaches to enhance self-efficacy, and problem-solving strategies to support information exchange during medication consultations.

Coproduction Workshops

Coproduction methods [42] informed the workshops, with the aim of developing a symptom diary in partnership with patients with BC and pharmacists. Recruitment of patients with BC took place in London, and Breast Cancer Voices and South Asian

XSL•FO
RenderX

Health Action circulated the call for contributors. Women with lived experience of MBCs and diverse sociodemographic characteristics (age, ethnicity, language, and socioeconomic status) were selected. Community pharmacy participants were recruited through Local Pharmaceutical Committee networks via RNDD North London (Community Pharmacy Research Champions) and included pharmacists, pharmacy technicians, and locums with experience dispensing HT medication. Interested individuals were asked to register via Microsoft Forms.

We planned for a workshop sample of 20 participants, equally divided between patients and pharmacists and organized into 2 mixed groups. Although there is no established guidance on workshop participant numbers [43], we considered that smaller mixed groups would better facilitate effective communication and engagement across different perspectives (patients and pharmacists). Workshop attendees included 12 patients with BC and 5 community pharmacists. A diverse group of patients with BC was purposively selected during recruitment and included participants of different ages (range 38-73 years; mean 56 years), ethnicities (8 White and 4 from minoritized ethnic groups), residential backgrounds from the most deprived areas (n=8) and least deprived areas (n=4), and 1 participant with a physical impairment. Community pharmacists' roles included locum pharmacist (n=1), superintendent pharmacist (n=1), pharmacy managers (n=2), and pharmacist (n=1), with a range of work experience (1-35 years; mean 20.6 years), serving communities in the most deprived areas (n=3) and least deprived areas (n=2). Attendee characteristics are presented in Table S2 in Multimedia Appendix 2. A summary of findings from the rapid scoping review was circulated to participants in advance.

A face-to-face workshop was held at London Metropolitan University in October 2024 and lasted 4 hours, including lunch and coffee breaks. The meeting began with a presentation of the ENABLE study, an introduction to the National Institute for Health and Care Research key principles of coproduction [44], the role of patients and stakeholders as research contributors, and the planned activities. In all workshops, pharmacists and patients worked together in small groups with 1 facilitator (1 Breast Cancer Now nurse, or 1 patient representative, or members of the research team [DS, RE, or YE]) to encourage understanding of each other's perspectives, experiences, and challenges. This shaped group discussions toward a more feasible and practice-focused approach to symptom diary implementation. A handbook guide was developed for each facilitator, including instructions on the aims, questions, probes, and group management. A voting system was used to complement discussions for some activities, such as a diary format and content. The session concluded with a whole-group discussion and feedback on the workshop. The workshop was audio-recorded. Additionally, 3 online workshops were held on October 25 and 30 and November 5, 2024, via Microsoft Teams with audiovisual recording, following the same structure described above. These workshops included screen sharing of presentations, tasks, and materials, with voting activities completed orally. Workshops lasted 1.5-2 hours.

Intervention Guiding Principles, Logic Model, and Intervention Planning Table

Based on the data triangulation conducted during the planning stage, theory-informed evidence on HT adherence interventions, the rapid scoping review, and workshop discussions, we developed the intervention guiding principles and logic model, as well as the intervention planning table (Table 3). The latter involved a behavioral analysis that first identified the mechanisms of action (MoAs) and subsequently the behavior change techniques (BCTs), based on the best available evidence reported in the Theory and Technique Tool [45], a resource for the development of theory-based interventions.

Patient Advisory Group

The group included 5 patients with BC with experience of MBCs from different ethnic backgrounds (South Asian, n=1; Indian, n=1; and White British, n=3), as well as BN, the patient and public involvement and engagement (PPIE) lead who chaired the group. As in previous recruitment strategies, participant selection aimed to ensure a plurality of lived experiences and demographic characteristics (see Table S3 in Multimedia Appendix 2). The initial patient advisory group (PAG) meetings were scheduled to provide feedback on the intervention components without prior involvement with the research team, in order to maximize members' perspectives on the intervention from a fresh viewpoint. The PAG members are based in England, and meetings take place online. Breast Cancer Now and South Asian Health Action supported recruitment. Members participate in a series of scheduled meetings throughout the study and receive payment for their time in line with National Institute for Health and Care Research recommendations. The PAG reviewed diary prototype 1 and provided suggestions for prototype 2.

Interviews With Pharmacists

A purposive sample of community pharmacists (n=6) and pharmacists representing professional bodies (n=5), including the Royal Pharmaceutical Society, Community Pharmacy England, and National Pharmacy Association, were interviewed (see Table S3 in Multimedia Appendix 2). The PBA recommends a flexible approach to sample size during intervention design (5-10 participants, depending on study scope) [46]. The aim was to gather feedback from target users and key stakeholders on their views and practice-based experiences of the intervention design, offering new insights to complement those of the PAG, whose members had been involved in the study from the outset. Community pharmacists were recruited using the same criteria and through the organizations described above, while representatives from professional bodies were recruited through snowball sampling via a contact provided by RE. No participants were known to the researchers before the interviews, and there were no dropouts. All participants received a PIS explaining the purpose of the study. The semistructured individual interviews used a topic guide to explore views on the intervention and insights into barriers and facilitators to implementation. A synopsis of the intervention was circulated in advance, and pharmacists provided suggestions for diary prototype 2. Interviews were conducted by YE via Microsoft Teams with audiovisual

XSL•FO
RenderX

recording and lasted 17-46 minutes. Interviews took place between November 28 and December 19, 2024.

Research Team and Reflexivity

Development Team

The core development team included those with expertise in community pharmacy and pharmacy education, applied health research, adherence behaviors in BC, patient involvement in research, qualitative methods, and the lived experience of BC. JC (health psychologist) has conducted research on postmastectomy lived experiences using qualitative approaches. RE (pharmacist and academic in education) and BN (patient representative) had experience with MBCs related to HT. DS (applied health researcher) has extensive experience researching pharmacy medication review services. YE (health studies) has expertise in qualitative research, with research interests in women's health, including BC adherence, behavioral science, and intervention development. Stakeholder input included a Breast Cancer Now nurse (collaborative partner), who supports patients through the charity's helpline and facilitated workshops, as well as reviewing diary revisions with the team. Research team meetings took place online.

Reflexivity

The research team, which represented a range of academic backgrounds and differing experiences and interests related to the research topic, agreed on the final analyses and interpretations presented here. Previously, we engaged in a coproduction process that addressed power imbalances through respectful and equitable relationships, while collaboratively challenging assumptions and generating and interpreting data. The iterative feedback process involving embedded groups (PAG) and external participants (pharmacists) engaged the research team in ongoing reflection on previous assumptions underlying the use of a diary.

Development of the Symptom Diary

We first produced a prototype of the diary, drawing on findings from the planning stage, rapid scoping review, and codevelopment workshops, which informed its format and content. The intervention planning table, alongside the intervention guiding principles and logic model, provided a framework for designing and mapping diary sections and items relevant to patient monitoring according to their potential to effect behavior change (ie, self-efficacy). Two further prototypes (2 and 3) incorporated modifications following feedback from the PAG, pharmacists, and the research team.

Analysis

Workshops, interviews, and meetings were recorded and transcribed verbatim by JC. Workshop materials were also collected for data analysis. Interviews with pharmacists followed a thematic analysis approach [25], including independent inductive coding by JC and YE. Data collection initially focused on capturing all participants' preferences and suggestions, followed by consideration of disagreements and consensus based on the number of contributors supporting each view. Final decisions regarding diary design and proposed modifications were based on their likely impact on facilitating behavior change and their alignment with the study protocol (eg, suggestions to use a mobile diary were documented but were not planned within the scope of this study). Modifications were recorded in a table of changes.

Ethical Considerations

Planning Stage

The studies received ethical approval from the London Metropolitan University Research Ethics Committee (approval number SSSP-4050119/SSPR 022). Written informed consent was obtained from all interviewed participants. Pharmacists received a £20 (US $27) voucher as a token of appreciation for their time. For the patient forum posts, individual consent was not obtained because of the practical challenges associated with obtaining authorization from a large online community. Authorization was granted by Breast Cancer Now forum moderators, and, following recommendations from the London Metropolitan University Research Ethics Committee, posts were paraphrased to minimize the risk of traceability through online searches.

Development Stage

Ethical approval was obtained from the Health Research Authority NHS (National Health Service) West Midlands-South Birmingham Research Ethics Committee (approval number 24/WM/0137) and the London Metropolitan University Research Ethics Committee (approval number SSSP-2024-025).

Workshops

All participants signed a consent form and received £75 (US $101) for their involvement, in line with National Institute for Health and Care Research recommendations, as well as a certificate of attendance. Pharmacists were also offered a fee for locum backfill.

Pharmacist Interviews

All participants provided electronic consent before the interview and were offered a £30 (US $40) voucher as a token of appreciation for their time.

Results

Intervention Planning

Barriers and facilitators experienced by patients and pharmacists across the 3 studies (data triangulation) are presented in Table S1 in Multimedia Appendix 4, alongside the behavioral determinants identified using the Theoretical Domains Framework [24].

Synthesis of Three Studies

Beyond Patient Factors: The Role of Health Care Systems

The findings provide insight into "health care team and system factors," including HCP interactions, drug distribution systems, drug availability (shortages), HCP beliefs about generics and side effects, and responsiveness to patients' concerns. Health care team and system factors represent one of the multifaceted domains that the World Health Organization associates with

XSL•FO
RenderX

medication nonadherence in chronic conditions [47]. Other domains include social and economic factors affecting patients, disease-related factors (disease progression and risk), therapy-related factors (treatment burden), and patient-related factors (self-efficacy and beliefs about medication) [47]. Overall, research on patients' behaviors and psychological needs has received more scholarly attention than system factors or environmental context and resources, despite their potential to influence patients' capability and motivation to adhere to treatment.

Convergences

All data sets provided evidence that some women are brand sensitive and that these experiences, alongside the search for a single or alternative brand(s), often led to fortuitous solutions depending on pharmacy stock availability, pharmacists' efforts to procure a specific brand, or GP agreement to prescribe by manufacturer name. Community pharmacists interviewed appeared responsive to patients' brand-seeking behaviors and attempted to secure medications within the constraints described above (see Table S2 in Multimedia Appendix 4). Most pharmacists (with one exception) believed that different brands could cause different side effects, and their explanations reflected both a biomedical model (different excipients and E numbers) and a belief in patients' lived experiences. Although there is no scientific evidence explaining how HT brands may cause different side effects, the explanations proposed by pharmacists, particularly the possibility that excipients may affect bioavailability, were shared by patients, who often scrutinized nonactive ingredients in search of validation for their perceived differences. Patients and pharmacists viewed community pharmacies as the ideal setting for HT medication consultations. Both groups recognized the need for pharmacist training on HT drugs and patients' medication concerns. Pharmacists also anticipated the need for clear guidelines to manage these conversations, similar to the New Medicines Service [48], to ensure consistent advice for patients. Both groups proposed the use of a patient diary to support greater awareness of side effects, drug attribution, and beliefs about medications.

Dissonances

Pharmacists described patients' requests for specific brands as challenging (time-consuming and, at times, costly for the pharmacy) and difficult to manage within the constraints of National Health Service prescription services and the Drug Tariff [49]. Although patients considered cost savings to the NHS as the reason underlying generic switching, they often did not understand the NHS prescribing framework or the financial implications for pharmacies operating as businesses. Some patients in the online forum described the process as "Every prescription pick-up is an anxiety-inducing moment" [P32-PaF], particularly when they sought only 1 specific brand, whereas pharmacists viewed this behavior as frustrating and, at times, unnecessarily self-inflicted:

> *So at least some people, they're willing to try something if they can't get it, but I'm like, why would you want to restrict yourself?* [CP5]

This was compounded by patients who claimed to follow their HCP's advice to stick to 1 brand,

> *So when I mentioned a side effect to the oncologist at my six-monthly review, he said: "Always stick to the same brand"...I would say [to the pharmacist]: "Can I have the AR* brand name please?" and they would say: "Well, we're not allowed to do that". And to be honest, I've been backwards and forwards so much about trying to check [this brand] that I just gave up. [Julie, interview quoted in* [11] p.10]

This highlights, first, that brand sensitivity is not uniquely triggered by patients and, second, a disconnect within the care team regarding how the medication supply framework operates. Patients reported that concerns about MBCs undermined their confidence in taking medication and could affect treatment continuation:

> *I've got one friend in the group..., who just stopped it altogether because she couldn't find a brand that was supportive to her, so she stopped. But again, she was like me, she couldn't get a discussion going about what the differences might be. [Diane, interview quoted in* [11], p.9-10]

We aimed to capture women's lived experiences in our behavioral analysis (see Table S3 in Multimedia Appendix 4), scrutinizing the identified barriers, negative emotions, lack of knowledge, limited confidence in managing symptoms, and feelings of being undermined (not listened to) during conversations with HCPs, who often questioned the validity of their experiences. The latter was carefully considered in our analysis of self-monitoring behaviors (diary use) proposed by women themselves, in a way that balanced their experiences with MBCs and those of pharmacists, for whom the need for specific communication skills and guidance in managing these conversations was acknowledged. Self-monitoring through digital technologies is widely used in the prevention and treatment of chronic conditions, but it has also been associated with "individual responsibility," shifting the burden of care onto patients [50]. Overall, women made it clear that support after discharge from the hospital was needed and that HCPs should listen to their concerns and offer better options for managing medication-related issues [11]. The research team envisaged pharmacy training and guidance as requiring alignment between existing medication consultation skills and the specificities of HT treatment in BC survivors. Further details on the online forum analysis and the patient and pharmacist interviews are available in Tables S1-S3 in Multimedia Appendix 4.

Taken together, these studies suggest that many patient interactions with community pharmacists could be construed as missed opportunities to provide care and advice for symptom management beyond a narrow focus on brand-related discussions. As it stands, system factors (wholesaler stock, medication shortages, and GP prescribing by brand name) and scientific principles (generic bioequivalence) appear to place self-management and side effect control beyond patients' capabilities and limit the support pharmacists can provide. In summary, the 3 intervention components identified during the planning stage were informed by the preferences of patients and

XSL•FO
RenderX

pharmacists and included a self-monitoring diary, a pharmacist training package, and consultation guidelines. The next section reports findings from the diary development process.

Development of a Symptom Diary

Rapid Scoping Review

A total of 29 reports (including 19 studies) published between 2007 and 2024 were identified, of which 8 were from the United Kingdom. Study designs included protocols (n=4); intervention design studies using mixed methods (n=3) and qualitative methods (n=3); feasibility studies (n=4); pilot studies (n=5); randomized controlled trials (n=3); postintervention studies using qualitative (n=1), quantitative (n=1), and mixed methods approaches (n=1); systematic reviews (n=2); an overview of reviews (n=1); and a Delphi study (n=1). Most were intervention studies (n=24) involving different cancer types (eg, uterine/cervical, breast, colon, and prostate and lung cancers, among others). Diaries were used to improve physical activity and healthy diet (n=18), QoL (n=2), symptom management (n=3), and medication adherence (n=2). Diary use required completion periods ranging from 3 days to 12 months, and the format was primarily digital (web- or app-based), paper only (n=3), or both paper and digital (n=1). Most articles used diaries to record activities, including the use of scales, whereas 2 studies used a diary more as a reflective tool [51,52]. Key diary components and outcomes were organized into potential barriers and facilitators (Table 1). Although evidence regarding the effectiveness of diary interventions remains limited (only 3 randomized controlled trials [52-54]), positive outcomes were reported across heterogeneous interventions (eg, increased physical activity, improved diet, or enhanced medication adherence) using behavioral targets relevant to supporting self-efficacy in our intervention (goal setting, problem solving, and social support). Evidence regarding factors that appeared to support or hinder engagement, usability, and acceptability of diary use among patients with cancer was also considered during workshop discussions.

Table 1. Summary of topics, facilitators, and barriers from the rapid scoping review of the literature.

Facilitator	Barriers
Patient enrollment/completion	
• High intervention/study completion [52,53,55-61]	• Team's inability to reimburse lost wages or offer interactions with a health care professional outside working hours [52]. • Intervention is inconvenient to everyday life/transport [58]. • Participants' unwillingness to self-manage lifestyle [52,62,63]. • Anxiety about participation [55]. • Ill health restricting participation [51,53,55,63-65].
Engagement, acceptability, and usability of the diary	
• Diaries seen as useful [54-58,61,65-69] • Easy to learn and use [55,56,58,61,65,66,69,70] • Cancer survivors appreciated knowledge gained about intervention target (eg, medication adherence/diet/physical activity) [51,54,58,66,69-71]	• Burden, difficulty, and time commitment required for diary keeping [55,56,63]. • Memory issues and fatigue [56]. • Technical issues with digital diaries [55,56,61,63,66,70]. • Literacy and language barriers for paper-based and electronic diaries [51,52]. • Diary lacked complexity or flexibility [72].
Interventions with a diary component and behavioral targets	
• Focus on goal setting [51,52,55,57-59,61,63,64,67,69-71,73-75] • Problem solving [51,52,54,57,58,64,67,69,71,73-76] • Social support: discussion with a health care professional and feedback on plans/goals/activities [51-55,57-60,62-64,67,71,73-78]	• No personalized information in automated feedback [69]. • Sustained lifestyle change is hard [61]. • Diary lacked interactivity [70].
Outcomes of interventions using a diary component (self-monitoring)	
• Increased self-management/control [53-55,66,69,70,72] • Intervention aided in symptom control, supporting participants to become aware of (medications and symptoms, food quality, exercise) and plan daily routines accordingly [52-55,66,69] • Improved communication with health care professionals [52,54,55,63,66,76,79] • Improved intervention outcomes [52-54,60,64,65] • Increased confidence [55,60,69]	• A few patients found recording side effects as drawing too much attention to them [66]. • Nurses found it challenging to no longer inform and advise patients in general. • They were expected to facilitate patients' own reflection [76].

Co-Development Workshops

Discussions were guided toward addressing key diary components based on patients' and pharmacists' needs and underlying behaviors identified during the planning stage, theoretical approaches related to self-efficacy in medication-taking behaviors, and findings from the scoping review identifying barriers and facilitators to diary engagement and relevant behavioral targets. The team outlined 2 broad

XSL•FO
RenderX

sections for workshop discussions: (1) diary content and (2) preparation of key information for a medication consultation with a pharmacist. The discussion topics and aims are listed in Table 2.

Table 2. Discussion topics and their aims.

Topic for discussion	Aim
• Usefulness of the diary	To explore what could be useful to record
• Diary format: frequency, medium; free text and tick boxes, scales, emojis; length; and reminders	To identify components that will ensure engagement and usability
• Information (hormone therapy drug common side effects and when to seek help) • Symptom recording (physical and emotional) • Personal circumstances and external factors (environmental and other medications) • Problem solving (actions taken to control symptoms)	To gather participants' preferences about the diary's main content
• Content summary (case scenario) • Problem solving (graph and table with summary of key points)	To organize and identify key information written in the diary to use in the discussion with the pharmacist

Participants' illustrative quotes and votes for the diary format are available in Tables S1 and S2 in Multimedia Appendix 5. At this stage, we drafted the intervention guiding principles and the logic model (see Tables S3 and S4 in Multimedia Appendix 5), which provided a framework to design and map diary sections and items for the intervention content.

Intervention Planning Table

The analysis reflects the barriers identified among patients with BC with concerns about MBCs, factors influencing diary engagement among patients with cancer (informed by existing evidence), and the diary components and content most likely to address these issues. The behavioral analysis identified the MoAs and BCTs most likely to be effective in facilitating behavior change, based on the best available evidence reported in the Theory and Technique Tool [45]. Table 3 presents the intervention planning table.

XSL•FO
RenderX

Table 3. Intervention planning table.

Barriers to target behavior	Intervention components	Mechanisms of action	BCT[a]	Content
Lack of knowledge on HT[b] medication and side effects (PS[c], T[d], WS[e], and SR[f])	• Information about potential side effects of HT drugs—supports women in identifying side effects.	• Knowledge, beliefs about consequences, attitude toward the behavior, and skill (self-efficacy in deciding when to seek help)	• Information about health consequences (BCT 5.1), credible source (BCT 9.1), and instruction on how to perform the behavior (BCT 4.1)	• A summary list of 4 HT drugs (tamoxifen, letrozole, anastrozole, and exemestane) with common, occasional, and rare side effects provided by Cancer Research UK—Advice on when to seek professional help.
Low confidence in managing side effects from the new brand (PS, T, WS, and SR)	a. Support women to self-monitor their HT medication. Keeping a record of side effects from different brands: physical, psychological, and environmental factors. b. Record actions taken to control symptoms c. Raising awareness about side effects from brands (avoidance of drug misattribution)	a. Goals, behavioral regulation, and behavioral cuing b. Behavioral regulation c. Attitudes toward the behavior	a. Goal setting (behavior) (BCT 1.1), action planning (BCT 1.4), and self-monitoring of the behavior (BCT 2.3) b. Problem solving (BCT 1.2) c. Framing/reframing (BCT 13.2)	a. The "My Symptom Diary" section has a set of questions about brand, date of new symptoms, physical/psychological (location, severity, and impact [activities, sleep, emotions]), and environmental factors (other medications, personal circumstances, and external factors). b. A question prompts women to record anything done to control symptoms, and if it worked. c. Repeat completion, revision, and reflection on responses.
Experience disbelief about symptoms from the new brand; disregard about concerns (PS and WS)	• Key summary of the diary and plans ahead of medication consultation.	• Goals, motivation, beliefs about capabilities, and behavioral regulation	• Goal setting (outcome) (BCT 1.3), problem solving (BCT 1.2), and reduce negative emotions (BCT 11.2)	• A dedicated section in preparation for the medication consultation—summary (symptoms, environmental factors, actions to control, and medication expectations)
Lack of meaningful engagement and support from professionals regarding HT side effects (PS, T, WS, and SR)	• Personalized pharmacist feedback informed by key diary summary points during a planned medication consultation (person-centered approach incorporating shared decision-making).	• Goals, motivation, feedback process, environmental context and resources, and social influences	• Review outcome goals (BCT 1.7), feedback on behavior (BCT 2.2), and social support (practical) (BCT 3.2)	• Medication consultation starts with key summary points (diary). Medication guidelines for pharmacists (6 steps). Pharmacists and patients discuss options until a mutually agreed new approach to deal with symptoms seems acceptable. Alternatives/resolution for no decision. Notes taking, follow-up consultation.

XSL•FO
RenderX

Barriers to target behavior	Intervention components	Mechanisms of action	BCT[a]	Content
Lack of acceptability and engagement with a diary (SR and WS): cumbersome tasks, burden (time-consuming/long), health literacy, nonnative speaker, and medium preference (paper and online)	a. Clear introduction on how to complete the diary b. Allow flexibility for diary completion (minimum 1 month to maximum 3 months) c. Lay language and easy to understand d. Discrete space for responses to questions with the option to expand e. Option to request from the pharmacist a paper copy or an electronic version f. Non-English speakers	a. Skills and belief about capabilities b. Behavioral cueing c. Environmental context and resources d. Emotion e. Environmental context and resources f. Environmental context and resources	a. Instruction on how to perform behavior (BCT 4.1) b. Action planning (BCT 1.4) and habit formation (BCT 8.3) c. Social support (practical) (BCT 3.2) d. Reduce negative emotions (BCT 11.2) e. Social support (practical) (BCT 3.2) f. Social support (practical) (BCT 3.2)	a. Simplicity of instructions b. Format is easy to navigate. Recommend writing 3 times a week. c. Key points: changes in brand and new/worsening of side effects; and simple, plain language, provided by the patient advisory group. d. The layout for responses allows for expansion (electronic version) or adding pages (paper version). e. Electronic version available in a free word processor; also offline to ensure accessibility. f. Offer translated versions of consent forms and diary in languages other than English.

[a]BCT: behavior change technique.

[b]HT: hormone therapy.

[c]PS: planning stage.

[d]T: theoretical approaches.

[e]WS: workshop.

[f]SR: scoping review.

Barriers to the target behavior identified through qualitative research informed the behavioral analysis. Some barriers, such as "experience disbelief about symptoms," were specifically derived from data collected during the planning stage (see Table S3 in Multimedia Appendix 4) and further expanded during the development stage through workshop discussions (see Table S1 in Multimedia Appendix 5). During the workshops, participants introduced a new perspective of the diary as a form of "evidence" that could support patients' reports of experiencing different side effects:

> *it might make him [pharmacist] think well, actually, you know, this does matter to her, it is important, it can happen.* [PA10]

There was agreement regarding the types of issues to record, except for "environmental factors/life circumstances," for which concerns about privacy were raised by participants from minoritized ethnic groups (patients and pharmacists). This consideration was incorporated into the diary instructions as an optional component. Regarding the "key summary of the diary" prepared for the consultation (problem solving), 1 patient found documenting actions taken to control symptoms problematic because "it dilutes the fact that it's the brand that is causing this specific problem" [PA8]. These points will be important to examine in future research, as they suggest that the extent of diary completion may differ among patients who feel more certain that side effects are brand-related, which may or may not influence reflective processes before the consultation. Of particular importance were patients' discussions about the need for pharmacist feedback to balance the burden of completing a diary, as expressed by 1 patient: "that means that you can use it [diary] to empower yourself beyond your own self patience" [PA5]. A pharmacist similarly stated, "It'll help them [patient] and the caring team make better decisions, definitely" [CP-1]. Social support was also identified in the scoping review [66] and theoretical approaches [37]. Finally, issues related to the acceptability of and engagement with the diary were informed by findings from the scoping review and workshops, during which participants voted on the main diary features (see Table S2 in Multimedia Appendix 5).

Once the barriers to MBCs had been identified through the planning stage and workshops, they were mapped onto the MoAs, a range of behavioral theoretical constructs, including those within the Theoretical Domains Framework, that represent the processes through which specific BCTs influence behavior. The team agreed to select BCTs for which evidence of a link to a specific MoA was available in the Theory and Techniques Tool [45].

Symptom Diary

Prototype 1 of the symptom diary consisted of 5 sections: (1) an introduction explaining the purpose of the diary and presenting 2 scales (pain and mood) for later reference; (2) "My Symptom Diary," containing 8 questions; (3) "Preparing Your Medication Consultation With the Community Pharmacist," designed to summarize key points; (4) feedback on the experience of using the diary; and (5) an appendix listing side

XSL•FO
RenderX

effects for each of the 4 HT drugs, categorized as common, occasional, or rare.

Details of subsequent changes to this prototype version are discussed below.

PAG and Pharmacist Interviews: Prototype 2

The PAG members were satisfied with the design and purpose of the diary because it allowed patients' different experiences and perspectives on what mattered to them to be captured. They also praised the prompts encouraging consideration of environmental factors, including personal circumstances, as a valuable approach for eliciting a broad range of factors to consider.

> *People would perhaps think about environmental factors, so I think it's good to have all the different ones as a prompt, but it's not compulsory that they fill it in, if it doesn't apply to them. So, I thought that was good.* [PG1]

Regarding the diary content, members proposed the inclusion of 2 additional items to record: the date on which the medication was changed and whether the symptom had resolved. This was considered important given the possibility that medications could change while using the diary and that symptoms could fluctuate or be successfully managed by women. Members also questioned the inclusion of "fatigue" within the mood scale, as they perceived it to be a physical sensation rather than a mood-related state. We agreed to remove fatigue from the scale because the primary purpose of the diary was to facilitate women's reflection rather than serve as a tool for quantitative data collection. Another point raised by the PAG concerned the summary of key points before the medication consultation. Patients suggested replacing "intentions" with "expectations," given that a patient's goals may not necessarily be fulfilled by the pharmacist, whereas "expectations" would empower women to express what they felt they needed and hoped to receive. In addition, participants suggested signposting patients to charity support before the medication consultation. Finally, 1 PAG member reviewed the entire diary for lay comprehension and made additional suggestions, which were incorporated alongside those described above.

All pharmacists were supportive of the use of symptom diaries, and many were familiar with their use for other medicines. Community pharmacists praised the diary for facilitating pharmacists' support and increasing patient awareness.

> *The benefits are huge....I think it would allow patients who are not medically minded to categorise and really work out how bad it is* [CP2-5]

No specific comments were made regarding the diary's set questions other than its general design: "I think make it really simple for patients" [CP2-2]. Some pharmacists interpreted the diary as giving pharmacists a more proactive role (ie, linking side effects to factors recorded for pattern observation in specific brands).

> *So having a symptom diary for, not just in this particular therapeutic area, but in lots of therapeutic areas is useful, to see both the symptoms and side effects and you can track and identify where those are linked to.* [PH2-3]

It was explained that the initial expectation was that pharmacists would not read the diary because of time constraints and privacy concerns, and that they would instead advise patients based on the patients' presentation of key points from the diary (medication expectations valued by patients). Medicine shortages were mentioned as a challenging issue for HT drugs, echoing previous qualitative evidence. There were also comments regarding the optimal time for introducing the diary to patients (ie, at medication initiation or when concerns arise). The research team initially planned to test the intervention among those who had concerns with brands, but its suitability at medication initiation could be explored in future studies, given the reported need for information and self-management support [2,11,13,14]. Feedback was incorporated into a table of changes, with relevant quotes included for illustration (see Table S1 in Multimedia Appendix 6).

Research Team and Nurse Discussion: Prototype 3

A final discussion took place among the research team, the PPIE lead, and a Breast Cancer Now nurse, who received a copy of prototype 2 in advance. The team revisited components of the diary and the underpinning behavioral techniques, such as self-monitoring (confidence in recording symptoms) and problem-solving (identifying key points ahead of consultations), which were reviewed alongside feedback from the PAG and pharmacists. Many of the pharmacists' views informed the training package (e-learning resource reported separately), in which patient-centered and shared decision-making approaches became more central to the intervention's aim of upskilling pharmacists. Current medicine shortages were discussed as a timely opportunity to introduce the intervention, given the additional challenges associated with requesting specific brands. Specific changes related to the diary layout to ensure ease of completion and flexibility in the allocated spaces, following data from workshop contributions. Additionally, the team agreed that pharmacists would be well placed to signpost patients to charity information alongside other recommendations included in the medication consultation guide. Further details and quotes are presented in Table S1 in Multimedia Appendix 6.

Prototype 3 of the symptom diary was designed as a paper copy and in a word-processor format (to support offline completion and adaptability to systems other than Microsoft Word). The diary will be delivered by community pharmacists after training with an e-learning resource and following a medication consultation guide. Eligible patients (identified by pharmacists) are those who have previously expressed or are currently expressing concerns about MBCs. The estimated duration for completing the diary during the testing period is a minimum of 1 month and a maximum of 3 months. Prototype 3 contains the sections outlined in Textbox 1.

XSL•FO
RenderX

Textbox 1. Sections of prototype 3.

1. How to use this diary
- When and what to record; presentation of pain and mood scales
- What happens next (medication consultation appointment)
- Signposting to feedback and information on drug side effects

2. My symptom diary
- Ten questions on drug name, physical and psychological symptoms, impact on daily activities, and anything done to control the symptoms
- Use of other medication(s)
- Personal circumstances and external factors
- Whether symptoms stopped

3. Preparing for your medication consultation with the pharmacist
- Summary of patients' symptoms
- Personal life and external factors that might affect symptoms
- Actions taken to control symptoms
- Medication expectations and plans

4. Feedback notes on your experience of using the diary
- Positive and negative views

5. Common, occasional, and rare side effects of hormone therapy drugs
- Lists of tamoxifen, anastrozole, letrozole, and exemestane side effects

Discussion

Principal Findings

In line with the PBA, our planning stage, supported by data triangulation, was an essential first step given the scarcity of studies specifically focusing on MBCs for HT drugs. Patients' concerns about brand changes first emerged as a potential adherence-related factor in our previous study on the impact of new guidelines extending HT from 5 to 10 years [21]. Online patient forums provide a valuable source of data, as patients perceive them as a space for sharing experiences of coping with the disease and seeking advice on managing side effects [14]. Our findings from 277 patients in the Breast Cancer Now forum, also confirmed through interviews, suggested that patients with MBC concerns encounter 2 types of HCP responses: 1 grounded in the biomedical model, which asserts that generic drugs are bioequivalent (ie, no difference exists), and 1 based on belief in patients' lived experiences, which depends on the HCP's sensitive approach and the patient's ability to advocate for themselves. Data triangulation also highlighted a disconnect in HCP advice (from GPs, oncologists, and nurses) regarding the constraints of the system-level drug distribution process. These studies further deepened our understanding of the complexities inherent in conversations about brand changes. Following patients' and pharmacists' initial proposals regarding the use of a diary (or another method of recording side effects and brands) and a medication consultation with the pharmacist, the research team shared these ideas with PPI, stakeholders, patients, and pharmacists during the development stage. Informed by evidence on behaviors underpinning adherence to HT (self-efficacy and Social Cognitive Theory), we used qualitative research to identify MoAs, barriers and facilitators of MBCs, and candidate BCTs based on existing evidence. Drawing on the PBA for intervention development, a symptom diary was coproduced with patients and pharmacists, prioritizing acceptability and engagement with users' preferences and, as recommended by the MRC [20], its potential implementation within the community pharmacy setting.

During the development stage, the scoping review showed that the use of diaries among patients with cancer is more effective when HCP interaction (social support) is embedded within the intervention. This aligned with a core practice standard of the General Pharmaceutical Council, which places patients' interests and perspectives at the center of patient consultations [80]. However, these principles proved difficult to apply in practice for patients with BC who were concerned about HT generic switching. Therefore, a different approach was needed to engage patients and pharmacists in person-centered and shared decision-making practices. The diary is intended to help patients better understand symptoms and changes in brands, and to reflect on their expectations regarding the medication. This reflective process may better position patients to engage in shared decision-making consultations [81], as recommended by National Institute for Health and Care Excellence (NICE) adherence guidelines [82]. Patients' preferences, needs, and lived experiences can "get a discussion going," as 1 participant described it. As social support from a pharmacist appeared to be a primary motivation for diary engagement, the medication consultation strengthens the potential feasibility and

XSL•FO
RenderX

acceptability of the intervention. This addresses repeated calls for clearer articulation of supported self-management within primary care provision [83], including pharmacy practice [16,34,79,84]. Furthermore, patients with BC in the England-initiated follow-up pathway have already reported a need for medication reviews [85].

Person-centered approaches focus on understanding how users engage with, use, and perceive the relevance of an intervention. This also includes HCPs such as pharmacists, who, in this study, would deliver the intervention in their practice settings. User and stakeholder engagement through coproduction and iterative feedback processes is likely to be critical for future service implementation and may support viability across diverse user groups. For example, concerns raised by ethnically minoritized patients and pharmacists about documenting personal circumstances led to making it optional for patients to decide how much personal information they wished to share in the diary. The use of lay language, readability considerations, and diary translations may further support acceptability among underserved populations. Disagreements arising during stages of the feedback process were evaluated by prioritizing the congruence of proposed modifications with the behavioral determinants and BCTs identified in our theoretical approach. Contributors' input is transparently reported in this paper, as recommended by Slattery et al [86], making it possible to trace changes discussed by this diverse group of contributors and potential users. Further adjustments to the diary will follow completion of the testing phase in community pharmacies, informed by participant feedback.

Limitations

Our approach was strengthened by a recruitment strategy that sought to capture a plurality of views and experiences across different sociodemographic groups. However, we acknowledge the limited inclusion of patients who do not speak English, as well as lesbian and nonbinary women. We also acknowledge that the current version of the diary could be more inclusive for women with other disabilities, including those experiencing drug-related side effects (eg, hand joint pain). In the future, a mobile version with voice-recording input could be developed alongside an offline version.

Conclusions

This study has begun to address the need for support for patients with BC who have concerns about changes to their HT medication brands. The use of different brands causes concern for some patients, lowers QoL, and in some cases may result in poor adherence and treatment discontinuation. We reported on the planning and development of a symptom diary designed to improve patients' self-efficacy in medication-taking and communication with pharmacists. Women perceived the diary as "empowering" because it helped them take control of their symptoms and share this information with their pharmacist, with the expectation of developing agreed-upon medication plans. Importantly, the diary is intended to complement a medication consultation with pharmacists, who will receive training and guidance as part of the ENABLE intervention. The symptom diary demonstrates the theory-, evidence-, and person-based methods used for intervention development, documenting the process used to gather qualitative evidence from patients and pharmacists, from needs identification to diary coproduction and refinement. Behavioral analysis (MoAs and BCTs) underpinned the rationale and decisions made when incorporating feedback from a diverse population group. The use of systematic intervention reporting, particularly regarding intervention components and BCT targets, will allow for further specific adjustments. It may also enhance transferability to other contexts in which generic switching is problematic for patients with other chronic conditions.

We preliminarily developed an intervention that appears engaging, relevant, and acceptable for patients to self-monitor their symptoms. Further revisions informed by user feedback will be incorporated after testing ENABLE in community pharmacies. Large-scale research will be needed to provide evidence of its impact on improving adherence and QoL.

Acknowledgments

We are very grateful to all participants for sharing their experiences in this study. Special thanks to the ENABLE Patient Advisory Group for their invaluable contributions to the study. We also extend our gratitude to all organizations and groups that helped recruit participants, including Breast Cancer Now, South Asian Health Action, Local Pharmaceutical Committee networks, and Community Pharmacy Research Champions at RNDD North London. Our special thanks to Ieva Steinberga for her research assistant work during the planning stage and Jane Murphy, Clinical Nurse Specialist at Breast Cancer Now, for her collaboration during the development stage. The authors declare that no artificial intelligence tools were used in the ideation or writing process.

Funding

This study was funded by the NIHR Research for Patient Benefit (grant NIHR206589). The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

Study files for the development stage are available from the OSF database: "Co-development of a symptom diary for breast cancer patients (2024-2025)" available online [87].

Abstract

Background: Focal high-intensity focused ultrasound (HIFU) is an emerging tissue-preserving treatment for localized prostate cancer (PCa) that aims to reduce functional impairment and psychological burden while maintaining oncological safety. Although its clinical use is increasing, prospective data on health-related quality of life (HRQoL) and psychological distress after focal hemiablation remain limited.

Objective: This study aims to evaluate longitudinal HRQoL trajectories and psychological outcomes in patients eligible for active surveillance who underwent focal HIFU following shared decision-making.

Methods: This prospective, multicenter, single-arm longitudinal study included men with unilateral, organ-confined PCa treated with focal HIFU hemiablation within the HEMI study (AP study protocol/reference number: 68/11, AUO). All patients had concordant multiparametric magnetic resonance imaging and biopsy findings, and underwent standardized unilateral HIFU. HRQoL was assessed at baseline and at 1, 3, 6, 9, and 12 months using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire—Core 30 (EORTC QLQ-C30, version 3.0). Psychological distress was measured with the Hospital Anxiety and Depression Scale. Longitudinal changes were analyzed using linear mixed-effects models with false discovery rate correction. In addition, univariate regression analyses were performed to assess associations between clinical and functional parameters, and HRQoL outcomes. Outcomes were compared with German and Norwegian normative populations, and clinical relevance was interpreted using Osoba criteria.

Results: Fifty-four patients were included, of whom 51 (94.4%) completed 12-month follow-up (mean age 63.4, SD 8.3 y). Baseline HRQoL, functional status, and symptom burden were favorable. One month after hemi-HIFU, a statistically significant and clinically moderate decline in global health status was observed (mean 75 [SD 17.8] vs 63 [SD 17.9]; P=.002; Cohen d=0.58). This transient deterioration was mainly driven by increased fatigue, pain, insomnia, appetite loss, and reduced physical, role, and social functioning, with social functioning most affected. Emotional and cognitive functioning remained stable. From 3 months onward, HRQoL and all functional domains recovered to baseline or higher levels, with no clinically relevant impairments at 12 months. Symptom burden normalized across most domains after 3 months, although mild constipation remained slightly elevated. Depression scores showed a transient increase at 1 and 3 months but remained below clinical thresholds, whereas anxiety scores were stable at all time points. In univariate regression analyses, no clinical or functional parameters were identified as independent predictors of HRQoL. Overall, recovery was rapid, long-term HRQoL was preserved, and treatment-related morbidity remained low.

Conclusions: Focal HIFU hemiablation preserves long-term HRQoL and psychological well-being in carefully selected patients with localized PCa. Early postoperative impairment is temporary, with recovery to baseline and convergence with normative population values from 3 months onward. Clinical and functional parameters were not significant predictors of HRQoL. These findings support focal HIFU as a minimally invasive quality-of-life–preserving treatment option.

Introduction

Prostate cancer (PCa) is one of the most commonly diagnosed malignancies among men worldwide and represents a major global health burden [1-3]. Although radical prostatectomy (RP) and radiotherapy (RT) provide excellent oncological control, both are associated with substantial risks of urinary incontinence and erectile dysfunction, which can significantly impair health-related quality of life (HRQoL) [4-7]. Concurrently, widespread early detection has increased the diagnosis of low-risk and potentially indolent tumors, intensifying concerns about overtreatment [8-10].

Active surveillance (AS) is an established strategy to avoid unnecessary intervention in low-risk PCa. However, it is limited by uncertainties in tumor staging and biological behavior. In addition, the psychological burden of living with an untreated malignancy leads up to 20% of patients to choose definitive treatment despite low oncological risk, and approximately one-third discontinue AS within 2 years [11,12]. Repeated prostate biopsies may further impair erectile function, prompting some eligible patients to pursue radical therapy [13,14].

These limitations highlight the need for treatment approaches that preserve oncological safety while minimizing functional and psychological morbidity. In this context, focal therapy has emerged as a promising alternative, aiming to eradicate the index lesion while sparing uninvolved prostate tissue. High-intensity focused ultrasound (HIFU) is one of the most extensively studied focal modalities and has been shown to reduce treatment-related side effects compared with whole-gland approaches [15-20]. Hemiablation—often referred to as “male lumpectomy”—provides lobe-directed tumor control in carefully selected patients [21-24]. Accurate tumor localization is essential for safe and effective focal therapy planning and is optimally achieved using multiparametric magnetic resonance imaging (mpMRI) combined with systematic and/or targeted biopsy [25-29].

Across all PCa treatment strategies, preservation of HRQoL has become a central outcome measure and an important component of shared decision-making. Quality of life, originally introduced as a sociopolitical concept in the 1960s [30,31], is defined by the World Health Organization as a subjective, multidimensional construct encompassing physical, psychological, social, and environmental domains [32]. Owing to its personal and nondirectly measurable nature, HRQoL assessment relies on validated patient-reported outcome measures [33,34].

In oncology, HRQoL reflects a paradigm shift toward a biopsychosocial understanding of disease and plays a growing role in clinical evaluation, health-economic decision-making, and outcomes research [35,36]. Given that oncological success may be offset by functional impairments, HRQoL often becomes a decisive factor in individual treatment selection [37]. Despite the increasing adoption of focal HIFU, prospective data on HRQoL and psychological outcomes following hemiablation remain limited.

This study therefore aimed to evaluate longitudinal changes in HRQoL and psychological distress in patients undergoing focal HIFU hemiablation for unilateral PCa who met the criteria for AS but opted for focal therapy after shared decision-making. In particular, this study examined short-term and 12-month patient-reported outcomes to assess whether focal HIFU preserves quality of life and psychological well-being in this carefully selected patient population.

Methods

Patient Cohort and Study Design

This study represents a secondary analysis of prospectively collected patient-reported outcome data from the multicenter HEMI study by Ganzer et al [38], a prospective single-arm clinical trial evaluating focal HIFU hemiablation in men with unilateral, organ-confined PCa. Key functional and oncological outcomes were predefined primary endpoints of the parent HEMI study and have been published previously [38]. The study was registered with the German Working Group on Urological Oncology (AUO) under study protocol AP 68/11.

Patient-reported outcomes, including HRQoL and psychological distress, were prospectively collected according to the study protocol. The present analysis was conducted after the completion of data collection and focuses specifically on longitudinal changes in these outcomes over a 12-month follow-up period.

The study population comprised 54 consecutively enrolled patients who fulfilled the criteria for AS [39] and presented with histologically confirmed unilateral disease and concordant findings on mpMRI. At the time of study conduct, focal therapy was recommended to be performed only within clinical trials. All patients were therefore recruited within the HEMI study after being informed about guideline-conforming treatment options, including AS, RP, and RT, within a shared decision-making process. The final sample size reflects the strictly selected patient population, which applied predefined inclusion and exclusion criteria to identify men suitable for focal hemiablation. All patients were consecutively enrolled at the participating centers during the study period. The present analysis included all patients with available baseline and follow-up patient-reported outcome data. No additional selection or sampling was performed. Therefore, the sample size represents the complete cohort of eligible patients within the study framework. Patients who developed secondary malignancies during follow-up were excluded from longitudinal analyses, as these represent competing health events that would confound the assessment of HRQoL outcomes.Textbox 1

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria (all must be fulfilled)

- Male patients aged 18 years and older
- Prostate-specific antigen (PSA) ≤10 ng/mL
- Clinical stage T1c-T2a
- Biopsy-proven unilateral prostate cancer detected by magnetic resonance imaging (MRI) or transrectal ultrasound scan (TRUS) fusion biopsy
- 30% or fewer positive biopsies
- Gleason score of 3+4=7 or less
- Peripheral zone height to be 30 mm or less and 40 mm or less on TRUS in patients treated with Ablatherm integrated imaging and the focal one device

Exclusion criteria (excluded if *any* of the following criteria applied)

- Significant cancer of the contralateral side on multiparametric MRI as defined by a score of 4 or greater on PIRADS (Prostate Imaging Reporting and Data System)
- Previous prostatic or urethral surgery
- Intake of 5-α reductase inhibitor
- Previous androgen deprivation therapy
- Incomplete clinical or imaging data (eg, missing PSA)

The therapeutic strategy and technical execution of focal HIFU therapy followed the standardized protocol described by Ganzer et al [38], which served as the clinical reference framework for the present analysis. Baseline assessments were performed on the day prior to treatment. Patient enrollment took place between April 2013 and March 2016, corresponding to a recruitment period of 2 years and 11 months. Follow-up evaluations were conducted at 1, 3, 6, and 9 months post intervention using standardized mailed questionnaires. The final 12-month assessment was performed in conjunction with a scheduled rebiopsy at the study center. Time was included as a fixed effect in the longitudinal models without specification of random slopes. The study protocol was initially approved by the institutional review board of the University of Regensburg (Ethics Committee reference: 11-101-0156; approval date: December 29, 2011) and thereafter by the other participating study centers. All participants provided written informed consent prior to inclusion. The inclusion and exclusion criteria applied during study selection are summarized in Textbox 1.

HRQoL Assessment (EORTC QLQ-C30)

HRQoL was assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire—Core 30 (EORTC QLQ-C30, version 3.0), a validated and internationally established instrument extensively used in oncological research [40]. The questionnaire comprises 30 items assessing:

- Global health status and quality of life
- Five functional domains (physical, role, emotional, cognitive, and social)
- Three multi-item symptom scales (fatigue, pain, and nausea and vomiting)
- Six single-item symptom dimensions (dyspnea, insomnia, appetite loss, constipation, diarrhea, and financial difficulties)

Items 1 to 28 are rated on a 4-point Likert scale, ranging from “not at all” to “very much,” whereas items 29 and 30 are scored on a 7-point scale assessing global health and overall quality of life.

All scales were scored and transformed according to the EORTC scoring manual [41], resulting in standardized scores ranging from 0 to 100. Higher scores on global and functional scales reflect better functioning and quality of life, whereas higher scores on symptom scales indicate greater symptom burden (Table 1). Raw scores were calculated as the arithmetic mean of completed items per scale and subsequently linearly transformed based on each scale’s scoring range.

Longitudinal changes in HRQoL were analyzed using linear mixed-effects models with random intercepts for participants to account for within-patient correlations over time. Time was included as a fixed effect. Analyses were conducted using restricted maximum likelihood estimation. To control for type I error inflation resulting from multiple testing, false discovery rate (FDR) adjustment according to Benjamini-Hochberg was applied.

RenderX

Table . Evaluation of global health status and quality of life, functional scales, general symptom and problem scales, and symptom scales.

Calculated scale symptoms score	Global health status and functional scales	Symptom scales
100	No impairment	Severe symptoms
76 - 99	Slight impairment	Moderate to severe symptoms
51 - 75	Mild impairment	Moderate symptoms
26 - 50	Moderate impairment	Few symptoms
1 - 25	Moderate to severe impairment	Slight symptoms
0	Severe impairment	No symptoms

Comparison With Normative Reference Data and Interpretation of Clinical Relevance

EORTC QLQ-C30 scores of the study cohort were compared with male normative reference values from 2 population-based datasets of the EORTC validation program: the German cohort reported by Schwarz and Hinz and the Norwegian reference population published by Hjermstad et al [42,43]. Inferential analyses were performed exclusively using the German normative dataset, while Norwegian reference values were used for descriptive comparison only. Statistical comparisons with the German population were conducted using Welch two-sided *t* test, with *P* values adjusted for multiple testing using the Benjamini-Hochberg FDR procedure.

Clinical relevance was interpreted according to the classification system proposed by Osoba et al [44], which defines mean score differences of 5 to 10 points as small, 10 to 20 points as moderate, and >20 points as clinically large. As these thresholds were originally derived from breast and lung cancer populations, their applicability to PCa should be interpreted with caution. Only differences meeting predefined criteria for clinical relevance were included in the comparative summary table. All comparisons with normative populations were performed without adjustment for age or comorbidity and are therefore interpreted descriptively rather than causally.

Psychological Assessment

Psychological distress was assessed using the Hospital Anxiety and Depression Scale (HADS), a validated self-report instrument specifically developed for use in medically ill populations [45,46]. The questionnaire comprises 14 items, with 7 items each evaluating anxiety and depressive symptoms. Each item is rated on a 4-point scale (0 - 3), yielding subscale scores ranging from 0 to 21. Clinically relevant cutoff values were set at ≥11, in accordance with published validation studies [47]. Scoring followed the recommendations of the official HADS manual.

Statistical Analysis

All questionnaire data were entered into an electronic database and analyzed using DATAtab (Seiersberg, Austria). Continuous variables are reported as mean (SD). Although individual questionnaire items are ordinal in nature, aggregated scale and subscale scores were treated as approximately interval-level variables to enable parametric statistical analyses.

Longitudinal changes in HRQoL were analyzed using linear mixed-effects models with random intercepts for participants to account for within-patient correlations over time. Time was included as a fixed effect, and analyses were conducted using restricted maximum likelihood estimation. Comparisons between the study cohort and normative reference populations were conducted using Welch *t* test to account for unequal variances. To control for type I error inflation resulting from multiple testing, FDR adjustment according to Benjamini-Hochberg was applied to all longitudinal analyses and normative comparisons across EORTC QLQ-C30 scales and time points. All statistical tests were 2-sided, and statistical significance was defined as $P<.05$.

Receiver operating characteristic (ROC) curve analysis was performed to assess the discriminatory ability of baseline clinical and functional parameters for HRQoL at 12 months. The EORTC QLQ-C30 global health score was dichotomized at the median. Univariate ROC curves were calculated, and the area under the curve (AUC) was used as a measure of discrimination. ROC curves were visually smoothed for presentation.

Auditing, Data Monitoring, and Confidentiality

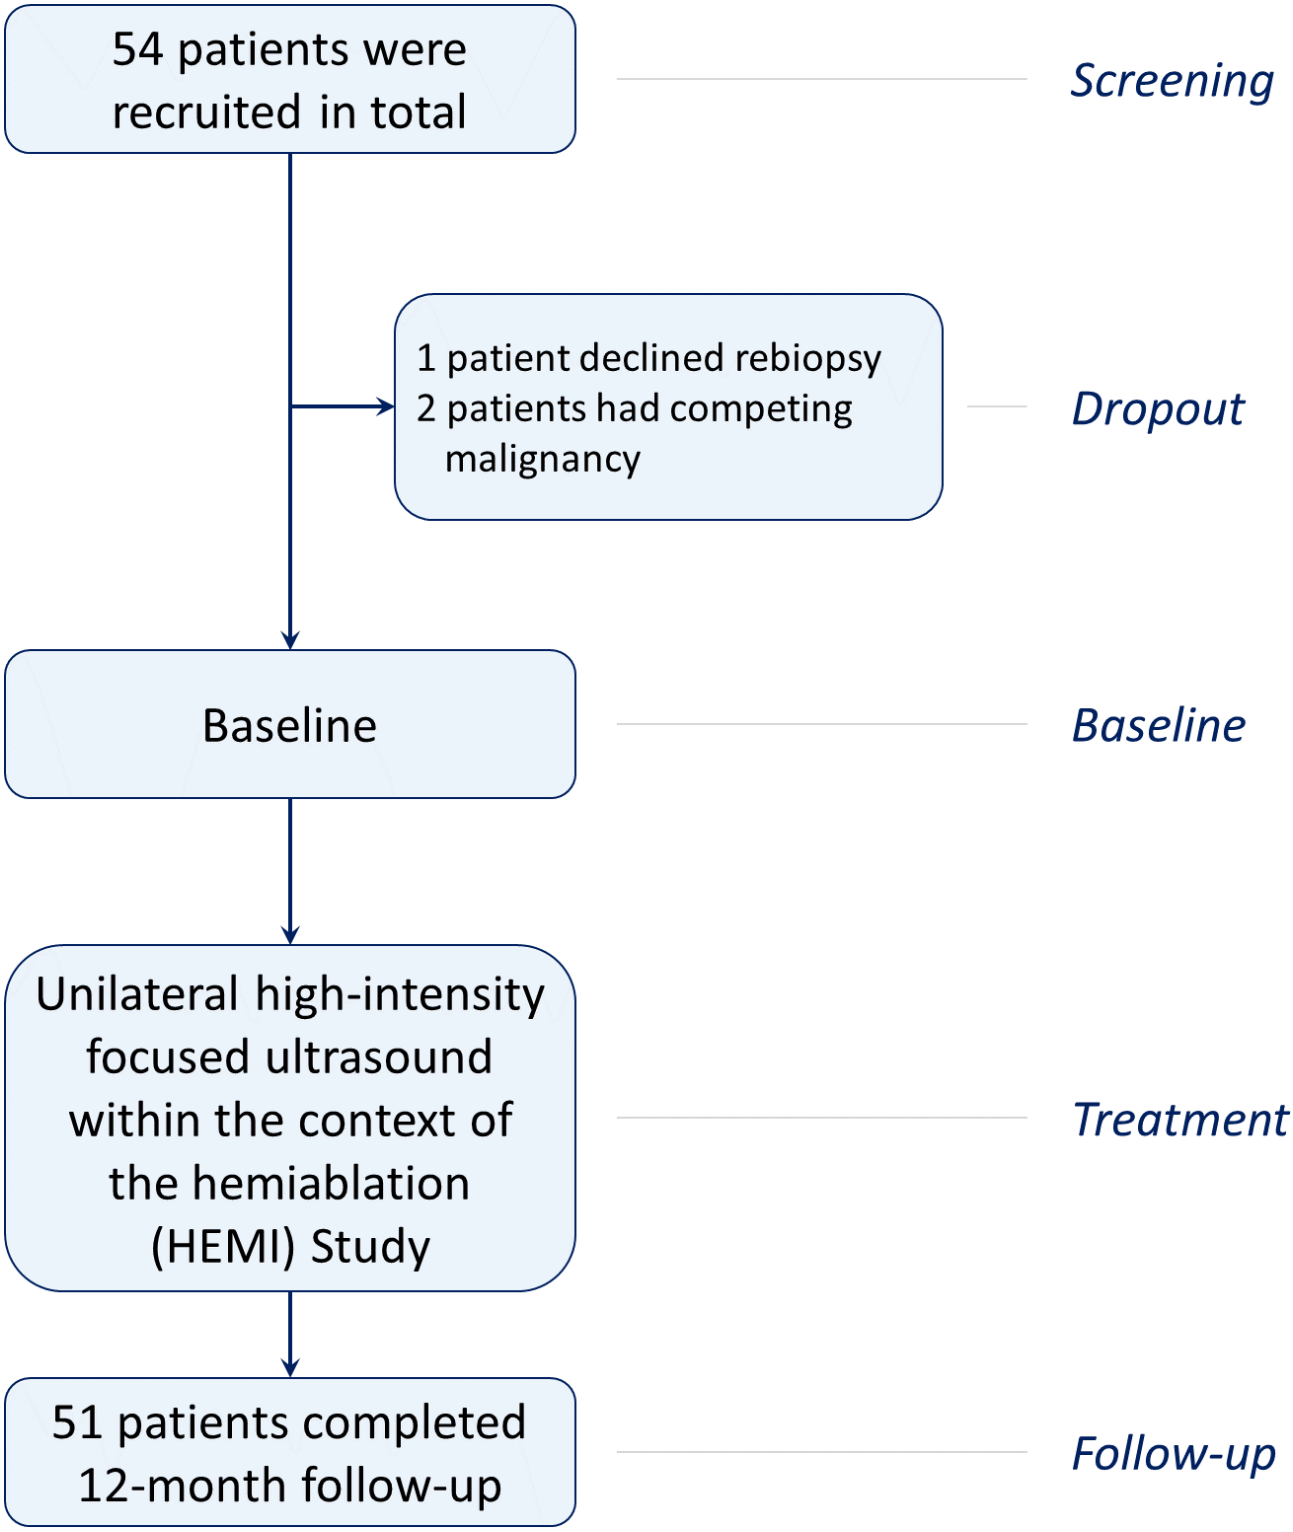
Semiannual audits and monitoring were conducted for data oversight at the study center. These procedures ensured data quality, protocol compliance, and proper conduct of the trial. Participant data were stored in a password-protected database accessible only to authorized study investigators. All personal information was handled in accordance with data protection regulations to ensure confidentiality. Within the framework of the study, patient insurance was in place to cover both the treatment and the entire follow-up period.

Ethical Considerations

The submitted manuscript meets all criteria of the ICMJE (International Committee of Medical Journal Editors) recommendations and COPE (Committee on Publication Ethics) guidelines. All procedures performed in this study were conducted in accordance with the ethical standards outlined in the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards of the institutional and national research committees. Ethical approval was granted by the Ethics Committee of the Medical Faculty of the University of Regensburg (Ethics Committee reference: 11-101-0156; approval date: December 29, 2011) and subsequently by the ethics committees of the other participating study centers. The committees confirmed that there were no ethical or scientific concerns. Written informed consent was obtained from all participants prior to their inclusion in the study. All data were

XSL•FO
RenderX

anonymized, and no information enabling individual identification is presented in this manuscript.



Results

Study Population and Follow-Up

Fifty-four patients were included in the analysis. Of these, 51 (94.4%) completed the planned 12-month assessment and were included in the final analysis. One patient declined the scheduled rebiopsy, and 2 patients discontinued follow-up due to secondary malignancies. Ultimately, data from 51 patients were available for the final analysis. The study selection process is illustrated in the CONSORT (Consolidated Standards of Reporting Trials) flow diagram (Figure 1). The mean age at treatment was 63.4 (SD 8.3) years, reflecting a typical PCa patient cohort, predominantly comprising a middle-aged population considered suitable for focal therapy. Patient characteristics are summarized in Table 2. Hemi-HIFU was associated with a significant but partial decline in erectile function, while urinary continence and lower urinary tract symptoms were largely preserved. These functional outcomes constituted the primary endpoints of the original study by Ganzer et al [38].

Health-Related Quality of Life (EORTC QLQ-C30)

Global Health Status and Quality of Life

At baseline, the mean global health status was 75 (SD 17.8), indicating only minor impairment. At 1 month posttreatment, a significant decline was observed (mean 63, SD 17.9; FDR-adjusted *P*=.002), corresponding to a clinically moderate deterioration. From 3 months onward, scores recovered to baseline or higher levels (3 mo: 78; 6 mo: 78; 9 mo: 77; and 12 mo: 74). Scores at 3 to 9 months were significantly higher than at 1 month (all FDR-adjusted *P*=.004, *P*=.003, and *P*=.004). By month 12, no significant difference from baseline was detected (FDR-adjusted *P*=.39), indicating full recovery of global quality of life (Figure 2; Table 3). The decline in global health status at 1 month corresponded to a medium effect size (Cohen *d*=0.58), and recovery between 1 and 3 months showed a comparable magnitude (*d*=0.61).

Figure 2. Overview of the absolute mean scale scores for global health status and overall quality of life and the functional parameters across the entire observation period. Higher scores reflect better functioning and a higher quality of life.

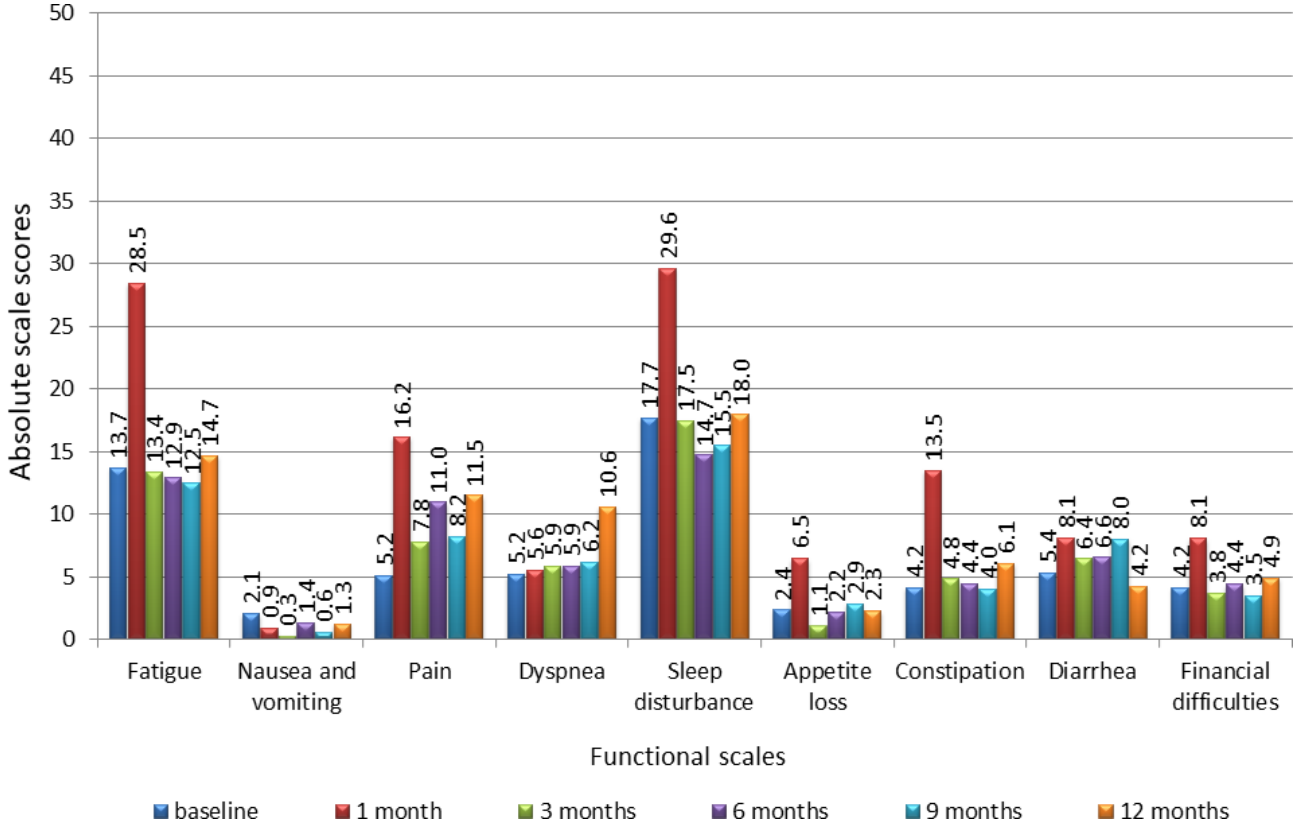
Functional Scales

Physical, Role, Emotional, Cognitive, and Social Functioning

At baseline, physical, role, and cognitive functioning were high (means ≥90, SD 9 and 15), while emotional and social functioning were slightly lower (means 89, SD 19 and 82, SD 17, respectively). At 1 month, physical, role, and social functioning showed transient deterioration, with social functioning demonstrating the most pronounced decline (mean reduction of 14 points, from 89 to 75, SD 25; *P*=.004, *P*=.04, and *P*<.001, respectively). Emotional and cognitive functioning remained stable throughout. From 3 months onward, all functional domains improved. By month 12, no significant differences from baseline persisted across any functional scale, and clinically relevant impairments were rare (Figure 2; Table 3).



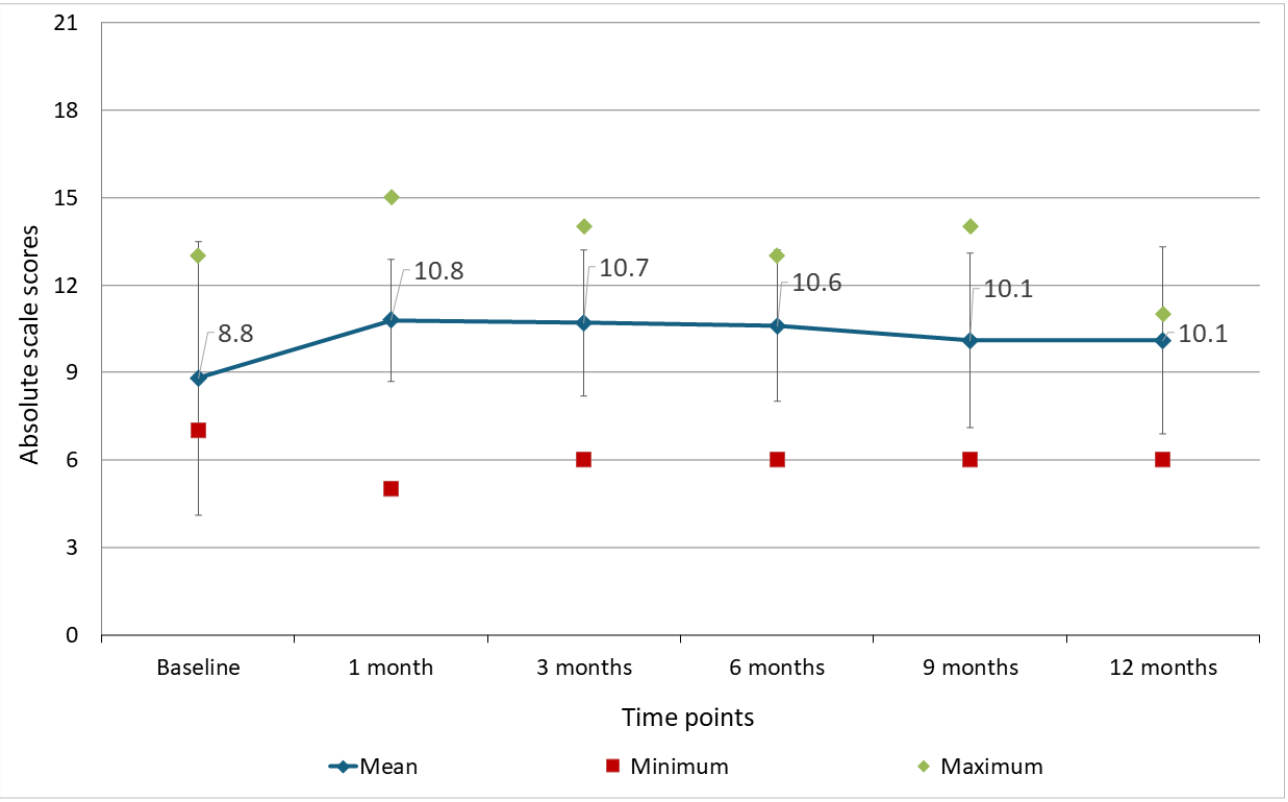
Symptom Scales—General Symptoms and Problem Burden

Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea, and Financial Difficulties

Baseline symptom burden was low across all domains. At 1 month, fatigue, pain, and insomnia increased transiently. Fatigue (mean increase of 15 points, SD 8.5; *P*=.007), insomnia (mean increase of 12 points, SD 6.9; *P*=.04), and pain (mean increase of 11 points, SD 4.4; *P*=.008) reached clinically moderate severity, while all other symptoms remained in the mild range.

From 3 months onward, symptoms normalized across all domains except for pain. In this domain, scores remained significantly different from baseline at 6 months (*P*=.03), but no differences compared to baseline were observed at 9 or 12 months. At no time point was the cumulative symptom burden suggestive of persistent treatment-related morbidity (Figure 3; Table 3).

Figure 3. Overview of the absolute mean scale scores for the symptom scales across the entire observation period. Higher scores indicate a greater symptom burden.

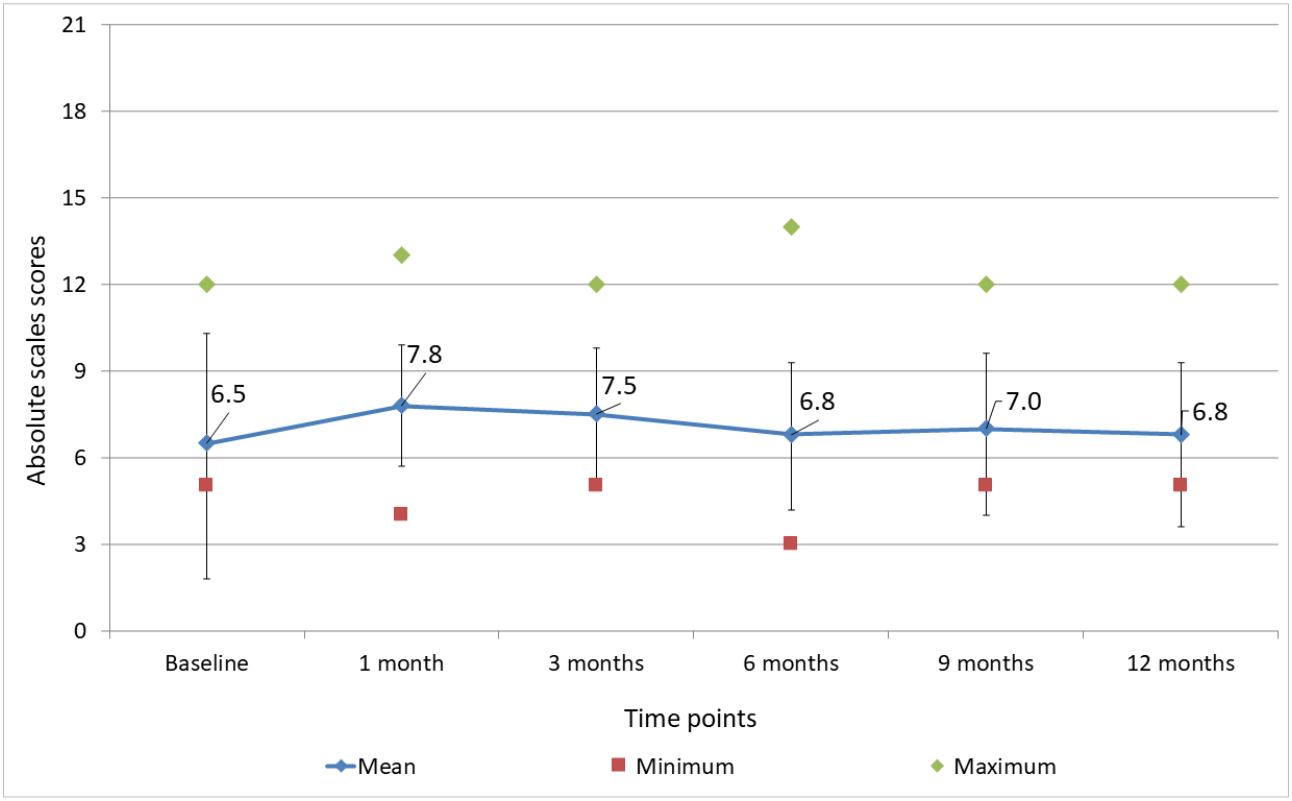


XSL•FO
RenderX

HADS—Depression

Mean depression scores remained below the clinical cutoff value (≥11) at all assessment points. Statistically significant changes were observed at 1 and 3 months (*P*=.02 and *P*=.02, respectively), indicating a transient but statistically detectable worsening in depressive symptom burden. From the 6-month assessment onward, no differences compared with baseline were detected (all FDR-adjusted *P*>.05 for pairwise comparisons). These findings indicate that clinically relevant depressive symptoms were not present at baseline, increased significantly at 1 and 3 months without exceeding the clinical threshold, and subsequently returned to baseline levels and remained stable throughout follow-up, suggesting recovery from a short-term postinterventional effect rather than persistent psychological deterioration attributable to HIFU therapy (Figure 4; Table 3).

Figure 4. Hospital Anxiety and Depression Scale depression scores over time.



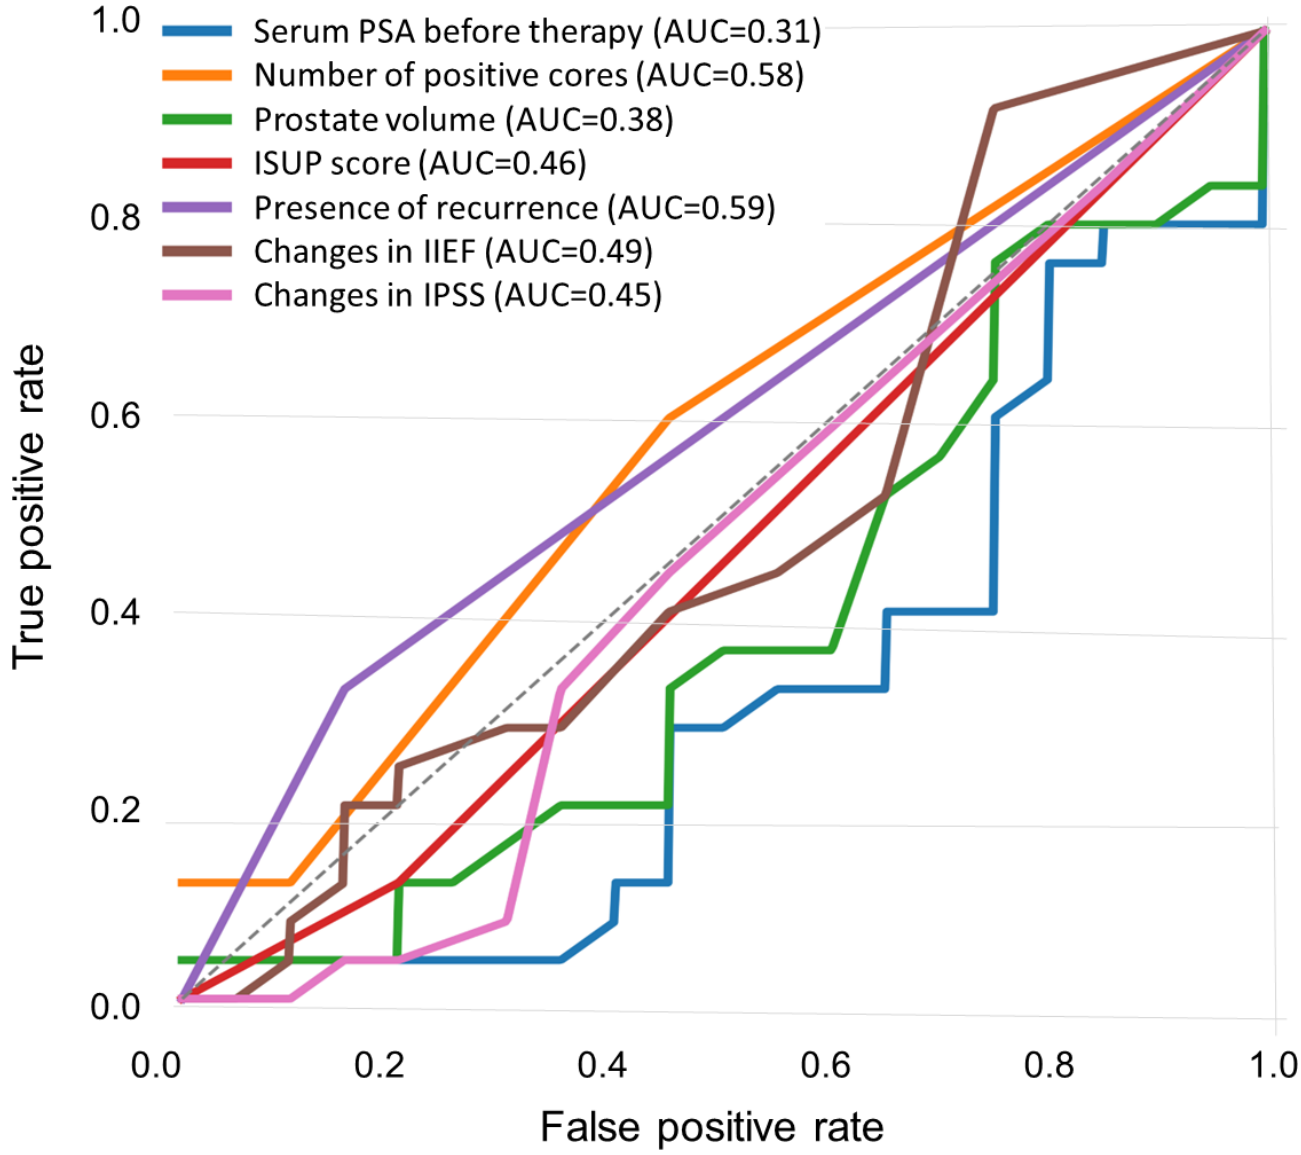
HADS-D—Anxiety

Mean anxiety scores remained below the threshold throughout, with no significant changes over time (FDR-adjusted *P*>.05). The proportion of patients within the nonpathological range increased slightly during follow-up (Figure 5; Table 3).

XSL•FO
RenderX

Figure 5. Hospital Anxiety and Depression Scale (HADS) anxiety scores over time.

An overview of all scale scores from both the functional and symptom domains of the EORTC QLQ-C30, as well as HADS values, including all baseline-referenced *P* values, is presented in Table 3.



Exploratory subgroup analyses comparing patients with and without histologically confirmed recurrence at 12 months revealed no statistically significant differences in any EORTC QLQ-C30 domain or HADS subscale (all *P*>.05). No clinically relevant differences in anxiety or depression scores were observed between the groups.

Exploratory ROC Analysis of Predictors of 12-Month Global Quality of Life

To further explore the discriminatory ability of selected clinical and functional parameters for 12-month global HRQoL, univariate ROC curve analyses were performed using dichotomized EORTC QLQ-C30 global health scores at 12 months. Overall, discriminatory performance was low across all variables. The highest AUC values were observed for the presence of recurrence (AUC=0.59) and the number of positive biopsy cores (AUC=0.58), indicating only weak predictive ability. Serum prostate-specific antigen before therapy showed an AUC of 0.31, suggesting an inverse association with the outcome. Prostate volume (AUC=0.38), International Society of Urological Pathology score (AUC=0.46), changes in IIEF (International Index of Erectile Function, AUC=0.49), and changes in IPSS (International Prostate Symptom Score, AUC=0.45) also demonstrated poor discrimination. Overall, none of the analyzed parameters showed clinically meaningful predictive performance for 12-month global quality of life (Figure 6).

XSL•FO
RenderX

Figure 6. Receiver operating characteristic curves illustrating the discriminatory performance of clinical parameters for predicting European Organization for Research and Treatment of Cancer Quality of Life Questionnaire—Core 30 (EORTC QLQ-C30) scores at 12 months. Univariate models were constructed for prostate volume, serum prostate-specific antigen (PSA), number of positive cores, International Society of Urological Pathology (ISUP) score, presence of recurrence, changes in IPSS (International Prostate Symptom Score), and changes in IIEF (International Index of Erectile Function). The dashed diagonal line indicates no discriminative ability (AUC=0.5). AUC: area under the curve.

Comparisons of the Individual Dimensions With the General Population

The present analysis compares EORTC QLQ-C30 scores of the study cohort with normative data from healthy male populations. Reference values were obtained from the German general population dataset published by Schwarz and Hinz [42] and from the Norwegian normative dataset reported by Hjermstad et al [43], the latter lacking SD values. Both datasets were originally generated as part of the EORTC validation program to assess the reliability and validity of the QLQ-C30. In the following figures, the study cohort is contrasted with these reference populations (Figure 7; Figure 8; Figure 9). Differences between the cohort and the German normative sample were examined using independent 2-sided *t* tests. To distinguish statistical differences from clinically meaningful differences, the interpretation framework proposed by Osoba et al [44] was applied, defining changes of 5 to 10 points as small, 10 to 20 points as moderate, and >20 points as large clinical differences.

Global Health Status and Quality of Life

After 1 month, patients reported significantly lower global health compared with the German reference population (P=.01), corresponding to a clinically moderate difference according to the Osoba classification. At 6 months, scores exceeded normative values (P=.02), although the magnitude of the difference remained clinically small. No clinically relevant deviation was present at 12 months (Figure 7; Table 4).

XSL•FO
RenderX

Figure 7. Global health status of the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire—Core 30 (EORTC QLQ-C30) in comparison with the German male normative population. The asterisk (*) indicates values that differ significantly.

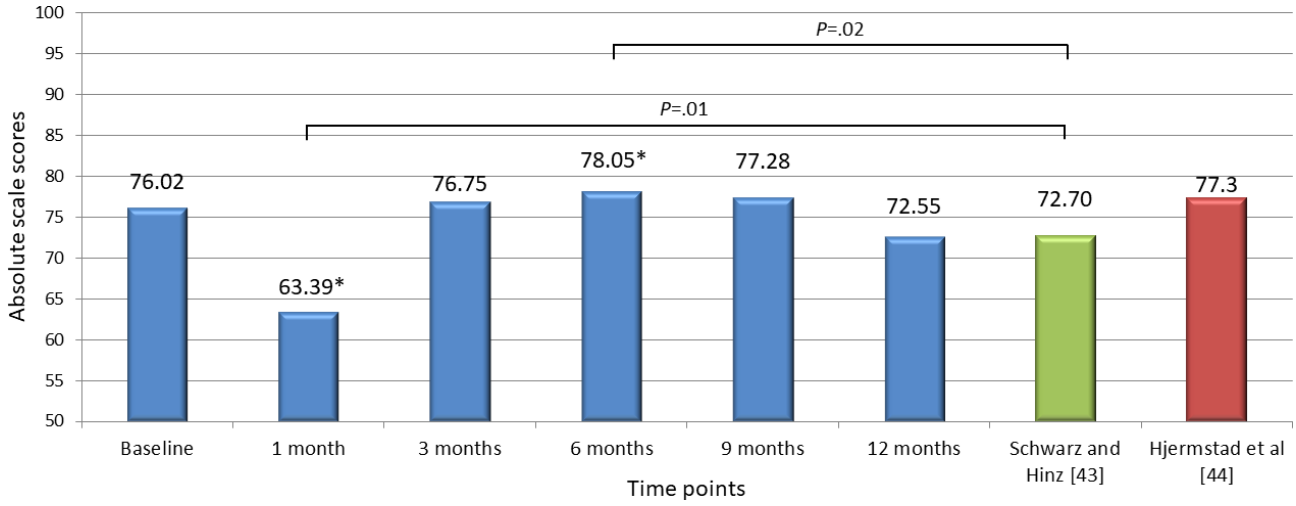


Table . Overview of functional and symptom scales showing clinical significance according to the Osoba criteria at each assessment time point.

Scale and time point	Scale score of the patient cohort	Reference group score	Difference between groups	Clinical relevance
Baseline				
Pain	5.15	13.0	7.85	Low
1 month				
Global health status	63.39	72.7	9.31	Low

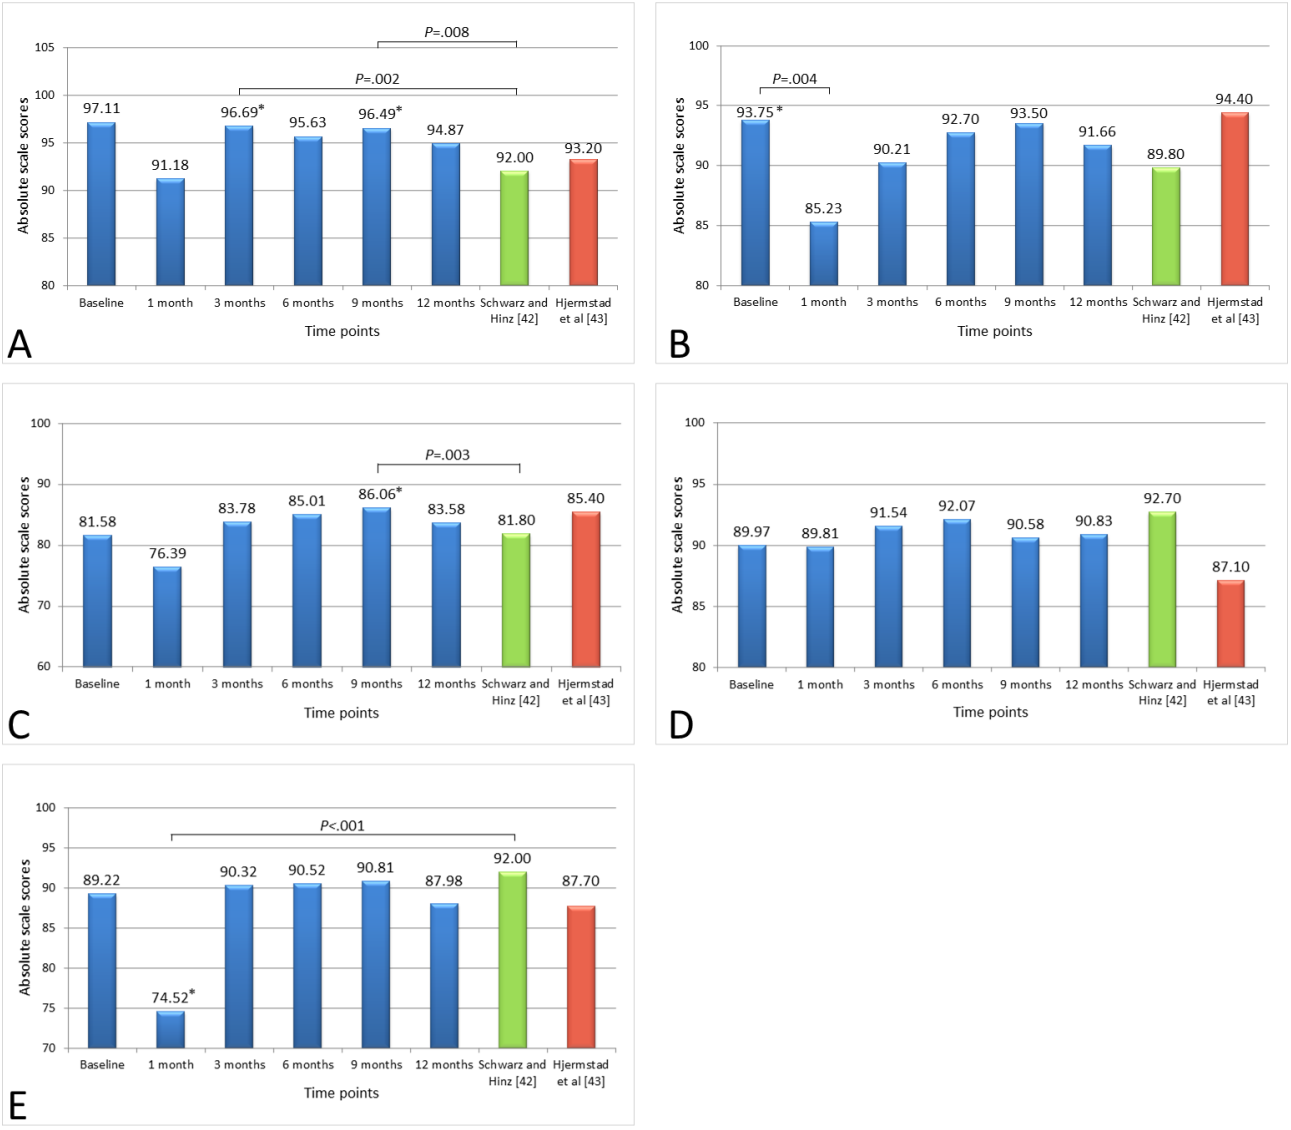
Functional Subscales



Physical, Role, Emotional, Cognitive, and Social Functioning

Physical functioning differed significantly from normative values at 3, 6, and 9 months (all FDR-adjusted P=.002, P=.03, P=.008, respectively); however, all differences remained below the threshold for clinical relevance. A small, clinically relevant advantage of the study cohort was observed at baseline. Role functioning showed a significant decline at 1 month (P=.04), while no difference from baseline was observed at 3 months, and values subsequently remained comparable to the normative population across all assessments with no significant differences. Emotional functioning showed a statistically significant improvement at 9 months compared with population data (P=.03) but the difference was clinically negligible. Cognitive functioning showed no deviations from reference values at any time point.

XSL•FO
RenderX

Social functioning demonstrated the most pronounced deviation. At 1 month, a moderate clinical deterioration of 15 points relative to the normative population was observed (*P*<.001). From 3 months onward, scores normalized completely (Figure 8; Table 4).

Figure 8. Functional scales of the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire—Core 30 (EORTC QLQ-C30): physical (A), role (B), emotional (C), cognitive (D), and social functioning (E) in comparison with the German male normative population. The asterisk (*) indicates values that differ significantly.

Symptom Scales—General Symptoms and Problem Burden

Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea, and Financial Difficulties

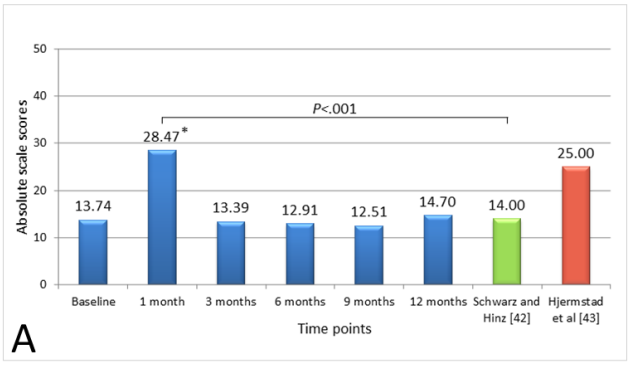
Baseline symptom burden was low across all domains compared with the German normative population. At 1 month posttreatment, fatigue increased significantly (items 10, 12, and 18; *P*<.001), corresponding to a clinically moderate deterioration (mean difference of 14 points, from 14 to 28, SD 23). Fatigue scores returned to baseline by 3 months and remained stable thereafter.

Nausea and vomiting (items 14 and 15) differed significantly from normative values at 3 and 9 months in favor of the study cohort (*P*=.004 and *P*=.03, respectively); however, absolute symptom levels remained negligible and were not clinically meaningful (maximum mean score of 2.08, SD 9.1). Pain (items 9 and 19) was significantly lower in the study cohort at baseline and 3 months compared with normative data (*P*=.002 and *P*=.31, respectively), corresponding to small-to-moderate clinical effects.

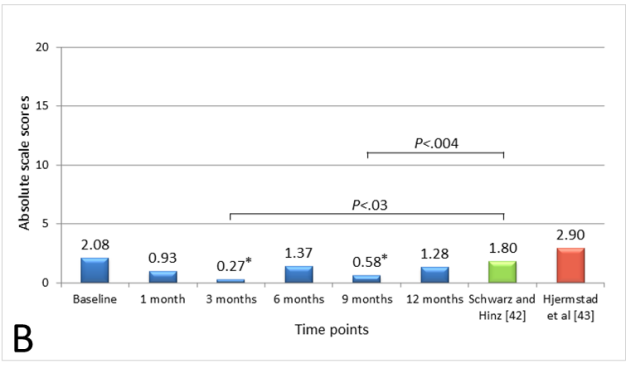
No significant differences were observed for dyspnea at any time point (all *P*>.05), with all deviations falling below clinical relevance thresholds. Insomnia (item 11) demonstrated a clinically moderate short-term deterioration at 1 month (mean difference of 17, SD 32 points; FDR-adjusted *P*=.005), which fully resolved by month 3.

Appetite loss (item 13) differed significantly from normative values only at 3 months (*P*=.002), but the magnitude of the difference was clinically negligible (<5 points). Constipation (item 16) was significantly elevated at 1 and 12 months

XSL•FO
RenderX



(FDR-adjusted P=.01 and P=.048), representing the only symptom with persistent clinically relevant impairment. Diarrhea (item 17) increased at 9 months (P=.02), with small but clinically meaningful differences.



No differences were detected for financial difficulties (item 28). Overall, symptom trajectories were characterized by transient early postoperative worsening—most notably for fatigue and insomnia—followed by recovery by month 3 across most domains. Persistent morbidity was limited to constipation, supporting a favorable tolerability profile of focal HIFU therapy (Figure 9; Table 4).

Discussion

Summary of Main Findings

This study evaluated psychological distress and HRQoL in patients undergoing focal HIFU hemiablation for localized PCa over a 12-month follow-up period. The primary objective was to characterize the temporal evolution of patient-reported outcomes from baseline through long-term follow-up. Overall, focal therapy was associated with low levels of psychological distress and preserved HRQoL. A statistically significant but transient decline in HRQoL and selected symptom domains was observed at 1 month, followed by recovery to baseline levels by 3 months. At 12 months, no clinically relevant impairments persisted. Depression scores showed a temporary increase without exceeding clinical thresholds, while anxiety levels remained stable throughout follow-up.

Contextualization

Across all psychological instruments and subscales, focal therapy demonstrated a favorable profile with respect to quality-of-life preservation. Mean scores consistently indicated a low overall psychological burden, with most patients reporting minimal or no impairment. Notably, no statistically significant differences were observed between baseline and 12-month values in any psychological domain, supporting the assumption that focal therapy is associated with stable long-term psychosocial outcomes [48,49].

The transient decline in HRQoL and psychological well-being observed at 1 month is most likely attributable to procedure-related factors, including peri-interventional stress, temporary functional impairment, and recovery from treatment. By 3 months, baseline values were restored and remained stable thereafter. Application of Osoba criteria suggests that clinically meaningful deterioration was largely confined to the early postoperative phase. Similar transient deteriorations have been described following focal ablative therapies and are attributed to perioperative stressors, including hospitalization, anesthesia, and temporary functional impairment [49]. Recent longitudinal studies using PCa-specific outcome measures (eg, IPSS, IIEF-5, EPIC [Expanded Prostate Cancer Index Composite]) similarly demonstrate a transient decline in urinary and sexual function at 1 month following focal HIFU, with recovery to baseline levels from 3 months onward, supporting the functional safety of this approach [50]. Overall, the early postoperative symptom increase appears primarily related to procedural stress rather than oncological anxiety.

Functional and oncological outcomes of the underlying HEMI study have been reported in detail elsewhere [38]. In brief, focal HIFU hemiablation was associated with preserved urinary continence and largely maintained erectile function, with no increase in incontinence rates and potency retained in the majority of preoperatively potent patients. These findings provide important clinical context for the present analysis and support the interpretation of preserved quality-of-life outcomes.

Comparison with normative population data revealed significant deviations primarily at the early postoperative time point, whereas later assessments showed convergence with population-based reference values. This pattern indicates that focal therapy does not result in sustained impairment relative to the general population. Similar recovery trajectories have been reported in previous studies of focal HIFU and other focal treatment modalities [51-53].

Psychological outcomes in this cohort were characterized by low baseline distress and stable trajectories over time. The predominance of patients with early-stage PCa may partly account for the low prevalence of clinically relevant psychological impairment. The temporary increase in depressive symptoms likely reflects a situational stress response rather than a persistent affective disorder. Importantly, no clinically relevant anxiety or depression was observed throughout follow-up. These findings are consistent with previous reports demonstrating that anxiety and depressive symptoms in patients undergoing focal therapy remain close to population norms and are associated with low levels of psychological burden and decision regret [49,54].

When compared with other established treatment modalities for localized PCa, these findings further support the favorable quality-of-life profile of focal therapy. RP and RT have been consistently associated with higher rates of urinary incontinence and sexual dysfunction, which are key determinants of long-term HRQoL [4-7,37]. In contrast, AS is generally associated with preserved functional outcomes but may be accompanied by an increased psychological burden due to ongoing uncertainty regarding disease progression. In this context, focal HIFU may represent a balanced approach, combining the low psychological burden observed in AS with the benefits of active oncological treatment while maintaining favorable functional outcomes.

Exploratory analyses did not demonstrate an association between short-term oncological outcomes and patient-reported quality of life or psychological distress. No statistically significant or clinically relevant differences in EORTC QLQ-C30 domains or HADS scores were observed between patients with and without histologically confirmed recurrence at 12 months. These findings suggest that short-term oncological outcomes, including the presence of residual or recurrent disease, did not translate into measurable impairments in HRQoL or increased psychological burden within the observation period. This may be explained by the low overall tumor burden and favorable disease characteristics of the study population, as well as structured follow-up and patient counseling within the study setting.

However, these results should be interpreted with caution. The number of recurrence events was limited, and the study was not powered to detect subtle subgroup differences. In addition, the relatively short follow-up period may not capture delayed psychological effects related to oncological uncertainty or disease progression.

Additional factors may include patient selection and individual coping mechanisms. Patients with localized, low-risk disease generally exhibit a lower baseline psychological burden than those with advanced cancer. Furthermore, the active decision to undergo focal therapy may enhance perceived control and facilitate psychological adaptation.

XSL•FO
RenderX

The deliberate decision to undergo focal HIFU may represent an additional psychological factor influencing patient-reported outcomes. By selecting a minimally invasive, organ-preserving treatment approach, patients may experience a greater sense of control and involvement in their care. Such perceptions have been associated with reduced feelings of helplessness and improved psychological adjustment. In this context, previously reported low levels of decision regret following focal therapy further support this interpretation [54].

Conclusion and Clinical Implications

Focal HIFU hemiablation is associated with preserved psychological well-being and sustained HRQoL in patients with localized PCa. Although transient postoperative distress may occur, recovery is rapid, and long-term outcomes remain comparable to population norms.

Taken together, these findings suggest that psychological stabilization following focal therapy is achievable in the context of preserved coping capacity and patient empowerment. Both confrontation with the diagnosis and postinterventional adjustment appear manageable within this treatment framework, supporting focal therapy as a patient-centered approach that balances disease control with quality-of-life preservation.

From a clinical perspective, routine psycho-oncological follow-up may be most relevant for vulnerable subgroups, whereas broader interventions may not be necessary in psychologically stable patients. Future research should focus on extended longitudinal follow-up, the use of standardized patient-reported outcome measures, integration of systematic psycho-oncological screening, identification of vulnerability profiles, and the parallel assessment of oncological and psychological endpoints.

Limitations

Several limitations should be considered. The predominance of patients eligible for AS reflects historical indications for focal therapy at the time of study initiation (2013 - 2016) and may limit the applicability of the findings to contemporary patient populations with clinically significant disease. Since study initiation, indications for focal therapy have evolved toward carefully selected patients with clinically significant localized disease, including favorable intermediate-risk PCa. At the same time, the use of a low-risk, AS-eligible population allowed for an isolated assessment of treatment-related quality-of-life outcomes with minimal confounding by advanced disease burden and contributed to the early evidence base supporting the broader application of focal therapy. Detailed data on the number of screened patients and reasons for nonparticipation were not systematically recorded due to the study design and shared decision-making process.

First, the sample size was relatively small (N=54), and attrition over the 12-month follow-up reduced statistical power, particularly for subgroup analyses and small effect sizes. The exclusion of patients due to protocol-defined dropouts, including competing health events and incomplete follow-up, may introduce a potential risk of selection bias in the longitudinal analyses. In addition, the highly selected study cohort limits generalizability to the broader PCa population.

Second, patient recruitment occurred between 2013 and 2016, and subsequent advances in imaging, biopsy techniques, and treatment guidelines (eg, European Association of Urology, 2024) may limit direct applicability to contemporary clinical practice. Third, the study lacked a randomized control group, relying instead on external normative reference populations, which restricts causal inference and increases susceptibility to unmeasured confounding.

Fourth, although validated instruments were used, patient-reported outcomes are inherently subjective and may be influenced by response and recall bias. In addition, the use of mailed questionnaires may have introduced additional selection bias. Fifth, clinical relevance was interpreted using the Osoba classification, which was originally developed in breast and lung cancer populations, and its applicability to PCa remains uncertain.

Finally, despite the use of mpMRI and targeted biopsies, focal hemiablation carries a risk of undertreatment due to unrecognized multifocal disease. Detailed oncological outcomes were not assessed, and follow-up was limited to 12 months, precluding the evaluation of late functional or psychological effects.

Acknowledgments

The authors would like to express their sincere gratitude to their colleagues and collaborators for their invaluable support and contributions throughout this study. Their expertise and dedication have been essential in advancing this research. The authors also extend their thanks to the University Hospital Leipzig for providing the opportunity and resources to conduct this study. Their commitment to fostering a collaborative research environment has been instrumental in the success of this work.

The authors declare that generative artificial intelligence (GAI) tools were not used for conceptualization, literature review, study design, methodology development, software development, data management, data analysis, ethics review, or supervision.

GAI (ChatGPT 5.3) was used solely for language-related support during the preparation of the manuscript, including refinement, correction, editing, and formatting to improve clarity and readability. This usage was comparable to that of spell-checking and grammar-checking tools.

All intellectual content, study design, data analysis, interpretation of results, and primary manuscript writing were performed independently by the authors. The authors take full responsibility for the content of the manuscript. Responsibility for the final manuscript lies entirely with the authors.

Abstract

Background: Postprostatectomy incontinence (PPI) is a common complication after robot-assisted radical prostatectomy and significantly impairs patients' quality of life. Although behavioral interventions such as pelvic floor muscle training and bladder diaries are evidence-based, their effectiveness is often limited by poor adherence and lack of personalization.

Objective: This study aimed to develop and evaluate a reinforcement learning (RL)–driven clinical behavioral intervention-supporting system (CBISs) for adaptive, personalized rehabilitation in patients with PPI.

Methods: The study comprised 2 sequential stages. First, the CBISs was developed through (1) construction of a medical record database from a prospective cohort of PPI patients using standardized 3-day bladder diaries, (2) design of functional modules and user interfaces based on clinical rehabilitation needs, and (3) development of an RL model using XGBoost (extreme gradient boosting) and Bayesian optimization to generate individualized training plans. Second, a separate cohort of 16 patients participated in a single-arm, pre-post pilot study to evaluate feasibility and preliminary outcome trends over a 3-month intervention period, with assessments based on bladder diary parameters and system usage metrics.

Results: The CBISs successfully implemented an adaptive, closed-loop behavioral rehabilitation framework that dynamically tailored training recommendations according to individual voiding patterns, fluid intake behaviors, and adherence signals. Feasibility outcomes were favorable, with high system engagement observed throughout the intervention (mean usage frequency 5.2, SD 1.1 times per day). In exploratory pre-post analyses (n=16), consistent directional improvements were observed across multiple outcomes. Mean daytime urinary frequency decreased from 5.74 (SD 1.21) episodes per day to 4.69 (SD 1.08) episodes per day, while median nighttime urinary frequency declined from 1.8 (IQR 1.6-2.2) episodes per night to 1.0 (IQR 1.0-1.6) episodes per night. Median incontinence episodes were reduced from 7.0 (IQR 6.0-11.0) episodes per day to 4.0 (IQR 2.0-6.0) episodes per day. Objective urine leakage measured by the 1-hour pad test decreased from a median of 8.5 (IQR 4.0-19.0) g to 3.5 (IQR 2.0-9.0) g. Patient-reported symptom burden, assessed using the International Consultation on Incontinence Questionnaire–Short Form (ICIQ-UI SF), showed a median reduction from 14.0 (IQR 12.0-20.0) points to 9.0 (IQR 6.0-16.0) points. Although several within-participant changes were statistically detectable, effect magnitudes varied across individuals. Given the single-arm design, small sample size, and lack of a control group, findings are presented as exploratory and hypothesis-generating rather than confirmatory of clinical efficacy.

Conclusions: The CBISs represents the first RL-powered digital therapeutic system for PPI, enabling adaptive, evidence-based behavioral optimization. By addressing limitations of static rehabilitation protocols and declining adherence, it offers a scalable approach for personalized PPI management. Future multicenter trials are needed to confirm its clinical effectiveness.

Introduction

Prostate cancer (PCa) is one of the most prevalent malignant tumors in men and currently represents the second leading cause of cancer-related mortality worldwide [1]. It is estimated that by 2025, approximately 313,780 new cases of PCa will be diagnosed in the United States, accounting for 15.4% of all newly diagnosed cancers [2]. Over the past decade, robot-assisted radical prostatectomy has been increasingly recognized as a primary treatment for localized PCa [3]. Owing to the removal of the prostate, seminal vesicles, and surrounding tissues, as well as the reconstruction of the urinary tract during surgery, patients frequently experience varying degrees of postoperative bladder dysfunction. Among these complications, postprostatectomy incontinence (PPI) is the most common functional sequela, severely affecting patients' daily activities, sexual function, and overall quality of life (QoL) [4-6]. The reported incidence of PPI varies widely, ranging from approximately 4.2% to 87%, largely due to differences in definitions of urinary incontinence, follow-up duration, and assessment methodologies [7]. PPI symptoms typically persist for 3-12 months and, in some cases, may extend for up to 10 years, rendering urinary incontinence a major long-term concern during postoperative recovery [8,9]. Consequently, improving PPI and related QoL outcomes remains a central objective in the comprehensive management of survivors of PCa [10].

Behavioral therapies, including pelvic floor muscle training (PFMT), bladder retraining, urge suppression techniques, and lifestyle modification, constitute the cornerstone of conservative management for urinary incontinence. High-quality evidence from systematic reviews and meta-analyses, including Cochrane reviews, has consistently demonstrated that behavioral therapy–based interventions can reduce incontinence episodes and improve patient-reported QoL across diverse populations [11,12]. These interventions are widely recommended as first-line or adjunctive strategies in clinical practice, reflecting their favorable safety profiles and broad applicability. Nevertheless, the effectiveness of behavioral rehabilitation in real-world settings is frequently compromised by inadequate adherence, limited access to professional supervision, and insufficient patient understanding of correct training techniques.

Advancing from this foundation, digital therapeutics (DTx) have emerged as a promising modality for delivering structured rehabilitation programs remotely, thereby improving accessibility and continuity of care for patients following postprostatectomy. DTx are interventions delivered via digital platforms [13], which have the potential to mitigate the challenges posed by chronic diseases, such as enhancing patient adherence and improving patient self-management [14]. By enabling real-time monitoring, personalized feedback, and flexible scheduling, digital platforms may help address many of the practical limitations inherent in traditional rehabilitation models [15]. However, many existing digital interventions for urinary incontinence remain largely static, relying on predefined rules or uniform training protocols that do not adequately account for individual variability in symptoms, adherence patterns, or recovery trajectories.

In this context, reinforcement learning (RL) represents a promising methodological framework for advancing personalization within digital therapeutic systems. RL is a machine learning approach whereby intelligent agents iteratively optimize decision-making models through cycles of action, feedback, and strategy adjustment [16]. Unlike traditional supervised learning methods, RL is particularly well suited to sequential decision-making problems where the effects of an action may be delayed, outcomes are uncertain, and the optimal strategy depends on the evolving state of the individual. In digital health applications, RL has been used to personalize "just-in-time" interventions—for example, adapting the timing, content, or intensity of behavioral prompts—based on each patient's history, context, and response pattern, thereby improving engagement and clinical outcomes compared with static or rule-based approaches [17]. Moreover, RL models are capable of processing sparse or noisy reward signals arising from heterogeneous patient behaviors and complex intervention-response relationships, making them especially suitable for individualized rehabilitation scenarios [18]. Applying it to DTx may facilitate individualized patient rehabilitation training.

In this study, to address the need for personalized rehabilitation, a Clinical Behavioral Intervention-Supporting System (CBISs) was developed. Using RL, the CBISs provides adaptive, individualized training guidance to patients with urinary incontinence following robot-assisted radical prostatectomy, aiming to accelerate functional recovery and improve QoL through data-driven support.

Therefore, the objectives of this study were to develop and preliminarily evaluate an RL–based CBISs integrated into a digital therapeutic platform to provide individualized pelvic floor and behavioral training for men with PPI after robot-assisted radical prostatectomy. The study was designed to examine whether an RL-driven CBISs could (1) demonstrate feasibility and acceptability, with favorable trends in urinary continence recovery and patient-reported QoL; and (2) enhance adherence to and engagement with the prescribed training over time.

Methods

Overview

The study was structured in two sequential phases, (1) the development of the CBISs, and (2) a feasibility and preliminary efficacy pilot test of the CBISs conducted with a separate cohort of 16 patients. The development of the CBISs consisted of three

XSL•FO
RenderX

main stages, (1) construction of a clinical behavioral database, (2) design of system functionalities and user interfaces based on rehabilitation needs, and (3) development and integration of RL models to support individualized training.

Recruitment of Participants

All patients were recruited during the follow-up visit of the Outpatient Department of Urology at Sun Yat-sen Memorial Hospital, Sun Yat-sen University. Patients were eligible if they were aged 18-75 years, had a confirmed diagnosis of urinary incontinence following radical prostatectomy, and could accurately maintain a voiding diary (recording fluid intake, urination, and leakage). Exclusion criteria comprised serious neurological diseases, concurrent conditions such as urinary tract infection or bladder stones, significant voiding dysfunction, and an inability to comply with the study protocol. During the CBISs construction phase, we recruited a total of 150 patients to participate.

Database Construction

This section details the complete workflow for building the analytical database, including the statistical procedures and tests for data curation and feature engineering, which collectively form the essential foundation for the subsequent development of the prediction model. Bladder diaries were prospectively collected from patients diagnosed with PPI at the urology department of a tertiary care academic hospital. To ensure data robustness, a minimum diary period of 3 days was required based on International Continence Society standards for reliable symptom capture [19].

Sample size determination addressed two dimensions. At the patient level, sample size considerations focused on ensuring sufficient coverage of behavioral variability for model development rather than hypothesis testing. A cohort of 150 patients was deemed adequate to support feature engineering, model training, and internal validation while minimizing the risk of overfitting. At the behavioral event level, more than 10,000 voiding events were targeted to ensure model generalizability, accounting for expected intrapatient variability (mean, 8 voids per day per patient). Sample size considerations therefore accounted not only for the number of patients but also for the volume of behavioral data, with a 3-day behavioral log per patient ensuring minimum model generalizability. Ethical approval for the collection of data required for system construction was obtained from the Medical Ethics Committee of Sun Yat-sen Memorial Hospital, Sun Yat-sen University (approval number: SYSKY -2023-925-01). Data collection was conducted between March 2022 and December 2023.

Determination of Key Features and System Functionalities

The research team conducted a systematic literature review and held 2 rounds of expert meetings to develop a checklist for the rehabilitation needs of patients with PPI. Based on this, researchers and software engineers collaborated to define the functional module division and design the human–computer interaction interface. The CBISs comprises 3 portals: patient portal, a health care team portal, and an administrator portal. The patient portal contains 4 modules: rehabilitation training, bladder diary, incontinence care, and assessment tool. The health care team portal displays the patient's bladder diary details and training completion status.

Reinforcement Learning Model Construction

The research team developed the conceptual plan and proposed the functional requirements of the model; algorithm engineers then constructed and validated the training model, which was subsequently embedded into the CBISs to complete the design and development. Individualized rehabilitation training models for patients with PPI include urination training, fluid intake training, and PFMT. To realize these features, the algorithm engineers used a preconstructed database and performed feature screening and dimensionality reduction through an exhaustive feature engineering step.

Data Preprocessing and Quality Control

Prior to model training, all raw bladder diary records and behavioral logs underwent a structured preprocessing pipeline. Missing values in continuous variables (eg, voided volume and urination interval) were imputed using patient-level mean strategy, while discrete variables (eg, fluid type and urgency score) adopted mode imputation. Abnormal values were detected through IQR filtering and time-series consistency checks. All timestamps were normalized to standard 24-hour format, and temporal alignment of drinking and voiding events was ensured using sliding-window techniques with a 60-minute threshold. Records from patients with <80% diary completion rate or >20% anomalous entries were excluded from analysis to guarantee robust data quality and integrity.

Feature Selection and Model Training Strategy

From the initial 29 behavioral and physiological features, recursive feature elimination and XGBoost's (extreme gradient boosting's) intrinsic gain-based importance ranking were jointly applied to refine input dimensions. Highly collinear features (Pearson r>0.9) were removed to prevent multicollinearity. Model development was performed using a stratified 70/15/15 train/validation/test split, preserving the distribution of leakage severity and adherence levels. Bayesian optimization was used to fine-tune hyperparameters (eg, learning rate, max_depth, and subsample) with the goal of maximizing prediction accuracy and minimizing overfitting. Model performance was evaluated using a composite metric, including area under the receiver operating characteristic curve (AUC), F_1-score, and mean absolute error (MAE). A 5-fold cross-validation strategy was used during the training phase to ensure model generalizability and robustness.

Reinforcement Learning Framework and Deployment

The customized offline RL architecture is adopted in the CBISs to support adaptive behavioral rehabilitation while clinical safety is maintained. The RL component is designed to function as a decision-support layer rather than as an autonomous optimizer of clinical outcomes, reflecting the exploratory nature of this pilot study.

Clinical state representations are constructed from multiday behavioral snapshots encompassing key metrics such as PFMT adherence, voiding intervals, fluid intake ratios, and

XSL•FO
RenderX

patient-reported outcomes. These inputs closely correspond to the information typically evaluated by clinicians when adjusting rehabilitation strategies, thereby ensuring that the RL state definition remains clinically interpretable and grounded in routine practice.

At each decision point t, the system observes a behavioral state s_t and selects an action a_t from a predefined discrete action space. Actions correspond to clinically admissible behavioral interventions; for example, when a patient demonstrates stable adherence to the prescribed training program but reports repeated episodes of urinary leakage, the system may recommend a modest extension of PFMT duration (eg, +15 minutes) while maintaining the current training intensity. Subsequent adjustments to PFMT intensity are then guided by changes in the frequency of reported leakage, allowing the intervention to progress in a gradual and clinically responsive manner. All actions are constrained within predefined safety ranges to avoid abrupt or excessive changes.

Reward Function Formulation

The reward function is designed to reflect clinically meaningful behavioral changes rather than to directly optimize long-term clinical outcomes. At each decision point t, the reward r_t is computed as a weighted composite function:

where A_t represents short-term adherence to prescribed training tasks, C_t reflects task completion and user engagement, Δ_t captures the magnitude of abrupt behavioral changes between consecutive recommendations, and P_t denotes penalty terms applied when predefined safety thresholds are approached (eg, overly frequent voiding prompts or rapid escalation of training schedules). All components are normalized to bounded ranges prior to aggregation to ensure numerical stability and interpretability.

In practical clinical terms, this formulation supports gradual and responsive rehabilitation adjustments. For instance, when a patient reports an increase in urinary leakage episodes, the system may recommend extending PFMT duration by 15 minutes, representing a moderate increase in task demand. If the patient demonstrates high adherence and engagement following this adjustment and a subsequent reduction in leakage frequency is observed, penalty terms decrease and the revised training plan is maintained. Conversely, if task completion or engagement declines and leakage frequency fails to improve, penalty values increase, indicating that the adjustment may be poorly tolerated. In such cases, the system may revise the recommendation by reducing the training extension (eg, to an additional 5 minutes) and continue monitoring adherence, engagement, and leakage trends before further modification. This iterative process mirrors routine clinical reasoning, emphasizing tolerability, patient response, and safety rather than rigid optimization.

Q Value Estimation and Policy Learning

Based on the defined reward, action values are estimated using standard Q-learning principles. The Q value represents the expected cumulative future reward of selecting action a_t under state and is updated offline according to:

where α is the learning rate and γ is the discount factor. Q values are learned entirely from historical behavioral data using offline batch updates, without real-time exploration in patients.

Conceptually, Q values estimate how beneficial a specific behavioral adjustment is expected to be over time. Actions associated with higher Q values are more likely to be recommended, as they have historically led to stable adherence and acceptable behavioral patterns.

To handle variability in patient engagement and avoid overreliance on historical patterns, an ε-greedy action selection strategy is used. In most situations, the system selects the action with the highest estimated Q value; however, with a small probability ε, alternative actions are explored. In simple terms, the model usually follows what has worked best before, but occasionally tests other reasonable options to prevent overly rigid behavior, particularly for patients with inconsistent adherence.

System Usability and Technical Validation

Usability testing was conducted with a pilot group of 30 patients drawn from the database construction cohort, recruited from September to November 2023, who participated in a 4-week trial from December 2023 to January 2024. Task completion rates, interaction time, feedback scores, and daily user feedback during usage were systematically recorded. The mean training plan navigation time was 56 seconds (SD 12 seconds), with a >92% completion rate of daily bladder diaries. The CBISs demonstrated full functional compatibility with both Android (v8.0+) and iOS (v13+) platforms. Backend performance stress testing indicated stable response under 1000 concurrent users with <500 ms latency. The final release version underwent security penetration testing to ensure robustness against common cybersecurity threats, such as injection attacks, data breaches, and unauthorized data access attempts.

Integration of Human–Artificial Intelligence Shared Decision-Making

To reinforce clinical safety and ensure alignment with real-world care standards, a “human–artificial intelligence (AI) shared decision-making” mechanism is integrated into the CBISs. This module operates as a safety net for low-confidence or guideline-sensitive scenarios, complementing the core RL model.

Specifically, when the model generates a recommendation with low predictive certainty or when the patient presents high behavioral variability or complex comorbidities, the CBISs triggers clinician review. Health care professionals evaluate the suggestion in a semiautomated interface, which also displays relevant confidence scores and patient history snapshots.

In addition, a rule-based expert constraint layer is provided, allowing clinicians to embed patient-specific limitations such as contraindications, comorbidity exclusions, or institutional

XSL•FO
RenderX

guidelines (eg, American Urological Association 2024 and International Continence Society). All final behavior plans are generated through an iterative approval flow that synthesizes algorithmic output, patient feedback, and clinician judgment.

This human–AI collaboration mechanism improves accountability, enhances clinical trustworthiness, and ensures DTx remain aligned with evidence-based care pathways.

Pilot Test of Clinical Behavioral Intervention-Supporting System

This pilot study was designed as an exploratory, single-arm, self-controlled evaluation to assess feasibility, adherence, and outcome trends rather than to establish definitive clinical efficacy. A separate cohort of 16 patients with PPI was recruited, distinct from the 150 participants was enrolled in the database construction phase. Participant recruitment and CBISs implementation occurred between January 2024 to March 2024. Participants eligibility criteria were consistent with the formal research protocol. Patient age and time since surgery were recorded. Voiding characteristics, including timing, intervals, and nocturia episodes (both frequency and total volume) were systematically collected. Patient compliance was evaluated based on completion of prescribed CBISs diary entries, with actual usage frequency tracked as the adherence metric. All participants were enrolled to use only the CBISs for postoperative rehabilitation for 3 months.

Both baseline data collection and postintervention outcome assessment were conducted over 5-day periods, with the mean values of these 5-day measurements used as pre- and postintervention results for comparison. The following parameters were recorded: daily voided volume (mL), daily fluid intake (mL), daytime urinary frequency, nighttime urinary frequency, incontinence episodes, urine leakage measured by the 1-hour pad test (g), total score of the ICIQ-UI SF (range 0-21), daily occurrence of urinary urgency, sensation of incomplete bladder emptying, postvoid dribbling, and dysuria (recorded as present or absent).

For each participant, the mean preintervention value was calculated as the arithmetic average of the baseline observations (the first 5 days of recording), yielding the preintervention daily average. The mean postintervention value was derived similarly from the final 5 days of recording. For symptom data recorded as binary outcomes (present=1, absent=0), symptom frequencies were calculated as continuous variables. Preintervention symptom frequency was defined as (number of days the symptom was present during the 5-day baseline period) / 5 × 100%. Postintervention symptom frequency was defined as (number of days the symptom was present during the final 5-day intervention period) / 5 × 100%. For all measured parameters, the change score (Δ) for each participant was computed as: Δ = postintervention value – preintervention value.

All statistical analyses were conducted using R software (version 4.4.2; R Foundation for Statistical Computing). Given the exploratory nature of this pilot study, analyses were performed to describe within-participant change patterns and estimate effect magnitude rather than to test confirmatory hypotheses. A 2-tailed α level of .05 was adopted for descriptive purposes only.

The distribution of individual change scores (Δ) was assessed using the Shapiro-Wilk test. Paired-sample 2-tailed *t* tests or Wilcoxon signed-rank tests were applied as appropriate based on distributional assumptions. Binary symptom variables were converted to symptom frequency percentages and analyzed as continuous outcomes when normality assumptions were met.

Spearman rank correlation coefficient was used to explore associations between changes in selected outcomes. No adjustment for multiple comparisons was performed due to the pilot design and limited sample size, and statistical findings should be interpreted cautiously.

Ethical Considerations

Ethical approval for data collection required for system construction was obtained from the Medical Ethics Committee of Sun Yat-sen Memorial Hospital, Sun Yat-sen University (approval number: SYSKY-2023-925-01). All participants provided electronic informed consent approved by the Medical Ethics Committee (SYSKY-2023-925-01), explicitly detailing (1) bladder diary and behavioral data collection for RL model training to generate personalized recommendations, (2) anonymized data use for system-wide model improvement, (3) right to withdraw data or consent at any time without impact on care, (4) potential implications of AI-driven personalization (eg, adaptive vs static guidance). Consent forms used plain language with examples and were available in Chinese and English.

To mitigate bias from incomplete or anomalous data, preprocessing excluded records with <80% diary completion or >20% anomalies (IQR filtering and time-series checks). Stratified sampling (70/15/15 train/validation/test) preserved leakage severity and adherence distributions. Model fairness was monitored through subgroup performance (age and time since surgery) during 5-fold cross-validation, with clinician override for low-confidence predictions ensuring equity.

For data security, uploaded records were protected using ShangMi 3 (SM3; a cryptographic hash algorithm for integrity verification) and ShangMi 4 (SM4; a symmetric block encryption algorithm for secure data storage and transmission), in accordance with national cryptographic standards. Data handling adhered to China's Personal Information Protection Law and the General Data Protection Regulation–equivalent standards for health data. Health care professionals accessed aggregated views through the CBISs using an authorization key. Additionally, patient-side interfaces integrated real-time alerts for suspicious login attempts or data anomalies, ensuring prompt intervention and maintaining data integrity and patient privacy.

Results

Demographic and Disease-Related Characteristics of Participants

In the first phase of this study, a total of 150 participants were included who provided data for system development, model construction, and demographic characterization. From this

XSL•FO
RenderX

cohort, a subset of 30 additional participants was selected to participate in the focused usability testing phase of CBISs.

The full modeling cohort (N=150) had an age range of 43-82 years, with a mean age of 54.32 (SD 7.51) years. Participants included in the usability testing subsample (n=30) showed a comparable age distribution, ranging from 43-81 (mean 53.70, SD 7.30) years.

Regarding educational attainment, the modeling cohort was predominantly composed of 46 (30.67%) individuals with junior high school education, followed by 35 (23.33%) participants with vocational school education, 28 (18.67%) individuals with undergraduate education, 22 (14.67%) with senior high school education, 12 (8.00%) with primary school education, 6 (4.00%) with postgraduate education, and 1 (0.67%) with no formal education.

In the usability testing subsample, junior high school education was the most prevalent, reported by 13 (43.33%) participants, followed by junior college education with 6 (20%) participants. Senior high school and primary school education were each represented by 4 (13.33%) participants, while vocational school education accounted for 2 (6.67%) participants, and undergraduate education for 1 (3.33%) participants. No participants reported postgraduate education or no formal schooling.

With respect to physical characteristics, the mean BMI of the modeling cohort was 23.44 (SD 3.11) kg/m^2. The usability testing subsample demonstrated a similar BMI distribution, with a mean value of 24.01 (SD 3.18) kg/m^2. Overall, participants included in the usability testing phase were broadly comparable to the full modeling cohort in terms of age and BMI, while exhibiting modest differences in educational composition.

In the pilot test of CBISs, participants used the CBISs an average of 5.2 (SD 1.1) times per day. A total of 11 (68.75%) participants met or exceeded the preset usage target, while 5 (31.25%) participants fell below the target, with a minimum usage of 3 times per day. This indicates generally high engagement with the system during the intervention period. All participants, being older adults, ranged in age from 61-74 years and had a mean age of 67.6 (SD 4.3) years. Among them, 11 (68.75%) participants were within 1-3 months after PCa surgery, and 5 (31.25%) participants were within 3-6 months postoperatively.

The Model of Clinical Behavioral Intervention-Supporting System: Feature Engineering

Based on the patient bladder diary and behavioral monitoring data, a total of 29 features in 6 categories were constructed in this study (Table 1), with the feature construction methods detailed in Table 2. Following data cleaning, the dataset was partitioned via stratified sampling. Model construction was performed based on XGBoost, incorporating Bayesian optimization for model and parameter tuning.

XSL•FO
RenderX

Table 1. Patient data collection form for clinical behavioral intervention-supporting system (CIBSs).

Data category	Instruction
Basic information	
Gender	Discrete variables (male/female)
Age	Continuous variable (years)
BMI	Continuous variable (kg/m^2); associated with symptom typing, behavioral competence, and training intensity appropriateness
Time of onset	Continuous variable; determines symptom chronicity
Urinary flow rate parameter (Q_{max})	Continuous variable; identifies storage, voiding disorders, or bladder hypo-compliance, etc
Urinary flow rate parameter (Q_{ave})	Continuous variable
Residual urine volume test records	Continuous variable
Urinary behavior	
Time of urination	Continuous variable (min); establishment of a 24-hour urinary rhythm
Urinary output	Continuous variable (mL); partially collected automatically by portable urine flow rate instrumentation
Urinary flow rate	Continuous variable (mL/min); automatically collected by portable urinary flow rate instruments
Urination interval	Continuous variable (min); imputed from voiding time difference
Nocturnal urination	Continuous variable (times/mL); includes nocturnal urine frequency and volume
Urinary urgency event	Continuous variable (grade); graded 0-5, subjectively scored by the patient
Symptoms associated with urination	Discrete variables, for example, presence of “urine odor,” “slow urine flow,” “painful urination,” “burning sensation,” “divergent urinary stream,” “feeling of not emptying,” “dribbling after urination,” and so on
Drinking behavior	
Drinking time	Continuous variable (specific time); establish temporal linkage with urination time
Drinking volume	Continuous variable (mL)
Drinking type	Discrete type variable, for example, water, tea, coffee, functional drinks, etc
Daily activity and sleep behavior	
Activity intensity (steps and body movement)	Continuous variable (steps/kcal); from wearable device or mobile health app
Activity period	Discrete variable (daytime/nighttime);
Sleeping time/number of night arousals	Continuous variable (min/times); basis for determining the rhythm between nocturia and nighttime arousal
Specialty scales and subjective scoring data	
Overactive Bladder Syndrome Score	Continuous variable; quantitative grading of symptoms to identify overactive bladder
International Prostate Symptom Score	Continuous variable; determination of symptom severity during storage/voiding phase
International Consultative Committee on Incontinence Questionnaire Short Form	Continuous variable; incontinence symptoms and quality of life implications
Self-assessment Scale for Anxiety and Depression	Continuous variable; assess anxiety and depressive states
Pittsburgh Sleep Quality Index–Sleep Quality Score	Continuous variable; determine the extent to which nocturia affects sleep
System interaction and training feedback data	
Record of training completion	Whether bladder training, water intake program, relaxation training, pelvic floor muscle training, etc, are completed as planned
Patient feedback score	Daily record of perceived efficacy, difficulty, and compliance
Abnormal events	Such as symptom exacerbation or incomplete training prompts

Table 2. Feature engineering methodology for clinical behavioral intervention-supporting system (CIBSs).

Feature category and name	Source data items	Construction method	Clinical significance
Temporal features[a]			
Daytime mean voiding interval	Urination time, day/night encoding	Mean time difference between voids during 9 AM to 9 PM	Evaluates bladder storage stability
Nocturnal polyuria ratio	Nocturnal urine volume, 24-hour total volume	∑ (nocturnal urine volume) / ∑ (24-hour urine volume) × 100%	Core diagnostic indicator for nocturnal polyuria
Urgency event frequency	Urgency event markers	Voids with urgency (7 days) / total voids (7 days)	Quantifies overactive bladder severity
Ratio features[b]			
Nocturia-arousal association index	Nocturnal voids, sleep interruptions	(Voided volume) / (voided volume + postvoid residual) × 100%	Differentiates pure nocturia from sleep disorders
Effective voiding rate	Voided volume, postvoid residual	Nocturia episodes / sleep interruptions	Reflects bladder emptying efficiency
Irritant beverage intake ratio	Fluid type, intake volume	Coffee + tea intake (mL) / total intake (mL) × 100%	Assesses bladder irritant exposure
Time-period features[c]			
Workday-weekend voiding pattern difference	Voiding time, date type	Mean weekend voiding interval − mean workday voiding interval	Detects stress-related voiding behavior changes
Postexercise urgency marker	Activity period, urgency markers	Binary indicator: urgency within 30 minutes after vigorous exercise	Identifies exercise-induced urgency
Contextual features[d]			
Fluid-void temporal association index	Intake time, voiding time	Voids within 60 minutes post intake / total voids	Evaluates bladder hypersensitivity
PFMT[e] adherence decay rate	Exercise logs, time	Adherence rate (last 3 days) / adherence rate (week 1)	Quantifies decline in behavioral intervention compliance

[b]Used for reflecting structural relationships.

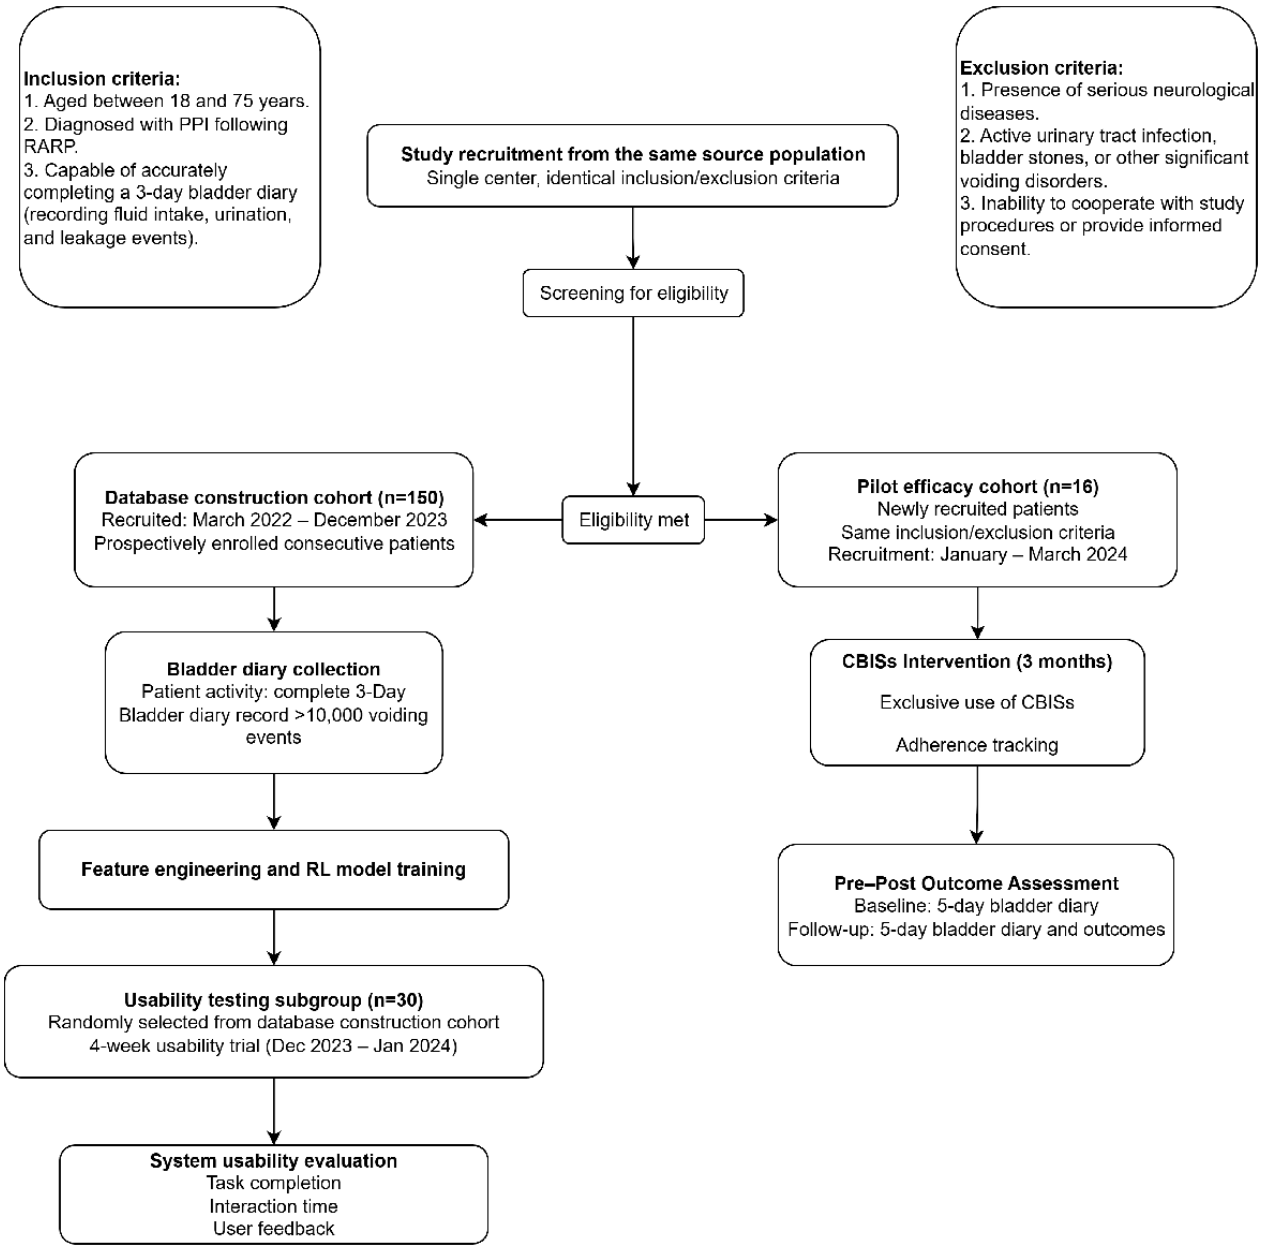
[c]Used for behavioral pattern recognition.

[d]Describes behavioral markers triggered by specific conditions.

[e]PFMT: pelvic floor muscle training.

Model Training and Validation

The preconstructed database was used to support feature matching and behavioral pattern recognition, which informed the generation of personalized training recommendations. The RL component subsequently updated these recommendations over time based on patient interaction and behavioral feedback, completing the adaptive model construction process (Figure 1).



In the current implementation, the RL framework did not incorporate explicit clinical outcome measures (eg, reduction in leakage episodes or symptom score improvement) as direct reward signals. Instead, reward signals were defined using conservative, behavior-centered proxy indicators, including task completion, adherence stability over time, and avoidance of abrupt behavioral changes potentially associated with symptom aggravation. This design choice was intentionally adopted to ensure clinical safety and model stability in this exploratory pilot setting, where outcome responses are delayed, heterogeneous, and not suitable for short-horizon optimization.

Clinical outcome measures were therefore reserved exclusively for post hoc exploratory evaluation rather than real-time reward optimization. Model evaluation metrics (eg, AUC, F_1-score, and MAE) were used internally during development and tuning to support system calibration but were not reported as final performance outcomes, as this study was not designed as a standalone predictive model validation.

XSL•FO
RenderX

Rather than optimizing a single mathematically fixed reward function, the RL component operated within a clinician-supervised decision-support framework, integrating multiple behavior-related feedback signals under predefined safety constraints. Accordingly, the RL module was designed to support adaptive behavioral guidance within a clinically supervised system rather than to function as an autonomous predictive model intended for direct performance benchmarking.

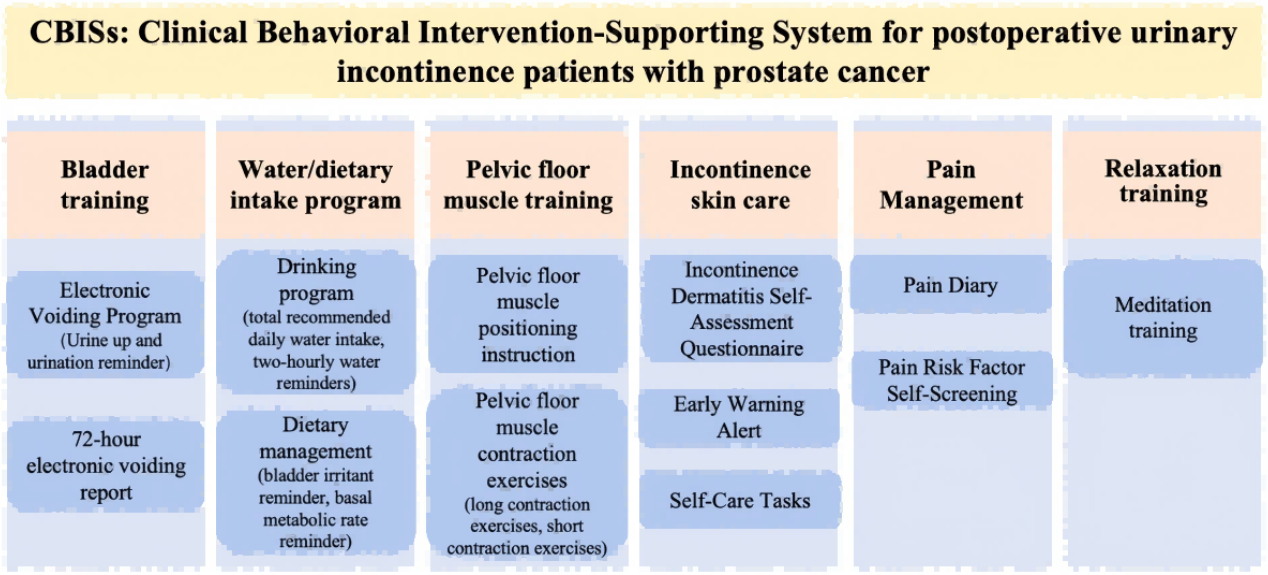
The Clinical Behavioral Intervention-Supporting System Mobile App

Overview

Based on the literature review and research team meetings, the main functional modules of the CBISs were identified (Figure 1). The CBISs provide patients with personalized voiding schedules, dietary and fluid intake plans, and pelvic floor muscle contraction training to enhance bladder function. A distinctive feature of the CBISs is its consideration of skin-related symptoms potentially caused by incontinence, offering patients guidance on incontinence-related nursing interventions, that is, the incontinence skin care function. Based on their evaluation of perineal skin condition and severity, the CBISs recommends tasks such as daily cleansing, application of skin-protective dressings, and use of incontinence products. The health care team and administrator portals also receive early warning notifications regarding the occurrence of incontinence dermatitis in patients.

Key Features and Capabilities



The functional sections of the app and its user interface were identified. The app has 2 interfaces: the home page and the personal center. The home page is divided into 4 sections:

XSL•FO
RenderX

"Training Sections," "Bladder Diary," "Assessment Tools," and "Incontinence Care." The "Personal Center" page provides the user's basic information, contact options for doctors or nurses, and counseling services (Figure 2). Users are required to register an account upon first login and can access the app after using their account number and password. Patients can access the training program after registering their behavioral logs for 3 days.

In the training section, the app provides training programs based on the aforementioned RL models. The initial training program is based on the raw data provided by the patient, and the training content specifically includes voiding interval time, drinking time schedules, rising urine training (bladder capacity training), and pelvic floor muscle contraction and relaxation training. Patient's data are regularly evaluated to assess rehabilitation progress and adjust the training program accordingly. The learning model iteratively adjusts the program, while the health care team may also adjust the program manually. The "Contact Doctor/Nurse" module offers patients support and training guidance throughout the course of their illness to ensure that they maintain good habits after discharge (Figure 3).

Figure 2. Key functional modules of clinical behavioral intervention-supporting system (CBISs).

XSL•FO
RenderX

Figure 3. Clinical behavioral intervention-supporting system (CBISs) user interface. (A) Initial app screen—outpatient; (B) initial app screen—inpatient (patient clinical and demographic characteristics); (C) personal homepage (top to bottom: patient overview—Illness severity, demographics, disease details, and responsible medical personnel; records and support—health and user records, alongside user assistance; rehabilitation log—tracks rehabilitation activities and outcomes; service purchase—handles the acquisition of additional services); (D) bladder ultrasound monitoring; (E) urinary pad test; and (F) questionnaire entry screen.

Safety and Feasibility

Regarding digital confidentiality, patients upload data by completing their own records as well as using wearable devices. Because the data are time series in nature, the app assigns timestamps to each data point and incorporates preprocessing interfaces to filter missing values and outliers. The study follows SM3 and SM4 encryption algorithms for desensitized and encrypted storage of data, alongside hierarchical management of data permissions, facilitating separate review processes for health care professionals and patients. Data privacy complies with the Personal Information Protection Act.

Pilot Evaluation of Clinical Behavioral Intervention-Supporting System Feasibility and Outcome Trends

Participants used the CBISs an average of 5.2 (SD 1.1) times per day. Following implementation of the CBISs-guided bladder function training program, directional changes were observed across multiple bladder diary parameters, incontinence-related outcomes, and patient-reported symptom measures (Tables 3 and 4). Given the exploratory nature of this pilot study and the limited sample size, results are presented to describe change patterns rather than to support confirmatory inference.

Mean voided volume increased from 984.6 (SD 132.7) mL at baseline to 1128.4 (SD 148.2) mL post intervention. Fluid intake also increased over the intervention period, suggesting changes in hydration and voiding behaviors consistent with the individualized training guidance delivered by the system.

Daytime urinary frequency showed a reduction from 5.74 (SD 1.21) episodes per day to 4.69 (SD 1.08) episodes per day. Nighttime urinary frequency similarly declined, with median values decreasing from 1.8 (IQR 1.6-2.2) episodes per night to 1.0 (IQR 1.0-1.6) episodes per night. Total urinary frequency demonstrated a comparable downward trend over the intervention period, reflecting changes in urinary storage and voiding patterns.

Incontinence episodes declined from a median of 7.0 (IQR 6.0-11.0) episodes per day at baseline to 4.0 (IQR 2.0-6.0) episodes per day after the intervention. Pad test measurements indicated lower postintervention urine leakage values compared with baseline, with a shift toward milder leakage severity categories observed among participants. Specifically, the number of patients classified as having severe or greater leakage decreased, while the number of patients classified as having mild leakage increased.

Patient-reported outcomes showed parallel trends. ICIQ-UI SF scores were lower after the intervention compared with baseline, indicating a reduction in perceived symptom burden. Exploratory correlation analysis suggested alignment between changes in patient-reported symptom scores and reductions in objective urine leakage measures; however, these associations should be interpreted cautiously given the small sample size and exploratory design.

The proportion of patients reporting urinary urgency and sensation of incomplete bladder emptying was lower following the intervention period. Dysuria incidence also declined, whereas changes in postvoid dribbling were less pronounced and more variable across individuals.

Effect size estimates were calculated to describe the magnitude of observed changes across outcomes. Several parameters demonstrated moderate to large effect size values; however, these estimates are provided for descriptive and hypothesis-generating purposes only and should not be interpreted as evidence of definitive clinical benefit in the absence of a concurrent control group.

Overall, the pilot results indicate that the CBISs can be feasibly implemented in postprostatectomy patients and is associated with consistent directional changes across multiple objective and subjective outcome domains. No causal conclusions regarding clinical efficacy can be drawn from this exploratory analysis.

Table 3. Exploratory changes in bladder diary parameters before and after the clinical behavioral intervention-supporting system (CBISs)–guided training program. Statistical comparisons are exploratory and intended to describe within-participant change patterns rather than to support confirmatory inference. Effect sizes are reported for descriptive purposes only.

Variable	Preintervention, mean (SD)	Postintervention, mean (SD)	Mean difference, 95% CI	2-tailed *t* test (*df*)	*P* value	Cohen *d*
Voided volume (mL)	984.6 (132.7)	1128.4 (148.2)	143.8 (69.2 to 218.4)	4.32 (15)	<.001	1.08
Fluid intake (mL)	1246.8 (181.4)	1428.2 (198.6)	181.4 (95.6 to 267.2)	5.12 (15)	<.001	1.28

Discussion

Overview

The pilot study provided preliminary evidence of improvements in urinary control and patient-reported symptoms, with the CBISs simulating professional supervision by dynamically adjusting behavioral prescriptions based on adherence patterns, symptom trajectories, and real-time data. Pilot results indicated enhanced urinary control and improved subjective symptom experiences among patients with PPI.

PPI etiology remains incompletely understood, with risk factors including age, BMI, prostate size, oncologic and surgical factors, and shorter membranous urethral length [20-23]. Despite refined surgical techniques and preoperative precautions, PPI persists, severely impacting QoL, finances, and psychology. Conservative treatment—lifestyle modifications, bladder diaries, and PFMT—is first-line for mild PPI, yet a significant implementation gap exists due to poor adherence influenced by fatigue, transportation, time constraints [24-27], inadequate PFMT technique comprehension, and lower cognitive ability [28]. Supervised rehabilitation outperforms unsupervised approaches [29,30].

Traditional in-person care faces geographical, resource, and adherence limitations. Digital health interventions extend support beyond clinics [31]. This study developed CBISs, which collects multidimensional data (diet, urination, activities, adherence, and perceived severity) to generate individualized RL-driven recommendations through XGBoost with rule-engine integration, continuously optimizing through cross-validation while preventing overfitting.

Several digital therapeutic approaches for PPI have been reported, including cognitive-behavioral therapy–based telehealth interventions for urinary incontinence control and QoL [31,32], mobile health apps combining bladder diary logging with PFMT prompts [33], perioperative telehealth programs with remote monitoring calls [28], WeChat-based health education and extended care services [34,35], social media platforms for patient education and community support [36], and proactive digital health interventions aimed at symptom reduction [37]. These platforms primarily focus on delivering educational content, standardized exercise instructions, symptom tracking, and periodic feedback through telehealth communication, messaging apps, or social media engagement. While such approaches improve accessibility and patient awareness, their rehabilitation protocols are generally static, relying on rule-based prompts, fixed schedules, or clinician-mediated adjustments. Consequently, they have limited capacity to adapt training intensity, content, or timing in response to individual patient trajectories, fluctuating adherence, or delayed and heterogeneous treatment responses.

In contrast, the CBISs introduces an RL–driven, closed-loop behavioral intervention framework that emphasizes continuous personalization rather than predefined content delivery, consistent with recent applications of RL in noncommunicable disease management and personalized medicine [38,39]. By iteratively integrating multidimensional patient data—including voiding behaviors, fluid intake patterns, and training adherence—the CBISs dynamically adjusts rehabilitation guidance in response to individual progress and engagement over time. This adaptive design is particularly suited to behavioral rehabilitation contexts, where patient responses evolve gradually and vary substantially across individuals, representing a key limitation of conventional static or rule-based digital platforms.

From a usability and scalability perspective, the CBISs is designed to translate complex behavioral information into actionable, individualized recommendations while reducing reliance on continuous clinician involvement. Clinicians primarily function as supervisors supported by automated monitoring and alert mechanisms, which may help mitigate workforce constraints in real-world clinical settings. Although this pilot study was not designed to establish definitive efficacy, the observed favorable trends in urinary symptom–related outcomes suggest that RL-driven adaptability may help address common challenges of existing digital rehabilitation approaches, including declining adherence and variable response patterns.

Collectively, these features distinguish the CBISs from existing digital therapeutic platforms by shifting the focus from content-centered delivery to behavior-centered, data-driven optimization. This paradigm more closely reflects the dynamic nature of rehabilitation processes and provides a plausible

XSL•FO
RenderX

pathway for improving long-term engagement and personalization in PPI management.

Several limitations warrant consideration. First, transparency and interpretability remain inherent challenges of machine learning–based systems. Although clinician oversight was incorporated into the CBISs workflow, the "black box" nature of RL algorithms necessitates ongoing monitoring to ensure the clinical appropriateness and reliability of generated recommendations. For example, the model may recommend aggressive voiding interval reductions (±15 min) for patients with irregular adherence decay without clearly explaining feature interactions (eg, fluid intake influencing urgency events). In pilot testing, 3 of 16 (18.8%) cases triggered low-confidence alerts routed to clinician override due to unexplained Q value shifts during nocturia spikes, highlighting the need for explainable AI techniques like Shapley additive explanations analysis in future iterations. CBISs relies on patient-reported bladder diaries and potential wearable integration, introducing variability from self-reporting inaccuracies (eg, underreported leakage) or device nonuse (12% dropout in usability testing). Participation may have induced Hawthorne effects, with improvements potentially attributable to heightened attention from research involvement rather than CBISs alone. Additionally, while pilot (n=16) and modeling (n=150) cohorts shared consistent inclusion and exclusion criteria, all participants were motivated outpatients from routine clinical settings, potentially overrepresenting compliant, tech-savvy patients and limiting generalizability to broader PPI populations with lower motivation or compliance challenges. In addition, the system processes large volumes of sensitive patient-level data, underscoring the importance of robust data security, privacy protection, and governance mechanisms for real-world implementation.

The pilot evaluation used a prospective self-controlled pre-post design, which is appropriate for early-stage investigation of interventions requiring high patient engagement and ethical sensitivity. By using patients as their own controls, this design reduced interindividual variability and improved statistical efficiency under small-sample conditions, supporting preliminary exploration of feasibility and potential effect sizes. The concurrent use of objective measures (pad test) and validated patient-reported outcomes (ICIQ-UI SF) further strengthened result interpretation.

Nevertheless, the absence of a concurrent control group limits causal inference, and the observed changes may be partially attributable to nonspecific factors such as time effects, repeated measurement, or expectancy-related bias. The relatively short follow-up period also precludes assessment of long-term effectiveness, sustainability of behavioral change, and delayed adverse effects.

Future studies incorporating appropriate control groups, blinded outcome assessment, and extended follow-up are warranted to establish the definitive clinical value of this intervention. In addition, future work will explore the integration of validated and delayed clinical outcome signals into the RL framework once sufficient longitudinal and controlled trial data become available.

Future studies with complete longitudinal labeling and independent test cohorts will enable formal reporting of model performance metrics such as AUC, F_1-score, and MAE. The lack of a fully formalized mathematical reward function reflects an intentional design choice in this exploratory phase and will be addressed in future work when sufficient validated outcome data become available. Comparative evaluation against simpler baseline models was beyond the scope of this feasibility-focused study and will be addressed in future controlled investigations.

Conclusions

This study describes the development and preliminary evaluation of a behavioral therapy–based CBISs designed to support personalized rehabilitation for PPI. By integrating multidimensional patient data—including voiding behaviors, fluid intake patterns, PFMT adherence, and patient-reported outcomes—the CBISs applies an RL framework to deliver adaptive, individualized behavioral guidance beyond static information delivery.

Rather than replacing clinician decision-making, the CBISs functions as a digital extension of guideline-based care, with the potential to enhance continuity, personalization, and accessibility of rehabilitation support outside traditional clinical settings. The findings from this early-stage study suggest feasibility and favorable trends, supporting further investigation of this approach.

Future multicenter randomized controlled trials are warranted to address several key research questions including whether (1) RL-driven personalization improves continence recovery, QoL, and adherence compared with standard or nonpersonalized digital rehabilitation; (2) observed benefits are sustained over longer follow-up periods; (3) the system performs across diverse patient populations, clinical environments, and levels of baseline motivation; and (4) adaptive, closed-loop interventions confer incremental value over conventional rule-based digital platforms. Addressing these questions will be essential for defining the clinical effectiveness, generalizability, and implementation potential of the CBISs.

As DTx continue to evolve, systems such as the CBISs may offer a scalable pathway toward precision rehabilitation, supporting individualized recovery trajectories for patients navigating functional challenges following prostate cancer surgery.

Abstract

Background: In recent years, the global incidence of thyroid cancer has been increasing.

Objective: This study aimed to examine the association between Hashimoto thyroiditis (HT) and papillary thyroid cancer (PTC) progression under active surveillance (AS).

Methods: Our retrospective study was conducted at Peking University Third Hospital and included 203 patients with PTC who underwent AS for ≥6 months before surgery. Patients were first categorized into 2 groups: the HT group (n=90) and the non-HT group (n=113). Cox proportional hazards models were then used to evaluate the association between HT and PTC progression during AS, adjusting for age, sex, baseline tumor size, BMI, pregnancy status, number of tumor foci, and thyroid-stimulating hormone level. Subgroup analyses stratified by the 6 covariates mentioned above were also applied to explore the potential effect modification.

Results: No significant difference was observed between the HT and non-HT groups in PTC progression-free survival (hazard ratio [HR] 1.11, 95% CI 0.61 - 1.99; *P*=.74), tumor enlargement-free survival (HR 1.02, 95% CI 0.56 - 1.86; *P*=.95), or lymph node metastasis-free survival (HR 1.76, 95% CI 0.31 - 10.12; *P*=.52). Subgroup analyses revealed a potential interaction between HT and BMI. Among patients who were overweight or obese (BMI >24 kg/m^2), HT was significantly associated with an increased risk of disease progression (HR 6.32, 95% CI 1.84 - 21.69; *P*=.003), while among patients with BMI ≤24 kg/m^2, no association between HT and progression risk was observed (*P*=.01).

Conclusions: We found no evidence of association between HT and PTC progression during AS. However, the relationship between HT and PTC progression may be modified by overweight or obesity status.

Introduction

Thyroid cancer is not only the most common malignant tumor of the head and neck but also the most prevalent endocrine malignancy. In recent years, the global incidence of thyroid cancer has been steadily increasing. Between 1990 and 2020, the number of newly diagnosed cases worldwide rose from 95,000 to 586,000 [1-3]. In China, the age-standardized incidence rate increased from 3.21 per 100,000 in 2005 to 24.64 per 100,000 in 2022 [4,5]. Clinically, papillary thyroid cancer (PTC) is the most frequently encountered, representing approximately 80% of all thyroid cancer cases worldwide [6].

As understanding of PTC has evolved, active surveillance (AS) has been increasingly adopted by Japan and Korea as part of a comprehensive management approach for low-risk PTC [7,8]. The US and Chinese guidelines also consider AS an acceptable treatment approach [9,10]. AS is an emerging management strategy that offers a more conservative alternative to immediate

XSL•FO
RenderX

surgery [9]. It involves active monitoring of the patient's condition without initiating surgical treatment unless there is evidence of tumor progression [11]. Active monitoring primarily refers to performing neck ultrasound every 6 months for the first 1 to 2 years, followed by annual examinations. Despite growing interest in AS for low-risk PTC, there is still no clear consensus on which patients should undergo immediate surgery and which are appropriate candidates for AS.

Hashimoto thyroiditis (HT) is an autoimmune disorder characterized by immune-mediated destruction of thyroid cells through both cellular and humoral mechanisms [12]. The incidence of HT has been increasing steadily over the years, and its coexistence with PTC is relatively common [13-15]. Some studies have suggested that HT may be a risk factor for the development of PTC, while others have indicated that HT could be a protective factor against postoperative recurrence of PTC [13,14,16].

Nevertheless, the vast majority of existing research has focused solely on the postoperative recurrence, overlooking the increasingly prevalent management strategy of AS in recent years. Currently, there is limited evidence on the association between HT and PTC progression during AS. Importantly, the risk factors for postoperative recurrence and those for disease progression under AS may differ substantially [9,17]. Identifying the risk factors for tumor progression during AS is crucial for selecting appropriate candidates, helping to avoid both undertreatment and overtreatment [9]. Moreover, patients with HT tend to be younger and more likely to be female compared to those without HT [14]; both sex and age have been independently associated with disease progression [18,19]. Therefore, it is essential to investigate the role of HT in PTC progression while carefully accounting for potential confounders.

Two reviews have investigated the role of HT in PTC progression [3,13]; however, they have several notable limitations:

1. Lack of stringent inclusion and exclusion criteria: most of the included studies focused on patients who underwent surgery, providing limited insight into the role of HT during AS.
2. Failure to account for confounding factors: key confounders such as sex and age were not adequately considered. For example, the observed association between HT and favorable prognosis in some studies may be attributed to the higher proportion of female patients in the HT group.
3. Unclear definition of outcome measures: these reviews did not clearly distinguish between the role of HT in tumor progression during AS and its effect on recurrence after surgery. This distinction is important, as the extent of surgery may differ for patients with HT and may itself act as a confounding factor in recurrence outcomes.
4. Lack of quantitative synthesis: one of the reviews did not include a quantitative meta-analysis, limiting the ability to draw robust conclusions [3].

Therefore, we investigated the relationship between HT and progression-free survival of PTC under AS—including tumor enlargement and lymph node metastasis (LNM)—while controlling for multiple potential confounding factors.

Methods

Ethical Considerations

The study was approved by the Medical Ethics Committee of Peking University Third Hospital (ethical project number: IRB00006761-M2022721). The requirement for informed consent was waived by the Ethics Committee due to the retrospective nature of the study. All patient data were deidentified and anonymized prior to analysis to ensure the privacy of individuals.

Study Population

The Electronic Medical Record system of Peking University Third Hospital was searched to retrieve cases of thyroid surgery with a subsequent diagnosis of PTC, covering the period from January 2012 to September 2022.

The AS strategy was routinely implemented at our institution beginning in 2015. Since then, all patients diagnosed with low-risk PTC have been introduced to the AS option during outpatient consultations. Following comprehensive counseling by clinicians regarding the risks associated with thyroid surgery, the potential need for thyroid hormone replacement therapy, and the possibility of disease progression during AS, patients make their decision based on individual circumstances—such as pregnancy plans and overall health status—on whether to pursue AS. Patients independently decided whether to undergo AS at our center.

Based on previous studies [20-23] and domain knowledge, the inclusion criteria for the study population were as follows: (1) patients with a pathological diagnosis of PTC in surgical paraffin-embedded specimens; this criterion was feasible because the specimen acquisition method is consistently documented in all pathology reports; (2) patients who underwent at least two thyroid ultrasound examinations prior to surgery at our center; and (3) patients who underwent ≥6 months of preoperative surveillance; (4) patients without surgical contraindications. Patients who presented with LNM or extrathyroidal extension (ETE) at baseline were excluded, as AS is generally not recommended for individuals with evidence of metastasis. For patients with multifocal PTC, only the lesion with the largest mean tumor diameter was considered for analysis [24]. Ultimately, based on the presence or absence of HT, the study population was divided into the HT group and the non-HT group.

Following relevant guidelines and previous studies [14,25], the criteria for diagnosing HT were defined as meeting at least one of the following conditions: (1) pathological evidence of HT in the peritumoral thyroid tissue on the postoperative pathology report or (2) thyroid function test results within 30 days before surgery showing thyroglobulin antibody ≥60 U/mL or ≥4.5 IU/mL, or thyroid peroxidase antibody ≥60 U/mL or ≥34 IU/mL.

Progression During Surveillance

The primary outcome of this study was progression-free survival, defined as the time from baseline to the progression

XSL•FO
RenderX

of PTC. Tumor progression was determined based on either of the following criteria [26] : (1) tumor enlargement, defined as an increase of ≥3 mm in any tumor diameter or (2) newly detected LNM during surveillance. In cases of suspected progression, original pathological, ultrasonographic, and surgical records were independently reviewed by senior clinicians and investigators to ensure accurate determination of disease progression.

Data Extraction

All authors involved in data entry for this study received standardized and targeted training to ensure consistency and comparability of the collected data. The demographic characteristics, imaging examinations, laboratory results, and pathological data extracted from the Electronic Medical Record system were entered and consolidated using Epidata software. To minimize subjective bias during data extraction, patient information was anonymized. Quality control was implemented at multiple stages. Initial and midterm audits were independently conducted by investigators: for each data entry personnel, 20 records were randomly selected and cross-checked against the original source documents to verify accuracy. After data entry was completed, a final spot-check review was performed by a senior physician to ensure the overall accuracy and reliability of the dataset. Data filtering was implemented in R (R Core Team) language according to the predetermined enrollment criteria.

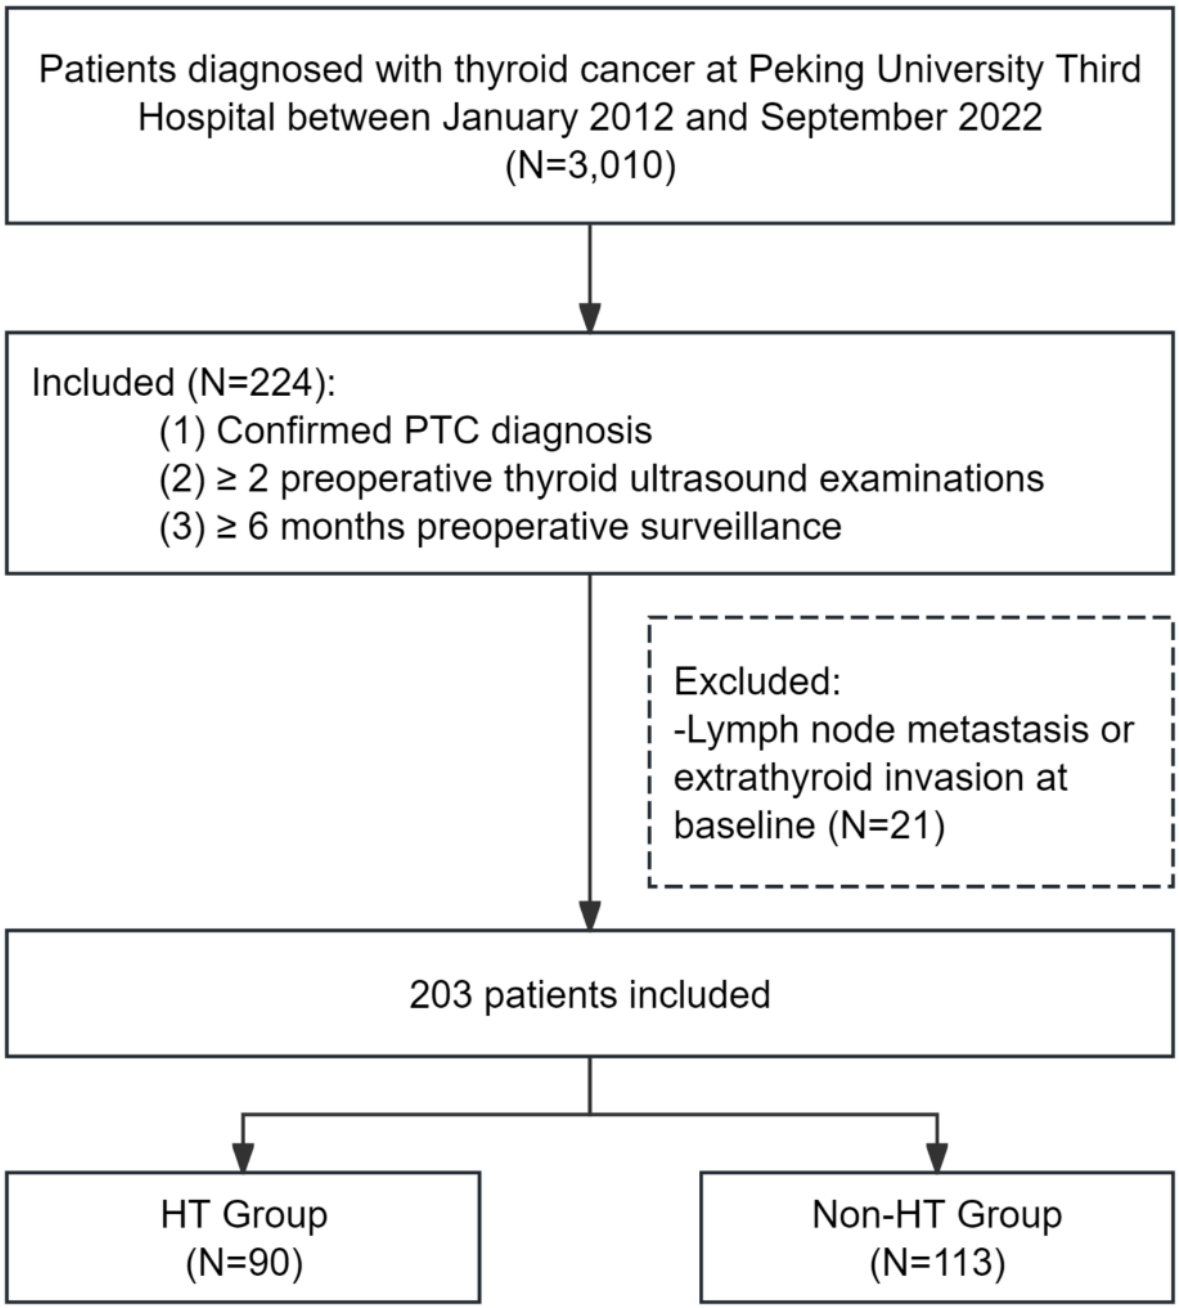
Statistical Analyses

First, we compared baseline characteristics between the HT group and the non-HT group. For categorical variables, frequencies and percentages were reported, and differences between groups were assessed using the Pearson chi-square test or the Fisher exact test when the expected cell count was ≤5. For continuous variables, normality was tested using the Shapiro-Wilk test. Since the data did not follow a normal distribution, group differences were analyzed using the Mann-Whitney *U* test.

Next, to examine the association between HT and progression-free survival, we first tested the proportional hazards assumption using Schoenfeld residuals. We then constructed a multivariable Cox proportional hazards regression model, adjusting for potential confounders, including age, sex, baseline maximal tumor diameter, BMI, pregnancy status, number of tumor foci, and thyroid-stimulating hormone (TSH) level [27,28]. To visually illustrate the survival differences between the HT and non-HT groups, adjusted Kaplan-Meier PTC progression-free survival curves were plotted.

Further subgroup analyses were conducted based on median age (≥36 or <36 y), median TSH level (>1.72 or ≤1.72 µIU/mL), sex (male or female), baseline tumor size (the maximum diameter >1 or ≤1 cm), number of tumor foci (single or multiple), BMI (>24.0 or ≤24.0 kg/m^2), and pregnancy status (pregnant or not). We evaluated the modifying effects of these variables on the association between HT and progression-free survival using interaction terms (subgroup variable × HT/non-HT group) within the Cox regression model. In the subgroup analyses, covariates other than the stratifying variable were adjusted for accordingly. For example, when stratifying by sex, adjustments were made for age, TSH level, baseline tumor size, number of tumor foci, BMI, and pregnancy status. Similarly, when stratifying by age, adjustments were made for sex, TSH level, baseline tumor size, number of tumor foci, BMI, and pregnancy status.

All statistical analyses were performed using R software (version 4.4.3; R Foundation for Statistical Computing). A 2-sided *P* value of <.05 was considered statistically significant.



Results

Characteristics of the Study Population

A total of 203 patients with PTC under AS were included in the study. The median age was 36 (IQR 30-42) years, and 187 (92%) patients were female. The median preoperative surveillance duration was 1.45 (IQR 0.89-2.60) years. Patients were categorized into the HT group (n=90) and the non-HT group (n=113). The study flow diagram is presented in Figure 1, and the baseline characteristics of both groups are summarized in Table 1. Significant differences in age and sex were observed between the 2 groups (both *P*<.001). Table 2 shows the progression status of the study population.

[d]Fisher exact test.

Association Between HT and Progression-Free Survival

The Schoenfeld residuals test indicated that our data met the proportional hazards assumption (*P*>.05). During the surveillance period, 63 (31.0%) patients experienced progression, with 30 (33.3%) patients in the HT group and 33 (29.2%) patients in the non-HT group. Among the 63 patients who progressed, 6 experienced both tumor enlargement and LNM, 54 had tumor enlargement only, and 3 had LNM only.

In the multivariable Cox regression analysis, after adjusting for age, sex, and baseline mean tumor diameter, no significant difference in PTC progression-free survival was observed between the HT and non-HT groups (hazard ratio [HR] 1.11, 95% CI 0.61 - 1.99; *P*=.74). Similarly, no significant differences were found in tumor enlargement-free survival (HR 1.02, 95% CI 0.56 - 1.86; *P*=.95) or LNM-free survival (HR 1.76, 95% CI 0.31 - 10.12; *P*=.52; Table 3).

The Kaplan-Meier curves for PTC progression-free survival revealed that the survival curves of the HT and non-HT groups were nearly identical, indicating no significant difference between the 2 groups (Figure 2).

XSL•FO

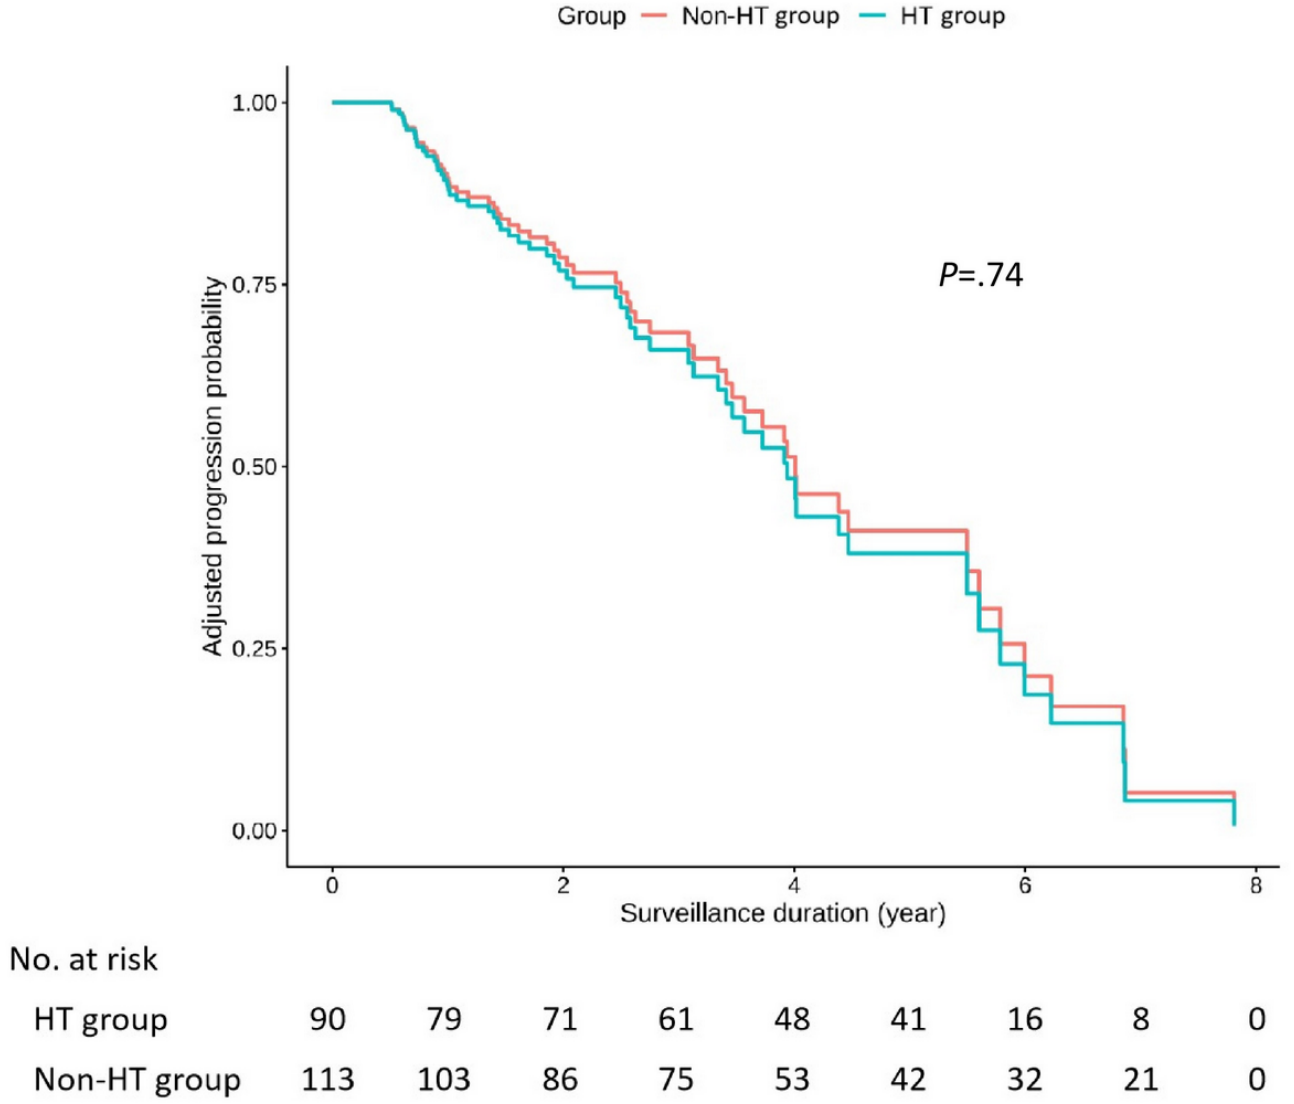
Table . Association between HT[a] and progression-free survival.

Outcomes	HR[b, c] (95% CI)	*P* value
PTC[d] progression	1.11 (0.61-1.99)	.74
Tumor enlargement	1.02 (0.56-1.86)	.95
Lymph node metastasis	1.76 (0.31-10.12)	.52



[a]HT: Hashimoto thyroiditis.

[b]HR: hazard ratio.

[c]Adjust for age, sex, baseline maximal tumor diameter, BMI, pregnancy status, number of tumor foci, and thyroid-stimulating hormone level.

[d]PTC: papillary thyroid carcinoma.

Figure 2. Kaplan-Meier papillary thyroid carcinoma progression-free survival curves. Adjust for age, sex, baseline maximal tumor diameter, BMI, pregnancy status, number of tumor foci, and thyroid-stimulating hormone level. HT: Hashimoto thyroiditis.

Sensitivity Analyses

In the sensitivity analyses, no significant difference in PTC progression-free survival was observed between the HT and non-HT groups (HR 1.23, 95% CI 0.60 - 2.53; *P*=.58). Similarly, no significant differences were found in tumor enlargement–free survival (HR 1.08, 95% CI 0.51 - 2.28; *P*=.84) or LNM-free survival (HR 2.44, 95% CI 0.23 - 25.23; *P*=.46). The findings from the sensitivity analyses were consistent with those of the primary analyses, suggesting the robustness of the results.

Subgroup Analyses

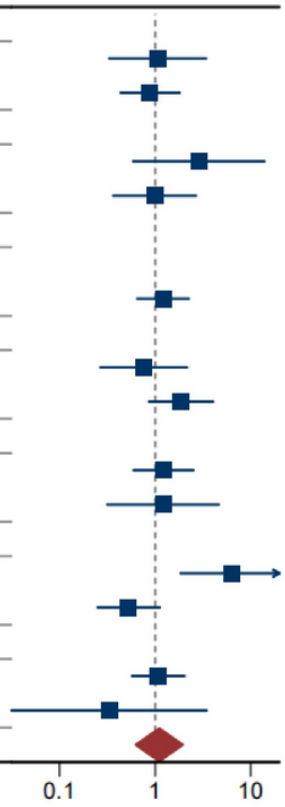


Figure 3 shows the forest plot of subgroup analyses. There was no significant difference in the association between HT and progression-free survival across subgroups classified by median age (36 y), median TSH level (1.72 µIU/mL), sex, baseline tumor size (the maximum diameter >1 or ≤1 cm), number of

XSL•FO
RenderX

tumor foci, or pregnancy status ($P_{interaction}$>.05). Notably, we found a potential interaction between HT and BMI ($P_{interaction}$<.01). Among patients who were overweight or obese (BMI >24 kg/m^2), HT was associated with a significantly higher risk of progression (HR 6.32, 95% CI 1.84 - 21.69; *P*=.003). In contrast, no association between HT and progression risk was observed in patients with BMI ≤24 kg/m^2 (*P*=.10).

Figure 3. Subgroup analysis of the association between Hashimoto thyroiditis (HT) and progression-free survival. TSH levels were missing in 93 patients during the observation period. In the male subgroup, only 1 patient had HT, and no progression was observed in this case; therefore, an estimate could not be provided. TSH: thyroid-stimulating hormone.

Discussion

Summary of the Findings

Over a median surveillance period of 1.45 years, our analysis demonstrated no significant association between HT and PTC progression under AS. This finding was consistent for both tumor enlargement and LNM. The results remained consistent in the sensitivity analysis. In the subgroup analyses, no significant association between HT and progression-free survival was found across strata defined by age, TSH level, sex, baseline tumor size, number of tumor foci, or pregnancy status. However, a potential interaction between HT and BMI was identified. Among patients who were overweight or obese (BMI >24 kg/m²), HT was significantly associated with an increased risk of progression.

These results suggest that HT is not independently associated with PTC progression during AS in the general population. However, our subgroup analysis revealed a potential interaction between HT and BMI, suggesting that the association between HT and PTC progression may be modified by overweight or obesity status. Overweight is an increasingly recognized clinical condition. The association between obesity and ETE, tumor multifocality, larger tumor size, as well as LNM remains controversial. However, it has been established that a positive correlation exists between elevated BMI and the presence of the BRAFV600E mutation [29]. Although HT has been proven to be a factor for a better prognosis, this study confirms that, compared to other clinical indicators, an association between HT and PTC progression can be observed specifically within the overweight subgroup in this study. Although the current understanding of the mechanisms underlying the interaction between obesity and HT in PTC progression remains unclear, we speculate that their association may involve the following aspects: (1) HT is associated with a lower BRAF V600E mutation rate [14], while obesity is associated with a higher BRAF V600E mutation rate [30,31]. When both conditions coexist, their opposing effects on gene mutation might offset each other. (2) HT is characterized by lymphocytic infiltration in thyroid tissue. Patients with HT and PTC have been observed to have reduced Tregs and increased interleukin 10 secretion [32]. Conversely, obesity induces Treg expansion and elevated interleukin 10 [33], which may indirectly promote tumor immune escape by suppressing the cytotoxic functions of CD8$^+$ T cells and natural killer cells, thereby counteracting the influence of HT on PTC. (3) Regarding metabolism, in the state of obesity, increased levels of free fatty acids provide more energy for tumor cells.

XSL•FO
RenderX

Further studies with larger cohorts and mechanistic investigations were warranted to validate and elucidate this interaction.

Comparison With Previous Studies

Previous studies have provided substantial evidence supporting a potential association between HT and PTC prognosis. For example, Marotta et al [34] conducted a multicenter retrospective cohort study in Italy involving 301 patients with PTC, of whom 42.5% had coexisting HT and reported significantly longer recurrence-free survival in those with HT. Similarly, Xu et al [14] performed a single-center retrospective cohort study in China involving 9210 patients with PTC, with a 19% prevalence of coexistent HT. Xu et al also suggested that HT was associated with better PTC prognosis.

Nevertheless, the association between HT and postoperative recurrence may differ substantially from its relationship with disease progression under AS. Yet, this distinction has been largely overlooked, as few studies have specifically investigated the impact of HT on PTC progression during AS. In a Korean cohort of 699 patients with PTC managed with AS, Lee et al [17] reported that tumor progression was associated with diffuse thyroid disease (DTD) as detected by ultrasound, with a 2.3-fold increased risk of progression in patients with HT compared to those without. Interestingly, although our study did not find a statistically significant association between HT and PTC progression under AS in the general population, we observed a 6.32-fold increased risk of progression associated with HT in patients who were overweight or obese. It is important to highlight that our study design differs from that of Lee et al [17]. First, HT represents only one type of DTD, which also includes other conditions such as Graves' disease and simple goiter. Second, according to Lee et al [17], DTD was diagnosed based on preoperative ultrasound examinations, while in our study, the diagnosis of HT was primarily based on postoperative pathological confirmation and preoperative serum antibody levels measured within 30 days before surgery.

Limitations and Strengths

Our study has several strengths. First, we applied strict eligibility criteria, including only patients who had undergone AS for more than 6 months preoperatively, to ensure that sufficient follow-up time was available for detecting clinically meaningful changes. The relatively low enrollment proportion is attributable to 2 main factors: (1) AS has only been widely adopted in recent years, and many preoperative cases did not undergo this protocol. (2) Some nonlocal patients or those seeking examinations at other hospitals underwent only a single ultrasound at our institution prior to surgery, making them largely ineligible. We also excluded patients with baseline LNM or ETE to reduce confounding by indication. Second, we employed Cox proportional hazards models to fully utilize time-to-event data, providing more robust estimates. Third, all outcome events were individually reviewed by experienced clinicians to ensure the accuracy of progression assessment. Fourth, beyond the overall analysis, we examined the association between HT and specific types of progression (including tumor enlargement and LNM) and conducted sensitivity analyses to assess the robustness of our findings. Furthermore, we investigated potential interactions and associations across various patient subgroups.

Nevertheless, our results should be interpreted with caution. First, this was a retrospective study based on data extracted from electronic medical records. We plan to conduct a well-designed, prospectively followed cohort study with standardized data collection to validate our findings. Second, in clinical practice, the decision to undergo AS is influenced not only by the biological risk of tumor progression but also by patient preferences. For instance, patients with significant anxiety may opt for surgery even if their clinical condition qualifies for observation. Such preference-based decisions could introduce selection bias in our study population. Third, as a single-center study, the generalizability of our findings may be limited. Fourth, the limited sample size restricted our adjustment to only a constrained set of confounders. Future studies with larger cohorts are needed to control for a broader range of potential confounding factors. Fifth, the relatively short follow-up period may have limited our ability to detect long-term disease progression dynamics. In several instances, surgical intervention occurred before tumor progression could be observed, which could introduce observational time bias and potentially affect the accuracy of outcome assessments.

These findings should be regarded as hypothesis-generating and may help inform the design of future prospective studies with longer surveillance and more comprehensive data collection.

Clinical Implications

Given the intensive resources required to conduct prospective cohort studies on AS, there are currently very few studies addressing this issue globally. Our study provides a foundation for future research and has important implications for clinical practice. With a methodologically sound design, we contribute relatively high-quality evidence suggesting that, in general, patients with PTC with coexisting HT who meet clinical criteria for AS do not face an increased risk of disease progression. However, among patients with HT who are overweight or obese (BMI >24 kg/m^2), particular attention should be paid to a potentially elevated risk of PTC progression.

Conclusion

The findings of our retrospective cohort study implied that for patients with PTC, the presence of HT alone might not be a major factor in determining eligibility for AS versus immediate surgery, except in cases where the patients were overweight or obese. We advocate for future prospective cohort studies on AS to validate these findings before they are applied to clinical decision-making.

Abstract

Background: Published evidence on patient experiences, perceptions, and challenges related to early breast cancer (eBC) in Italy is limited. Understanding these aspects is critical for improving diagnosis, treatment outcomes, and quality of life (QoL).

Objective: This study used social media listening (SML) to explore the patient journey, treatment perceptions, QoL, and unmet needs of patients with eBC, caregivers, and health care professionals (HCPs) in Italy.

Methods: This retrospective noninterventional SML study analyzed publicly available posts from December 2021 to November 2023 using breast cancer–related keywords in English and Italian through Sprinklr, a web-based aggregator tool. Posts sourced from social media platforms, such as X (formerly known as Twitter), blogs, forums, Facebook, Instagram, and YouTube, were filtered by geographic location to include only users in Italy. Posts were filtered using natural language processing (NLP) for relevance and duplicates, followed by manual review and stakeholder identification (patients, caregivers, and HCPs). Key themes of discussion were identified through thematic analysis of posts across the stages of the patient journey (symptoms, diagnosis, treatment, etc). Ethical guidelines were followed by using anonymized, publicly available data. Descriptive statistics were used to analyze the data, and posts with missing data were excluded. Consequently, denominators varied across analyses and were adjusted based on data availability for specific variables.

Results: Of the 20,008 posts initially extracted, 1580 posts were retained following NLP filtering, and 530 posts were included after manual screening. The majority (493/518, 95%) of the posts were sharing information about diagnosis and treatment journeys, emotional challenges, QoL concerns, and symptoms (eg, lumps, breast pain), while 27% (141/518) of the posts sought information on diagnostic dilemmas, treatment options, and second opinions. Patients contributed 60% (318/530) of the posts, and caregivers contributed 21% (111/530) of the posts, with over half (57/107, 53%) discussing their mothers' diagnosis and treatment struggles. HCPs contributed 16% (85/530) of the posts, primarily sharing clinical trial updates, drug approvals, and disease awareness efforts. A total of 88 posts included discussions on QoL, and eBC significantly impacted patients' emotional, physical, functional, and social well-being. Discussions revealed key unmet needs, including limited awareness of adjuvant therapy options, lack of peer support groups, suboptimal patient-HCP communication, and insufficient access to specialty care facilities.

Conclusions: This study highlights gaps in eBC management related to patient education, HCP communication, and access to specialty care and describes an associated worsening of QoL for patients as reflected in social media posts. Within the limitations of an observational SML design, increasing patient and caregiver awareness of available adjuvant therapies to improve adherence and reduce recurrence risk, alongside expanding access to regional breast cancer centers, may help optimize patient experiences and outcomes. Further research using complementary data sources is needed to confirm and extend these findings.

Introduction

In the year 2022, female breast cancer (BC) was projected to be the most prevalent form of cancer globally, accounting for 2.3 million new cases, which constitutes 11.6% of all cancer diagnoses [1]. It is also the leading cause of death among women, accounting for 670,000 deaths globally, and ranked fourth in terms of cancer-related mortality worldwide [1]. Similarly, BC is the most commonly diagnosed cancer among women in Italy. It was estimated that there would be a total of 55,900 new cases in 2023, with over 90% of them being detected in the early stages [2,3].

Despite the availability of various treatment options for early BC (eBC), a significant number of patients still experience recurrence. For luminal BC, there is a long-term cumulative risk, with Italy reporting up to 10.5% distant recurrence within the first 5 years [4].

Patients with BC encounter numerous challenges throughout their journey, from identifying symptoms to receiving a diagnosis, undergoing treatment, and managing the disease [5-7]. Early diagnosis and effective management of BC are crucial in improving patient outcomes and reducing health care expenses [8,9]. To understand the diverse challenges of patients with eBC, conventional methods, such as questionnaires, interviews, and patient-reported outcome measures, are often used to gather qualitative data. However, these studies frequently involve a limited number of participants or require extended durations to be conducted, resulting in a limited understanding of the unique obstacles faced by individual patients [10-13]. Recently, social media listening (SML) has gained prominence as an approach to gain deeper insights into these challenges [14-16].

High internet penetration and presence of various social media platforms have greatly influenced health care [17,18]. Social media platforms have become valuable sources of information, allowing patients to share their beliefs about diseases, treatment experiences, satisfaction with outcomes, and other factors that impact their lives [19].

SML is a new approach for gathering information from social media platforms and can be useful in generating insights from user experiences. SML has been used to monitor discussions on health-related topics in various cancers [16,19-25]. However, there is limited published literature on the use of SML to investigate the needs and experiences of patients with eBC [15]. This study explores SML as a research tool to provide insights into the journey of patients with eBC.

This study aimed to understand the patient journey, treatment perceptions, quality of life (QoL), unmet needs, and concerns of patients with eBC by analyzing the social media posts from patients, caregivers, and health care professionals (HCPs).

Methods

Study Design and Data Source

This study was a noninterventional retrospective analysis of social media data available in the public domain. A comprehensive search was conducted on various social media platforms, including X (formerly known as Twitter), blogs, forums, Facebook community groups, Instagram, and YouTube, from December 2021 to November 2023 using keywords related to BC in both Italian and English languages. The initial keyword list was developed by a multidisciplinary study team comprising researchers with expertise in oncology, social media analytics, and qualitative research. The team first compiled candidate terms based on clinical terminology (eg, “early breast cancer,” “chemotherapy”) and commonly used lay terms (eg, “chemo,” “cancer journey,” “tumor,” “lump”), informed by prior SML and patient-experience literature [19,26]. Preliminary scoping searches were then conducted in the Sprinklr tool to test and refine this list; identify additional relevant terms and hashtags used by patients, caregivers, and HCPs; and optimize precision and recall. Boolean operators (eg, AND, OR) were used to structure the search strings, and all terms were translated into both Italian and English to reflect the bilingual nature of online discourse in Italy. This iterative, expert-informed process aligns with best practices in SML research [19,27,28] and was used to finalize the search strategy prior to full data extraction. The data have been reported in accordance with the SRQR (Standards for Reporting Qualitative Research) checklist (Checklist 1). The specific search terms and list of forums and blogs are reported in Multimedia Appendix 1.

Each social media platform was selected based on its potential to capture unique dimensions of the patient, caregiver, and HCP experience. The inclusion of multiple platforms allowed this study to triangulate insights from different types of user engagement:

- X: Real-time updates, public sentiment, and awareness campaigns
- Facebook groups: Peer support, community discussions, and shared experiences
- Forums: Anonymous, in-depth discussions among patients and caregivers
- Blogs: Detailed personal narratives and reflections on the cancer journey
- Instagram and YouTube: Visual storytelling and video-based sharing of experiences

While blogs are not inherently discussion-based, they offer rich, first-person accounts of the lived experience of illness. Prior SML studies have consistently included blogs as valuable sources of qualitative data [19,26,27].

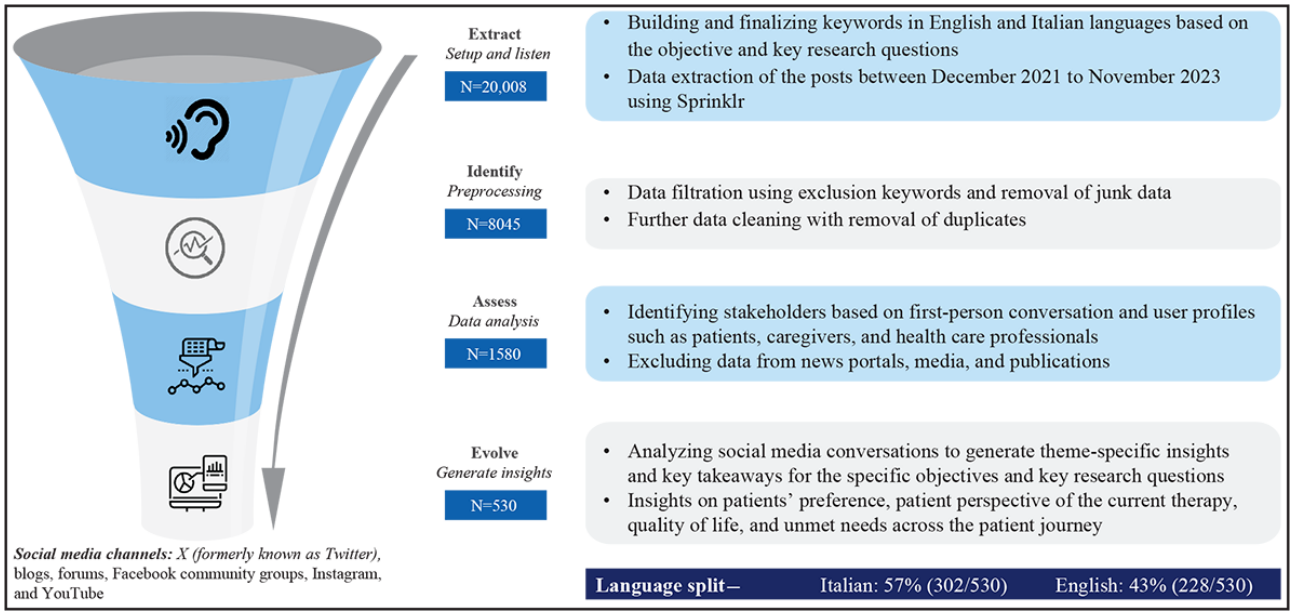
Forums and blogs were identified through Sprinklr’s indexing of publicly accessible websites and were selected if they (1) hosted user-generated content related to BC, (2) were accessible without registration or password protection, and (3) had contributors whose profiles or content indicated an Italian context (eg, language, self-reported location).

Eligibility Criteria

This study included posts that (1) were publicly available (ie, not private, password-protected, or restricted content); (2) originated from users located in Italy (based on profile or geolocation information); (3) contained 1 or more keywords related to BC; and (4) appeared to reflect the experiences,

XSL•FO
RenderX

perceptions, questions, or opinions of patients with eBC, their caregivers, or HCPs involved in BC care. This study excluded (1) posts that were clearly unrelated to BC, despite containing 1 or more keywords (eg, spam, advertisements, financial content); (2) posts from news portals, media outlets, and scientific journals; (3) posts with commercial or promotional content; and (4) duplicate post links. These eligibility criteria were applied consistently across all platforms and are reported in detail in Multimedia Appendix 1.



Data Collection, Selection of Posts, and Data Cleaning

Data from public posts were collected using Sprinklr [29], a web-based aggregator tool. This tool allows downloading of posts along with the date stamp and geographic location information of the users. Based on the geographic location of the user profile, only posts from Italy were downloaded. Each post was assigned a unique ID by the tool. Data filtration techniques were applied using exclusion keywords to remove junk data to maintain data quality using natural language processing (NLP). Furthermore, NLP was used to clean the data and eliminate duplicates for reliable analysis.

Data Analysis

Manual screening was conducted to analyze the data. Each post was indexed to identify the stakeholders based on first-person conversations and user profiles, including patients, caregivers, and HCPs. Posts related to news portals, media, and publications were excluded to focus solely on social media posts from patients, caregivers, and HCPs. The analysis included examining the posts based on the social media channel (X, blogs, forums, Facebook community groups, Instagram, and YouTube), the tone of the posts (positive, neutral, or negative), and the key themes of discussion (Figure 1). The themes were identified based on the type of information relevant to the study objective discussed in the posts. A single post could be categorized under more than 1 theme based on the information mentioned in the post.

Figure 1. Social media listening (SML) methodology: from extraction of posts to insights generation. "N" denotes number of posts.

The thematic analysis in this study followed a predominantly deductive approach. The themes were derived based on a conceptual framework aligned with the typical patient journey for individuals diagnosed with eBC. This framework included key stages such as symptom onset, diagnosis, treatment, disease management, and quality of life. Additionally, this study incorporated themes related to online patient behavior, such as sharing disease awareness and discussing clinical trial or research updates, which are commonly observed in social media discourse among patients, caregivers, and HCPs.

The deductive nature of the thematic analysis was guided by predefined categories informed by existing literature on the eBC patient journey and prior SML studies [19,28]. These categories were used to structure the coding process and ensure alignment with the study objectives. While the primary approach was deductive, the analysis remained open to emergent subthemes within each category during manual screening, allowing for flexibility in capturing nuanced insights. Each post was coded and analyzed by a qualified researcher with expertise in oncology, social media analytics, and qualitative research.

The theoretical underpinning of this approach draws from the patient-centered care model and the concept of the illness trajectory, which emphasizes understanding the lived experiences of patients across different stages of their condition. This framework supports the identification of themes that reflect both clinical milestones and psychosocial dimensions of the patient experience. The review and coding were led by a primary analyst (A Maurya), who has expertise in oncology, social media analytics, and qualitative research, using structured spreadsheets and a predefined codebook. To enhance the reliability of the reviewing and coding process, we applied techniques, such as iterative codebook refinement and regular team discussions, to review preliminary themes and ensure consistency with the study objectives. Data analysis and interpretation were led by A Maurya in collaboration with SP, with input from the other

XSL•FO
RenderX

coauthors, who contributed to the refinement of themes and final interpretation of the findings.

For analysis and reporting, the terms "post" and "mention" were used. The term "post" referred to a single post. The term "mention" referred to the number of times a symptom, treatment, diagnostic test, or other parameter was mentioned in each post. It is important to note that the number of mentions was independent of the number of posts. The unit of analysis is posts and mentions, not unique individuals, and due to data anonymization, users could not be tracked across different platforms. Descriptive statistics were used to analyze the data, which were presented in the form of post counts (N), mention counts (n), and percentages (%). The percentage calculation was performed by dividing the number of posts or mentions by the total number of posts or mentions providing specific information, respectively. Missing data were neither imputed nor considered in the analysis. Consequently, denominators varied across analysis and were adjusted based on the availability of data for specific variables.

Ethical Considerations

All data used in this SML study were collected exclusively from publicly accessible sources, without accessing any password-protected or nonpublic information. This study involved social media analysis and did not report any data with identifiable participants. All web-based content was anonymized and is in compliance with the Health Insurance Portability and Accountability Act (HIPAA). Approval was obtained from the Novartis safety registry 1P1R—the governing body that holds oversight on the use of social media by Novartis (DE014963-V1). All relevant local and global laws affecting and relating to the use of social media, aligned with and as reflected in Novartis processes, were followed in the conduct of this study. The authors of this study consent to the publication of the submitted manuscript and declare that no individual patient data requiring consent have been presented.

Results

Overview

A total of 20,008 posts were initially extracted from social media platforms using BC-related keywords during the study period. After filtration using exclusion keywords, removal of junk data and further data cleaning with the removal of duplicates using NLP, it resulted in retaining 1580 posts. These 1580 posts were then screened manually to check for relevance and identify stakeholders based on first-person conversation and user profiles, such as patients, caregivers, and HCPs. After excluding nonrelevant data, such as data from news portals, media, and publications, a total of 530 posts were included in the final analysis for insights generation (Figure 1).

Most posts were from patients (318/530, 60%), compared with 21% (111/530) from caregivers; 16% (85/530) from HCPs; and 3% (16/530) from unidentified persons. Of the 448 posts mentioning the cancer type, 95% (427/448) mentioned de novo BC and 5% (21/448) mentioned recurrent BC. Of the 107 posts mentioning the caregiver relationship with the patient, 53% (57/107) were posts from children discussing their mothers' diagnosis and treatment challenges. Patients' current age was reported in 89 posts, with most (56/89, 63%) posts reporting the patient age range of 21 - 50 years. Time since diagnosis was reported in 90 posts, with 31% (28/90) of the posts mentioning patients being diagnosed within 6 months to 1 year. Demographic and clinical characteristic details are reported in Multimedia Appendix 2.

Social Media Landscape and Online Behavior

Social Media Platform Distribution and Interaction Trends

Forums and X were the most commonly used social media platforms, accounting for 47% (249/530) and 31% (164/530) of the posts respectively, followed by Facebook (69/530, 13%), YouTube (21/530, 4%), Instagram (16/530, 3%), and blogs (11/530, 2%). Posts from 10 forums and 5 blogs were included in the analysis, and a list of forums and blogs is available in Multimedia Appendix 1. Among the forums, Medicitalia+, Aimac, Triste Mondo, and Carenity were the forums with the most posts. Most posts concentrated on the treatment and management of the disease, followed by discussions on diagnosis (Table 1). Among the 518 posts categorized as either sharing or seeking information, approximately 95% (493/518) involved sharing information, while only 27% (141/518) sought information.

Table . Discussion themes from the posts.

Topic of conversation	Mentions of the specific topic of conversation from the total mentions (n=1037), n (%)
Treatment and management	425 (41)
Diagnosis	249 (24)
Quality of life	135 (13)
Symptoms	124 (12)
Disease awareness	73 (7)
Clinical trial or research update	31 (3)

Sharing Information

Patients shared various aspects of their experiences, providing insights into their diagnostic journey, emotional support needs, and treatment courses. In discussing their diagnostic journey, patients shared their experiences of undergoing multiple diagnostic tests and the associated waiting periods, aiming to

XSL•FO
RenderX

reassure their peers who were facing similar challenges. Time since diagnosis was reported in 90 posts. Regarding emotional support, 17% (15/90) of the posts mentioning a recent diagnosis frequently expressed anxiety and concern about the progression of their treatments, whereas 12% (11/90) of the posts mentioning a diagnosis 4 to 6 years earlier were particularly active in addressing queries related to available treatment options and medication choices. Concerns about HCP interactions were also prevalent, with some patients expressing dissatisfaction due to multiple visits and the perceived lack of cordiality from certain HCPs. Furthermore, patients detailed the impact of their condition on their overall QoL and described pain, discomfort, and the effects on personal relationships and overall well-being.

Seeking Information

In the context of information-seeking behavior, patients expressed various concerns, including the interpretation of ambiguous symptoms, wherein they sought clarification from peers regarding concerning lumps or masses, as online resources often exacerbated confusion and anxiety. Additionally, there were diagnostic dilemmas, with individuals inquiring about preparation for upcoming breast examinations and biopsy results. Regarding treatment options, patients asked about improved disease management strategies to overcome the adverse effects of medications. Furthermore, patients expressed apprehension about medical consultations, especially regarding the frequency of medical consultations in the absence of clear guidance, and frequently sought second opinions from HCPs. This was largely driven by anxiety and worry induced by online testimonials read by patients.

A summary of insights from individual social media channels is provided in Multimedia Appendix 3.

Insights From Patients' and Caregivers' Discussions

Online Engagement and Support Seeking Pattern

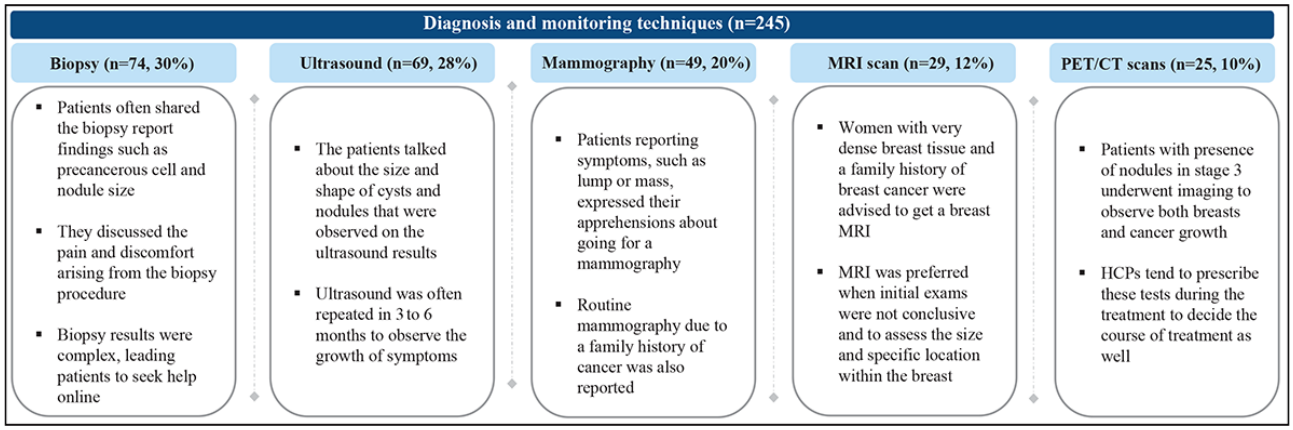
Insights from patients' and caregivers' discussions highlighted that women aged 31 - 40 years, as reported in 26% (23/89) of the posts, were more active in sharing their patient journey and seeking peer experiences and community inclusiveness. Online platforms served as their preferred method for seeking clarification and addressing concerns, with approximately 30% (28/90) of the posts mentioning active online engagement within the first year of their diagnosis.

Symptoms

Key symptoms reported by patients included lumps, cysts, and breast pain (Table 2). Of the 128 mentions on symptoms, approximately 33% (42/128) of the mentions revealed that women identified a lump or mass as the first symptom through self-examination after a diagnostic checkup. Some mentions revealed that patients discovered their BC only through routine mammograms, as they were asymptomatic. Individuals educated themselves on self-examination at home by reading patient testimonials or watching videos or blogs from peers or medical websites. However, the uncertainty surrounding initial symptoms left patients unsure about whether to wait or visit a doctor, as the information available online was inconclusive. The physical impact of the symptoms, such as changes in breast appearance and severity of nipple discharge, made patients feel self-conscious and uncomfortable.

Table . Key symptoms reported in posts.

Key symptom	Mentions (%) of the specific symptom from the total mentions (n=128), n (%)
Lumps or mass	42 (33)
Cyst or calcification	20 (16)
Breast pain	17 (13)
Skin irritation	15 (12)
Nodules	14 (11)
Swelling of breasts	12 (9)
Nipple discharge	5 (4)
Others	5 (4)



Diagnosis

Diagnosis and Monitoring: Procedures, Preferences, and Concerns

Diagnostic procedures, such as biopsy, ultrasonography, and mammography, played a vital role in confirming the diagnosis, accounting for 77% (190/245) of the mentions. These procedures were often repeated to establish a definitive diagnosis by radiologists and oncologists (Figure 2).

XSL•FO
RenderX

Figure 2. Diagnosis and monitoring techniques reported in posts. "n" denotes the number of mentions. CT: computed tomography; HCP: health care professionals; MRI: magnetic resonance imaging; PET: positron emission tomography.

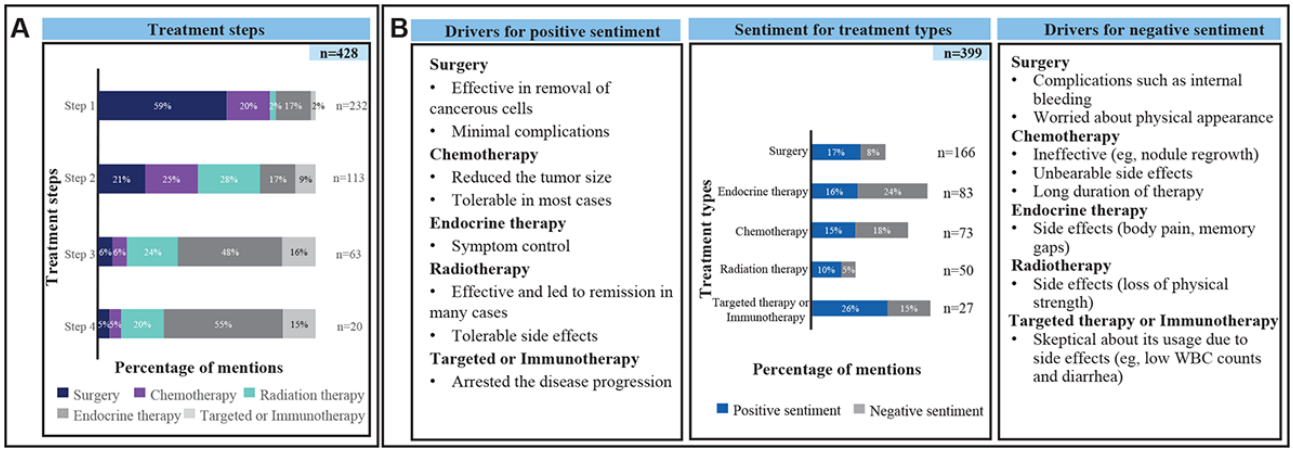
The analysis of diagnostic and monitoring techniques from 245 mentions highlighted distinct preferences and concerns among patients. Biopsy, representing 30% (74/245) of the mentions, was frequently discussed, with patients sharing results that revealed conditions, such as precancerous cells and nodule sizes. Of the 73 mentions in which patients underwent biopsy, 22% (16/73) reported experiencing pain and discomfort after the procedure and often sought additional online resources due to the complexity of the biopsy results. Ultrasound, accounting for 28% (69/245) of the mentions, frequently involved discussions about the size and shape of cysts and nodules observed in the results, with follow-up ultrasounds typically scheduled every 3 to 6 months to monitor symptom progression. Mammography, mentioned in 20% (49/245) of the mentions, commonly induced patient apprehensions, especially in those reporting symptoms, such as lumps or masses. It was also routinely used by individuals with a family history of cancer. Magnetic resonance imaging (MRI) scans, comprising 12% (29/245) of the mentions, were particularly useful for patients with dense breast tissue and a significant family history of BC. MRIs were preferred when initial exams lacked conclusive results, offering a comprehensive assessment of the size and specific locations of the tumors within the breast. Positron emission tomography (PET) or computed tomography (CT) scans, constituting 10% (25/245) of mentions, were predominantly used to evaluate nodule presence in advanced cancer stages and track cancer growth. These scans were crucial during treatment phases to assist HCPs in determining appropriate treatment courses. Overall, these findings underscored the diverse diagnostic approaches and patient experiences in breast health monitoring.

Key Drivers for Diagnosis

Drivers for diagnosis included routine mammography and ultrasound screening, particularly among younger adults who were more informed. A family history of cancer made patients more vigilant in noticing symptoms and undergoing regular screenings. The self-examination for BC symptoms, proactive communication from gynecologists or breast specialists, and clear guidance from oncologists were also key factors.

Treatment

Surgery to Adjuvant Therapies: Experiences and Expectations



Before initiating treatment, patients often sought validation online for their prescribed treatments. Mastectomy was the most mentioned surgical method (137/232 mentions, 59%) for managing local cancerous cells at the first stage. After surgery, oncologists advised patients to undergo histological analysis to determine the further treatment course. Specific drug names were rarely discussed, but patients sought medications that had fewer side effects and higher efficacy. Some common chemotherapy and hormonal drugs mentioned for the first to third steps of treatment included paclitaxel, letrozole, and tamoxifen among others. Patients expressed anxiety about starting adjuvant therapies due to concerns about severe side effects. Adjuvant therapy was used intermittently to provide better relief to patients at high risk of disease progression. From the patients' and caregivers' perspective, HCPs rarely had transparent conversations with patients about the risks associated with hormonal or adjuvant therapies.

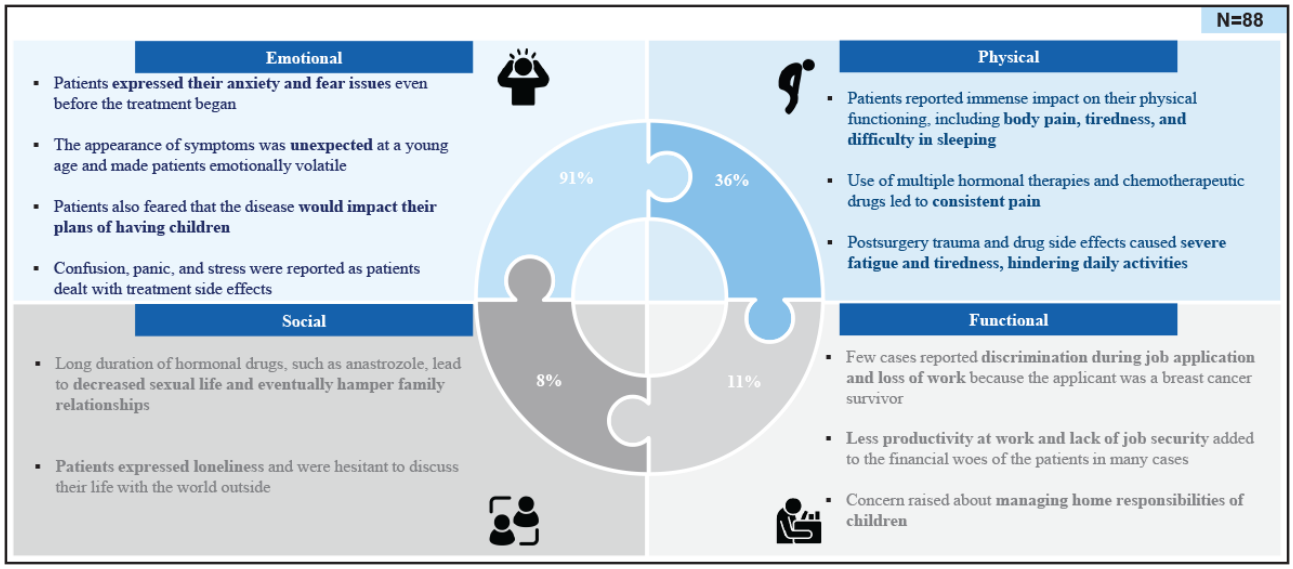
Treatment Sentiment

Patients experienced relief from surgery due to effective cancer cell removal and minimal complications. However, long-term treatments were challenging, negatively affecting their QoL. Chemotherapy reduced tumor size but had severe side effects and long durations. Endocrine therapy helped with symptom control but caused issues, such as body pain and memory gaps. Radiation therapy was effective, leading to remission but also resulted in the loss of physical strength. Targeted therapy or immunotherapy arrested disease progression but was met with skepticism due to side effects, such as low white blood cell counts and diarrhea (Figure 3).

XSL•FO
RenderX

Figure 3. (A) Treatment steps and (B) treatment sentiment. "n" denotes the number of mentions. WBC: white blood cell.

Unmet Treatment Needs



The treatment journey for patients with eBC is often further complicated by a lack of therapy knowledge and poor patient-HCP interactions. One of the key unmet needs identified is the perception of care.

- Limited treatment knowledge: Patients frequently lack awareness of available adjuvant treatment options that are critical for effective eBC management.
- Lack of trusted online peer groups: During treatment initiation, patients often seek support from trusted online peer groups, authenticated Google searches, or medical blogs. However, the absence of a standardized care system leaves them without proper guidance during this challenging period.
- Limited access to specialty breast care units: There is a pressing need for more tertiary cancer care centers across various regions to enhance patient access to specialized care.
- Poor patient-HCP communication: Treatment steps are often not openly discussed by HCPs during consultations, which places the burden of understanding and managing the treatment course on the patients themselves.
- Need for advanced drugs: Patients with recurrence highlighted the need for more advanced drugs to prevent recurrence.

Quality of Life

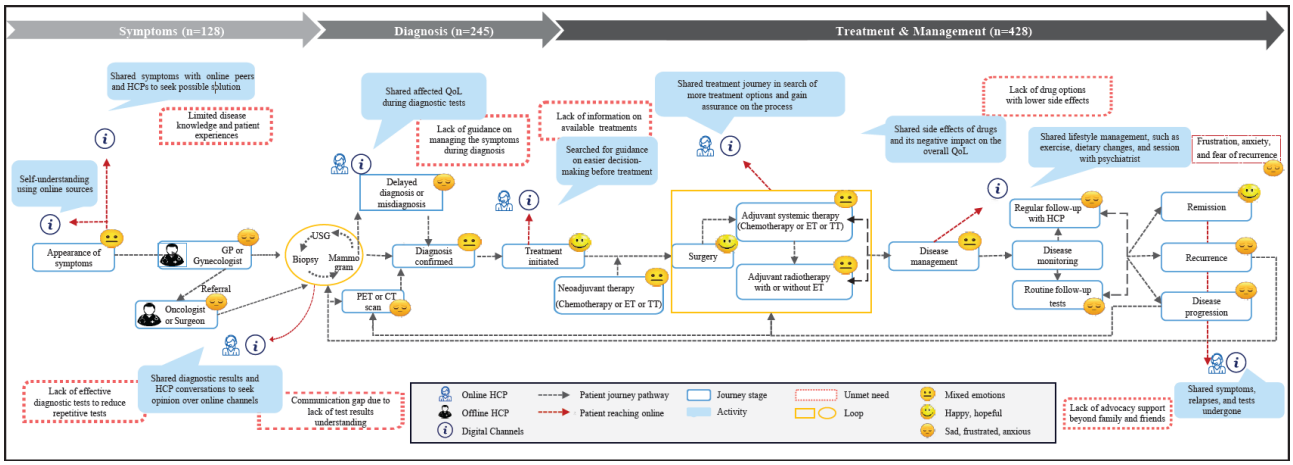
A total of 88 posts included discussions regarding QoL. eBC substantially impacted patients' QoL, affecting emotional well-being (80/88, 91%) on domains, such as anxiety and fear; physical functioning (32/88, 36%) in body pain, tiredness, and difficulty in sleeping; functional well-being (10/88, 11%), characterized by less productivity at work and lack of job security; and social well-being (7/88, 8%), including decreased sexual life, eventually hampering family relationships and resulting in loneliness (Figure 4).

Figure 4. Impact of disease on quality of life of patients with early breast cancer. "N" denotes the number of posts.

Recurrence and Associated Challenges

A total of 21 posts reported information on recurrence. Patients and caregivers expressed anger and disbelief upon recognizing symptoms of recurrence, which were often detected only after the cancer had metastasized to other organs. Symptoms, such as nodules and swollen breasts, were reported in 24% (5/21) of the posts on relapse. This led to repeated diagnostic tests,

XSL•FO
RenderX



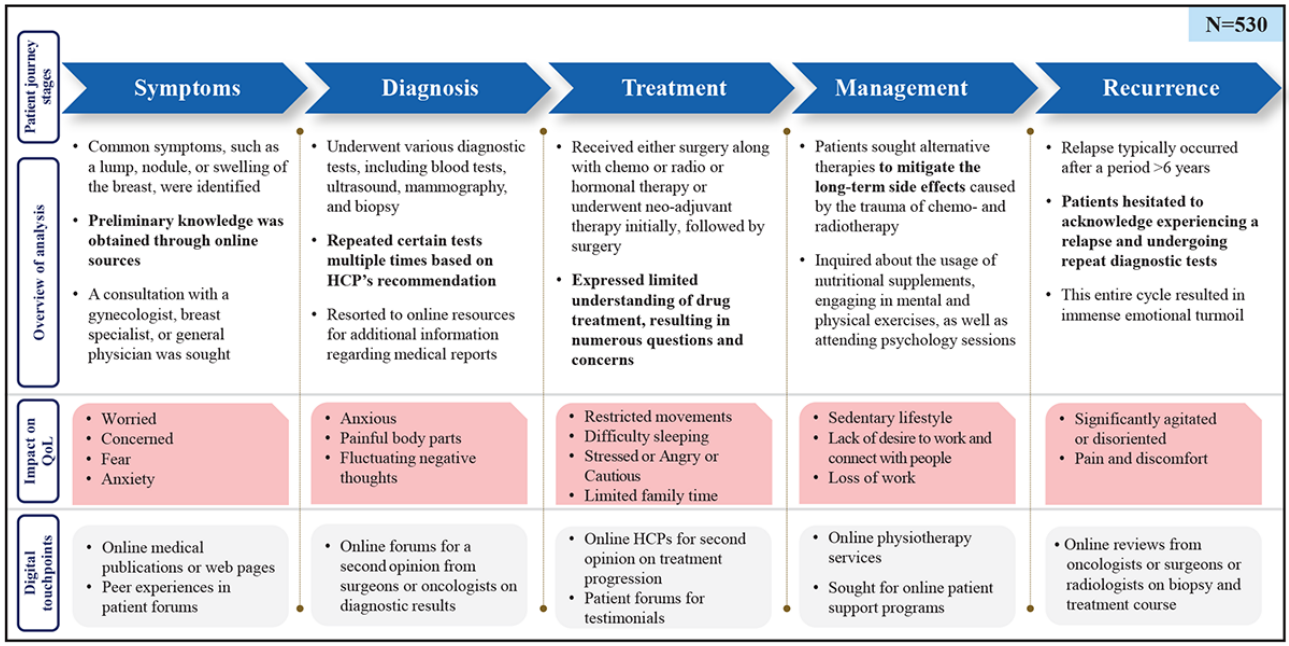
including CT, MRI, and PET scans as described in 33% (7/21) of the posts. The increase in disease activity on imaging tests was associated with feelings of devastation, as described in 33% (7/21) of the posts.

Recurrence had a profoundly negative impact on patients' QoL, causing frustration with the repetitive diagnostic tests and the treatment process. Overall, 19% (4/21) of the posts highlighted delays in disease monitoring, often due to false positive or negative biomarker results. Instances of negligence by radiologists were mentioned, with 10% (2/21) of the posts reporting that symptoms were initially ignored, leading to a later diagnosis of recurrence after seeking second opinions. Additionally, the long waiting periods for treatment in some areas of Italy prompted some patients to consider relocating for faster access to care, as reported in 10% (2/21) of the posts.

Considering 12 posts reporting data on remission, 59% (7/12) of the posts reported that patients were in remission for more than 6 years, 33% (4/12) for 3 - 6 years, and 8% (1/12) for less than 3 years.

The patient journey highlighted the reliance on digital channels for information, support, and communication through different stages, while it highlighted both online and offline interactions. Throughout their journey, patients experienced various emotions, including anxiety, sadness, frustration, hope, and happiness. Positive emotions were typically associated with successful treatments and management, while negative emotions often resulted from misdiagnoses, treatment side effects, and disease recurrence. Figure 5 illustrates the patient journey map, focusing on digital touchpoints—online platforms (Facebook, X, Instagram, YouTube, forums, and blogs) where patients seek information, support, and communicate with HCPs and peer networks—at various stages: symptoms, diagnosis, and treatment and management.

Figure 5. Digital touchpoints across the patient journey map. "n" denotes the number of mentions of the specific attribute. CT: computed tomography; ET: endocrine therapy; GP: general practitioner; HCP: health care professional; MRI: magnetic resonance imaging; PET: positron emission tomography; QoL: quality of life; TT: targeted therapy; USG: ultrasonography.



Insights From HCPs

This study highlighted optimism among HCPs regarding advancements in eBC care. They shared research through book publications focusing on diagnostic techniques and provided guidance on radiation therapy. Clinical advancements were discussed, including the role of artificial intelligence in BC management, phase 3 clinical trial results, and insights on new drugs for BC. Furthermore, a lot of emphasis was placed on raising disease awareness among patients. This included discussions on proactive measures for fertility preservation, sharing advancements in screening techniques, and underlining the importance of regular check-ups. HCPs also emphasized the harmful impacts of alcohol consumption on BC risk. They actively engaged patients through various channels to promote better disease management and prevention.

A summary of insights from this study at various stages of the journey of patients with eBC is shown in Figure 6.

XSL•FO
RenderX

Figure 6. Summary of insights at various stages of the journey of patients with early breast cancer (eBC). "N" denotes the number of posts. HCP: health care professional; QoL: quality of life.

Discussion

Overview of Findings

Key Themes Identified Across the Journey of Patients With eBC in Italy

This SML study provides insights into how patients with eBC, caregivers, and HCPs in Italy describe their experiences, perceptions, and unmet needs on social media. Through the analysis of posts from various social media platforms over a 2-year period, we identified recurring themes related to initial symptoms and diagnosis, treatment experiences and concerns (including adjuvant therapies), impact on QoL, perceived recurrence and ongoing monitoring, communication gaps with HCPs, and access to support and specialized care. These findings underscore the significance of social media as a supplementary resource for understanding patient experiences in real-world settings and highlight critical areas that necessitate attention to improve patient care and support systems.

Social Media Landscape and Online Behavior

This study reveals that most social media posts were initiated by patients themselves, highlighting their willingness to share experiences and seek peer support. This aligns with previous research that indicated that patients are increasingly turning to online platforms for emotional and informational support [16,30]. The prevalent use of forums and X emphasizes the role of these platforms in disseminating information and fostering community engagement [14,17]. However, as the sample is limited to users who are active online, these insights may reflect the perspectives of more digitally engaged patients rather than all individuals with eBC.

Initial Symptoms and Diagnosis

The most common symptoms reported in this study include lumps, cysts, and breast pain. These early indicators drive patients to seek diagnostic interventions, such as mammography, biopsy, and ultrasound, with patients having varied anxiety levels toward these methods.

Patients frequently discussed the diagnostic journey, expressing concerns about the multiple tests and the associated waiting periods. These findings were similar to those of a previous study that found that prolonged diagnostic processes contribute to substantial patient anxiety and stress [31]. Patients' inability to describe their disease stage during discussions indicated a generally low level of awareness about the disease and its clinical characteristics (eg, staging and interpretation of test reports). Consistent with previous research [32,33], the findings of this study indicated that self-examination for BC symptoms, proactive communication from gynecologists or breast specialists, and clear guidance from oncologists were key drivers for diagnosis, supporting the early identification of BC and the potential for improved survival outcomes. Given the nature of SML data, these observations are hypothesis-generating and should be interpreted as qualitative insights rather than definitive epidemiologic estimates.

Treatment Experiences and Sentiments

Patients also expressed great concern regarding the long durations and side effects of chemotherapy and endocrine therapy, leading them to seek alternative treatment strategies. This aspect of patient experience is well documented in the literature, where adverse effects of treatment often result in diminished QoL [34]. The challenges in understanding the complexities of adjuvant therapies indicate a need for more transparent communication from HCPs [4]. Furthermore, negative perceptions of adjuvant therapies significantly impact treatment adherence. Prolonged low adherence or nonadherence increases the risk of recurrence, ultimately leading to poorer patient outcomes [35-37]. In our dataset, patients often described doubts about the benefits of ongoing treatment and concerns about side effects. Although actual adherence behavior could

XSL•FO
RenderX

not be measured, these narratives signal areas where enhanced patient-HCP dialogue and shared decision-making may be beneficial.

The discussions reflected a lack of open communication from HCPs regarding treatment options. Similar findings were observed in a social media study conducted on patients with metastatic BC from Europe [19]. Collectively, these findings indicate that enhancing the clarity, frequency, and empathy of patient-HCP communication may help address some of the concerns expressed in online discussions.

Impact on QoL

The impact of eBC on patients' QoL was another critical theme identified in this study. Consistent with the literature, the findings of this study show that eBC substantially affects emotional well-being, physical functioning, functional well-being, and social well-being [38]. Patients reported anxiety, fear, pain, and fatigue, which also influenced their productivity at work and personal relationships. The prevalence of emotional distress among patients with eBC underscores the importance of comprehensive supportive care that addresses both the physical and psychological needs of patients [34,39-42]. Because the data were derived from spontaneous posts, individuals experiencing higher levels of distress may have been more likely to share their experiences online, potentially amplifying the prominence of negative QoL themes.

Recurrence, Ongoing Screening, and Continuous Therapy

The findings of this study indicated that recurrence had a substantial impact on QoL, necessitating regular imaging tests and repeated cycles of chemotherapy, which became an integral part of the treatment journey. This study highlights a critical unmet need for timely and accurate monitoring to prevent recurrence and mitigate long-term impacts. Although we could not independently verify clinical details, such as recurrence status or specific testing protocols, repeated patient discussions regarding continuous imaging, biomarker testing, and changes in therapy underscore the burden of long-term surveillance from the patient perspective.

Unmet Needs and Communication Gaps

Despite the availability of various treatment options, a notable number of patients indicated unmet needs in treatment knowledge and patient-HCP communication. The lack of trusted online peer groups and limited access to specialty breast care units were also prominent concerns. These findings are supported by previous studies [43-45] that emphasized the importance of accessible, timely, and accurate information for patients to make informed decisions about their care, as well as the role of patient advocacy groups [46].

Poor patient-HCP communication was frequently mentioned, with patients expressing dissatisfaction with the clarity and frequency of consultations. Patients complained about multiple tests and ineffective communication with HCPs about test results, prompting patients to seek help online. Effective communication is critical in oncology care, yet often remains suboptimal, contributing to patient distress and a sense of being unsupported [11,19]. This suggests that targeted interventions to improve patient-HCP interactions could enhance patient satisfaction and perceived outcomes.

Role of HCPs and Social Media

HCPs also engaged actively on social media, sharing advancements in eBC care and offering guidance on disease management. This active participation aligns with the findings from previous studies that underscore the role of social media in bridging knowledge gaps and fostering public health education [47,48]. The discussions by HCPs on clinical trials, diagnostic techniques, and preventive measures, such as regular screenings and lifestyle modifications, reflect an ongoing effort to raise disease awareness and improve patient care. Nevertheless, our analysis suggests that HCP-driven content may not always directly address the specific questions and concerns raised by patients and caregivers, indicating an opportunity to better align online communication with patient or caregiver needs.

New Insights From the Findings of This Study

New insights from the findings of this study are as follows:

1. This SML study revealed gaps that are not typically captured by traditional research methods, including the generational shift in how younger patients (aged 31 - 40 years) are using online platforms as their primary source of both emotional and informational support. This highlights an urgent need for formal integration of digital tools into cancer care frameworks, for example, through moderated online communities, validated educational content, and digital navigation tools.
2. The study provides new evidence regarding the reported geographic inequities in access to care. Patients in underserved areas reported delays in treatment and follow-up, highlighting a systemic issue that could be addressed with regional policy innovations, such as expanding specialized breast care units or creating mobile health care services. These insights should be interpreted cautiously as they are based on self-reported locations and experiences, but they point to priority areas for further health services research.
3. Recurring diagnostic inaccuracies, particularly in biomarker testing during recurrence monitoring, emerged as a unique and actionable finding. While specific clinical details could not be confirmed, addressing these perceived inaccuracies through standardized protocols and advanced imaging techniques could significantly alleviate patient distress and potentially improve outcomes. Future studies combining SML with clinical data or registry information may help validate and quantify the extent of these issues.

Strengths and Limitations

This study has several strengths and limitations. One key strength is its relatively novel approach, utilizing SML to gather real-world insights into patient experiences and perceptions without intruding on their privacy. This method captures spontaneous and candid discussions among patients, caregivers, and HCPs that are difficult or time-consuming to elicit through traditional research methods, such as surveys or interviews. A

XSL•FO
RenderX

second strength is the breadth and diversity of data sources. Posts were collected from multiple social media platforms (X, Facebook, forums, blogs, Instagram, and YouTube), which provides diverse perspectives and a broader understanding of the journey of patients with eBC in Italy. Third, the study benefits from a systematic methodological framework. The search strategy was developed by a multidisciplinary team and iteratively refined with scoping searches and clearly defined eligibility criteria. Data processing combined NLP-based filtering and manual review to exclude junk, spam, and irrelevant content and focus on posts reflecting experiences of patients, caregivers, and HCPs. Thematic analysis was guided by a patient-journey–based conceptual framework. Together, these elements enhance the methodological rigor, transparency, and reproducibility of the study. Finally, the study generated a substantial volume of qualitative material for a focused national context. From 20,008 initially extracted posts, 530 relevant posts were retained for detailed analysis, enabling an in-depth exploration of specific themes, such as diagnostic pathways, perceptions of adjuvant therapies, QoL impacts, recurrence-related challenges, communication gaps, and access barriers.

However, the study has certain limitations. First, the social media users included in the analysis may not be representative of the broader population of patients with eBC, resulting in a potentially nonrepresentative sample. We attempted to mitigate this by including multiple platforms and both Italian- and English-language posts from users in Italy. However, selection bias toward more digitally engaged, younger, or health-literate individuals is likely. This may overemphasize certain themes (eg, online information-seeking) and underrepresent less connected or older populations. Future studies could integrate SML with survey or registry data to improve generalizability. Second, as the study relies on self-reported information, the accuracy and completeness of the data may vary, and it is not possible to verify the authenticity of individual posts. Third, the retrospective, cross-sectional design captures content from a specific period, from December 2021 to November 2023, which may not fully reflect changes over time or emerging trends. As such, temporal shifts in treatment paradigms, public awareness, or health policy may not be fully captured. Longitudinal SML analyses or repeated cross-sectional assessments could provide a more dynamic picture of evolving patient needs. In addition, the anonymous nature of social media data from publicly available posts prevents tracking individual users across platforms and precludes the verification of key demographics or clinical characteristics (eg, age, disease stage). This limits the ability to draw robust conclusions about specific subgroups. Our subgroup insights (eg, younger patients or those in underserved regions) should therefore be interpreted as indicative patterns rather than statistically confirmed differences. Future work that links deidentified social media data with structured demographic or clinical information, where ethically and legally permissible, could refine these subgroup analyses. Finally, the quality, depth, and specificity of shared information differ considerably between the posts, which may introduce gaps and uncertainty in data analysis and interpretation.

These strengths and limitations provide a comprehensive understanding of the study and emphasize the need for additional research and ongoing methodological improvements in the use of SML to inform patient-centered cancer care.

Conclusions

This study highlights the utility of SML in understanding the nuanced experiences of patients with eBC, caregivers, and HCPs in Italy, as expressed through publicly available social media posts. The identified themes reveal critical unmet needs in patient education, support systems, access to specialty care units, and patient-HCP communication. While the findings are exploratory and reflect the perspectives of social media users rather than all patients with eBC, they provide valuable, real-world insights that can complement traditional research approaches. Addressing these gaps through targeted interventions and leveraging social media's potential for tailored information, peer support, and enhanced patient-HCP communication can enhance patient experiences and perceived outcomes. Further research is encouraged to develop and implement effective strategies for improving cancer care in the digital age, including the integration of digital health tools, evaluation of patient-HCP communication interventions, and linkage of SML data with clinical and health services datasets where feasible and ethical.

Acknowledgments

The authors acknowledge Pradeep Basa (Novartis Healthcare Pvt. Ltd., India) for editorial and writing support, in accordance with the Good Publication Practice (GPP3) guidelines of the International Society for Medical Publication Professionals.

Abstract

Background: Growing interest surrounds how internet search behaviors might provide digital signals of disease prior to diagnosis, for example, when people search symptoms online. Internet browsing data offer novel opportunities for understanding response to symptoms, public health surveillance, and early intervention in conditions such as cancer. However, the acceptability of using such sensitive data in medical research remains unclear, particularly among individuals at higher risk of health and digital exclusion, such as older adults and those from minority ethnic groups or with a lower socioeconomic status.

Objective: This study aims to explore the feasibility and acceptability of using internet browsing history data for health research.

Methods: Participants were purposively sampled to ensure representation from groups at risk of digital and health inequalities via community organizations and charities. We conducted semistructured and think-aloud interviews allowing participants to reflect on hypothetical research involving sharing their internet browsing data. The adapted theoretical framework of acceptability guided the interview structure and coding. The interviews were transcribed, coded in NVivo, and thematically analyzed. Patient and public involvement informed the study approach, participant-facing documents, and the interpretation of the findings.

Results: Twenty participants (10 with a history of cancer and 10 without) were included in the study representing a range of age, gender, and ethnic and socioeconomic groups. Key themes focused on factors necessary for acceptability, including trust, transparency, and control and on perceived feasibility and individual willingness. Trust and transparency were fundamental to participants' willingness to share data. Trust in researchers would have to be earned through clear communication, ethical data handling, and familiarity with a named research team. Privacy concerns were prominent, with participants wanting control over what was shared, particularly regarding nonhealth-related information (such as details related to banking) or activity related to others (such as their children). Potential use or misuse of data beyond the original research purpose caused more concern than the nature of the shared data itself. Digital literacy varied; many expressed concerns over the technical aspects of sharing data. Participants also doubted the value of their individual internet browsing history, for example, as they chose not to search for health information due to the prevalence of misinformation. However, they described wider benefits arising from internet browsing history research, such as potential advancements in early detection and opportunities to promote credible online sources.

Conclusions: Participant recommendations balanced privacy concerns against the potential of internet history data for early diagnosis and health research. The study highlights ethical and inclusive approaches to health research using internet browsing history. Future researchers should consider defining the scope of health-specific data filters, providing user-friendly information and guidance for study participants, and ensuring that participants are able to contact research team members to build trust and facilitate data sharing.

Introduction

For many medical conditions, good prognosis and effective treatment rely on timely diagnosis [1,2]. There is also a large economic burden of delayed diagnosis when disease becomes advanced or requires more invasive treatment, longer hospital stays, and greater impact on quality of life [3,4]. In particular, early detection of cancer is a national priority in England, with the National Health Service (NHS) Long-Term Plan aiming to diagnose 75% of cancers at an early stage by 2028 [5-7]. A patient's pathway to diagnosis of cancer may begin weeks or months before they seek help from a health care provider, when

XSL•FO
RenderX

they first notice changes in their body and make decisions about the next steps, including doing nothing, monitoring, self-managing (eg, through medication or rest), seeking external information, or consulting a health care provider [8]. Misinterpreting symptoms as not needing health care appears to be the most important reason for diagnostic delays, constituting approximately 60% of the overall time from first symptoms to diagnosis in cancer [9].

There is growing interest in exploring how the internet is used in response to symptoms and the decision to seek help. Accessing health information online prior to appointments can empower patients and enable more informed conversations with health care providers [10]. Individuals typically search for specific symptoms rather than diagnoses before visiting a health care professional [11,12], although over 40% of individuals opt against seeing a doctor after researching their symptoms [10,13,14]. Recent research has suggested that internet search activity history may provide valuable early digital signals of disease at an individual level. For example, there has been pilot work into the predictive utility of internet searches in relation to gynecological malignancies [15]. The researchers found differences in online search data between malignant and benign gynecological conditions, up to a year before general practitioner referral. Similar findings have been reported in lung cancer [16] and pancreatic adenocarcinoma [17]. However, studies have found variable opinions on sharing internet browsing history data [18-20], and there is a lack of diversity in studied populations. This has the potential to compound existing inequalities [21]. It is known that older adults, those from minority ethnic groups, and those with the lowest levels of socioeconomic status have differences in linguistics, disease rates, digital literacy, and help-seeking behaviors [21-23]; are less likely to use the internet for health information [24-26]; face barriers to internet access [22,27]; and are more likely to experience inequalities in cancer care and outcomes [28]. Disadvantaged groups are also less likely to be willing to share health information more generally [29,30].

Crucial to successful research into internet browsing history is ensuring this research is acceptable to research participants and achieves representative participation. There is currently a lack of knowledge about public and patients' perceptions of acceptability of using individual level internet search data for medical research or the criteria that would enhance engagement. This is important as low or biased engagement could limit the potential of these studies. In this study, we define acceptability as a multifaceted construct, which reflects how potential research participants consider the proposed research to be appropriate [31]. We apply the adapted theoretical framework of acceptability [32], which highlights 8 constructs relevant to establishing acceptability, to explore the feasibility and acceptability of sharing internet browsing history data for health research among individuals with and without a history of cancer, including those from disadvantaged groups.

Methods

Participants and Recruitment

Recruitment took place through in-person engagement and recruitment posters (with a study email and phone number) at community organizations, local networks, and charities using a purposive sampling strategy to ensure representation of groups at higher risk of poorer health and digital exclusion, such as individuals experiencing higher levels of deprivation, older adults, individuals with lower educational attainment, and ethnic minority groups. Participants were adults of any gender, had access to a portable web-browsing–enabled device; were able to read and speak in English; and self-reported either no history of cancer or a history of cancer as an adult (excluding nonmelanoma skin cancer) to explore whether previous experience of cancer influenced willingness to share (see Multimedia Appendix 1 and Checklist 1 for full recruitment details). Individuals interested in taking part were screened in person or by phone for eligibility and sampling by MR, provided with study materials, and a date for the interview booked in pending consent. Interviews were conducted by MR or SA and took place between September 2024 and January 2025 at the university, community organization (London), or online (any location, England), whichever was preferred by the participant. Recruitment was ceased when we had captured a broad range of experiences and attitudes across a diverse group and achieved sufficient information power [33].

Study Design

This research was led by an experienced health services research team, supported by a research assistant and a medical student. The team has expertise in psychology, anthropology, digital health, inequalities, clinical practice, and policy and was supported by patient and public involvement (PPI) contributors from diverse backgrounds (see the *Patient and Public Involvement* section), allowing us to bring together different perspectives during the study design, data collection, and analysis.

Taking a critical realist position, a mixed "reactive" and "reflective" "think-aloud" interview approach was used [34,35], in which participants were invited to speak their thoughts aloud in response to material prompted by the interviewers. After a "warm-up" think-aloud activity, participants were asked to think aloud while reading sections of a participant information sheet for a hypothetical future study, which asked people to share internet browsing data for health research (either prospective or retrospective data sharing). A second think-aloud activity involved participants viewing information on "Google Takeout" (a Google service that allows users to export data from other Google products, which has been used in previous studies to allow participants to share their internet history). To visualize this, participants were also shown an example image of internet search history and encouraged to view their own internet search history via their personal devices, if available. Participants were then asked broad questions on their attitudes to data sharing and the feasibility of taking part in internet sharing research projects. Interviews lasted approximately 60 minutes and were conducted by MR or SA.

XSL•FO
RenderX

Data Analysis

Interviews were audio-recorded and professionally transcribed verbatim, and notes were made by the interviewer as a memory aid during the think-aloud portion of the interview. A framework analysis approach was employed, guided by the adapted theoretical framework of acceptability [32]. Familiarization and initial inductive and deductive coding were conducted by NCG using NVivo (version 1.6; Lumivero). To ensure consistency in the coding and thematic framework development, MR reviewed a subset of transcripts. Code definitions, grouping, and theme development were led by NCG and refined through discussion with MR, SS, and CD via a series of consensus meetings and validated with patient and public contributors. These discussions were informed by field notes kept by SA and MR, and analysis notes were kept by NG. Microsoft Excel was used to chart codes, develop a framework matrix, and compare responses between participants with and without a history of cancer.

Ethical Considerations

Ethical approval was granted from Queen Mary University of London (QMUL) Research Ethics Committee (reference QME24.0548). The study protocol is available on OSF [36], and there were no deviations from this protocol. Informed consent was obtained from participants through a written consent form that was explained by the researcher following a detailed participant information sheet. Participation was voluntary, and participants could withdraw at any point of the study. Participants' identifying information has not been included in this study. Participants were reimbursed £25 (US $33.50) for their time.

Patient and Public Involvement

Three patient and public involvement contributors were recruited from the Centre for Cancer Screening, Prevention and Early Diagnosis (Queen Mary University of London) PPI pool. This is a working database of over 150 people who have expressed an interest in contributing to research. We requested engagement particularly from people aged 55 years or older and from a Black, Asian, or other minority ethnic background. PPI contributors discussed the overall study approach; reviewed the study documents, such as participant information sheets and interview guides; and validated the interpretation of the results and the study recommendations. Recommended changes that were implemented included improved wording on the study recruitment posters and clarification of the study purpose in the participant information sheets. PPI reporting is included in Checklist 2.

Results

Participant Characteristics

In total, 22 interviews were conducted. Two transcripts were excluded from the final analysis following team discussion. In both interviews, there was little engagement, the participants repeated information included within the question and were unable to provide details about their own experiences. As a result of this, the relevance and reliability of the data were insufficient for meaningful analysis. Half (n=10, 50%) of the participants had no history of cancer and half (n=10, 50%) had a history of cancer, representing a range of age, gender, and ethnic groups. Half of those with no history of cancer (n=5) and one third of those with a history of cancer (n=3) lived in areas described as high deprivation (ie, local postcode scores 1 or 2 according to the English Indices of Deprivation), where 1 represents the highest level of deprivation and 10 represents the lowest level of deprivation [37]. The full details of participant demographics are included in Table 1.

Interview Results

The key themes focused on factors necessary for acceptability, including trust, transparency, personal control, and setting digital boundaries and on the perceived feasibility and individual willingness of participants to share internet browsing history for health research. Finally, participants offered recommendations on how future studies using this approach could facilitate trust and encourage participation.

Trust and Transparency as Foundations for Acceptability

Trust and transparency emerged as central factors influencing participants' willingness to share their browsing history data. Trust was not automatic but needed to be actively earned through clear communication, familiarity with the research team, transparency about who would access the data, and integrity in data handling. Direct interaction with researchers, a clear understanding of the study's purpose, and reassurance about data access enhanced participants' sense of security and credibility.

> *I'd feel comfortable because I've met you guys and you've explained clearly what your research is about, if it was a third party, then that's kind of weird because I've never met that person.* [P02, 35-39 years, female, no history of cancer]

Participants consistently articulated that their trust in the research team was closely tied to the perceived transparency of the team's actions and intentions. Providing clear information about the researchers' identities, data use, and opportunities to ask questions would foster reassurance and informed participation. Transparency also entailed setting clear boundaries around what data would be accessed and outlining the safeguards in place to protect privacy. Participants were generally willing to share information provided researchers strictly adhered to stated objectives, maintained ethical standards, and implemented robust data handling protocols, such as anonymization and secure deletion.

> *It is always reassuring to see that you are following all the right things and that you delete information*

XSL•FO
RenderX

> *once you've collected it for your analysis.* [P43, 75-79 years, female, history of cancer]
>
> *Because of the sensitivity of that nature, I need to be 100% sure that this data are being used in the right way, are stored, accessed by a limited number of people for the purpose that is being clearly described and given consent for.* [P54, 35-39 years, male, history of cancer]

Importantly, participants noted that it was not the nature of their data that caused concern but rather the apprehension that would arise if researchers deviated from the agreed scope of use. Such actions would raise doubts about the researchers' intentions and significantly undermine trust. Thus, trust and transparency were seen as mutually reinforcing, whereby transparency was essential to the development and maintenance of trust throughout the research process.

> *Providing that the researchers are open about what they're doing and only do what they say they're going to do, then that's fine. If they start going beyond that then it would concern me … because it makes you question why they're wanting to look for other things.* [P47, 60-64 years, female, history of cancer]
>
> *As long as it's for research … If they are properly trained researchers, they'll be ethical and respectful and will observe people's confidentiality and privacy.* [P43, 75-79 years, female, history of cancer]

Several participants highlighted the importance of having choice and autonomy, including the ability to opt out or withdraw consent at any time. These features reassured participants that their involvement remained voluntary and under their control.

> *It's quite good that it's got an opt-out clause … you don't have to take part if you don't want to and that it won't affect you in any way.* [P26, 55-59 years, female, history of cancer, responding to the PIS]

Trust in the organizations managing search data was a fundamental factor in acceptability, with participants clearly differentiating between trusted public bodies and commercial companies. Institutional affiliations with reputable entities, such as the NHS (United Kingdom) and universities, were seen as markers of legitimacy, with logos, branding, and clear consent processes being mentioned as ways of reinforcing this trust. Commercial companies were often not trusted due to their profit-driven motives and concerns about data misuse, such as selling personal information to health insurance companies leading to potential discrimination.

> *I'm not sure I saw a university or NHS trust logo … Just to give me that added confidence.* [P43, 75-79 years, female, history of cancer, responding to the PIS]
>
> *I think with the NHS it's okay, but if it's a private corporation or some commercial that engages with marketing stuff, then I'd be quite apprehensive about that.* [P02, 35-39 years, female, no history of cancer]
>
> *If it is for other reasons like health insurance, then they can target you and make you pay a higher premium, then I don't think that is fair. And then I'm not happy with it.* [P17, 60-64 years, female, no history of cancer]

Personal Control, Privacy Concerns, and Setting Digital Boundaries

Privacy and data security emerged as critical concerns for participants, reflecting broader mistrust in digital systems. The foundations of trust in data management were heavily dependent on participants' perceptions of how their personal information would be treated. While some participants were open to sharing their data for medical research, many expressed reservations about the potential misuse of their personal information or information of other individuals using their devices, as well as data breaches. They highlighted the importance of maintaining control over their personal data.

> *The only thing I'd worry is if certain things have been hacked.* [P09, 20-24 years, male, no history of cancer]
>
> *It's that right to say yes or no, I have the right to keep my private things private.* [P49, 60-64 years, female, history of cancer]

The concept of privacy was also viewed as inherently linked to transparency, with many participants seeking clear assurances about how their data would be used. Individuals described their internet history as deeply personal, a window into their habits, interests, and private moments and therefore a reflection of their day-to-day lives. Participants expressed strong concerns about the intrusiveness of using this type of data, emphasizing that it could feel like a violation of privacy if there was a risk of others accessing their data, making its use in research a potentially sensitive issue without clear ethical safeguards in place.

> *I need to be convinced about this and get some reassurances that privacy issues will be dealt with accordingly. Otherwise, I find it intrusive.* [P54, 35-39 years, male, history of cancer]

Interestingly, 6 out of the 20 participants, all those without a history of cancer, reported using incognito mode for reasons such as accessing restricted websites, watching YouTube, avoiding cookies or pop-ups, and conducting private searches related to health or banking.

Some participants expressed a strong desire to maintain autonomy over their personal information. While many would feel comfortable sharing health-related information, they were clear that they did not want to disclose any other personal or sensitive details, frequently citing financial information, political views, or family matters as examples.

> *I like to have this agency over my digital data … I wouldn't like such sensitive data to sneak in my internet use history and shared with irrelevant people.* [P54, 35-39 years, male, history of cancer]

To overcome this, several participants emphasized the importance of having a filtering system that would allow them to share only health-related data, reassuring them that irrelevant or sensitive information, such as bank details or private communications, would not be accessed. This idea of a "health filter" was repeatedly mentioned as something that would make

XSL•FO
RenderX

people feel more comfortable and in control of what was being shared.

> *I do personally think that if this research is medical, then there has to be a way that all you are taking are medical notes.* [P49, 60-64 years, female, history of cancer]

> *I mean obviously no computer programme is 100% going to sift out everything that's medical, but I think it would probably come close to answering my concerns.* [P26, 55-59 years, female, history of cancer]

Participants did not state a preference for prospective or retrospective data collection. When prompted to reflect on whether knowing they would share their data with researchers would change their behavior, only 1 participant felt that they would be on "good behavior" and potentially delete personal activities. Other participants stated they were not concerned as they "had nothing to hide," felt that "everything's big brother as it is," or that they would "forget."

> *I don't believe people would necessarily be mindful about what they look, what they search, knowing that somebody else is checking on it.* [P17, 60-64 years, female, no history of cancer]

Perceived Feasibility and Willingness to Participate in Health Research

Burden of Effort and Digital Literacy

Willingness to share internet browsing history was influenced by perceptions of effort and confidence with digital tools. While many participants were open to the idea, concerns emerged about the time and technical knowledge required to download and share these data. The process was seen by some as potentially tedious or confusing, particularly over a year-long period. One participant joked, "you'd be there all day with mine" [P40, F, 60‐64, history of cancer], reflecting anxieties about data volume and complexity.

Digital literacy varied considerably. While some participants felt comfortable navigating online platforms, others described themselves as "not expert" or relied on others for support. Tools such as Google Takeout were unfamiliar to many, and concerns were raised about storage, filtering content, and whether the process could be made simple and secure. For those less confident, the technical aspects posed as a potential barrier to engagement. These concerns were more commonly expressed by older participants, particularly those aged over 70 years, often unfamiliar with basic terms such as "browser" and relying on others for support; for example, 1 person told us: "I say I'm too old to learn" [P19, 75‐79, F, no history of cancer]. However, confidence did not always coincide with age, as some younger participants also expressed uncertainty.

> *It's too new to me, I didn't know about Google Takeout and I didn't know there was such a thing as a Google account.* [P01, 70-74 years, male, no history of cancer]

> *I don't mind sharing it as long as it's easy for me to actually share it.* [P48, 55-59 years, female, history of cancer]

Personal Experience and Online Health Information

Participants with a history of cancer expressed notably higher levels of privacy concern, emphasizing the sensitive nature of their health data and the need for strict anonymity, whereas participants without a history of cancer, while still valuing privacy, were generally more pragmatic and less emotionally driven in their concerns. These differences suggest that a cancer diagnosis may intensify apprehensions about data sharing and potential identification. Some participants with cancer also highlighted that their main interaction with online health information came after their diagnosis, limiting the utility of their browsing history for early diagnosis ("… for me, … I don't go looking for stuff on-on the internet until it's happened").

Innovation and Societal Impact

Participants recognized the potential for using internet browsing history data to improve individual health outcomes and also contribute to broader societal benefits. During the think-aloud interviews, many participants spoke more broadly about health, cancer, and internet search behavior, with some focusing on how people search for symptoms before diagnosis, while others mentioned improvements in accessing trustworthy information. Many commented on the culture of online health information, expressing frustration over "fake news" and the negative tone of many search results. There was hope that the research could help promote credible sources and bring trustworthy sources such as NHS websites to the forefront.

> *I think it's a really interesting premise, looking at if people are Googling their symptoms before they seek medical help … because intervening earlier might lead to earlier diagnosis and this would be very positive.* [P26, 55-59 years, female, history of cancer]

> *Google search symptoms can be a little bit doom and gloom … it would be great if people actually get more access [to] information … that [is] practical.* [P02, 35-39 years, female, no history of cancer]

Participants expressed strong support for the use of digital tools and online behaviors in health contexts, particularly if related to improving early diagnosis and accessing trustworthy advice.

> *If people can be helped earlier and better, then yes, I support it.* [P17, 60-64 years, female, no history of cancer]

> *Technology can really help people with health stuff.* [P02, 35-39 years, female, no history of cancer]

> *People like to be involved and want to know what effect it might lead to.* [P43, 75-79 years, female, history of cancer]

> *Only by sharing our data can progress be made in medical research.* [P47, 60-64 years, female, history of cancer]

Early diagnosis emerged as a powerful motivator for data sharing and health research participation, with several

XSL•FO
RenderX

participants emphasizing the importance of online data to prompt earlier help-seeking and therefore improve health outcomes. Participants' experiences of cancer shaped their perspectives on the potential value of the research.

> *I always feel really happy if I can help with a study that is going to absolutely make someone move forward with an early diagnosis.* [P49, 60-64 years, female, history of cancer]
>
> *We shouldn't be going to stage three in cancer. I think we should be able to fix it at stage one.* [P46, 45-49 years, female, history of cancer]

However, while people felt the research was worthwhile for early diagnosis, some questioned the usefulness of their own browsing history, describing it as "low value" or highlighting that they did not frequently use the internet to look up health questions.

Discussion

Principal Findings

This study explored the acceptability of using individual-level internet browsing history data for health research focusing on earlier cancer diagnosis. To our knowledge, no previous study has assessed the acceptability of using such data with respect to health inequalities and cancer.

In this study, participants placed greater confidence in public institutions such as the NHS and universities rather than commercial companies with fear of data misuse, discrimination, and profit motives being predominant reasons, similar to other studies [29,38,39]. Transparency played a foundational role in fostering trust, and this could be built and sustained through clearly communicating study aims, respecting participant boundaries, and keeping participants informed throughout the process.

Participants expressed ongoing concerns about the potential for their data to be hacked or misused once shared, reflecting broader mistrust in digital systems and the sensitive and private nature of internet browsing data. This sentiment was particularly strong among those with a history of cancer who linked their online searches to periods of emotional vulnerability and distress, particularly around diagnosis and treatment phases, similar to previous studies [40,41]. Younger participants took steps toward digital privacy, using "incognito mode" or alternative browsers or search providers seen as more secure, presenting a potential barrier for future research which relies on search history data.

To overcome these concerns of data intrusiveness, a key recommendation across interviews was the implementation of a robust filtering mechanism to isolate health-related data from other forms of personal information. Not only did this offer reassurance that sensitive or irrelevant information would not be accessed, but it also served as a practical mechanism to enhance participation by directly addressing concerns around data intrusion and potential misuse. Previous studies have applied health filters using a list of symptoms, diseases, and medications and their synonyms [15,42]. However, patient descriptions of symptoms may vary according to sociodemographic, linguistic, cultural, regional, and other factors [43,44], which may not be taken into account in lists developed from clinical lexicons. The definition of health-relevant information may also vary according to the condition a study focuses on: for example, negatively valenced web pages in individuals with depression [45], or typing speed and error rate in the presence of cognitive changes, such as in multiple sclerosis [46]. Future research approaches using browsing data will need to clearly define and communicate the limitations of any such filtering to participants.

Additionally, the study revealed wide variation in digital literacy, with both older adults and some younger participants expressing confusion around basic digital terms and concerns about making mistakes during the data-sharing process. This uncertainty about the technical aspects of using unfamiliar tools to download internet browsing data (such as Google Takeout) posed as a barrier, especially for those with limited digital confidence, highlighting the need for simple, user-friendly processes and tailored, individual support. Table 2 outlines key recommendations to enhance participation for future studies.

XSL•FO
RenderX

Table . Recommendations for research involving individual-level internet browsing history, as suggested by participants, linked to the study's themes and the adapted theoretical framework of acceptability (ATFA) [32].

Area (ATFA construct)	Recommendations for research involving individual-level internet browsing history
Trust and transparency (ethicality, intervention coherence)	• Provide clear and accessible information about the study and data use • Use NHS[a] or university branding to build trust where possible • Ensure participants have control, including opt-out options • Maintain open communication with participants • Ensure each participant has a point of contact to direct queries • Include clear information on the research team members including name and credentials
Privacy, data control, and digital boundaries (ethicality, trust)	• Implement a robust filtering system to isolate health-related data and exclude nonhealth-related content (eg, finances, politics, schools); potentially including the option to remove browsing activity related to, or on behalf of, others such as friends and family • Reassurance regarding anonymity, data storage, data protection, and confidentiality
Burden of effort and digital literacy (burden, self-efficacy)	• Offer simple, step-by-step guidance on how to share search history • Include visual aids or videos to support less digitally confident users • Provide technical assistance when needed
Innovation and societal impact (affective attitude, perceived effectiveness)	• Emphasize the societal benefits, such as improving early diagnosis • Highlight how the research could help others • Reassure participants that their contribution is meaningful and valued

[a]NHS: National Health Service (United Kingdom).

Comparison With Prior Work

A recent review of harnessing internet search data as a potential tool for medical diagnosis identified ethical, bias, technical, and policy challenges [47]. In our study, several key factors emerged as influencing participants' willingness to share their internet browsing data, consistent with previous research, which broadly categorized these into four key themes: (1) the relationship between the participants and the researchers, (2) fears and harms of data sharing, (3) purposes, and (4) benefits [48]. Similar recommendations were made in studies to share other digital data, such as loyalty card (purchase history) for academic research [49,50].

Across our study and other work, trust and transparency are integral components and prerequisites for willingness to share data. Trust is not a singular concept but multi-layered, operating at 3 distinct levels: interpersonal (trust in individual researchers), institutional (trust in health care or academic organizations), and systemic (trust in the digital infrastructure more broadly) [51]. Key "enablers" and "impediments" within these trust levels include sociodemographic factors and the reputation of the institution fitting into both categories [39]. Understanding these intersecting factors is key to ensuring research utilizing internet browsing history data for health research is equitable: for example, 1 study suggested that internet and social media data may be viewed by the public as more sensitive than electronic health record data [20]; another found that medical records were seen as the most sensitive type of data, but this was willingly shared with health researchers, while sharing banking data (seen as the second most sensitive) raised more concerns [50]. Attitudes to data protection and sharing may also vary by demographic group: for example, younger people and people with more education were more likely to choose an option to pay for a service to keep their data private, regardless of income level [52]. Additionally, people with long-term health conditions and those from ethnic minority backgrounds express higher concern about sharing data in general [53], and trust in researchers may vary by ethnic group [54]. Smart Data Research UK's recent public engagement also found that while information about the purpose and benefits of the research positively influenced willingness for their data to be used in research, there was low trust in government and public institutions for these findings to impact policy [55]. This highlights the need to build trust at all levels to ensure that research using digital data targets those who would benefit the most from the earlier detection of cancer and to prevent the risk of exacerbating inequalities. Participants stressed the personal nature of establishing trust ("I've met you guys"), and prospective studies must consider the practical and resource implications of maintaining these relationships over the course of a study to support sustained participant engagement.

Our study also highlighted potential issues of feasibility related to sharing internet browsing history. Previous research has utilized "Google Takeout" as a method for data porting in this type of research. This study identified potential limitations to this approach: for example, participants used other browsers (eg, did not use Android devices); did not have a Google account or were not logged in. Further fragmentation of the digital ecosystem occurs through social media channels, in-app data access, and the impact of generative artificial intelligence on how people seek and review health information—such as only reading the in-browser artificial intelligence summary or asking

XSL•FO
RenderX

ChatGPT [56]. A review of the use of internet search data in diagnosis research found no studies that integrated data from across different platforms and noted the complexity of standardizing such data for analysis and a need for supporting infrastructure and guidance on best practice.

Participants' individual behavior also impacted feasibility; for example, they avoided "cyberchondria" by not using internet searches for health, used incognito mode to hide searches, and searched for health-related data for others (leading to potentially "messy" data). One study recruiting women with gynecological symptoms reported that one quarter of potential participants did not have a Google account and nearly 30% did not have relevant data or faced technical issues with sharing their data [15]. While the median age was similar in those included and excluded in the study, other potential demographic differences were not discussed. Other studies have identified similar issues, including participants consenting to take part in the study but deciding they did not want to share their Google searches [57]. One study that focused on internet use in older age groups (mean age 81 years) found that even among individuals who used computers, 22/76 (29%) did not conduct any searches during the duration of the study, and a further 12 did not conduct any searches in a particular 3-month period [58]. Some studies have only included individuals with a Google account [59-61], but this may impact the utility of this type of research approach in sociodemographically diverse populations.

This study found that in most domains, participants with and without a history of cancer shared similar perspectives. It is possible that the differences in the use of incognito mode between the participants with and without a history of cancer may relate to individual variability in digital literacy, as other participants were not aware of this function. This was not necessarily limited by age or education level, as those who used it were within age brackets from 20 to 64 years. In contrast, participants with a history of cancer expressed notably higher levels of privacy concern, although they were similarly willing to share their data given adequate safeguards. We speculate that this may be due to their closer experiences with the health system, potentially identifying the nature of rare cancers and their focus on their browsing activity postdiagnosis. Qualitative studies in cancer survivor populations have found similar willingness to share and made similar recommendations for building trust [62], and comparisons of individuals with and without a history of cancer found similar willingness to share information and a higher willingness in those with a history of cancer to share sensitive information (such as genetic information) [63]. This suggests an opportunity to examine in more detail how individual health experiences may impact willingness to share data for research related to specific health risks.

Studies that have involved sharing of internet search logs and health data with researchers have typically been retrospective, and there is limited evidence regarding differences in search patterns in study participants who donate data prospectively [47]. A study of the observer effect on social media use did find differences in posting behavior including frequency and topics [64]. Participants were prompted to discuss this during the interview and reported that it would not impact their (long-term) browsing activities. Nevertheless, this remains an important area to explore.

Strengths and Limitations

This study aimed to explore the acceptability of sharing internet browsing history for research, ensuring representation from groups more at risk of experiencing digital and cancer inequalities. We know that 3% of the population of the United Kingdom do not use the internet, facing barriers such as cost, poor connectivity, and lack of digital skills and that people in this group are more likely to be older and/or earning less [65]. Any future research of this kind would require individuals to use the internet; this required us to find a balance when recruiting and designing the methods. Offering both online and face-to-face interviews (at a convenient location) improved accessibility and allowed those who only use the internet on their phone or on shared devices (eg, library computers) to participate. Additionally, we purposively sampled groups affected by health and digital inequalities, enhancing the relevance of the findings across diverse populations. The participants with a history of cancer were more likely to have a tertiary level of education and showed more variability in whether they lived in more or less deprived areas. However, as limited comparisons were made between the groups, we feel this sample shows sufficient variability across different groups affected by health and digital inequalities. The interviews were restricted to English to support the think-aloud exercises, and as current internet history research has focused on single-language searches. However, future approaches should consider how the internet activity of more diverse populations can be included, particularly as diaspora populations may choose to seek and act on health information from their country of origin [66]. While self-selection bias is possible as participants may have had a preexisting interest in health research or felt comfortable discussing digital data, the diversity and depth of responses suggest that a broad range of perspectives was captured. This was an exploratory study (n=20), and future studies may wish to explore specific barriers and solutions in populations at different risks of exclusion.

Conclusion

This study highlights the steps required to improve the viability of internet browsing data to support earlier diagnosis and enhance public health outcomes. While concerns around privacy, data use, and institutional trust persist, they were not seen as insurmountable. Participants generally expressed positive attitudes toward this innovation, when use is clearly linked to tangible health benefits, provided there are ethical safeguards, simple guidance, and opportunities for consent. The integration of internet browsing data with a patient's medical records may present an opportunity for identifying early signals of disease and holds promise for future research.

Importantly, this research approach offers unique opportunities to reach individuals who may face barriers to accessing traditional health care services, potentially reducing health inequalities and promoting more inclusive approaches to early diagnosis. However, the implementation of this approach requires careful attention to issues of accessibility, digital literacy, and infrastructure; otherwise, the same approach is at

XSL•FO
RenderX

risk of inadvertently exacerbating existing sociodemographic disparities.

To fully harness the benefits of internet search data in health care, systems must become more integrated, secure, and person-centered. As global health pressures grow, such as the rising incidence of cancer, leveraging digital data responsibly offers a path toward more preventative and sustainable health care strategies.

Acknowledgments

We would like to thank patient and public involvement contributors for their valuable inputs during this project. We would also like to thank participants for their time and interest in this study. No artificial intelligence tools were used in the conceptualization, data collection, analysis, or preparation of this manuscript.

Funding

Google provided unrestricted funding for this research through a Privacy Research Faculty Award to SES. SES is also supported by Barts Charity (G-001520; MRC&U0036). The funders had no role in the study design; collection, analysis, or interpretation of data; writing of the paper; and/or decision to submit for publication.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Authors' Contributions

SES acquired funding. SES and MR contributed to conceptualization and were responsible for project administration. MR and SA undertook the data collection, and NCG and MR undertook the analysis, with input from SES and CD. NCG and MR drafted the original manuscript. All authors contributed to writing – review and editing.
MM and RP are not affiliated with an organization but contributed as patient and public contributors.

Conflicts of Interest

The Data Liberation Front (based at Google) was a collaborator on the study and advised on accurate description about Google Takeout. They had no other input on the study design or conduct. The research team (SES, MR) was the sole decision-makers on research design and outputs.

Abstract

Background: African American caregivers are more likely to be sole unpaid caregivers, spend more hours on caregiving tasks, and receive less external support compared to White caregivers; yet, limited research focuses on their specific needs. Even less attention has been paid to health care provider perspectives on how to better support this population, despite providers' critical role in connecting caregivers to resources and implementing systems-level changes.

Objective: This study aimed to understand health care providers' experiences supporting African American cancer caregivers and to identify actionable recommendations for improving care. Specific objectives were to (1) identify unmet needs that providers observe among African American cancer caregivers, (2) explore barriers preventing these needs from being met, and (3) elicit provider recommendations for interventions to enhance caregiver support.

Methods: Between January and May 2023, we conducted semistructured online interviews with 12 health care providers across 7 US states. Providers were purposively sampled from facilities serving patient populations with ≥20% African American representation. Participants included physicians (n=7), social workers (n=2), nurses (n=2), and other providers (n=1), with 58% identifying as Black or African American and 83% having more than 15 years of clinical experience. Interviews lasted ~60 minutes and were conducted via Zoom (Zoom Video Communications, Inc) with audio recording. Data were analyzed using condensed thematic analysis guided by the McKillip needs assessment framework and socioecological model.

Results: Thematic analysis revealed 2 overarching categories of findings. First, providers identified three types of unmet needs among African American cancer caregivers (1) practical needs, including transportation, financial constraints, and competing family obligations; (2) social-emotional needs, including stress, burnout, and fear; and (3) cultural barriers, including medical mistrust rooted in historical trauma, "superhero Black woman" expectations, tensions between faith and medical treatment, and stigma around mental health. Second, providers offered four themes of recommendations for transformational change: (1) formal acknowledgment and compensation of caregiving as essential work; (2) integration of caregivers as equal members of multidisciplinary care teams; (3) recognition and leveraging of cultural assets, including strong family networks, community values, and faith-based support; and (4) strengthening providers' roles as hubs for individual-level support and systems-level advocacy.

Conclusions: Health care providers readily identify substantial unmet needs among African American cancer caregivers and offer practice-based recommendations that extend beyond individual-level support to emphasize structural and systems transformation. Findings suggest that meaningful improvement requires multilevel intervention. This includes policy changes to formalize and compensate caregiving work, organizational restructuring to integrate caregivers into care teams, provider training in cultural humility and asset-based approaches, and institutional commitment to addressing historical trauma and rebuilding trust with African American communities. This novel provider-focused approach offers actionable pathways for clinical settings to reduce disparities and improve outcomes for African American cancer caregivers and the patients they support.

Introduction

Cancer Caregiving

As cancer survivorship increases in the United States due to medical advances, the burden of long-term caregiving has grown substantially [1-5]. This burden falls disproportionately on communities of color, who face higher rates of chronic disease, greater caregiving responsibilities, and significant structural barriers, including limited health care access, lower socioeconomic status, and systemic medical mistrust rooted in historical trauma [6-8].

Caregivers play a crucial role in addressing the health and social needs of individuals with chronic conditions, providing essential support that significantly impacts patient outcomes [5]. For instance, cancer caregivers dedicate an average of 32.9 hours per week to caregiving tasks, with 32% reporting more than 40 hours of caregiving weekly [6]. Informal caregiving, which involves providing care without formal employment or financial compensation, is particularly common [4]. However, the burden of informal caregiving falls disproportionately on communities of color [7,8].

Systematic reviews and meta-analyses focused on caregiving within communities of color consistently reveal negative effects on caregivers' physical and mental health [9-11]. One meta-analysis identified a significant association between caregiving and increased levels of self-reported depression and stress, along with reduced general well-being [10]. Additionally, caregivers were found to have lower odds of engaging in preventive health services and personal wellness activities compared to noncaregivers, often prioritizing the needs of those they care for over their own health [12,13].

Studies of access to medical support also show significant gaps. For instance, 54% of caregivers reported having no contact with a health care team in the past year [14]. Among cancer caregivers, many performed complex medical tasks without prior training, and few addressed their own self-care needs during medical visits [6].

Prior Work on African American Caregivers

The prevalence of caregiving is higher among African American (28.1%) and Hispanic (21.9%) populations compared to White populations (19.8%) [7]. However, these groups often face greater health disparities, including higher rates of negative health outcomes, limited access to health care, lower health literacy, and lower income and education levels than White populations [15]. Furthermore, caregivers from diverse backgrounds frequently receive less empathetic communication from health care providers, obtain less medical information, are less involved in medical decision-making, and feel less confident in requesting training or social assistance from health care professionals [16,17].

African Americans are more likely to be the sole informal and unpaid caregivers compared to White caregivers (55% vs 44%), more likely to live full-time with the individuals they care for (45% vs 36%), and more frequently report receiving no external support for their caregiving duties (41% vs 30%) [7]. Additionally, they tend to spend more hours per week on caregiving tasks and are more likely to assist with both activities of daily living, such as managing incontinence and bathing, and instrumental activities of daily living, including medication and financial management. Despite these increased responsibilities, African American caregivers are only half as likely to receive respite services compared to their White counterparts [7].

Caregiving can negatively impact caregivers' health, with only 34% of African American caregivers rating their health as excellent or very good, compared to 45% of White caregivers [7]. African American caregivers also face greater financial challenges, reporting lower household incomes and higher levels of financial strain than their White counterparts [18-21]. Among African American caregivers, 74% have had to modify their employment status due to difficulties balancing work and caregiving responsibilities [19]. Social values, such as familyism—which emphasizes prioritizing family needs over individual needs—are prevalent in African American and other communities of color, adding further strain and contributing to poorer health outcomes for caregivers [12,19]. Additional complexities can arise from the fact that only 3% of oncologists in the United States are Black [22], limiting the potential positive effects of racial concordance on patient-provider (and caregiver-provider) interactions during care visits [23,24].

The Critical Role of Provider Perspectives in Understanding Caregiver Needs

Health care provider perspectives on African American cancer caregiver needs remain understudied. This represents a critical gap given providers' roles as gatekeepers to resources, care coordinators, and drivers of institutional change. Providers like physicians, nurses, and social workers occupy a unique structural position at the intersection of individual patient and caregiver needs and institutional resources and policies [25]. Unlike caregivers who experience their own individual challenges, providers are in a unique position to observe patterns across multiple patients and caregivers, allowing them to identify common issues, effective strategies, and systemic gaps that may not be apparent from individual caregiver accounts.

Provider awareness, attitudes, and behaviors directly influence whether and how caregivers receive support during clinical encounters [26]. Providers who recognize caregiver burden and prioritize caregiver needs are more likely to initiate conversations about support services, make appropriate referrals, and engage caregivers as partners in care planning. Conversely, when providers lack awareness of caregiver challenges or hold implicit biases about caregiver capacity based on race or

XSL•FO
RenderX

socioeconomic status, caregivers may be overlooked in care processes despite having substantial unmet needs [27].

Providers also serve as the primary conduit through which caregivers access formal support services, including social work, care navigation, palliative care, respite services, and community resources [28]. One of the strongest predictors of patients and caregivers accessing support services is provider recommendation. Understanding what providers observe about caregiver needs and what improvement recommendations they offer directly informs how to optimize referral pathways, given their position to influence institutional and systems-level change [29]. They often hold positional authority that allows them to champion policy changes, implement new care models, secure resources, and influence organizational priorities.

Further, understanding provider perspectives can identify discrepancies between caregiver-reported needs and provider perceptions, revealing potential blind spots in current health care delivery across specialties and well beyond oncology [28,30]. When providers underestimate caregiver burden, misunderstand cultural factors shaping caregiver experiences, or fail to recognize specific issues faced by African American caregivers, these gaps in awareness translate directly into inadequate support. No studies, to our knowledge, have specifically examined provider perspectives on the unique challenges and support needs of African American cancer caregivers, despite well-documented disparities in both cancer outcomes and caregiving experiences within this population [31].

Goals of This Study

Existing research addresses caregivers' general needs, but there is a gap regarding African American cancer caregivers' specific needs and even more so considering how providers might play a supportive and constructive role in improving the caregiving experience. This study aims to engage with this understudied area by describing the unique challenges faced by these caregivers in three key ways: (1) within the context of cancer caregiving, (2) specific to the experiences of African American caregivers, and (3) from the provider's viewpoint, rather than solely from the caregiver's perspective. This study seeks to offer valuable insights into how health care professionals can better assist and work alongside African American cancer caregivers, guided by the following research questions:

1. What are health care providers' experiences in supporting the needs of African American cancer caregivers?
2. What unmet needs do health care providers observe among African American cancer caregivers, and what barriers prevent African American cancer caregivers from having their needs met?
3. What recommendations do providers offer for improving support for African American cancer caregivers at individual, organizational, and systems levels?

This provider-focused approach offers unique insights into systemic barriers and solutions that can inform practice improvements and policy changes to better support African American cancer caregivers.

Innovation and Implications for Participatory Cancer Care

This study offers methodological and conceptual innovations aligned with advancing participatory, patient-centered cancer care. Methodologically, we apply a needs assessment framework through the provider lens to explicitly link identified needs to actionable, multilevel solutions [32]. Unlike traditional needs assessments that document gaps without pathways to change, our approach positions providers as both informants about needs and architects of solutions, recognizing their capacity to translate insights into implementable interventions.

Conceptually, this research advances participatory care models by identifying mechanisms to formally integrate caregivers as essential members of multidisciplinary care teams rather than peripheral figures. By centering provider perspectives on caregiver integration, we identify specific strategies for operationalizing truly collaborative care that includes patients, caregivers, and health care professionals as partners.

Our findings also have direct implications for designing technology-enabled interventions responsive to African American caregiver needs. Provider recommendations regarding accessibility, communication, and cultural responsiveness can inform the development of telehealth platforms, mobile health (mHealth) apps, patient and caregiver portals, and digital care coordination tools that address rather than perpetuate existing disparities.

Finally, this work directly addresses health equity priorities in cancer care by focusing on an underserved population and identifying concrete, systems-level strategies for improvement, providing actionable pathways for health care organizations committed to reducing disparities in cancer survivorship.

Methods

Study Context and Background: Research Context and Rationale

This research emerged from identified gaps in understanding the specific needs and experiences of African American cancer caregivers within US cancer care systems. Provider perspectives are essential for several reasons. First, providers are positioned at the intersection of individual patient and caregiver needs and institutional resources, making them uniquely situated to identify both clinical-level and systems-level barriers and potential solutions. Second, provider awareness and prioritization of caregiver needs directly influences whether and how caregivers receive support during clinical encounters. Third, providers observe patterns across multiple patients and caregivers that individual caregivers may not recognize, offering a broader view of common challenges and effective strategies. Finally, understanding provider perspectives illuminates opportunities for professional education, clinical practice improvement, and institutional policy change that can create more supportive environments for African American cancer caregivers.

Institutional and Geographic Context

Participants in this study represented diverse cancer care settings, including academic medical centers, community

XSL•FO
RenderX

hospitals, comprehensive cancer centers, and outpatient oncology clinics, representing the range of settings where cancer care is delivered. This diversity of institutional contexts provides insights into how different care delivery models and resource environments shape both the challenges caregivers face and the support providers can offer.

Temporal and Sociopolitical Context

Data collection occurred between January and May 2023, a period marked by heightened national attention to health equity and racial disparities in health care. This timeframe followed widespread recognition during the COVID-19 pandemic of the disproportionate health impacts on African American and other marginalized communities, as well as growing public discourse about systemic racism in health care institutions. National initiatives from organizations including the American Cancer Society, the National Cancer Institute, and the Centers for Disease Control and Prevention were emphasizing the urgent need to address cancer disparities affecting African American populations. Professional medical organizations were increasingly calling for cultural humility training, diversification of the health care workforce, and structural changes to reduce disparities.

This sociopolitical context is relevant to understanding provider perspectives captured in this study. Providers interviewed during this period were practicing within an environment of increased awareness, institutional pressure, and professional discourse around health equity. Their insights may reflect not only their direct experiences but also evolving consciousness about systemic factors contributing to disparities and the imperative for change. This context may have made providers more willing to engage in critical reflection about shortcomings in current care delivery and more open to discussing unmet needs, structural barriers, and potential solutions. Throughout this paper, we use “unmet needs” to describe gaps in support or resources required by caregivers and “barriers” to describe specific obstacles preventing those needs from being met.

Funding and Study Development Context

This study represents a secondary analysis of interview data originally collected under funding from EMD Serono to Gryt Health, a patient and caregiver support organization. The original data collection was designed to inform the development of culturally responsive support programs and resources for African American cancer caregivers. The partnership between a pharmaceutical company (EMD Serono), a patient advocacy organization (Gryt Health), and academic researchers (University of Texas at Austin) reflects a collaborative model increasingly common in patient-centered outcomes research, wherein industry funding supports community-focused research with academic rigor and independence.

The current manuscript represents an independent academic analysis conducted by the research team coordinated at the University of Texas at Austin under appropriate institutional review board approval and data use agreement (though not all authors are affiliated with the university). While the original project produced internal reports to guide program development at Gryt Health, the current analysis employs different theoretical frameworks, such as the McKillip needs assessment model [32] and social-ecological theory [15]. Also, this analysis uses analytical approaches such as condensed thematic analysis with multilevel intervention classification [33] to generate novel insights for academic dissemination and broader health care system application. This secondary analysis allows extraction of maximum knowledge value from rich qualitative data while adhering to ethical principles of research efficiency by avoiding redundant data collection that would place additional burden on health care providers already stretched thin by clinical demands.

The research team maintained complete independence in conducting analysis, interpreting findings, and preparing this manuscript for publication. EMD Serono and Gryt Health had no role in the design of the secondary analysis, interpretation of findings reported here, manuscript preparation, or the decision to submit for publication.

Recruitment and Data Collection

Semistructured interviews were selected as the optimal method to explore provider experiences and elicit detailed, contextually rich insights that cannot be captured through quantitative approaches. Qualitative methods are particularly appropriate for this study because they enable exploration of under-researched topics where validated measurement instruments do not yet exist, allow investigation of the “how” and “why” questions underlying observed patterns, and generate rich contextual understanding needed to inform culturally responsive interventions [33-35]. Also, the semistructured interview format allowed providers to share experiences in their own words while ensuring core topics were consistently addressed across interviews. Twelve health care providers participated in online key informant interviews conducted via Zoom (Zoom Video Communications, Inc) between January and May 2023. Participants represented a range of professional roles with diverse experiences and firsthand knowledge of supporting African American cancer caregivers in their clinical practice.

Sampling Strategy and Inclusion Criteria

Participants were recruited via purposive sampling with snowball recruitment according to explicit inclusion criteria. To be eligible, participants had to be 18 years of age or older and self-identify as health care providers who support African American cancer caregivers in their professional role. Additionally, providers had to work in facilities serving patient populations with at least 20% African American representation. This threshold was established to ensure that providers had substantial, sustained experience working with African American patients and caregivers rather than relying on limited or anecdotal encounters. The 20% threshold exceeds the overall US African American population proportion (approximately 13%), ensuring recruitment of providers with above-average exposure to these communities and deeper understanding of the specific challenges and strengths characteristic of African American cancer caregiving experiences. We acknowledge this threshold is somewhat arbitrary and represents a pragmatic research decision rather than an empirically derived cutoff.

XSL•FO
RenderX

The research team engaged in directed outreach through systematic review of LinkedIn (LinkedIn Corporation) profiles and affiliated faculty websites of providers who met the inclusion criteria. This directed outreach focused on facilities providing cancer care with significant African American patient populations and, when possible, providers with lived experiences as people of color themselves. After each interview, participants were invited to refer others in their professional networks to the study in a snowball sampling approach. In total, 25 providers were contacted for participation and 12 completed interviews (48% response rate).

The sample size of 12 was established a priori based on qualitative research guidelines indicating that samples of 6-15 participants are sufficient for focused research questions [36,37]. This sample size was deemed appropriate given the study's high "information power" (the richness of data from knowledgeable participants) [37] stemming from the narrow study aim (provider experiences with a specific caregiver population), sample specificity (participants with substantial experience supporting African American cancer caregivers), established theoretical framework [32], quality of dialogue (in-depth interviews), and systematic analysis strategy [36]. Data saturation was observed beginning at approximately the ninth interview, with no fundamentally new themes emerging in the final 3 interviews. The sample size was further constrained by the limited pool of eligible providers; fewer than 12% of oncologists in the United States are from underrepresented minorities, and fewer than 3% are Black, limiting the available recruitment pool [22].

Positionality Statement

Qualitative research is inherently shaped by the perspectives and experiences of researchers. To promote transparency, we acknowledge how our research team's characteristics may have influenced this study. The research team included BL, PhD (health communication researcher with 20 years of experience in cancer caregiving research and personal experience as a cancer caregiver); AS, MA (anthropology background focused on marginalized groups, 10 years amplifying patient voices); GD (doctoral student in community health with personal caregiving experience and diverse urban upbringing); and SU, PhD (health communication professor with 10+ years of qualitative research at a university cancer center).

Our team's racial and professional diversity provided multiple perspectives during data collection and analysis. Team members brought both insider perspectives (shared racial and ethnic identities with many participants and caregivers, personal caregiving experiences) and outsider perspectives (different racial backgrounds, academic positions) that shaped our interpretations. We acknowledge this study involved layered interpretation; providers interpreted caregiver experiences, and we then interpreted provider accounts. This twice-removed relationship to caregivers' lived experiences means both provider perspectives and our interpretations are filtered through our own frameworks and potential blind spots.

Our research was informed by commitments to health equity, asset-based rather than deficit-based framing of communities, and the belief that providers can play active roles in addressing systemic inequities. Two team members' affiliation with Gryt Health reflected engagement with patient and caregiver communities while potentially biasing us toward pragmatically feasible solutions. To mitigate bias, we employed multiple independent coders, maintained reflexive memos throughout analysis, actively sought contradictory evidence, and grounded findings in direct quotations that allow readers to assess our interpretations. We recognize our positionalities likely influenced which themes drew our attention and how we interpreted provider statements, particularly regarding structural solutions and cultural assets.

Interview Procedures and Data Collection

All interviews were conducted online via Zoom video conferencing software. The online format was selected to remove geographic limits to participation and allow recruitment of providers from diverse locations across the United States.

Interviews were conducted by 2 members of the research team. BL, PhD (Associate Professor of Health Communication and Chief Research Officer at Gryt Health), conducted 75% (9/12) of interviews, and AS, MA (Senior Vice President for Outcomes and Impact at Gryt Health), conducted the remaining 25% (4/12) of interviews. Both interviewers have extensive training in qualitative research methods through their graduate education and substantial experience with cancer caregiver research (see Positionality Statement for detailed backgrounds).

Interviews were scheduled at various times throughout the week and day to accommodate the complex and variable schedules of health care providers. Interview duration ranged from 45 to 60 minutes (mean 54 minutes, SD 4). This timeframe was selected to respect providers' time constraints while allowing sufficient depth of exploration. The shorter duration compared to many qualitative interviews (often 60-90 minutes) was a deliberate accommodation to the realities of provider availability and was deemed appropriate given the focused nature of the research questions and the providers' ability to offer rich, experience-based insights efficiently.

Interview Guide Development and Pilot Testing

The semistructured interview guide (Multimedia Appendix 1) was developed collaboratively by the research team through an iterative process. Development was informed by the McKillip needs assessment framework [32], which emphasizes identifying community needs, available resources, and gaps requiring intervention, as well as by a comprehensive literature review on caregiver experiences, African American health disparities, and provider perspectives in cancer care. The guide was designed to balance structure, coverage of key topics, and flexibility to allow providers to share unexpected insights and follow emergent themes.

To ensure clarity, cultural sensitivity, and appropriateness of language, the interview guide underwent rigorous review and pilot testing before full implementation. The guide was first reviewed by 2 community stakeholders, a cancer survivor and a community health manager, both with lived experience relevant to cancer caregiving in underserved communities. Their feedback informed refinements to question wording, sequencing, and cultural framing. Following this review, the guide was pilot tested with 2 health care providers who met the study inclusion

XSL•FO
RenderX

criteria but were not part of the final sample. Pilot testing revealed that some questions required refinement to reduce interview length and that certain prompts could be reworded to encourage more open-ended, expansive responses rather than brief confirmatory answers. Based on pilot feedback, the research team made minor adjustments to shorten the overall guide while maintaining coverage of essential topics and revised question phrasing to enhance elicitation of detailed narratives. No major structural changes were required, as pilot testers confirmed the guide was effective in exploring the intended topics.

Audio Recording and Data Capture

All interviews were audio recorded using Zoom's recording function with participants' informed consent (as described in Ethical Considerations). To enhance data quality and capture nuances that might not be fully represented in automated transcription, each interview was accompanied by a dedicated note taker who documented detailed observations in real time. The note taker recorded not only the content of responses but also observed emphases, emotional tone, pauses, and other contextual elements that provide interpretive depth.

Following each interview, Zoom's automated transcription feature was used to generate initial transcripts of the audio recordings. These automated transcripts, along with the detailed notes taken during interviews, were then systematically verified for accuracy against the original audio recordings by research team members, who corrected transcription errors, verified observations, and began considering emerging themes to ensure comprehensive and accurate data capture. This dual approach of combining Zoom automated transcription with human-verified contextual notes provided both efficiency and rigor in data documentation.

Data Analysis Procedures

Interview data were stored and coded using Atlas.ti software (ATLAS.ti Scientific Software Development GmbH) for Mac (RRID:SCR_022920). A condensed thematic analytic approach was used to identify key themes. The methods of this analysis were guided by the McKillip model of needs assessment [32], which emphasizes identifying specific community needs, available resources, unmet needs, and linking each topic to community-driven solutions. The analysis also employed a socioecological framework [38,39] to categorize themes at micro (individual), meso (organizational or community), or macro (structural or policy) levels of intervention.

A socioecological framework allows for conceptualization of health determinants and interventions across multiple interconnected levels (1) micro level (individual-level factors affecting individual caregivers and their immediate support systems), (2) meso level (organizational and community-level factors including health care systems, community organizations, and social networks), and (3) macro level (structural and policy-level factors including health care policy, reimbursement structures, and societal norms). This multilevel framework recognizes that comprehensive solutions require coordinated change across individual, organizational, and structural domains. This classification helps identify which stakeholders and systems must be engaged to address each category of unmet needs.

Preliminary analysis was completed by a PhD-level graduate research assistant and a member of the publication team, who together created a coding scheme through reading 3 interview transcripts independently and then using an open coding technique to identify themes within the transcripts following a modified thematic analysis informed by Strauss and Corbin [40]. The analysis included both inductive and deductive reasoning that followed open coding, axial coding, and then selective coding. Emerging themes related to the research questions were established.

Provider experiences with African American cancer caregivers were coded using the thematic analysis approach to better understand the lived experiences of providers in supporting the unique needs of these caregivers. Notes taken by the research team during the interview process were reviewed for each interview, and memos were included with the data for the initial development of a codebook. Codes were developed into a themed codebook starting with the "thickest" file and then building upon the initial codebook with every subsequent transcript and note analysis. Subcodes were created and evidence through cited quotations of interviewees was placed within the matrix.

Trustworthiness and Rigor

To promote scientific rigor, we used multiple strategies aligned with Lincoln and Guba's criteria for qualitative research trustworthiness: credibility, transferability, dependability, and confirmability [41].

Credibility was established through purposive sampling of experienced providers with substantial exposure to African American cancer caregivers (facilities with ≥20% African American patient populations), detailed field notes documenting content and contextual elements during interviews, dual data capture combining Zoom transcription with human verification against audio recordings, and probing follow-up questions to deepen understanding and verify interpretation of participants' meanings in real time.

Transferability was enhanced through description enabling readers to assess applicability to their own contexts, including comprehensive participant characterization (provider types, racial or ethnic backgrounds, years of experience, and geographic locations), explicit articulation of sampling procedures and inclusion criteria rationale, description of temporal and sociopolitical context, and transparent reporting of all procedures from recruitment through analysis.

Dependability was addressed through systematic documentation of all research procedures and maintenance of an audit trail, including recruitment contacts and response rates, interviewer assignments, data verification procedures, dated codebook versions, coding decisions and rationale, team meeting notes, and reflexive memos. Atlas.ti software provided systematic, transparent organization of coded data. The semistructured interview guide ensured consistency across interviews while allowing flexibility for emergent themes.

XSL•FO
RenderX

Confirmability was enhanced through independent coding by 2 team members who compared codes, discussed discrepancies, and developed the codebook iteratively through regular team meetings until consensus was reached. Atlas.ti provided transparency in coding decisions, allowing verification by other team members. Reflexive memos documented interpretive decisions, assumptions, and potential biases, which were discussed in team meetings to make implicit processes explicit and subject to critical examination. Both inductive and deductive coding approaches balanced exploratory discovery with theoretical structure, reducing the risk of purely subjective interpretation. Extensive use of direct quotations in reporting allows readers to assess whether interpretations are well-grounded in participant language.

Data saturation, as noted in the recruitment and data collection section, was observed beginning at approximately the ninth interview, with core themes clearly emerging and subsequent interviews reinforcing rather than expanding these themes. No fundamentally new themes emerged in the final 3 interviews. While sample size was constrained by the limited pool of eligible providers (fewer than 12% of US oncologists are from underrepresented minorities, and <5% are Black), the observation of saturation combined with focused research questions and high "information power" of experienced, knowledgeable participants provides confidence that findings meaningfully capture provider perspectives.

Ethical Considerations

This study received exempt determination from the Institutional Review Board at the University of Texas at Austin (Protocol #STUDY00005543). The research met criteria for exemption under 45 CFR 46.104(d)(2), as it involved interviews with health care professionals about their professional experiences and observations in their roles as providers, rather than direct research involving vulnerable populations or sensitive personal information about the participants themselves. Although the study involved discussion of patient and caregiver populations, participants (providers) were asked to reflect on their professional practices and aggregate experiences without sharing identifiable information about specific patients or caregivers under their care.

The data used in this manuscript were originally collected by Gryt Health under funding from EMD Serono. The current analysis represents a secondary analysis of these interview data, conducted under an independent research protocol at the University of Texas at Austin. Data sharing between institutions is governed by the Nondisclosure Data Use License Agreement UTAUS-DUA00001286, which establishes terms for appropriate use, storage, and reporting of the data in accordance with research ethics standards and participant protections established during the original data collection.

All participants provided verbal informed consent before interview participation. Given the online nature of the interviews conducted via Zoom, verbal consent was deemed appropriate and was audio recorded as documentation. Prior to beginning each interview, the interviewer reviewed the following elements with each participant the purpose of the study (to understand health care providers' experiences supporting African American cancer caregivers and to identify recommendations for improved support), study procedures (participation would involve a single 45-60 minutes semistructured interview conducted via Zoom), voluntary nature of participation (participants could decline to answer any question and could withdraw from the study at any time without penalty), recording practices (the interview would be audio recorded using Zoom's recording function for transcription and analysis purposes), data use (deidentified interview data would be used for research analysis, academic publications, and to inform development of caregiver support resources), right to ask questions (participants were invited to ask questions before, during, or after the interview), and contact information (participants were provided with contact information for the research team and the institutional review board).

Participants verbally confirmed their understanding of these elements and their willingness to participate before interviews commenced. For this secondary analysis, the original informed consent obtained during data collection explicitly allowed for analysis and publication of deidentified data for research purposes. The University of Texas at Austin Institutional Review Board reviewed the scope of the original consent and confirmed that it was sufficient to permit the secondary analysis reported in this manuscript without requiring additional consent from participants.

Multiple measures were implemented to protect participant privacy and maintain confidentiality of research data. All interview data were deidentified, with participants assigned numeric codes used in analysis files. Any potentially identifying information mentioned during interviews was redacted. During interviews, participants were explicitly instructed not to share identifying information about patients, caregivers, or colleagues. All audio recordings and analysis files are stored on password-protected, encrypted servers maintained by Box (Box, Inc), with access limited exclusively to research team members who completed human subject research training and signed confidentiality agreements. Following verification of data accuracy and quality, all audio recordings were permanently deleted from Zoom's cloud storage and from local research team devices. Only deidentified data and analysis files are retained for the duration of the research project and the required institutional retention period.

Data sharing between Gryt Health (original data collector) and the University of Texas at Austin research team is governed by the nondisclosure agreement mentioned above, specifying appropriate data use, establishing data security requirements, limiting who may access the data, and prohibiting reidentification efforts or sharing of data with unauthorized parties. In reporting results, illustrative quotations from provider interviews are presented without attribution to specific participants to prevent potential identification based on distinctive speech patterns, roles, or institutional characteristics. Given the relatively small sample size (n=12) and the specialized nature of providers who work extensively with African American cancer populations, additional care was taken to avoid presenting combinations of demographic characteristics that might enable deductive identification.

XSL•FO
RenderX

Participants did not receive financial compensation for their participation in this study. The decision not to provide compensation was based on several considerations. First, participation involved health care professionals sharing insights from their professional practice, which is commonly considered part of professional development and service to the field rather than an activity requiring payment. Second, the interview duration (45-60 minutes) was relatively brief and scheduled at participants' convenience to minimize disruption to their work schedules. Third, many participants expressed intrinsic motivation to contribute to research aimed at improving support for underserved caregiver populations, indicating that the opportunity to shape future interventions served as a meaningful nonfinancial incentive. Finally, the absence of financial compensation helped ensure that participants' decision to participate was based on genuine interest in the research topic rather than external inducement, which may enhance the authenticity and thoughtfulness of responses.

Results

Participant Characteristics

Participants included physicians (7/12, 58.3%), social workers (2/12, 16.7%), nurses (2/12, 16.7%), and other providers (1/12, 8.3%). More than half of providers (7/12, 58.3%) identified as Black or African American, with additional representation from Latinx and Hispanic (3/12, 25%) and White (2/12, 16.7%) providers. Most participants (10/12, 83.3%) had more than 15 years of experience in their field. Providers practiced across 7 US states: California, Florida, Georgia, North Carolina, Ohio, Pennsylvania, and Tennessee. Detailed participant characteristics are presented in Table 1.

Table 1. Participant characteristics (N=12).

Category and subcategory	Values, n (%)
Provider type	
Social worker	2 (16.7)

Evaluation Outcomes

Thematic analysis revealed two overarching categories of findings: (1) unmet needs and barriers faced by African American cancer caregivers, and (2) opportunities and recommendations for improving caregiver support. The first category, unmet needs and barriers, comprises 3 subthemes practical barriers (transportation, financial constraints, housing insecurity, and competing obligations); social-emotional barriers (stress, guilt, burnout, fear, and unexpressed emotions); and cultural barriers (medical mistrust, superhero expectations, faith or spirituality tensions, and stigma around mental health and medications).

The second category, opportunities and recommendations, comprises four subthemes representing providers' suggestions for transformational change: (1) acknowledgment and formal compensation of caregiving work, (2) integration of caregivers into multidisciplinary care teams, (3) recognition and leveraging of cultural assets, and (4) strengthening the provider's role as a hub for change. These themes and subthemes are discussed below with supporting quotations from provider interviews.

The first theme of unmet needs and barriers covers 3 major categories practical, social-emotional, and cultural. Practical needs included lack of transportation, lack of food, lack of childcare, lack of available sick time for the caregiver, housing insecurity, and competing family obligations of partners and children. Additionally, several providers noted that African American cancer caregivers they have encountered cannot afford to sustain the caregiving role over the long term, as they lose income from the time they are performing their caregiving roles. Social-emotional challenges discussed included providers observing feelings of guilt or shame for not being able to be there for the family member as much as they would like. Also, providers discussed the range of unique emotions of African American cancer caregivers that they have observed, including anger, fear, grief, and sadness; both the ones that they express and other emotions that are not outwardly expressed but still noticed.

The third and most influential theme discussed relates to the cultural barriers unique to African American cancer caregivers. Providers frequently observed overwhelming stress among African American cancer caregivers. This stress stemmed both from the demands of caregiving and from previous negative experiences with the health care system, which contributed to medical mistrust and reluctance to participate in care decisions. Providers also discussed the cultural expectations of the "superhero Black woman" who takes on multiple roles in the family beyond cancer caregiving. Several providers discussed unspoken norms in African American communities that cancer caregiving is a family responsibility and that responsibility is often expected to occur in the home where there is limited support. Providers also discussed the role of faith and spirituality with African American communities, which is often complex when trying to provide care in a manner that is also responsive to a commonly held view of putting care "in God's hands." Finally, providers discussed cultural stigma at length, focusing on how African American communities can view caregiving, medications, and emotional labor. These thematic categories with illustrative quotes are listed in Table 2.

The second thematic category, opportunities and recommendations, comprises four subthemes representing providers' suggestions for transformational change and centers around (1) acknowledgment and compensation of the caregiver role, (2) incorporation of the caregiver into an expanded caregiving team, (3) reliance on the use of cultural assets as protective factors, and (4) the active role of the provider in providing support and facilitating systems change. Themes and selected illustrative quotes are listed in Table 3 and then discussed below in the context of their social-ecological placement to contextualize the findings as nested opportunities for change.

XSL•FO
RenderX

Table 2. Thematic barriers of African American cancer caregivers.

Theme	Example	Illustrative Quote
Practical barriers	Money, paid family sick leave, transportation, food, housing, competing obligations	• "If I call out means I don't get paid. Who's gonna watch the kids? How long is this gonna take? Is this a half day of work? Is this a full day of work? You see them doin' the calculations and you're understandin' because people need to take care of themself as well." • "It's essential they need to work to pay their bills, to survive. You understand the struggle." • "They understand that it's important. They want to be there and part of their care and their treatment plans, but they also have to do what they need to do to survive." • "Housing and then followed by transportation, followed by food, those seem to be the big three, but in that, I think transportation just gets the most, because that's the one we see quickly when someone doesn't show up for their appointment. I think underlying that, there seems to be a larger challenge with housing." • "That's a great need for a lot of, um, our minority patients, you know, African American patients, where you're having to take care of different generations. So it's not just that you have maybe a spouse or you have a parent, but you also have younger generations for whom you're caring for, and so you are torn." • "The wife was not only responsible for caring for her husband who was in the terminal process, but she had grandchildren in the home who she was caring for. She was trying to use the income that she did have to support adult children in the home." • "They've been tryin' to pay these bills. They've been tryin' to find daycare. They've been tryin' to find transportation. They're at the point where they have to go to work. They have to pick up a extra shift. They have to work two jobs. Now they can't be that caregiver because they have to do what they need to do for themselves."
Social emotional barriers	Stress, guilt, burnout, anxiety, fear, sadness, anger	• "They wanna protect their loved one and that they're not trusting. They may also pour that on to their loved one, the patient that have those reservations and fear. I think medical mistrust is just a huge blanket of an issue that should be addressed across African American community as a whole." • "That lead caregiver, begins to just take the rings and starts making really hard concrete decisions much to a loss to themselves because they forget, or they have to shelve their own emotion so that they take care of everyone else." • "That guilt and that anger, they're angry. Like, hey, I've put so many things on the backburner. I've sacrificed. That thought of still losing their family member even all that they've sacrificed is heartbreaking. They do get angry." • "A lot of the times they're not vocal. They kinda just deal with it. They're like, oh, I'm just used to doin' what we have to do. A lotta the times when they meet their breakin' point when they can't come anymore, they can't drop 'em off, they can't do this. Lots of times it's we're at that point where it's just so much that it's a lot too late where we don't have the grants or resources to help them through because they've been tryin' to get past it." • "There's definitely this duty, and I'm not quite sure if there's a lot of coping. The duty to get more information, the duty to be there, even if it means hurting themselves and not caring for themselves."

Theme	Example	Illustrative Quote
Cultural barriers	Mistrust or distrust, stigma and discrimination in health care, limited reflective providers, historical trauma, feels of exclusion or isolation, norms of caregiving expectations, cultural stigma of medications, stigma or taboo of mental health concerns or emotional needs, feeling of inferiority	• "This superhero Black woman thing is incredibly burdensome on caregivers because not only does she have to be the one for her father—and she loves it. She loves her father and will do it, But I'm sure she's the one who is the pillar of her kids and her husband, and at work she's taking on many roles. I think people put all these things on themselves." • "In the African American community, um, you know, family support is such a great thing. Um, and sometimes when we think about those patients that are hospitalized and have to go home or they need to go to, like, a rehab, sometimes they may not want their loved one to go to rehab or a skilled nursing facility. They would rather have them home. But when they're home, um, there may not be available equipment." • "In the African-American…the thought of going on hospice means that they are giving up, and they are not doing everything they can to live." • "Typically, in my experience in African American families, faith is very strong. When you're dealing with trauma or turmoil, the common notion is to put it in God's hands. God's got this, I put it in God's hands, and if I claim this disease, that means I'm going against the word of God." • "We have to look at the historical trauma and the mistrust that's developed over many, many, many years because of the disparities in care, the health inequities, the poor treatment that African Americans have and consistently still do experience. We're overcoming maybe a situation that we never had anything to do with, but we still have to recognize and honor it in the place that it is." • "When it comes to things like medications, there can be a stigma against pain medication, for example, I've had scenarios where there maybe was substance abuse in the family so there's this avoidance of, we're not gonna take anything but an aspirin for stage four metastatic cancer to the bones." • "My experience in the Black community is that it's uncommon or not a comfort space to admit that you're feeling vulnerable or to admit that you're struggling with anxiety or depression or fear, sadness, grief, any of those things because an acknowledgment of that can be seen as either weak or there's a lot of stigma associated with mental health and mental health illness. I think what that does is leave some really glaring gaps for our caregivers." • "My experience with African Americans looks different, from my experience with African Americans in the South. Some of what, like I brought up earlier, I think some of that might be colored by systemic racism that's pervasive in regions, that may not have anything to do with cultural challenges." • "What I've seen in the past is that, particularly among minorities and African Americans, they would come with very limited expectations, so whatever the doctor said was fine. They didn't ask questions among all of my other cultural components of patients. They didn't ask as many questions, because they assumed whatever was given was enough." • "If we think about mental health, and traditionally that's been a very taboo thing to address in the African American community. It's been very taboo for us to even admit, 'Hey, I need help. I think something's wrong.' It's not something that traditionally African Americans seek services for." • "'Just pray about your cancer, God don't hear you have your cancer.' Sometimes there's a disconnect with a person being seen as spiritually weak if they are seeking man for clinical services."

XSL•FO

Table 3. Opportunities and aspirations for African American cancer caregivers.

Theme	Level of intervention	Quotes
Theme 1: acknowledgment of African American cancer caregiving as formal work with adequate compensation and support	Macro (structural)	• "We don't really think of what the caregivers go through and talk about the grief and everything. They always focus on the patients, all the emotions they go through, but the caregivers go through so much as well as far as all the emotions. Understand when they're angry it's valid because they don't get to voice that a lot of the times. We have so many mental health resources for our patients, but we don't really have a lot as far as the caregivers when it comes to oncology clinics." • "African Americans, I think more than any other community, because of the historical mistrust, should allow us first to start with being able to embrace their voices. Everybody's voice, they've gotta be able to own it." • "We've got social workers, we've got psychotherapists, we've got caregiver support groups, we've got art classes, we have tai chi, we have healing touch, we have all of what people call the soft and fuzzy stuff, but it's open to not just the individual with the diagnosis, but the caregiver too, knowing that the caregiver is also feeling the pain and the suffering, and is also walking through the journey and also carrying the extra weight of being in charge of the care, that's a herculean task." • "They're trying to hold the entire ocean in their hands. Just acknowledging, man, this is a lot. You're going through so many things, you're doing and pointing out the things that are going really well like you handled that beautifully. I don't know that I could have done so well."
Theme 2: acknowledgment and integration of African American cancer caregiving in a core multidisciplinary care team alongside providers and navigators.	Macro (structural)	• "I believe that it's absolutely, um, important to engage caregivers, for them to be part of the care team, so that this is not just, um, the providers and the patient, um, but allowing caregivers to be part of decision-making." • "The social worker will say, this caregiver is burned out, this caregiver needs this, and I'm always so happy because that's usually the perspective that the social worker can find quickly. I would say, I don't know that providers always have the best perspective on that, but I think having another person on the team see that, is probably even more useful." • "You know, caregivers expect that not only are we going to be, um, a team that provides the best care available to our patients, um, but also availing all the resources to make that successful." • "I think everyone needs to be listened to very closely, the provider and the patient. I think that caregivers are that link that translate the patient to us. They add information that we may not get." • "I think it's very important with just educating caregivers as well that you're an integral part of this journey as well. I want to empower them to ask questions, to question things because they need to understand what's goin' on with the patient as well so that they can help better take care of them." • "Yeah, it's important for—I think my way of doctoring is one that is very much—I'm gonna use this word—it's collaborative, in the sense that—or inclusive, or it is important that we're on the same team, that we have the same—that we're working together toward this."

XSL•FO
RenderX

Theme	Level of intervention	Quotes
Theme 3: recognition of African American diverse cultural and social assets as key outcomes to success.	Meso (community)	• "Sometimes, the best supportive care is providing hospice, and a lotta times, in the African-American community, they (don't) wanna do that either. They feel that they either have very good networks in their church, their religious communities that may be able to provide things." • "I think the first thing is trying to develop trust and trying to show that you care about them as a person, them as a believer in their faith and in what they actually feel is strong in their own persona and trying to not appear to be trying to coerce them or push them into one thing or the other and allow them as many options as possible." • "I think fortunately in the African-American community, usually that bond of family is very strong, and I think that helps." • "Churches in the African-American community are oftentimes a very central player in the lives of patients and the caregivers, and a huge source of strength and the support of being able to go to a church as well as knowing that everyone's praying for them, prayer circles, different things like that, that I feel are almost more specific to African Americans than some of our other groups." • "You only survive if there's a family network. There's no housing. There's no health care. There's no services. But if you have a family that is tight-knit that takes care of the elderly and the young, they take care of the addicted and the not addicted, people do well." • "If the pastor says to do it, people do it. Again, oftentimes women are very strong in their households. The matriarch of the family, if she says do it if grand-mama says do it, everybody's gonna do it. It's understanding the dynamics of what the relationships are in those families but resources like the faith nurse ministry, wonderful resource, because they're often embedded within their own community and providing not just health education, but the empathy side of things as well." • "Someone comes and someone else is there, and if the patient doesn't ask, a caregiver is asking, and that doesn't have to be a traditional caregiver, and I like that." • "They're bringing a niece, they're bringing a neighbor, they're bringing somebody a part of the faith that was big in the south, a minister or someone from church. I think that that's huge, and I think that's where the shift has been. I think where we are making strides." • "There's a large church just a few miles from my home that offers health ministry. People and their families can come to those and get some support and have a community of people who understand what they're going through."
Theme 4: solidifying the role of the provider as the hub for both individual level and transformational systems level change to better meet African American cancer caregiving needs.	Micro, Meso, Macro (individual, community, structural)	

XSL•FO
RenderX

Theme	Level of intervention	Quotes
		• "I play connect the dots every day, and sometimes I collect dots of names and organizations and resources because I may not need 'em today, but at some point, I'm gonna encounter someone that needs me to connect that next dot. I'm a professional dot collector, also known as a junk drawer because I keep all those things knowing that someone at some point may reach out and I wanna be able to help them to weave their way through the tsunami that's not only a health diagnosis but the system itself." • "She was so focused on the assessment papers that she had as her task and her duty and her job that she was missing that golden opportunity to just sit alongside this family and embrace where they are and listen to what they needed to share and express. I think there's so much we can learn from people's stories if we as providers leave our agenda behind." • "I realized in my case that thinking about, particularly when African Americans and Latinos, that the adherence to treatments depends upon us showing the commitment to the patient…I learned that if I give my cellphone to my patients, even though they don't call me, they show up to clinic. If I don't, they don't show up to clinic. I was able to increase adherence to the treatment just by giving my cellphone." • "I think that we need to make ourselves available to caregivers to make their job easier. We need to make more telemedicine available. We have to make ourselves more available. We have to answer questions more readily. We have to have that, but we also probably need to reach out and see what they need. I don't think we're asking enough." • "I feel like there's not a lot offered for caregivers in the clinical setting that I'm working in." • "I feel like we have a brief intervention during the clinic visit where we may turn attention to a caregiver's concern, but just acknowledging and really supporting that caregiver and having anything to offer them at all, I don't feel like that's something that I'm aware of or that I was trained to do during all of these years of medical practice and training. I don't feel like that's something that has ever been magnified or highlighted or focused on." • "I think that we need to make ourselves available to caregivers to make their job easier. We need to make more telemedicine available. We have to make ourselves more available. We have to answer questions more readily. We have to have that, but we also probably need to reach out and see what they need. I don't think we're asking enough." • "In the same way that we have thermometers of stress in patients, we should have thermometers of stress on caregivers. That would be very easy to deliver. It could be an after-visit survey that you can give out, then the institution can then appoint services to that." • "I think also understanding even the caregivers may feel overwhelmed, and they may not feel like they have the right to ask so they themselves may not be straightforward. I think that we go so fast that we just—okay. It's all a monologue, 'I'm telling you X, X, X, X. Okay. Bye.' Next. It's really a conversation. This was lovely. Do you need anything else in the future, or if you wanted to talk to caregivers, I could find some."

Theme 1. Acknowledgment of Cancer Caregiving as Formal Work With Adequate Compensation and Support (Macro)

All providers interviewed acknowledged cancer caregiving as work. Providers discussed the need for formal acknowledgment and compensation for African American cancer caregivers, with changes being made at a structural or governmental level. Providers discussed that caregivers need to be compensated at appropriate levels or minimum "living wages." Providers stressed that this formal employment should include benefits that acknowledge workplace hazards and stress and provide resources to support social and emotional health. This formal acknowledgment, compensation, and support are particularly salient for African American cancer caregivers who face unique practical, social-emotional, and cultural barriers to cancer caregiving.

Theme 2. Acknowledgment and Integration of African American Cancer Caregivers in a Core Multidisciplinary Care Team Alongside Providers and Navigators (Macro)

Providers overwhelmingly discussed the need to integrate caregivers as part of the cancer care team, along with the primary care provider, navigator, and social worker. This care team should be collectively trained, oriented, and prepared to meet the needs of the patient. African American cancer caregivers should play an essential and equal role in the care team as they serve as "transformational interpreters" for the patient with cancer. This newly realized care team should include open communication and mutual respect to transform the health outcomes of patients. The thematic analysis highlights

XSL•FO
RenderX

key attributes that would be necessary for the provider role, including having providers that are reflective of the community with shared lived experiences. Therefore, initiatives that seek to diversify providers are necessary. Many interviewed participants also highlighted the essential role of the navigator, especially when serving African American communities. Navigators can provide value to the patient and facilitate better outcomes for the entire team. This defined care team has the potential to be especially effective, as data show that supported African American caregivers show less stress in their caregiving role than other races and ethnicities and are well equipped to respond as part of the care team.

Theme 3. Recognition of African American Diverse Cultural and Social Assets as Key Outcomes to Success (Meso)

Participants noted that African American cancer caregivers have unique assets within their families, communities, and culture that can drive transformational change. Participants noted the diverse support systems and assets among African American communities, such as the cultural norm of taking pride in the caregiving roles and valuing a strong family support network. Participants also observed the African American community having a unique advantage of having a collectivist culture where community caregiving is the norm and often performed by a variety of people, including partners, children, friends, neighbors, pastors, and faith leaders. Religion and spirituality serve a unique and influential role in having the potential to positively affect the emotional health, well-being, and health outcomes of both the patient and the caregiver.

Theme 4. Solidifying the Role of the Provider as the Hub for Both Individual-Level and Transformational Systems–Level Change to Better Meet African American Cancer Caregivers' Needs (Micro, Macro)

Participants who were interviewed also acknowledged the contributing and transformative role that providers could and should play in supporting African American cancer caregivers and their networks. Participants noted that providers are intentionally situated as an intermediary between individual (micro) and organizational and managerial (macro) influence to make these suggested changes to better care for caregivers. Due to this level of influence, participants emphasized that it is essential for providers to be trustworthy, humble, sincere, authentic, caring, and empathetic throughout this process. The provider serves as a central hub for "resource capture" and ensures the functioning of the system at all levels. Participants noted that to be successful, providers must listen, support, and communicate effectively. A key attribute to this success is being available both in appointments and by providing cues of being open and available. Participants shared personal successes of sharing emails or phone numbers that signaled availability and care to caregivers, showing, "I am here. I care. You can reach me."

Discussion

Principal Findings

This study reveals how providers identify and support the needs of African American cancer caregivers, highlighting both the unique challenges these caregivers face and opportunities for improvement. Within health practice settings, this research presents an opportunity for care providers to work with African American cancer caregivers to meet their needs and improve the health outcomes for both themselves and those they care for.

Findings from this study highlight issues faced by African American cancer caregivers, as reported by health care professionals experienced working with these populations. The insights offered cover practical and social-emotional topics as well as culturally specific challenges unique to the African American cancer caregiving experience. The data offered by providers highlight the increasing need for the acknowledgment and support for the caregiving role, especially among African American communities. Further, the findings support structural interventions, including the establishment of the caregiving role as one that is respected, compensated, and formally included in the care team system.

Providers interviewed for this study identified multiple cultural assets unique to African American communities that they observed serving as protective factors for both caregivers and patients. As detailed in Theme 3 and Table 3, providers described witnessing the pride and dedication African American caregivers demonstrated in their caregiving roles, the centrality of family networks in mobilizing support, the influential role of religion and faith communities in providing emotional support and practical assistance, the collectivist orientation where caregiving was shared among extended family and community members rather than falling to one individual, and the strength derived from these interconnected support systems.

These observations represent providers' interpretations of cultural strengths they witnessed in their clinical practices and offer important insights into community resources that health care systems might better recognize and leverage in supporting African American caregivers, particularly drawing from extensive quotations tied to Theme 3. Finally, providers identified their influential and important role that they need to take to support African American cancer caregivers and transform systems to better meet needs. Health care providers have the opportunity to work directly with caregivers to ensure their needs are met and their status is elevated in the caregiving role, though doing so would reasonably need additional administrative and organizational support.

Implications for Innovation in Participatory Cancer Care

This research offers important implications for innovation in cancer care delivery, particularly regarding participatory care models, technology implementation, and health equity initiatives.

XSL•FO
RenderX

Advancing Participatory Care Models

Our findings provide a roadmap for operationalizing participatory cancer care. Provider recommendations for formally integrating caregivers into multidisciplinary care teams (Theme 2) offer specific mechanisms defining caregivers as official team members with designated roles, including caregivers in care planning meetings, providing training and resources, and creating communication channels that position caregivers as partners. Health care organizations committed to patient- and family-centered care can use these provider-generated recommendations to redesign care delivery models and team structures.

The emphasis on formal acknowledgment and compensation of caregiving work (Theme 1) has implications for health care policy and payment models. As value-based care increasingly recognizes the importance of care coordination and outcomes beyond acute treatment, there are opportunities to reimagine how caregiving contributions are valued and supported. Provider recommendations point toward policy innovations such as caregiver stipends, paid family leave expansions, and coverage for family caregiver training and support.

Informing Technology and Digital Health Innovation

Provider insights have significant implications for designing digital health tools responsive to African American caregiver needs. Providers emphasized accessibility, cultural responsiveness, and addressing practical barriers such as time constraints and competing obligations. These insights can inform the development of telehealth platforms designed with African American caregiver needs in mind (addressing medical mistrust through culturally concordant providers, flexible scheduling, and technical support); mHealth apps addressing practical needs while providing emotional support and culturally relevant resources; patient and caregiver portals that recognize caregivers as partners with appropriate information access and care coordination tools; and remote monitoring systems that engage both patients and caregivers sustainably.

Critically, providers highlighted the importance of recognizing and leveraging cultural assets such as faith communities, extended family networks, and collectivist values (Theme 3). Digital innovations that facilitate rather than replace these existing support systems—for example, by enabling coordination among multiple family caregivers or connecting caregivers with faith-based resources—may be more culturally acceptable and effective.

Reducing Disparities Through Systems Innovation

Providers' emphasis on systems-level change (Theme 4) points toward structural innovations, including workforce diversification initiatives to increase representation of underrepresented minority providers and navigators, institutional policies requiring caregiver assessment and support planning with specific attention to barriers affecting communities of color, care navigator programs specifically designed to address barriers faced by African American caregivers, provider training incorporating cultural humility and asset-based approaches, and quality metrics including caregiver support as a measured component of cancer care quality.

Translation to Practice and Policy

The multilevel nature of our findings provides several entry points for intervention. Health care organizations can begin with feasible changes such as provider training and caregiver assessment tools while advocating for policy changes like caregiver compensation and employment protections. Importantly, our asset-based findings (Theme 3) offer a counter-narrative to deficit-focused approaches, providing a foundation for interventions that leverage community strengths while addressing systems-level barriers, an important shift toward equity-oriented innovation.

Limitations

Limitations of this research include the fact that it employs a purposive sample of 12 participants. This sample was established a priori due to the limited number of qualifying providers in the United States. The research represents the lived experiences of a group of providers reporting interactions with African American cancer caregivers and may not be fully reflective of the caregiving experience. Further, this data does not represent the lived experiences of African American cancer caregivers but provides some external insights into the health care experiences of this population and how participants in systems interact with these caregivers. Our purposive sampling strategy, while methodologically appropriate for exploratory qualitative research [40,42], introduces potential selection bias that limits generalizability. Providers who responded to recruitment outreach and agreed to participate may differ systematically from nonresponders in important ways, including greater awareness of or commitment to health equity issues, more positive experiences working with African American caregivers, higher comfort discussing issues of race and health care disparities, or more flexible schedules allowing research participation. Additionally, recruitment via LinkedIn profiles and institutional websites may have skewed toward more digitally engaged or academically oriented providers working at larger institutions. These selection effects mean our findings may not fully represent the perspectives of providers who work in smaller community practices, have less experience or comfort working with African American populations, hold views less aligned with patient-centered care models, or face greater time constraints that prevented participation. Readers should interpret findings as representing the perspectives of a motivated, experienced subset of providers rather than all providers caring for African American patients and caregivers with cancer. Despite these limitations, the rich, detailed insights from experienced providers provide valuable direction for intervention development even if not necessarily generalizable. Significant accessibility limitations must also be noted. Recruitment and data collection were completed online. Potential participants without a significant online presence or less familiar with Zoom may not have participated. These limitations may result in a younger, more technologically savvy, and more urban sample. Following best practices of qualitative research, the interview guide was flexible but not substantially adapted during the iterative process of data analysis. Many culturally sensitive and stigmatized topics were discussed in the research. Participants may not have fully shared experiences related to prejudices or medical experiences due to distrust or social desirability.

XSL•FO
RenderX

Comparison With Prior Work

Our findings confirm and extend prior research on African American caregiver experiences while offering novel insights from the provider perspective. Previous literature documented that African American caregivers are disproportionately burdened as sole caregivers, often receiving no external support [7]. Our provider interviews corroborated these disparities, with participants observing the "superhero Black woman" phenomenon, where caregivers assume multiple family roles beyond cancer care, often without adequate support systems.

Additionally, our provider observations aligned with prior research identifying that only a few African American caregivers rate their health as excellent or very good [7]. Our findings here note significant social-emotional barriers, including stress, guilt, and burnout among African American caregivers (Table 2).

Existing literature highlighted that African American caregivers face greater financial strain, with 74% modifying employment status due to caregiving demands [19]. Our provider participants confirmed these practical barriers, emphasizing transportation, housing, and competing family obligations as primary challenges. Importantly, providers observed how financial pressures create impossible choices: "They have to pick up an extra shift...Now they can't be that caregiver because they have to do what they need to do for themselves."

Previous studies noted limited provider diversity, with only 3% of oncologists being Black [22], potentially limiting racial concordance benefits. Our findings suggest this deficit profoundly impacts care delivery, with providers emphasizing the need for workforce diversification as essential for building trust and improving communication.

Novel Contributions

While prior research documented caregiver challenges through direct caregiver accounts, our study uniquely reveals provider perspectives on these same issues, offering novel insights. First, we identified cultural assets that providers observe as protective factors, including strong family networks, faith communities, and collectivist caregiving approaches, each of which has been underexplored in deficit-focused caregiver literature. Second, our findings reveal specific recommendations from providers for systems-level change, including formal caregiver compensation and integration into care teams, which existing literature has not addressed. Third, we document how medical mistrust, previously identified as a barrier [15,16], manifests in provider-caregiver interactions and affects care delivery from the provider perspective.

These provider insights complement existing caregiver-focused research by identifying actionable intervention points within health care systems and revealing potential misalignments between caregiver experiences and provider perceptions that could inform targeted improvements in care delivery. Our study also extends the understanding of caregiving by revealing that providers often witness caregivers suppressing emotions ("a lot of the times they're not vocal, they kinda just deal with it"), suggesting the health impacts may be even more severe than self-reported measures indicate.

Conclusions

This research lays a foundation for understanding and responding to the needs unique to African American cancer caregivers. It provides key data from providers to support the need for health care transformation and better meet the needs of African American cancer caregivers. With increases in the number of cancer caregivers within the African American population, it is essential to understand mechanisms of support in a culturally responsive manner.

Caregiver support is always and everywhere a systems phenomenon; individual interventions cannot address structural inequities that require institutional transformation. Data shows that this population faces significant health disparities coupled with numerous barriers within the physical, social, cultural, and political environments. This research can positively contribute to the long-term goals of addressing unmet needs and their practical barriers, supporting an assets-based approach to meeting the needs of this population through transformational systems change.

Also, this research will contribute to a better understanding of how providers can specifically help to meet the unique needs of the African American cancer caregiver population. Caregivers cannot be peripheral to care teams when they are central to patient outcomes, as providers note in this project. Future work should seek to provide evidence-informed guidelines for the implementation of these suggested strategies in addition to adding the perspectives of caregivers themselves so more of the care team is included in the dialogue. Full implementation of these strategies will require substantial organizational commitment and resources, which may pose challenges.

Additional research is needed that (1) provides an evidence-informed guide to organizational transformation to better meet the needs of African American cancer caregivers, (2) explores the readiness and resources of health care organizations and their staff to implement such changes, (3) explores the readiness of African American cancer caregivers to be more formally acknowledged and included in the caregiving process, and (4) evaluates the effectiveness of the suggested transformation.

Acknowledgments

All providers interviewed acknowledged cancer caregiving as work. Providers discussed the need for formal acknowledgment and compensation for African American cancer caregivers, with changes being made at a structural or governmental level. Providers discussed that caregivers need to be compensated at appropriate levels or minimum "living wages." Providers stressed that this formal employment should include benefits that acknowledge workplace hazards and stress and provide resources to

XSL•FO
RenderX

support social and emotional health. This formal acknowledgment, compensation, and support are particularly salient for African American cancer caregivers who face unique practical, social-emotional, and cultural barriers to cancer caregiving.

Funding

The data used in this research comes from a project funded by EMD Serono in a contract with Gryt Health as part of the initial stages of planning the creation of culturally responsive support programs and resources for African American caregivers. The authors received no specific funding for this secondary data analysis.

Data Availability

The data generated in this study are available upon request from the corresponding author. Interested researchers may contact the corresponding author to discuss access arrangements that maintain ethical obligations to participants while supporting research transparency. Interview transcripts contain potentially identifying information about participants and the health care settings in which they work, so any arrangement would need to respect participant anonymity, also recognizing the need for the depth of the qualitative data.

Abstract

Background: Chemotherapy-induced alopecia is among the most psychologically distressing adverse effects of systemic cancer therapy. Although scalp cooling is increasingly used to mitigate hair loss, it is still largely perceived as a cosmetic intervention. Its broader psychological relevance and the biological basis of treatment success, particularly the preservation of follicular integrity under ongoing cytotoxic exposure, remain insufficiently explored.

Objective: This study aimed to reconceptualize scalp cooling beyond visible hair preservation by examining its psychological impact on patients receiving highly alopecia-inducing chemotherapy, while integrating quantitative objective hair preservation metrics with structural and ultrastructural analyses of hair follicle damage to identify avenues for improving follicular integrity and scalp-cooling efficiency.

Methods: A total of 82 patients undergoing highly alopecia-inducing chemotherapy consisting of a sequential anthracycline-taxane regimen (4 cycles of epirubicin and cyclophosphamide followed by 12 weekly paclitaxel applications) received standardized scalp cooling. Objective hair preservation was quantified using the hair mass index (HMI) as a standardized and reproducible measure of hair retention. Structural and ultrastructural follicular integrity was assessed using light microscopy as well as scanning and transmission electron microscopy. Objective hair preservation metrics were analyzed in relation to patient-reported quality-of-life outcomes (EORTC [European Organisation for Research and Treatment of Cancer]–based measures), subjective treatment burden, and cognitive appraisal of the scalp-cooling experience. Multivariable regression models were applied to identify determinants of posttherapeutic quality of life.

Results: Visible chemotherapy-induced alopecia was successfully prevented in more than half of the treated patients. Scalp cooling resulted in substantial objective hair preservation as quantified by the HMI. However, HMI values showed only a limited association with posttherapeutic quality-of-life outcomes. In contrast, the cognitive appraisal of scalp cooling emerged as a central determinant of posttherapeutic quality of life, independent of the degree of objective hair retention. Structural and ultrastructural analyses demonstrated that the preservation of follicular integrity was closely associated with successful macroscopic hair retention under ongoing cytotoxic exposure, supporting a biological basis for the clinical effectiveness of scalp cooling.

Conclusions: The clinical relevance of scalp cooling extends beyond objective and visible hair preservation and appears to reside predominantly in its psychological impact on patients undergoing highly alopecia-inducing chemotherapy. Importantly, the identification of structural and ultrastructural markers of follicular vulnerability provides a mechanistic foundation for the future optimization of scalp-cooling approaches and for the development of adjunct follicle-directed protective strategies to enhance follicular integrity and support patient well-being during cytotoxic therapy.

Introduction

Background

Chemotherapy-induced alopecia (CIA) remains one of the most visible and psychologically distressing adverse effects of systemic cancer therapy. Beyond a transient cosmetic change, hair loss functions as a public marker of disease, disrupts personal identity, and continuously reinforces the illness experience for patients and their families [1,2]. Despite substantial advances in oncologic treatment, the psychosocial burden of CIA remains inadequately addressed.

Scalp cooling is currently the only US Food and Drug Administration–approved intervention shown to mitigate CIA and has gained broad clinical acceptance. However, its efficacy is highly heterogeneous: while some patients achieve near-complete hair preservation, others experience pronounced alopecia despite identical chemotherapy regimens and standardized cooling protocols [3,4]. This interindividual variability represents a major limitation of current approaches and indicates that key determinants of treatment response remain insufficiently understood.

Although direct clinical evidence remains limited, experimental human hair-follicle models and scalp-cooling outcome studies support the biological plausibility that intrinsic follicular characteristics, including hair-shaft integrity and pigmentary-unit stability, may contribute to interindividual variation in chemotherapy-induced damage and scalp-cooling response [5-10]. At the same time, the subjective experience of hair loss and individual coping strategies substantially shape quality of life, highlighting CIA as an interface between biological vulnerability and psychosocial resilience.

In this context, this study examines scalp-cooling efficacy in a homogeneously treated cohort receiving highly alopecia-inducing chemotherapy. By integrating objective follicular parameters with patient-reported outcomes (PROs), this work aims to contribute to a more nuanced, biopsychosocial understanding of hair preservation and to enable a more individualized approach to supportive care strategies [6,11].

Study Population

The study enrolled 82 patients with early-stage breast cancer, all of whom received curative-intent chemotherapy. A uniform treatment regimen was applied, consisting of epirubicin and cyclophosphamide followed by weekly paclitaxel. This standardized approach ensured comparable cytobiological effects on hair follicles across the cohort and provided a consistent basis for evaluating scalp-cooling efficacy. Given the predictable and uniform severity of alopecia associated with this regimen, a control group without scalp cooling was not included.

Scalp cooling was performed with a sensor-controlled device designed to maintain a consistent scalp temperature below 22 °C. By ensuring reproducibility in both chemotherapy and cooling parameters, the study sought to isolate patient-specific and follicle-specific determinants of hair preservation. Patients were excluded from scalp cooling in cases of clinically manifest scalp metastases, generalized hematologic malignancies such as leukemia, scalp injuries, or cryoglobulinemia.

Objectives

The primary objective of the study was to evaluate the efficacy of scalp cooling for hair preservation during chemotherapy, using the hair mass index (HMI) as an objective measure obtained through cross-sectional trichometry.

Three primary efficacy end points were defined:

1. Posttreatment HMI as a measure of residual hair mass,
2. Avoidance of visible alopecia, defined as HMI ≥50,
3. Absolute hair loss, calculated as the difference between posttreatment and pretreatment HMI (ΔHMI).

Secondary objectives included the characterization of treatment-associated trichological and ultrastructural hair alterations, the exploratory assessment of biological and clinical factors associated with hair preservation, and the evaluation of patient-reported treatment experiences and the psychosocial burden related to hair loss and scalp cooling. Trichological and biological secondary outcomes included pretreatment and posttreatment assessments of hair density, anagen rate, and hair shaft and bulb diameter, as well as ultrastructural hair-shaft surface alterations. Particular emphasis was placed on melanosomal features, with transmission electron microscopy (TEM) used to quantify melanosome morphology and density.

Potential predictors and influencing factors of hair preservation were evaluated across multiple domains, including general health parameters (eg, age, comorbidities, alopecia-inducing co-medications, nicotine use, and menopausal status), individual hair characteristics and practices (eg, hair color, length, structure, and hair treatment), and treatment-related biological vulnerability markers. These included hematologic toxicity during chemotherapy (eg, neutrophil nadirs) as well as laboratory parameters reflecting liver function, renal function, and thyroid status. In female patients, endocrine profiling (follicle-stimulating hormone, luteinizing hormone, and estradiol) was explored to contextualize gonadal function.

PROs were collected to assess the subjective experience of scalp cooling, including perceived burden and treatment acceptance. Psychosocial impact was evaluated before and after the intervention using selected items derived from the EORTC QLQ-C30 (European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire), complemented by study-specific questions to capture treatment-related psychosocial effects associated with hair loss and the cooling procedure.

Methods

Overview

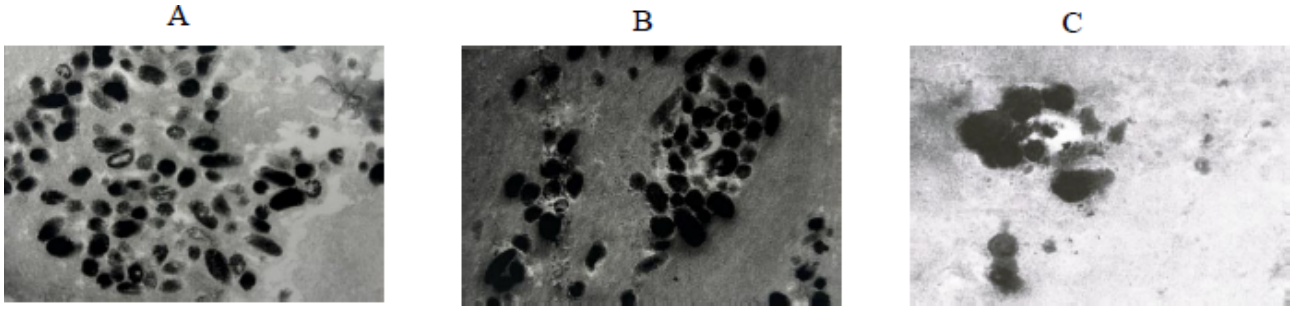
To determine hair density, measurements were carried out at the frontal vertex before and after treatment using the Cross Section Trichometer (Cohen HMI device) [12]. This tool enables standardized quantification of hair mass within a 4-cm² scalp area. The procedure was designed to deliver consistent, reproducible results at single time points, assuming the examiner had received appropriate training. Only hairs longer than 2.5 cm were considered. Outcomes were expressed as the HMI, defined as the surface area of hair in mm² per cm² of scalp,

XSL•FO
RenderX

multiplied by 100. Values typically fall between 75 and 100; a score ≥50 was predefined as the threshold for the absence of clinically visible alopecia consistent with established HMI methodology, indicating that visible thinning typically emerges below this level [12], while values below 20 correspond to advanced alopecia [12]. For analysis, around 50 follicles were extracted from the selected 4 cm^2 scalp region and positioned between 2 glass slides with the roots exposed, sampling for reproducible trichogram assessment. At the same time, the number of extracted follicles was intentionally kept as low as possible to minimize additional hair removal in a psychologically vulnerable patient population, with the explicit aim of hair preservation [12].

Light microscopy was applied to capture images of untreated hair samples at magnifications of 10× and 40× using a Leica DM3000 (Leica Microsystems) microscope. Measurements included bulb diameter (typical range: 150 - 200 µm) and shaft thickness (normal for the frontal vertex: 75 - 85 µm) [13]. The growth phase of the follicles was assessed based on the characteristic bulb morphology: according to established trichogram and hair cycle morphology criteria, anagen follicles showed normal bulb dimensions, while catagen and telogen follicles presented with smaller bulbs and club-shaped ends. Structural abnormalities such as shaft irregularities, breakage, and deformation were interpreted as signs of follicular dystrophy [14].

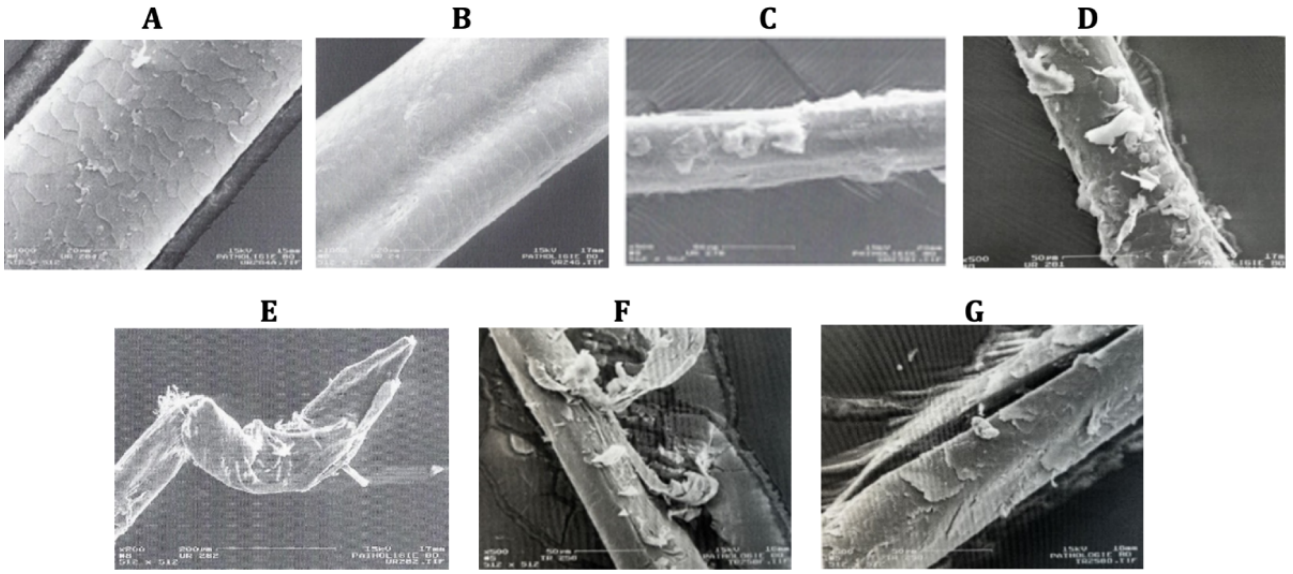
To study melanosome distribution, TEM was applied to ultrathin hair shaft sections obtained from 52 participants before and after treatment (Figure 1). These cases represented the first consecutively available samples for which electron microscopic processing was feasible. The subset was not selected according to clinical outcomes, degree of alopecia, treatment response, or any other biological characteristics. Rather, the number of evaluable cases was determined by the substantial technical complexity, limited pathology resources, and the labor-intensive nature of ultrastructural tissue preparation, image acquisition, and quantitative analysis. Consequently, no intentional enrichment for responders, nonresponders, or specific morphological patterns was performed, minimizing the risk of selection bias. Two types of organelles were identified: pheomelanosomes, typically smaller and more rounded, and eumelanosomes, which tend to be elongated and fibrillar in form. The quantitative assessment showed that blond hair contained relatively few melanosomes (about 9 per 100 $µm^2$), while markedly higher densities were observed in darker hair, averaging around 66 per 100 $µm^2$ in brown and 70 per 100 $µm^2$ in black samples [15]. For preparation, follicles were fixed in glutaraldehyde, dehydrated through successive steps, and embedded in Epon. Sections approximately 50-nm thick were cut, stained with uranyl acetate and lead citrate, and examined at magnifications ranging between 1500× and 15,000× (JEOL 2100).



Scanning electron microscopy (SEM) was applied to evaluate surface alterations of the hair shaft in untreated and treated samples. Examinations were performed with a Zeiss Gemini 982 (ZEISS Microscopy) field emission SEM at magnifications ranging from 200× to 2000×. Prior to imaging, the hair was sputter-coated with a thin gold layer. The extent of structural impairment was categorized using a system comparable to the Kim scale, which is commonly used for classifying extrinsically induced hair damage. For illustration, representative patient samples showing different levels of hair surface deterioration are displayed in Figure 2 [16].

The Kim scale (adapted) is as follows:

- Grade 0: intact, untreated hair with a uniform cuticle layer.
- Grade 1: slight irregularities of the cuticle, including shallow dents or uneven overlap, without cracks or loss of material.
- Grade 2: pronounced lifting of cuticle layers, with fissures or small perforations, but the cortex is still covered.
- Grade 3: partial exposure of the underlying cortex.
- Grade 4: complete loss of the cuticle layer, leaving the cortex unprotected.



Sections of hair shafts from 52 participants were examined to confirm consistency in the detected alterations. The analysis concentrated on grading intrinsic surface damage from 0 to 4 in relation to the therapeutic procedure.

Figure 1. Exemplary transmission electron microscopy photos. (A) Patient with brown dense hair (pre-HMI=100). Pretherapeutic pigmentary status: 89 total melanosomes, 44 pheomelanosomes, 45 eumelanosomes, and ratio of eumelanosomes to pheomelanosomes=1.02. Scale: approximately 8000:1. (B) Same patient with no visible hair loss (post-HMI=58). Posttherapeutic pigmentary status: 75 total melanosomes, 31 pheomelanosomes, 44 eumelanosomes, and ratio of eumelanosomes to pheomelanosomes=1.42. Scale: approximately 8000:1. (C) Patient with bad hair retention beginning of visible alopecia (post-HMI=35). Pigmentary status: disordered melanogenesis characterized by clumping of melanin. Scale: approximately 12,000:1. HMI: hair mass index.

Figure 2. Different patterns and grades of hair shaft damage. (A) Normal roof tile scale pattern; (B) Dents, grade 1; (C) Deposits on hair shaft, grade 1; (D) Lift-ups of cuticle, grade 2; (E) Distortion and crack of hair shaft, grade 3; (F) Severe lift-ups with partial exposure of cortex; (G) Extensive exposure of cortex with dents, deposits, and cracks, grade 4.

Patient-Centered Outcomes (Self-Report Measures)

Patient-centered outcomes were assessed using self-report measures obtained at baseline and after the intervention. The subjective appraisal of treatment and the overall quality of life were rated on Likert-type scales ranging from 1 (very poor) to 7 (very good). Treatment-related burden and discomfort were assessed on a 4-point scale from 1 (none) to 4 (very strong).

Quality-of-life domains were evaluated using selected items from the EORTC QLQ-C30, complemented by additional study-specific questions addressing treatment experience and procedure-related aspects.

Patient-reported questionnaires were used to capture patients' subjective treatment experiences, perceived burden, and overall well-being. Psychosocial data were collected prospectively from the study's initiation onward as part of the observational study protocol. Consequently, analyses examining associations between cognitive appraisal, hair preservation, and quality of life were conducted using prospectively collected data.

Statistical Procedures

Descriptive statistics (median, IQR, and percentage) were used to summarize patient and treatment characteristics, as well as hair retention outcomes. Multiple linear and binary-logistic regression models were conducted as exploratory analyses to assess associations with hair retention and quality of life. Because some variables included in the models were measured after treatment, the models were not intended to strictly establish causal or temporal effects. Baseline variables were interpreted as potential predictors, whereas posttreatment parameters were interpreted as correlates of the corresponding outcome. The joint approach was used to examine these associations while simultaneously adjusting for baseline characteristics and posttreatment morphological parameters.

All key model assumptions were assessed and met for all models, including linearity, normality, and homoscedasticity of residuals, absence of influential outliers, and acceptable multicollinearity. For the 3 outcome variables of hair retention (post-HMI, HMI≥50, and HMI difference), clinically relevant and biologically plausible correlates were identified within thematic domains and entered into multivariable models if they were at least borderline significant (P=.006). Only standardized regression coefficients are reported, and the intercept was omitted from the models' tables because it is not interpretable in standardized form. Finally, we used Spearman correlation coefficients to test associations between melanosomes and damage degree because of their ordinal scale and potential outliers. Statistical significance was defined as P=.003.

Ethical Considerations

This study was approved by the Research Ethics Committee (2016 - 011-f-S Ethikkommission Westfalen-Lippe, Münster, Germany). All research data were deidentified and coded with unique identifiers, and the data were transmitted using secure encrypted protocols and stored on encrypted disks on secure servers. The study included only patients who had agreed to the use of their medical information by signing the respective consent form. No compensation was provided to participants for survey completion. This paper does not include any images or information that could identify individual participants.

Results

Among 82 patients, 80 (97.6%) were women, and the median age was 56.5 (IQR 49 - 65) years. The baseline median HMI score was 75 (IQR 58 - 92) and declined after treatment to a median of 51 (IQR 17 - 58). At follow-up, 52% (n=43) of participants still had an HMI score of 50 or higher, corresponding to the absence of visible hair loss. For patients with initially low hair density, maintaining the HMI may be of particular clinical importance, highlighting the role of relative HMI preservation as a meaningful end point. The median decline in the HMI score from baseline to posttreatment was −27 (IQR −45 to −10). In those starting with an HMI below 50 (n=12),

XSL•FO
RenderX

the median reduction amounted to −19 (IQR −27 to −5). Comprehensive baseline characteristics, treatment-related factors, and posttreatment clinical parameters together with variables derived from light microscopy, TEM, and SEM are summarized in Table S1 in Multimedia Appendix 1. Complete ultrastructural data were available for a quality-controlled subset of 52 patients.

While longitudinal changes in HMI provided a robust quantitative measure of treatment-associated alterations in scalp hair density, this global metric does not fully capture the underlying biological mechanisms at the follicular level. To contextualize these numerical changes, we also examined the microstructural integrity of individual hair follicles using complementary morphological approaches. These microscopic assessments capture complementary aspects of follicular and hair shaft integrity, encompassing surface morphology—particularly ultrastructural damage features—as well as pigmentation patterns, which cannot be adequately reflected by global quantitative indices alone.

In order to comprehensively characterize hair retention outcomes, 3 complementary HMI–based efficiency parameters were evaluated: (1) posttreatment HMI as a measure of residual scalp hair density, (2) the proportion of patients maintaining an HMI ≥50, corresponding to the absence of visible hair loss, and (3) the absolute change in HMI from baseline, capturing individual longitudinal dynamics and relative hair preservation. Together, these parameters allow for a differentiated assessment of treatment-associated effects on scalp hair beyond absolute posttreatment values.

The initial modeling steps are summarized in Tables S2-S5 in Multimedia Appendix 1, showing multivariable regression analyses thematically grouped by general clinical characteristics, as well as light, TEM, and SEM variables to identify independent factors associated with each of the 3 HMI efficiency parameters.

These supplementary tables provide the structural and biological context for the subsequent efficiency-focused analyses and are presented separately to maintain clarity and readability of the main results. Only variables meeting the predefined relevance threshold of $P=.08$ were retained in the final multivariable models for posttreatment HMI, HMI ≥50, and absolute HMI change and are therefore presented in Tables 1-3.

To address the temporal structure of the data, baseline variables and posttreatment variables were conceptually distinguished. Baseline variables were analyzed as potential predictors of treatment outcomes, whereas posttreatment variables were included to characterize biological features associated with treatment responses. Accordingly, the models including posttreatment variables should be interpreted as exploratory analyses of associations rather than predictive models in a strict temporal sense.

When analyzing factors associated with posttreatment HMI (Table 1), the degree of hair shaft damage difference showed a statistically significant negative association (β=−.29, *P*=.046), indicating that greater increases in hair shaft damage were linked to lower posttreatment HMI values. Comorbidity exhibited a borderline negative association (β=−.28, *P*=.066), suggesting a tendency toward reduced hair retention in patients with comorbid conditions. Posttreatment anagen frequency showed a borderline positive association (β=.30, *P*=.06), indicating a trend toward improved posttreatment HMI with higher anagen proportions.

For HMI ≥50 (Table 2), the baseline hair shaft diameter was significantly associated with visible hair retention (odds ratio [OR] 1.12, 95% CI 1.04-1.27; *P*=.02), indicating that a larger baseline hair shaft diameter was linked to higher odds of maintaining visible hair. Comorbidity showed a borderline negative correlation (OR 0.05, 95% CI 0.01-0.75; *P*=.05), suggesting a tendency toward a reduced likelihood of HMI-defined hair preservation (HMI≥50). A greater increase in hair shaft damage was also related to lower odds of preventing visible hair loss, although this did not reach statistical significance (OR 0.28, 95% CI 0.06-1.06; *P*=.08). No relevant associations were observed for neutrophil count or bulb size parameters. Overall, model performance was very good (Nagelkerke R^2=0.65).

Finally, in the linear model for HMI difference (Table 3), age (β=.31, *P*=.02), pheomelanosome difference (β=.34, *P*=.009), and eumelanosome difference (β=.27, *P*=.04) were significantly associated with the HMI change, indicating that older age and lower degrees of melanosome loss were linked to a smaller decline in the HMI. Medication use showed a significant inverse relationship to greater HMI reduction among patients receiving alopecia-inducing medication (β=−.35, *P*=.009). Overall, the model fit was moderate (adjusted R^2=0.33).

Given the exploratory design and the number of tested influencing factors across models, no formal adjustment for multiple testing was applied; the results should therefore be interpreted as exploratory. CIs were wide for some estimates, reflecting the limited precision associated with the sample size.

In addition to biological and treatment-related variables, psychosocial parameters were specifically examined for their association with hair retention outcomes. This analysis, summarized in Table 4, addresses the psychological dimension of hair preservation and its contribution to the overall treatment experience and quality of life. Finally, in a linear regression model using posttherapeutic quality of life as the dependent variable, we entered pretreatment quality of life, subjective appraisal of scalp cooling, emotional burden, and HMI difference as candidate variables. QoL pre (β=.41, *P*<.001) and scalp-cooling appraisal (β=.53, *P*<.001) showed significant positive associations with moderate-to-strong effect sizes, indicating that higher baseline QoL and a more favorable appraisal of scalp-cooling outcomes were linked to better QoL after therapy. Age, burden, and HMI change were not independently associated with posttreatment quality of life. Overall, the model fit was high (adjusted R^2=0.48).

Table . Final exploratory linear regression for associations with posttreatment quality of life (QoL)[a].

Variables	β (95% CI)	*P* value
Age	.04 (−0.17 to 0.26)	.69
QoL pre	.41 (0.21 to 0.62)	<.001
Appraisal	.53 (0.27 to 0.79)	<.001
Burden	.05 (−0.19 to 0.29)	.67
HMI[b] difference	−.01 (−0.24 to 0.23)	.97

[a]Model fit was adjusted R^2=0.48.

[b]HMI: hair mass index.

Discussion

Principal Findings

This study provides an integrated analysis of scalp cooling that extends beyond the traditional dichotomy of hair preservation versus alopecia. In a cohort exposed to highly alopecia-inducing chemotherapy, visible hair loss was avoided in 53% (n=43) of patients, representing a clinically meaningful level of effectiveness that exceeds purely cosmetic expectations. Importantly, this efficacy signal was consistently accompanied by distinct structural and ultrastructural features of follicular integrity, indicating that treatment response is biologically modulated rather than binary. These findings further suggest that the effectiveness of scalp cooling is not solely determined by temperature reduction per se but reflects a more complex biological response at the level of follicular resilience. While these observations are biologically plausible, they should be interpreted as exploratory. This study was not designed to establish causal mechanistic relationships but rather to identify clinically relevant associations. In particular, relative melanosome stability and hair shaft surface integrity appear to

XSL•FO
RenderX

represent a coherent biomarker constellation of follicular health, supporting the concept that scalp cooling modulates intrinsic follicular vulnerability to chemotherapy-induced damage rather than acting as a purely physical cooling intervention. However, these structural features were assessed in a limited subset of samples using high-resolution ultrastructural techniques, reflecting their technically demanding nature and should therefore be interpreted with caution.

Previous large-scale registry data, such as the Dutch Scalp Cooling Registry, including more than 7400 patients, have consistently demonstrated that the type of chemotherapy regimen is a key determinant of scalp-cooling efficacy [17]. Consistent with these findings, we have similarly observed variability in scalp-cooling efficacy across different treatment settings in previous work [18]. In addition, we have reported variable success rates across different regimens in prior work. In contrast, this study applied a uniform chemotherapy protocol consisting of epirubicin and cyclophosphamide followed by weekly paclitaxel, a regimen invariably associated with complete alopecia in the absence of scalp cooling. This approach was deliberately chosen to minimize treatment-related heterogeneity and to allow for the assessment of scalp-cooling effects within a highly standardized clinical setting. However, the absence of a control group represents a methodological limitation, as comparative conclusions regarding absolute treatment effects cannot be drawn. At the same time, the use of a uniform chemotherapy regimen allowed for a more focused analysis of interindividual variability in follicular response under comparable treatment conditions. Furthermore, establishing an untreated control group was considered ethically challenging, given the expected near-complete alopecia associated with this regimen.

Although prior investigations have primarily focused on the chemotherapy regimen type and general patient-related factors, our analysis extends this perspective by systematically addressing structural and ultrastructural determinants of follicular preservation.

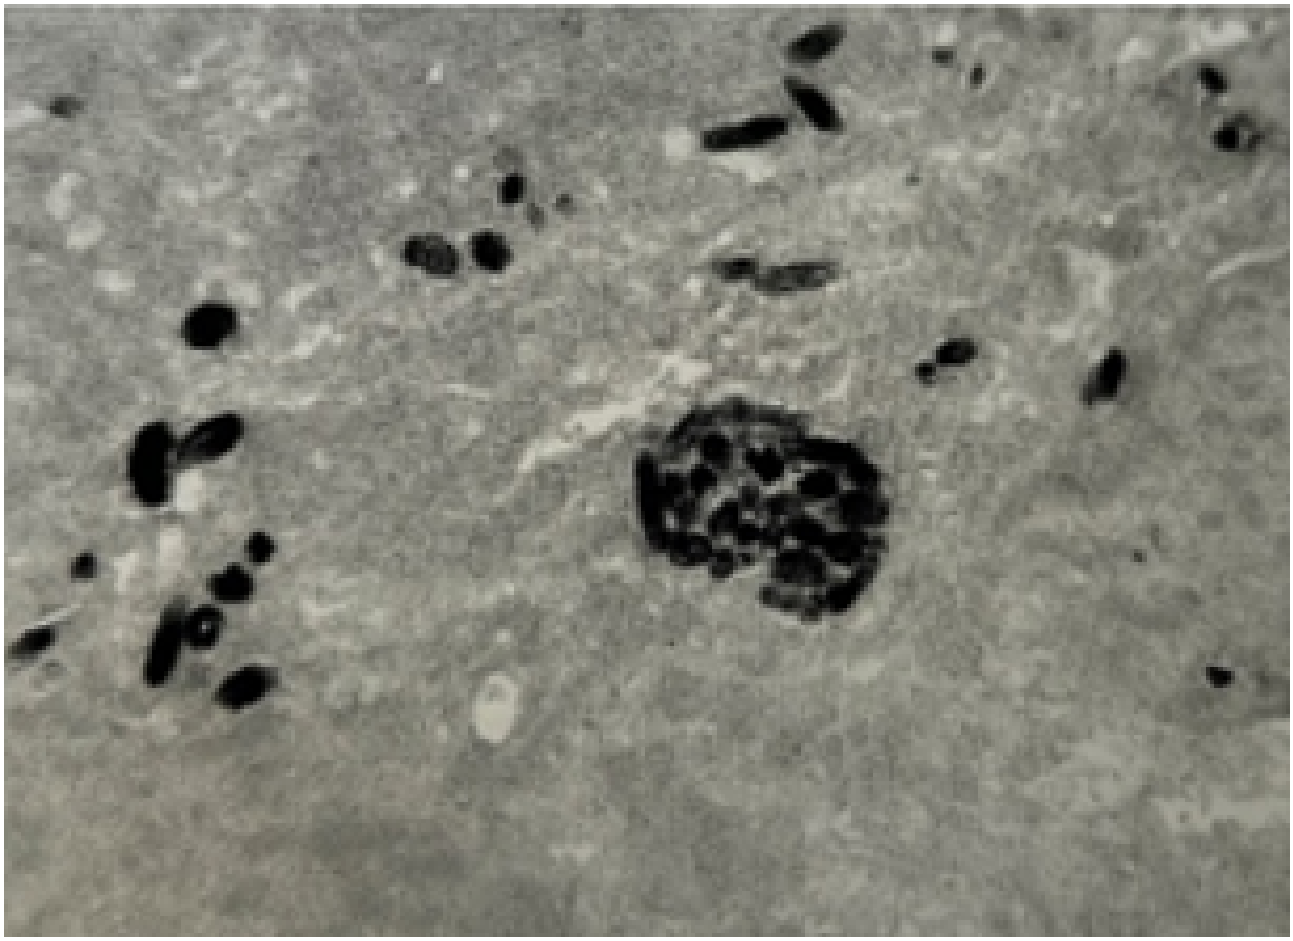
Our findings indicate that the relative preservation of melanosome abundance—particularly pheomelanosomes—together with a larger pretreatment hair shaft diameter and minimal posttherapeutic shaft surface damage, represents independent correlates of successful hair preservation.

Importantly, these observations should be interpreted as biologically plausible associations rather than strictly causal relationships. Nevertheless, they consistently point toward a central role of melanogenesis integrity and keratinocyte proliferative capacity in maintaining follicular resilience under cytotoxic stress. In this context, chemotherapy-induced impairment of melanogenesis and keratinocyte turnover appears to directly compromise follicular homeostasis. While scalp cooling may attenuate these effects, it does not fully prevent them, thereby highlighting both the biological potential and the inherent limitations of the intervention.

Collectively, these findings support the concept that scalp-cooling efficacy is not solely determined by physical temperature modulation, but rather reflects a biologically modulated preservation of follicular integrity.

From a pathophysiological perspective, anthracyclines and taxanes preferentially target rapidly proliferating keratinocytes within the hair matrix while simultaneously inducing the formation of reactive oxygen species (ROS). This dual mechanism not only disrupts keratinocyte turnover but also functionally impairs components of the follicular pigmentary unit, including melanocytes and associated sebocytic structures [19-21].

Even in the presence of scalp cooling, the residual exposure of follicular melanocytes to cytotoxic agents may induce a prematurely dysregulated state of melanogenesis. Morphologically, this may manifest as increased melanin aggregation, reduced melanosome density, and a compositional shift from pheomelanin toward eumelanin synthesis [19,22].



This shift is mechanistically plausible in the context of oxidative stress, as cysteine—a critical substrate for pheomelanin synthesis—is increasingly diverted toward glutathione production under conditions of elevated ROS. Consequently, the balance of melanogenic pathways is altered in favor of eumelanogenesis, thereby reflecting an adaptive but functionally disruptive antioxidative response [23-25].

These mechanisms provide a molecular basis for the observed reduction in melanosome density and the elevated eumelanin-to-pheomelanin ratio post treatment (Mdn_{pre}=0.34 to Mdn_{post}=0.52; Table S1 in Multimedia Appendix 1). Importantly, the role of melanosomes extends far beyond the mere determination of hair color. Their perinuclear distribution around keratinocyte nuclei confers both photoprotective and antioxidative benefits, safeguarding keratinocyte genomic stability and ensuring controlled proliferative activities that ultimately drive proper hair shaft development [26-28].

Posttherapeutically, occasional melanosome clustering (Figure 3) was observed. However, this feature did not show a significant association with hair retention, suggesting that clustering represents a secondary or epiphenomenal structural alteration rather than a determinant of follicular resilience.

XSL•FO
RenderX

Figure 3. Cluster (more than 5 touching pigments).

In contrast, preserved melanosome abundance and the relative stability of melanosomal organization emerged as a potential surrogate marker associated with more favorable hair preservation. Minor qualitative shifts in melanosome composition were observed but were not formally quantified and are therefore reported descriptively. These exploratory and hypothesis-generating observations may reflect lower treatment-associated cellular stress and could represent a morphological correlate of relative follicular resilience. Preservation of melanosomal architecture thus extends beyond cosmetic relevance and may contribute to the maintenance of hair shaft integrity. Melanocytes and keratinocytes exist within a tightly coordinated functional unit characterized by reciprocal paracrine signaling and direct cellular cross talk. Mediators such as stem cell factors, endothelin-1, and basic fibroblast growth factor contribute to maintaining melanogenic activity and broader follicular homeostasis. This coordinated interaction provides a biological framework, linking the preservation of melanosomal architecture with follicular stability, and may help explain why the maintenance of an intact melanogenic process is associated with improved hair preservation [26,29]. Although both melanosome stability and shaft-surface integrity contribute significantly to hair retention under scalp cooling, statistical modeling identified them as independent correlates. This phenomenon can be explained by their distinct biological roles: the relative preservation of melanosome density provides intracellular photoprotection and antioxidative buffering, whereas shaft-surface conditions primarily determine the mechanical resilience of the emergent hair fiber. Therefore, each factor contributes additively, but not redundantly, to follicular protection, highlighting the multifactorial nature of CIA [27,28,30].

Increased oxidative cellular stress resulting from residual exposure to cytostatic agents can compromise both the hair bulb and the hair shaft surface. In contrast to metabolically active cells, the extracutaneous compartments of the hair shaft lack sophisticated antioxidative defense mechanisms, including enzymatic and nonenzymatic radical scavenging systems. As a consequence, structural components of the hair shaft remain particularly vulnerable to oxidative degradation, thereby amplifying the impact of chemotherapy-induced injury [31-33].

ROS compromise the hair's protective lipid envelope, most notably the 18-methyleicosanoic acid monolayer, which is crucial for shaft cohesion. Loss of this barrier renders the cuticle highly susceptible to endogenous and environmental damage. Under chemotherapy, excessive ROS not only damage cuticular elements but also affect cortical structures, leading to fibrillary misalignment. Subsequent oxidative events, including keratin modification, disruption of disulfide cross-links, and alteration of amino acid residues, irreversibly deteriorate the cortical architecture, resulting in fragile, dull, and fracture-prone hair fibers [32,34-37].

From a clinical perspective, the significance of hair shaft surface damage cannot be overstated. SEM demonstrated that a higher

XSL•FO
RenderX

damage grade is associated with visible alopecia or lower HMI in general, and descriptive results appear to suggest that a damage grade of 3 (cortical exposure) may constitute a critical threshold for visible alopecia (Table S6 in Multimedia Appendix 1). This observation parallels earlier findings in cosmetic dermatology, where chemical cuticle disruption progressing to cortical exposure invariably results in irreversible hair fragility [16,37].

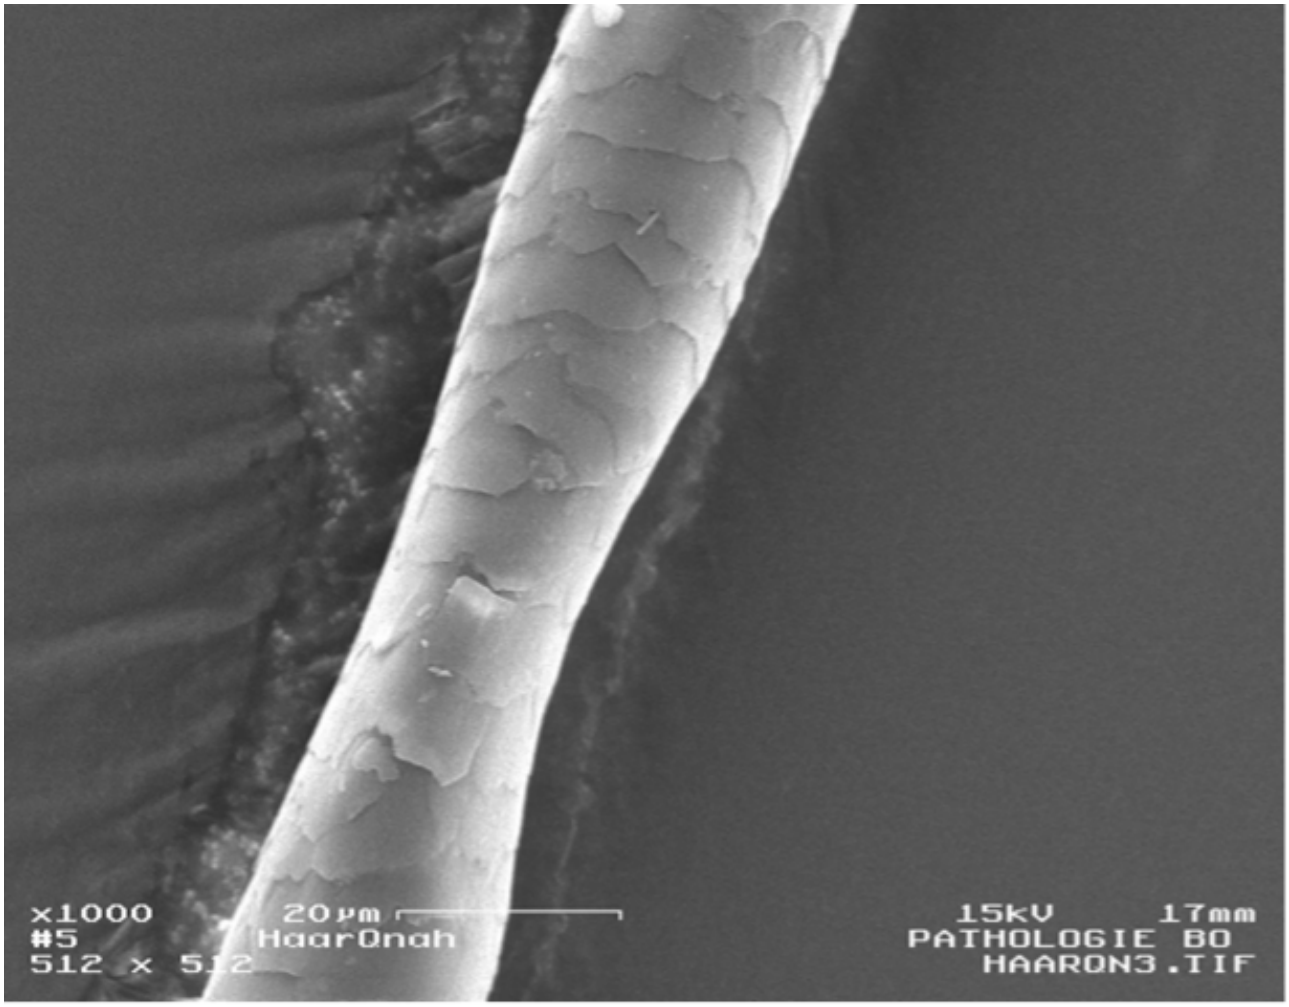
Within the follicular pigmentary unit, sebocytes act as integral partners to keratinocytes and melanocytes. Their secretory activity not only supports hair shaft emergence but also contributes to the antioxidative and immunomodulatory milieu of the follicle. Anthracycline-based chemotherapy may impair the sebocyte function, thereby reducing the protective capacity of sebum and increasing hair shaft vulnerability [14,19,38,39].

The lipid-rich sebum film reduces friction, minimizes breakage, and provides a hydrophobic barrier that limits transepidermal water loss, chemical irritation, and microbial penetration [40]. Acting as a lipid matrix, sebum enriched with antioxidants such as vitamin E and squalene may facilitate the scavenging of ROS and the absorption of ultraviolet radiation, indirectly reducing oxidative and inflammatory stress on keratinocytes and melanocytes [5,41-43].

After characterizing the impact of chemotherapy on the hair follicle and shaft quantitatively by hair loss assessed through the HMI, structurally by shaft alterations ranging from tapering detectable by light and SEM to ultrastructural surface damage, as well as indirectly by changes in melanosome density and patterning as surrogate markers of oxidative stress within the follicular pigmentary unit, these parameters may explain the individual variability in hair retention observed under scalp cooling.

However, further lowering of scalp-cooling temperatures has not improved efficacy in preclinical models when combined with highly cytotoxic regimens such as TAC (simultaneously administered docetaxel, doxorubicin, and cyclophosphamide), underscoring the need for additional protective or restorative strategies [44,45]. Consequently, recent efforts have shifted toward dermatological approaches designed to preserve the follicular pigmentary unit during chemotherapy under scalp cooling, thereby enhancing hair preservation.

Potential strategies to augment scalp-cooling outcomes include topical antioxidants (eg, melatonin and vitamin C encapsulated in nanovesicles) [46]. Another experimental concept involves transient pharmacological cell cycle arrest to reduce chemotherapy susceptibility of follicular keratinocytes. Preclinical studies have demonstrated that topical palbociclib induces temporary G1 arrest in follicular keratinocytes, protecting them from cytotoxic apoptosis while maintaining the subsequent anagen activity [20]. By reducing local perfusion and metabolic activity, scalp cooling limits follicular exposure to cytotoxic agents and lowers chemotherapy-induced oxidative stress. In this context, controlled oxidative stress may paradoxically induce p53-dependent cell cycle arrest rather than apoptosis, consistent with the protective effects of scalp cooling [47], providing a plausible, though not causally established, mechanistic explanation.



Another promising direction involves targeting the transforming growth factor-beta pathway. The chemotherapy-induced upregulation of transforming growth factor-beta 2 promotes catagen transition and apoptosis. The inhibition of this pathway by agents such as cartogenin has shown encouraging results in preclinical models, extending anagen duration and improving follicular resilience. While these findings are promising, clinical validation in human settings is currently lacking. Within this context, the integration of such pharmacological approaches represents a rational translational avenue that warrants further investigation [48,49].

Conceptually, ultrastructural analysis by SEM or TEM provides the most detailed assessment of follicular morphology.

In this study, ultrastructural analyses by SEM and TEM were available for a subset of 52 patients (Figures 4 and 5). This restriction did not reflect a biological or clinical selection criterion but was primarily driven by technical and logistical constraints related to the availability of specialized pathology resources. Consequently, these findings should be interpreted as hypothesis-generating rather than fully representative, while still providing valuable mechanistic insights into follicular structural integrity. However, such techniques are not feasible in routine clinical practice. In everyday settings, macroscopic and light microscopic observations must therefore guide the selection of topical interventions to avoid unnecessary polypharmacy. Light microscopy can reveal surface fragility through cortical irregularities, fissuring, or shaft tapering, features that may reflect oxidative stress as well as impaired matrix activity. Indicators of oxidative stress may further manifest as irregular or diminished pigmentation, uneven melanosome distribution, or translucent cortical segments. Collectively, these structural features may serve as practical surrogate markers of underlying biological vulnerability. However, their predictive validity requires prospective validation before routine clinical applications. Such insights may help stratify patient expectations, inform clinical decision-making regarding scalp cooling, and guide the use of adjunctive restorative strategies to further enhance follicular protection.

Preventing visible hair loss, defined as an HMI greater than 50 and achieved in 53% of patients, represents not only a biological endpoint but also a meaningful psychological resource, highlighting the broader relevance of scalp cooling beyond esthetics with respect to self-image, quality of life, and potentially treatment engagement. At the same time, the observational single-arm design precludes the causal attribution of psychosocial effects specifically to scalp cooling, as quality-of-life outcomes are influenced by multiple clinical and individual factors.

These observations suggest that patients' subjective interpretation and personal evaluation of scalp cooling may, in some individuals, be more closely associated with posttreatment quality-of-life measures than the objectively quantified extent of hair preservation itself. However, these relationships should be interpreted cautiously and as associative rather than causally established within the limitations of the present observational design. Accordingly, these findings are best understood as preliminary interpretive observations that require further validation before broader psychosocial conclusions can be drawn. Any potential links between biological hair preservation, ultrastructural follicular findings, and psychosocial outcomes should therefore currently be regarded as descriptive and not as evidence of a directly established mechanistic relationship.

From a psychological perspective, these findings may be interpreted within the framework of cognitive appraisal theory [50]. According to this model, individuals continuously evaluate situations in terms of personal relevance and controllability. Within this context, a positive appraisal of scalp cooling may contribute to a greater sense of security and subjective control during treatment, both of which may act as protective psychological resources. Such resources reduce perceived burden by mitigating feelings of helplessness and uncertainty, while acting as a buffer against stress. In this way, hair preservation under scalp cooling contributes not only to external appearance but also to psychological stability, reinforcing its role as a cornerstone of supportive cancer care [51-53].

In addition, the relative stability of quality of life between preintervention and postintervention assessments may partly reflect the influence of underlying psychological dispositions. However, this pattern is unlikely to be determined by attitudes alone and may also be shaped by patients' experiences during treatment. These factors are closely linked to body image and psychosocial self-perception, both of which are well-established determinants of quality of life in oncological care [45].

Taken together, these observations suggest that cognitive appraisal represents not only a statistical correlate but also a potentially clinically relevant psychological mechanism. Positive appraisal may be associated with greater resilience and more adaptive coping strategies and could contribute to psychological well-being throughout treatment. Thus, beyond the biomedical effects of scalp cooling, the subjective evaluation of the intervention may represent an important mediator of psychosocial outcomes [50,54-56].

XSL•FO
RenderX

Within the framework of cognitive appraisal, it is conceivable that the integration of adjunctive strategies targeting the follicular pigmentary unit may further support patients' sense of control and bodily integrity. Interventions aimed at stabilizing pigmentary functions and thereby enhancing the effectiveness of scalp cooling could contribute to a more favorable subjective treatment experience. We hypothesize that patients receiving not only scalp cooling but also adjunctive follicle-directed supportive measures could potentially experience improved coping with the overall burden of cancer therapy. Such an integrative approach may therefore contribute to psychological well-being and maintain quality of life throughout treatment [5,45,57].

The study has several limitations, including its single-center design and the relatively small cohort of 82 patients. The availability of electron microscopy data was limited to the first 52 consecutively enrolled patients. This restriction was determined by the labor-intensive and technically demanding nature of ultrastructural processing and the finite pathology resources available for electron microscopy analyses, rather than by clinical, biological, or outcome-related selection criteria. Consequently, the risk of selection bias within the ultrastructural subgroup is considered low. Although menopausal status was assessed exclusively in female participants, no association with hair preservation was observed in our cohort. Therefore, the absence of an equivalent classification for male participants is unlikely to have substantially influenced the interpretation of our findings and thus represents only a minor limitation.

Consistent with previous reports, no increased risk of scalp metastasis was observed, supporting scalp cooling as a safe option in cancer treatment [58-60].

In summary, this study broadens the current understanding of scalp cooling by identifying the stability of the follicular pigmentary unit and the preservation of shaft integrity as biologically relevant markers of follicular resilience. The findings support a translational perspective in which adjunctive follicle-directed protective strategies may complement scalp cooling. Potential approaches ranging from antioxidant support to the modulation of cell cycle dynamics, for example, by stabilizing or prolonging the anagen phase, remain exploratory and require prospective validation. Collectively, such concepts may contribute to improving the consistency of hair preservation beyond the currently observed response rates of approximately 50% across heterogeneous patient populations. Ultimately, the clinical relevance of these approaches may lie in achieving more reliable treatment-related hair preservation and supporting patient-centered outcomes.

Conclusion

Taken together, these findings suggest that the clinical relevance of scalp cooling may extend beyond the binary end point of hair preservation. Preserved hair mass was associated with more favorable PROs and appeared to interact with patients' appraisal of treatment-related changes, supporting a broader biopsychosocial perspective on the treatment experience. While causal relationships cannot be established from this observational study, the results indicate that the impact of scalp cooling may not be fully captured by hair-retention thresholds alone.

By integrating the ultrastructural evidence of follicular vulnerability with patient-reported psychosocial outcomes, this study highlights the multidimensional nature of treatment-related hair loss. These findings support a more nuanced, patient-centered evaluation of scalp cooling and provide a rationale for future strategies aimed at improving both the biological protection of the hair follicle and patients' experiences during chemotherapy.

Abstract

Background: Mobile health (mHealth) interventions may improve provider-parent communication on human papillomavirus (HPV) vaccination to reduce concerns, and increase intention and uptake. HPVVaxFacts (233 Analytics) is a novel, mobile web app delivering tailored education based on the Health Belief Model and Theory of Reasoned Action, addressing parental concerns preclinic visit.

Objective: This study aimed to assess the feasibility, acceptability, and preliminary efficacy of HPVVaxFacts among parents of adolescents aged 9 - 17 years.

Methods: We conducted a pilot, randomized controlled trial in 2 urban Tennessee clinics from June to September 2023 comparing 2 groups: tailored education via HPVVaxFacts mobile web app (intervention, n=27), and nutrition education (attention control, n=30). Eligible parents had or were caregivers to a child aged 9 to 17 years unvaccinated against HPV, had a mobile phone, had an upcoming clinic visit, and spoke English. The recruitment strategy was patient intake software—Phreesia (Phreesia, Inc) and eClinicalWorks (eClinicalWorks). Although unblinded, parents could deduce their study arm assignment. Providers were blinded. Feasibility, acceptability, and preliminary efficacy (HPV vaccine knowledge, concerns, intentions, and vaccination rates) were assessed using multimethod evaluation. Parents were assessed at baseline and immediately post intervention via surveys. Vaccination rates were assessed at 12 months post intervention via electronic health records. Nineteen parent interviews were conducted up to 9 months post intervention. A clinic staff consultation (n=6) was 1 month post intervention.

Results: Of 57 enrolled parents, most were female (52/57, 91%), non-Hispanic White (44/57, 77%), had ≤US $80,000 household income (32/57, 56%), and had some college or less (27/57, 47%). In total, 81% (29/36) of parents viewed HPVVaxFacts. Post intervention, HPV vaccine initiation was higher in the intervention group compared to the attention control group (48% vs 17%; difference 0.24; 95% CI 0.03-0.46; *P*=.01). Parents in the HPVVaxFacts arm demonstrated a greater reduction in knowledge (ie, knowledge increase; mean change: −0.6 vs 0.1) and concern scores (mean change: −3.4 vs −1.4) than those in the nutrition education arm. However, between-arm differences were not statistically significant (*P*=.13 and *P*=.14, respectively). The majority found the study protocol and HPVVaxFacts acceptable. Benefits of HPVVaxFacts include confirming their decision to vaccinate,

XSL•FO
RenderX

supporting parent-child discussion on the vaccine, and answering questions preclinic visit or offering questions for the provider. Study protocol delivery and mobile web app instructions were suggested areas for improvement. Barriers for HPVVaxFacts use include content in English only and digital format.

Conclusions: Our study suggests HPVVaxFacts was feasible and acceptable among parents to provide previsit, tailored information on HPV vaccination. Outcomes offer a positive trajectory but need more exploration. Next steps include a well-powered efficacy trial to determine the impact of HPVVaxFacts on initiation vaccine rates and parental hesitancy factors, as well as to explore an interaction, effect modification, and mediation among different variables.

Trial Registration: ClinicalTrials.gov NCT04380623; https://clinicaltrials.gov/study/NCT04380623

Introduction

Parental vaccine hesitancy remains a critical barrier to suboptimal rates of human papillomavirus (HPV) vaccination. Studies show up to 63% of US parents are hesitant [1,2] (ie, reluctant or refuse to vaccinate) despite its availability and proven effectiveness [3]. This contributes to stalled HPV vaccination rates among adolescents aged 13 - 17 years, 63% in the United States and 64% in Tennessee in 2025 [4]. Unvaccinated adolescents are at risk for HPV infection, which is implicated in almost all cervical cancers and 63% - 90% of penile, vulvar, vaginal, anal, and oropharyngeal cancers [5]. Many of these HPV-related cancers are rising in incidence [6]. Based on several US studies, parental predictors for HPV vaccine hesitancy are complex and multifactorial [7-9]. Common reasons include concern about safety or side effects, lack of knowledge on HPV and associated cancers, and lack of or poor-quality provider recommendations and communication [10]. Hesitant parents often report dissatisfaction with patient-provider communication, further undermining their confidence and decision-making to initiate and complete HPV vaccination [11-14]. There is an urgent call to identify evidence-based practices (EBPs) to address vaccine hesitancy globally and nationally [4,13,15].

Few interventions to date have been found impactful in addressing parental HPV vaccine hesitancy. Mobile health (mHealth) interventions show promise in enhancing traditional medical care. With provider-based strategies (eg, a strong recommendation and motivational interviewing), mHealth interventions could positively impact parental concerns by countering misinformation or addressing lack of information about HPV vaccination [16-22]. Some data exist on mHealth in promoting HPV vaccination, but important limitations remain. A systematic review from January 2017 to July 2022 identified 24 digital health interventions for HPV vaccination, with only 4 using theory-based mHealth interventions [23-26]. Limitations of these interventions are (1) a focus on general HPV vaccine promotion and not unique concerns of vaccine-hesitant parents, (2) targeted only at girls or younger adolescents, and (3) limited testing across diverse sociodemographics and geography. Two of these studies tailored information using reminders or by individual vaccine status [23,26-29], but these approaches were limited in impact. There remains an unmet need to develop an efficacious mHealth program that provides parents succinct, resonating messages individually tailored to their concerns on the HPV vaccine for use by providers to supplement parent-provider in-clinic discussion [30,31].

Past studies suggested that many parents wanted HPV vaccine information before a clinic visit with their child's provider. Information could be delivered prior to the clinic visit using mHealth [16-22]. The purpose of receiving this information was to get the answers to the questions they may have about HPV and the vaccine prior to the visit. Furthermore, parents used this information to engage in parent-provider communication about the vaccination and support shared decision-making (J Cunningham-Erves, unpublished data, June 2022).

This study's objective was to conduct a pilot test of a mobile web app intervention, HPVVaxFacts (233 Analytics), designed to provide tailored, previsit education to improve HPV vaccination rates. We hypothesized that : (1) the HPVVaxFacts intervention arm would achieve acceptability and feasibility rates ≥70%; and (2) parents in the intervention arm would show greater reductions in vaccine concerns and greater increases in knowledge, intentions, and vaccination rates compared to the attention control arm. To prepare for a future full-scale randomized controlled trial (RCT) to determine efficacy, our aims were as follows:

- Aim 1: To assess feasibility of the HPVVaxFacts intervention and overall study protocol.
- Aim 2: To assess acceptability of the HPVVaxFacts intervention within 2 urban pediatric clinics.
- Aim 3: To explore preliminary efficacy of the HPVVaxFacts intervention on the parent's decision to get their adolescents the HPV vaccination.

Methods

Setting and Study Design

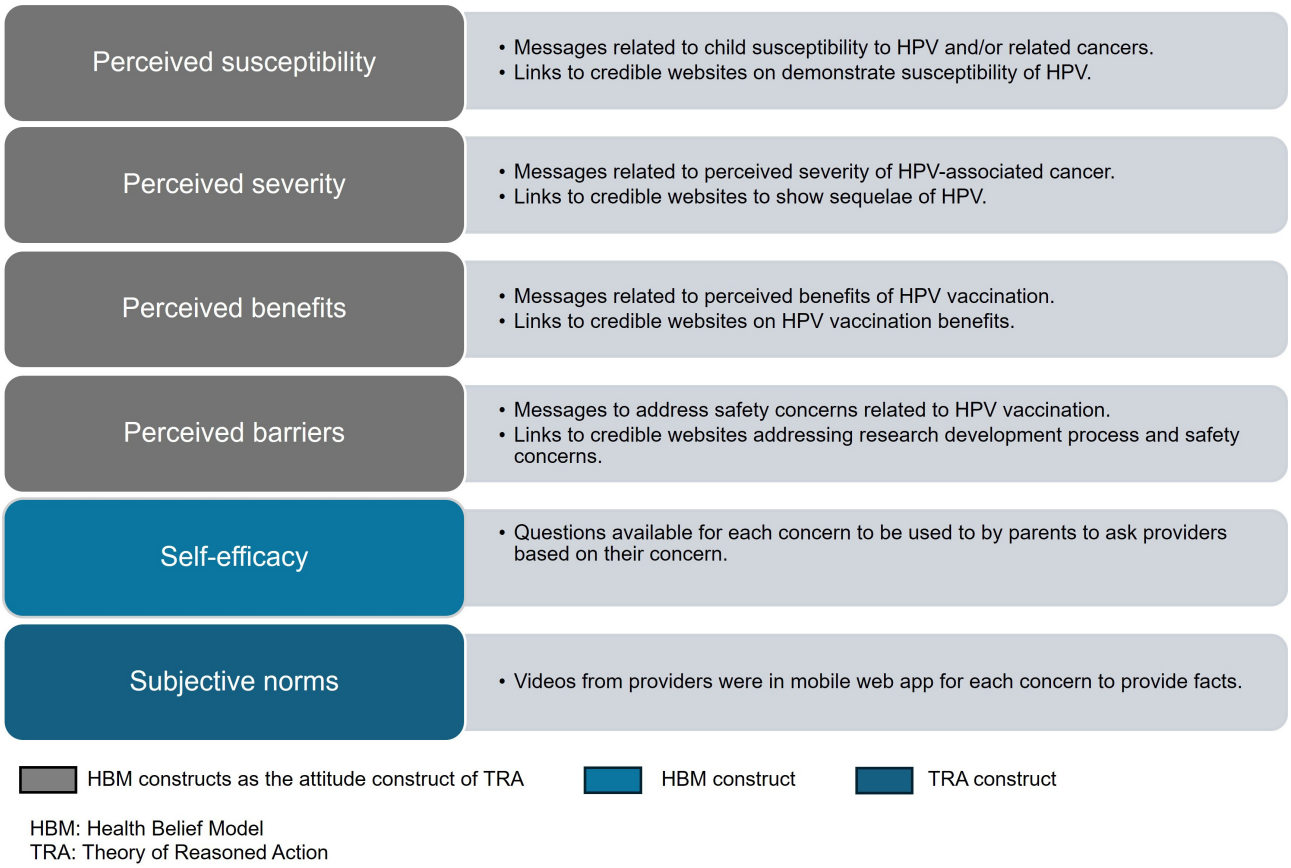
A multimethod approach was used to evaluate the feasibility, acceptability, and preliminary efficacy of a mobile web app, HPVVaxFacts, among parents of unvaccinated children aged 9 to 17 years [32]. A pilot, 2-arm, multisite RCT was conducted at 2 urban pediatric clinics in Tennessee to determine feasibility and acceptability. Clinic Site 1 is an urban pediatric clinic serving more than 8000 children with a broader demographic of families with varied socioeconomic backgrounds. There were

XSL•FO
RenderX

421 unvaccinated children at Site 1 from June to September 2023. In contrast, Clinic Site 2 is an urban pediatric clinic serving more than 5000 children primarily uninsured, underinsured, and marginalized children. A total of 23 unvaccinated children were at Site 2 for 1 week in August 2023. Clinic providers and staff stated they had higher vaccination rates, so they chose a 1-week back-to-school event where vaccinations were offered. This time was perceived to have the highest volume of unvaccinated patients. While operational workflows (ie, administrative protocols, patient volume, and technology adoption) and catchment areas differ, both had patient intake management platforms for recruitment and followed the standardized protocols to be discussed in detail below.

Parents in both arms who agreed to follow-up were interviewed to explore acceptability and feasibility of the protocol using a qualitative, descriptive study design. Intervention acceptability and parent-child discussion were examined among parents in the intervention arm only. The reporting of the pilot RCT follows the CONSORT (Consolidated Standards of Reporting Trials) 2010 guidelines to report a pilot or feasibility trial (Multimedia Appendix 1) and the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist to evaluate web-based apps (CONSORT-HEALTH checklist in Checklist 1) [33].

Ethical Considerations



The Institutional Review Board (IRB) of Meharry Medical College (Protocol Number: 18-12-890) approved this study as expedited as it was considered no more than minimal risk. The study was registered at ClinicalTrials.gov (NCT04380623) and performed in line with the principles of the Declaration of Helsinki. Electronic consent was obtained from participants using REDCap (Vanderbilt University) [34,35] for the pilot RCT, and verbal consent for the semistructured interviews. To protect participant information, survey and interview data were stored via REDCap and on a password-protected server. Data were deidentified prior to provision to statisticians and research team members for data analysis. Dissemination of results was aggregate and anonymous. Participants were compensated with a US $30 gift card for pilot study participation, and a US $20 gift card for completing a follow-up interview.

Intervention

HPVVaxFacts provides individually tailored education on HPV and the vaccine to parents [36]. Education and video content for each concern was developed using the Health Belief Model and Theory of Reasoned Action (Figure 1). To tailor the education in the app, each parent answered a 10-item baseline survey adapted from the Vaccination Confidence Scale [37] to identify parental concerns. The survey responses are mapped to an algorithm that selects the top 3 parent concerns. Parents can change the selection if they disagree. Parents then review the content (ie, educational information, provider's video, questions for the provider, and links to other credible sources verifying content) associated with each concern. An adolescent corner is available for parents to share with and/or have an optional discussion with their child about each concern. Finally, parents could submit concerns or additional needs via the provision of feedback. Refer to Cunningham-Erves et al [36] for full description of HPVVaxFacts development.

XSL•FO
RenderX

Figure 1. Examples of theory application in HPVVaxFacts development. HPV: human papillomavirus.

Attention Control

Parents in the attention control arm received a link to a website providing nutrition education for parents of children and/or teens [38], a program unrelated to the study outcome. This approach served two purposes: (1) ensuring all parents receive a benefit regardless of study arm assignment, and (2) balancing time and effort between groups [39]. Because parents' perceptions of HPV vaccination significantly influence vaccination outcomes [40], an attention control group allowed us to account for potential placebo effects and isolate the specific effects of HPVVaxFacts. Furthermore, the study arm activities were comparable to the intervention activities. Parents completed a 5-item brief quiz with immediate feedback on correct or incorrect responses and explanations.

Study Participants

This study was conducted with parents who were caregivers for children in 2 urban pediatric clinics in Tennessee who were representative of the continuum of vaccine hesitancy. Eligible parents had a child aged 9 to 17 years who was unvaccinated against HPV, had a mobile phone, had an upcoming clinic visit, and spoke English. When multiple children per eligible caregiver existed, random selection determined which child would participate. Random numbers were first generated in Stata version 17 (StataCorp LLC). Children were ordered from youngest to oldest (or alphabetized by first names if twins or triplets). The child with the lowest corresponding random number was selected for the parent to be sent a study invitation. Eligibility criteria were chosen based on participating providers and staff input. They stated it was not feasible to enroll only hesitant parents. Instead, they perceived it was equally beneficial to recruit parents representing the continuum of hesitancy. Exclusion criteria were parents who did not consent, or their child had initiated or completed the HPV vaccination series.

Multimethod Evaluation

Quantitative Phase

Training and Preparation

The clinic sites had different recruitment approaches. Clinic Site 1 recruitment was conducted by 2 trained clinic staff. Clinic Site 2 recruitment was done by 2 members of the research team. Recruitment and enrollment procedures were standardized through 2-hour training. Training included a review of the study protocol and documents, integration with clinic workflow, and potential recruitment and retention challenges. Post training, a study protocol run-through was conducted at each clinic site to familiarize the study team with the protocol and identify necessary adjustments prior to implementation.

Site-Specific Recruitment Methods

At Clinic Site 1, parents were first introduced to the study via a post to the clinic's Facebook (Meta Platforms, Inc) page to increase study awareness in their clinic. At Clinic Site 2, flyers were posted in the clinic. Eligibility was determined via electronic health record (EHR) data by 2 trained clinic staff at Clinic Site 1 and 2 trained research staff at Clinic Site 2. The research team was trained by clinic staff to use EHR and eClinicalWorks (version 12.0.2; eClinicalWorks).

XSL•FO
RenderX

Enrollment Communication

Eligible parents received an IRB-approved text message explaining the study and inviting study participation, with emphasis on the HPV vaccination. If parents text "yes," a screener was sent text to parents to confirm eligibility. Trained clinic staff at Clinic Site 1 contacted parents via Phreesia, a HIPAA (Health Insurance Portability and Accountability Act)-compliant patient intake management platform that automates the check-in process as well as supports patient-provider communication [41]. At Clinic Site 2, parents were contacted via eClinicalWorks by study team members. Parents received up to 3 text messages on their mobile phones requesting participation.

Sample Size

GPower 3.1 program (version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) was used to conduct power analysis to determine the sample size. The necessary sample size for the pilot trial was calculated using a 1-sided 80% CI and the expected effect size of the future RCT [42], based on the expected proportion in the attention control arm (0.20 - 0.30) and the clinically meaningful difference to be observed in the intervention arm in the future RCT (at least 0.10 higher) [42,43]. A total pilot sample size of 46 - 60 accounts for expected attrition and was deemed sufficient. Our study goal was to enroll 70 parents, expecting 10% - 15% attrition (eg, no-show for clinic visit), yielding a final sample of 60 - 63 parents (28 - 30 per arm).

Randomization and Blinding

All data were collected via the parents' mobile phones. A member of the research study (coauthors: JC-E, ECS, and MS), all trained and with social science backgrounds, enrolled parents in the study. The biostatistician (coauthor DL) generated 2 randomization lists prior to study implementation. Using blocked randomization, randomization was conducted with blocks of 10 (using n=10 from each group). Group labels (denoted as 1 or 2) were generated in Stata version 17. Although parents could deduce their study arm assignment, providers were blinded. We had 2 protocol deviations in which 1 participant who decided not to participate later decided to participate, which led to 2 parents being assigned to the HPV program at the same time. We decided to retain both participants for the analysis. The second deviation was the continued enrollment of 7 participants more than the planned sample size due to consent initiation. However, these individuals were not a part of the random allocation process and were excluded [44].

Procedures

After confirming participant eligibility, parents were sent a REDCap link to their mobile phones to provide electronic consent up to 48 hours prior to the clinic visit. They were assigned to either the intervention or attention control arm post consent based on the computer-generated randomization numbers listed by a trained research team member with a social science background (lead author: JC-E). Parents were asked to view HPVVaxFacts or nutrition programs at least once prior to their upcoming clinic visit. At baseline, parents took the presurvey assessing their sociodemographics and knowledge and concerns related to HPV and the vaccine, and intentions to initiate vaccination. If randomized to the intervention arm, parents were sent a personalized link to the presurvey to assess knowledge and intention and then went to the mobile web app HPVVaxFacts to assess, receive, and confirm or change their top 3 concerns. After viewing the assigned mobile web app, parents took a postsurvey before the clinic visit with similar presurvey questions except for the sociodemographics. Parents in the intervention arm were also asked questions related to program acceptability. If any participant did not complete a survey or view the mobile web app, up to 3 reminders were sent for completion. Post study, the trained clinic staff provided a dataset on the child's HPV vaccine status at 0 and 12 months.

Outcomes

Overview

The clinic provided the vaccination status of each child at 12 months post intervention using the EHR (Primary Outcome). The pre-post survey asked parents about their knowledge, concerns, and intentions for their child to initiate the HPV vaccination process. Intervention acceptability and intervention use for parent-child discussion were assessed on the postsurvey of parents in the intervention, "HPVVaxFacts" study arm only. Intervention feasibility was assessed via several feasibility indicators (Secondary Outcomes). Sociodemographic data were collected on the presurvey only (Covariates).

Primary Outcome: HPV Vaccination Status (1-Item)

HPV vaccination status post study was retrieved from the clinics' EHR system. The child's vaccination status post study was labeled as "yes" and "no." Vaccination status was assessed at 12 months post intervention.

Secondary Outcomes

Knowledge of HPV and the Vaccine (10-Item Scale)

A validated knowledge scale [45] assessed parental knowledge of HPV and HPV vaccination. Response options were true, false, or unsure, in which some answers were true and others false. For analysis, false responses were reverse-coded, false and unsure answer responses were combined, and mean scores were calculated for pre- and postassessments. The lower the score, the greater the degree of knowledge a parent had. When measuring internal consistency reliability, the Cronbach α for knowledge data on presurvey was 0.80 and 0.81 on the postsurvey.

Concerns (9-Item Scale)

An adapted attitudes scale, the Vaccine Confidence Scale [37], assessed parental concerns on HPV vaccination based on a 4-point Likert scale to determine agreement. The parents receiving nutrition education completed this measure in REDCap, while parents receiving HPVVaxFacts completed these items in the mobile web app. The HPVVaxFacts mobile web app prompted parents to take a survey, receive their top 3 concerns based on a preexisting algorithm, and confirm and/or change their selection. The final selected top concerns were tracked within the app. For inferential analysis, mean pre- and postscores were calculated for both groups with the greater score indicating more parental vaccine concerns. Internal consistency was strong: Cronbach α 0.90 (presurvey) and 0.91 (postsurvey).

XSL•FO
RenderX

HPV Vaccination Intention (1-Item)

One question asked, "How likely is it that you will get your child the HPV vaccine?" with the response options "Definitely not likely," "Not likely," "Somewhat likely," and "Very likely" [46].

HPV Vaccine Recommendations

Parents were asked, "Has your child's doctor offered the HPV vaccine?" with answer options yes or no.

HPVVaxFacts Feasibility

We followed guidelines of Teresi et al [47] to assess various aspects of feasibility in our pilot study. We describe each below.

Data Collection Protocols and Data Availability

We documented whether participants complied with assessment and data collection protocols. This included (1) completion rates of the pre-post survey, (2) mobile web app tracking of parent concerns and selected top 3 concerns by date and time, and (3) the ability to obtain the necessary data from clinic administrative records, particularly age and HPV vaccination status. Feasibility was measured as 70% of parents viewing the mobile web app.

Conceptual and Psychometric Adequacy of Measures

We assessed the internal reliability of the concerns, knowledge, and intervention acceptability scales. Participants were allowed to provide feedback on the HPVVaxFacts mobile web app to determine whether important concerns were missing from the app, which suggests missed questions on the concern scale.

Intervention Implementation

We assessed the number of participants recruited and retained for the study.

HPVVaxFacts Acceptability (4-Items)

Parents were asked their acceptability of HPVVaxFacts using a validated, 4-item scale. Response options were on a 5-point Likert scale based on agreement [48]. An example item is "The HPV Education Program meets my approval." Acceptability was measured as 70% or more of parents stating they agree or strongly agree with each statement. Internal consistency yielded the Cronbach α value of 0.91 on presurvey data in this study.

Parent-Child Discussion (1-Item)

Developed by the research team, parents in the intervention arm were asked whether HPVVaxFacts was helpful in discussing the HPV vaccine with their child post study. The answer choices were on a 5-point Likert scale based on agreement.

Covariates: Sociodemographics (12-Items, Presurvey Only)

These variables were in 2 categories—parent and child sociodemographics.

Parent Sociodemographics

Age was a continuous variable. Sex was categorized as male, female, and prefer not to disclose. Parent sexual orientation included categories of asexual, bisexual, straight, fluid, and gay. Categories were combined to straight (heterosexual), prefer not to disclose, and other. Parents' race or ethnic categories were non-Hispanic White, African American, Latino or Spanish origin, Native Hawaiian or Other Pacific Islander, and Prefer Not to Answer. Education categories were General Educational Development (GED) or high school diploma, associate's degree, some college, bachelor's degree, master's degree, and doctoral or professional degree. Annual household income categories were less than US $20,000, US $20,001 to US $40,000, US $40,001 to US $60,000, US $60,001 to US $80,000, and more than $80,000, or did not answer.

Child Sociodemographics

Age, a continuous variable, was categorized to 9 - 10, 11 - 12, and ≥13. Sex was categorized as male, female, and prefer not to disclose. The child's race or ethnic categories were non-Hispanic White, African American, Latino or Spanish origin, American Indian and Alaskan Native, Prefer Not to Answer, and Other. The child's sexual orientation had several categories including aromantic, asexual, bisexual, fluid, straight, and gay. These categories were combined to straight (heterosexual), questioning or unsure, prefer not to disclose, and other.

Data Analysis

Descriptive statistics characterized the sample: continuous variables are reported as means and SDs, and categorical variables as frequencies and percentages. Between-group comparisons were conducted using appropriate statistical tests: Fisher exact test or chi-square tests for categorical variables and Wilcoxon rank-sum tests or *t* tests for continuous variables. Comparison of pre-post scores of HPV vaccine knowledge, concerns, and intention by study arm was performed using exploratory visual analysis. Provider recommendation was not included as a covariate because (1) recommendations were expected to be similar across study arms and (2) are rarely systematically documented in clinical practice [49], making reliable data collection impractical. Parents took the survey in the HPVVaxFacts mobile web app and were allowed to select their top concerns. The research team categorized the top 3 concerns and summed the concerns by question. The summed scores were sorted from highest to lowest, with the top 3 values being the top concerns.

Qualitative Phase

Recruitment

Interviews were conducted up to 9 months post intervention based on parent availability. On the postsurvey, 15 in the intervention study arm and 18 in the nutrition attention control agreed to be contacted for follow-up interviews. Of these participants, 9 in the intervention study arm and 10 in the nutrition attention control completed an interview. Other parents either could not be reached (n=9) to complete or later decided not to complete the interview (n=5).

Procedures

Parents in both intervention and attention control groups who agreed to be contacted for the follow-up interview were called to schedule the 20-minute interview. The purpose of these interviews was to complement quantitative data. Interviews were audio-recorded and transcribed for data analysis.

XSL•FO
RenderX

Interview Protocol

The semistructured interview protocol for parents who were assigned to the HPVVaxFacts intervention arm included questions that explored intervention acceptability. Parents in both study arms were queried regarding their study experiences and ways to improve the study protocol and implementation procedures.

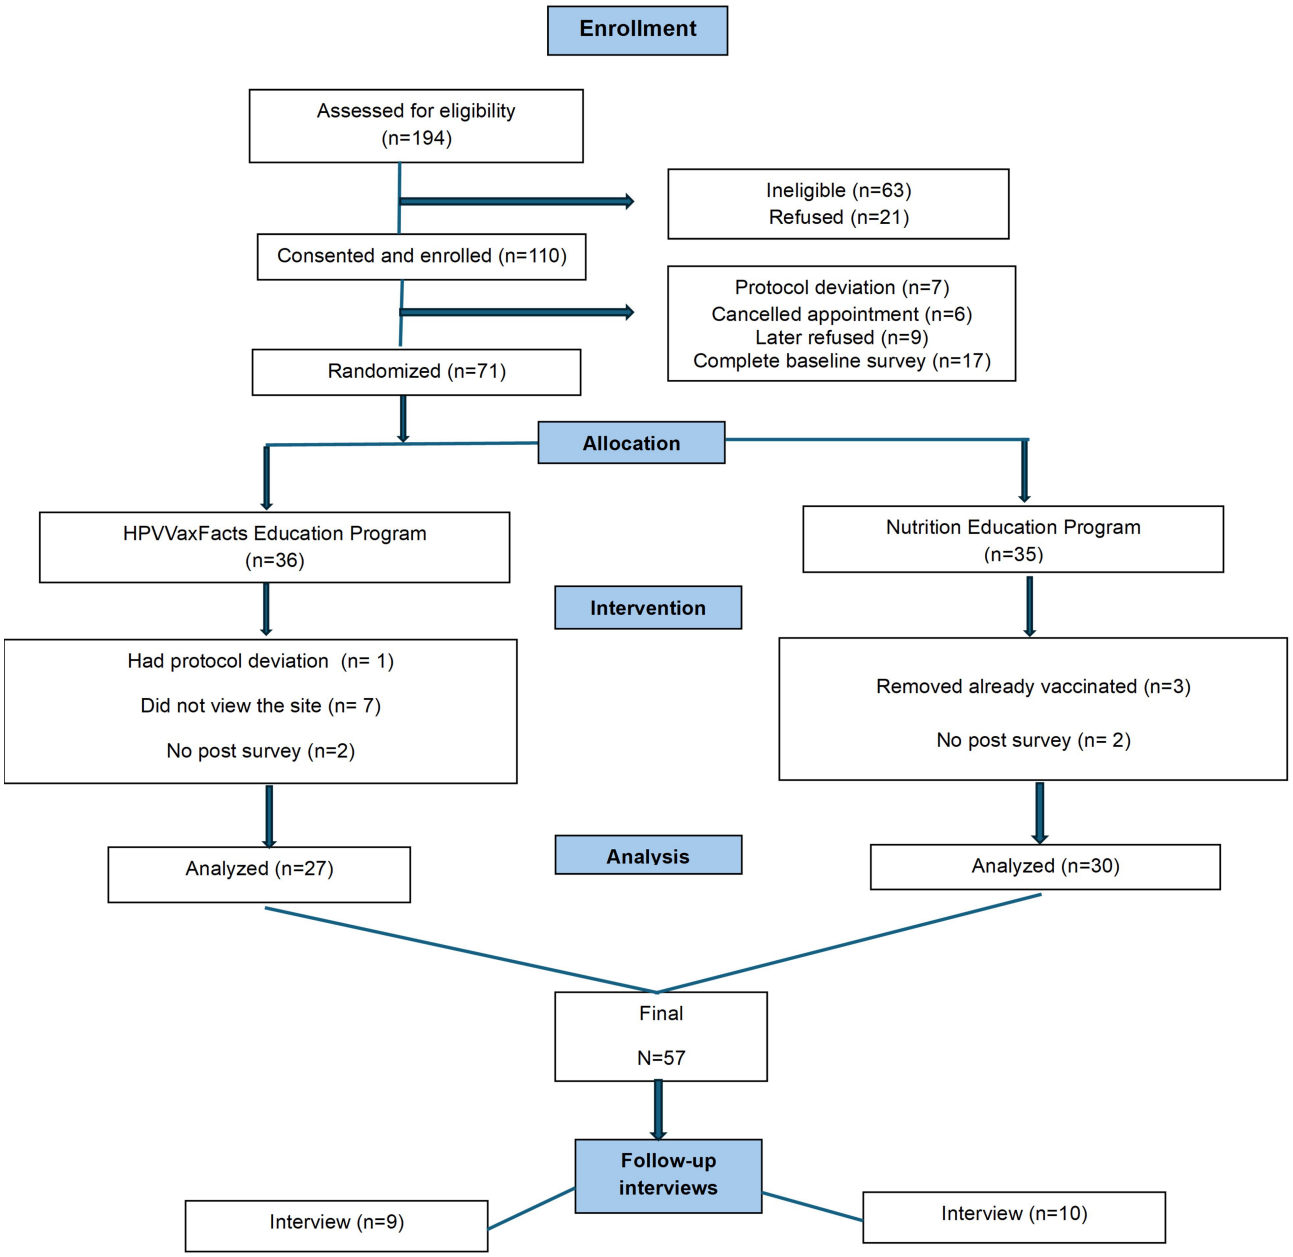
Data Analysis

Interview transcripts were analyzed using a modified version of Braun and Clarke's 6-step thematic methodology [50]. A trained qualitative researcher and analyst (coauthors JC-E and TB) conducted the data analysis led by lead author JC-E, both with backgrounds in social science. Using the first 3 interview transcripts, coauthor JC-E created a codebook of a priori codes using line-by-line coding. Both coders used the codebook to independently code each transcript, creating reliability in the system and having each coder serve as a referent. The analysts then met to review coding decisions and reach a consensus on whether to accept, modify, remove, or add codes until a percentage agreement of >90% was reached. Coding saturation was met when no new codes emerged. Patterns and themes were generated by combining related codes and applying constant comparison methods across transcripts. Rigor was established using thick, rich descriptions of interview data. Interview data were managed using Excel (version 26; Microsoft 365).

Clinic Staff Feedback From Consultation

One month post intervention (October 2023), we held a 1-hour consultation (ie, an engagement strategy) with 2 clinic providers and 4 staff members over lunch to gather informal feedback on study protocol and implementation. Trained clinic staff coordinated the date and time of the consultation. The consultation explored ways to improve the study protocol and implementation procedures, and perceived barriers and facilitators to implementing HPVVaxFacts in routine clinic practice. This session was not audio-taped nor formally analyzed as qualitative research; instead, notes were recorded by coauthors JC-E and ES.

Overall, providers perceived that the program offered clinic benefits. Offering education preclinic visits to their patients was a top benefit. This complemented their recommendations and lessened clinic time for education. Another perceived benefit was the increased vaccination rates in the clinic. Regarding barriers, providers and clinic staff highlighted the need to improve logistics for large-scale implementation. Because the intervention was manual and required efforts from clinic staff and the research team to aid in recruitment and retention, providers questioned the feasibility of this study without full integration into the EHR but still perceived offering preclinic information in general as feasible. However, providers and staff stated they understood this was a pilot study and hoped their suggestions improved future implementation.



Results

Feasibility: Recruitment and Retention

We met our goal of training 2 clinic staff to aid in recruiting participants through Phreesia. For this study, the clinic staff sent potential parents an IRB-approved REDCap link with a screener. If they screened eligible, they received the presurvey, viewed the intervention, and took the postsurvey. Of the 194 assessed for eligibility, 63 were ineligible. A total of 21 (16%) declined to participate and 9 more later refused, increasing the refusal rate to 23%. We recruited 110 participants who consented and enrolled in the study (107 were recruited from Clinic Site 1 and 3 from Clinic Site 2) with an enrollment rate of 84%. Parents were enrolled 15 to 20 minutes up to 24 hours prior to the clinic visit. In total, 71 people were allocated to the study arms, a 35.5% reduction from enrollment to randomization. A total of 36 parents were randomly assigned to the HPVVaxFacts intervention arm, of which 7 did not go to the mobile web app. Of those who viewed the mobile web app (81%), 2 did not complete the postsurvey. These participants were excluded with a retention rate of 75%. A total of 35 people were randomly assigned to the attention control arm. We were unable to determine whether participants viewed the nutrition education website. However, 2 did not complete the postsurvey with a retention rate of 94% (Figure 2).

RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

Quantitative: Child and Parent Characteristics

The sociodemographic and clinical data by study arm assignment reported by parents demonstrated that most children belonged to the 11 - 12 age group with 44% and 50% in the HPVVaxFacts and nutrition study arms, respectively. Children in both groups were predominantly female, non-Hispanic White, and heterosexual. Among parents who participated in the survey, most of them were heterosexual. The mean age for participants in the HPVVaxFacts intervention arm was 41.8 (SD 14.6) years compared to participants in the nutrition attention control arm at 41.6 (SD 7.5) years. In terms of education level, a higher proportion of the parents in the HPVVaxFacts intervention arm had a bachelor's degree or higher (18/27, 66%) than those in the nutrition attention control arm (11/30, 40%). Additionally, the majority in both arms reported an annual household income of more than US $60,000. In the HPVVaxFacts intervention arm, 59% (16/27) of parents had been offered the HPV vaccine for their child by a provider compared to 70% (21/30) in the nutrition attention control arm. More than half in both arms were iPhone users (Table 1).

HPV Vaccine Initiation Status Poststudy by Study Arm

HPV vaccine status was obtained for 57 children aged 9 - 17 years who were nonvaccinated for HPV prior to their parent participating in the clinical trial. HPV vaccine initiation (ie, those who received the first dose) rates of children whose parents participated in the HPVVaxFacts intervention arm were significantly higher than those of children whose parents were assigned to the nutrition attention control arm (48% vs 17%; Table 2).

Table . HPV[a] vaccine rates 12 months poststudy by study arm (N=57).

	HPVVaxFacts Intervention (n=27)	Nutrition Attention Control (n=30)	Total (N=57)	*P* value
Received >1 dose of HPV vaccine, n (%)				.01
Yes	13 (48)	5 (17)	18 (32)	
No	14 (52)	25 (83)	39 (68)	

[a]HPV: human papillomavirus.

Factors Associated With HPV Vaccination by Study Arm

We determined the impact of the HPVVaxFacts intervention and nutrition attention control on knowledge, concerns, and intention related to HPV vaccination. Analysis revealed that parents in the HPVVaxFacts intervention arm showed higher improvement in knowledge scores but remained largely unchanged in the nutrition attention control arm with no significant difference in knowledge before or after intervention. Similarly, parents in the HPVVaxFacts intervention arm had a larger reduction in concern toward HPV vaccination compared to those in the nutrition attention control arm. However, the difference in concern scores was not significant (Table 3).

XSL•FO
RenderX

Table . Knowledge and concerns by study arm assignment (N=57).

	Knowledge, mean (SD; 95% CI)			Concerns, mean (SD; 95% CI)		
	HPVVaxFacts program	Nutrition program	*P* value	HPVVaxFacts program	Nutrition program	*P* value
Pre	2.1 (0.5; 1.2 to 3.0)	2.1 (0.4; 1.3 to 2.9)	.97	26.6 (1.8; 23.1 to 30.1)	27.3 (1.4; 24.6 to 30.1)	.75
Post	1.4 (0.3; 0.8 to 2.1)	2.2 (0.5; 1.2 to 3.1)	.22	23.2 (1.7; 19.9 to 26.5)	25.9 (1.4; 23.3 to 28.6)	.21
Post-pre	–0.6 (0.4; –1.4 to 0.1)	0.1 (0.2; –0.4 to 0.5)	.13	−3.4 (1.2; −5.8 to −1.0)	−1.4 (0.5; –2.4 to –0.4)	.14

Analysis demonstrated parents had varying degrees of intent (ie, an imperfect surrogate for vaccine hesitancy) to vaccinate their child. Before the intervention, 74% (20/27) of the parents in the HPVVaxFacts intervention arm had the intention of "Very likely" or "Somewhat likely" to get their children vaccinated compared to 60% (18/30) in the nutrition attention control arm. Post intervention, parents who reported intentions (very likely and somewhat likely) were 70% (19/27) in the HPVVaxFacts intervention arm and 63% (19/30) in the nutrition attention control arm. However, when examining pre-post changes in parents' intentions, 3/27 (11%) parents in the HPVVaxFacts intervention arm and 1/30 (3%) parent in the nutrition attention control arm reported an increased likelihood of vaccinating their children. The pre-post intervention arm and between-arm differences were not statistically significant (Table 4).

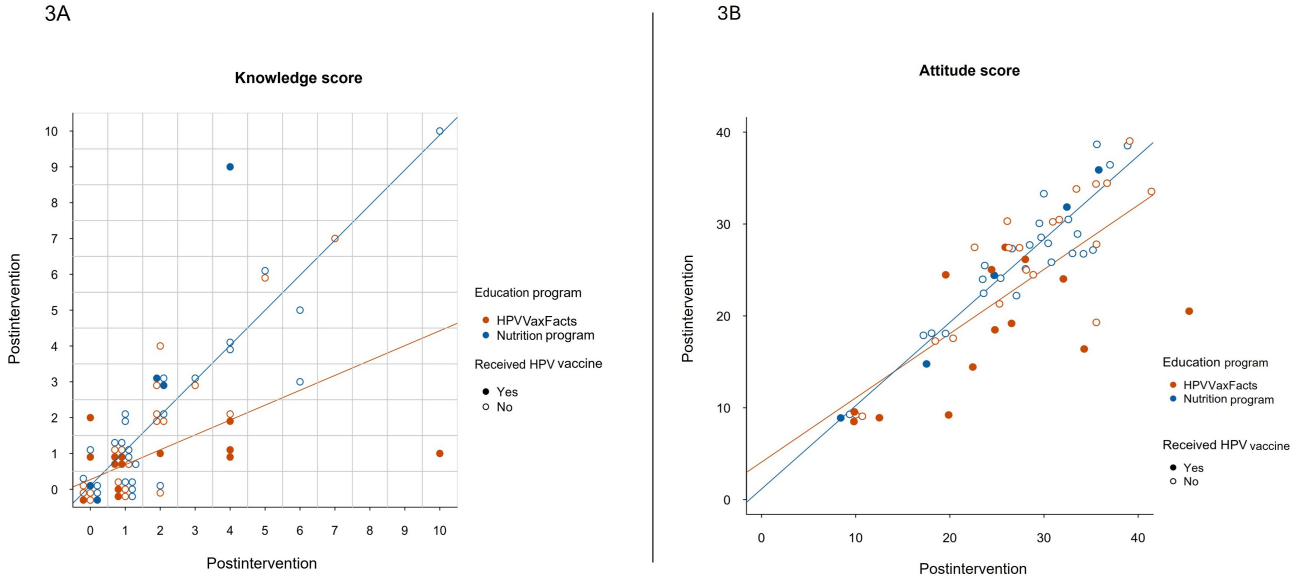

Table . Intention by study arm.

	HPVVaxFacts (n=27)	Nutrition program (n=30)	*P* value
Preintent: HPV[a] vaccine likelihood, n (%)			.56
Definitely not likely	4 (15)	5 (17)	
Not likely	3 (11)	7 (23)	
Somewhat likely	8 (30)	9 (30)	
Very likely	12 (44)	9 (30)	
Postintent: HPV vaccine likelihood, n (%)			.32
Definitely not likely	3 (11)	6 (20)	
Not likely	5 (19)	5 (17)	
Somewhat likely	6 (22)	11 (37)	
Very likely	13 (48)	8 (27)	
Change in intention, n (%)			.51
No change	22 (81)	27 (90)	
Less likely	2 (7)	2 (7)	
More likely	3 (11)	1 (3)	

[a]HPV: human papillomavirus.

XSL•FO
RenderX

Figure 3. Exploratory analyses comparing pre-post scores of human papillomavirus vaccination knowledge and concerns with human papillomavirus vaccination status based on study arm assignment. HPV: human papillomavirus.

Note: The lower the score, the greater the knowledge and lesser concerns related to the HPV vaccination though not significant.

Figures 3A and 3B show an exploratory analysis between pre- and postintervention knowledge and concern scores in both study arms. For knowledge in Figure 3A, the estimated slope was 0.76 (95% CI 0.48-1.04) for HPVVaxFacts intervention arm and 0.98 (95% CI 0.78-1.18) for the nutrition attention control arm, with no evidence that the association differed by study arm ($P_{interaction}$=.21). For concern in Figure 3B, the estimated slope was 0.70 (95% CI 0.52-0.89) for HPVVaxFacts intervention arm and 0.91 (95% CI 0.69-1.12) for the nutrition attention control arm, with no evidence of a differential association between study arms ($P_{interaction}$=.16; Figure 3). In summary, although participants in the HPVVaxFacts intervention arm showed lower postintervention knowledge and concern scores than those in the Nutrition attention control arm, consistent with greater knowledge and fewer concerns based on the scoring of these measures, the differences between the study arms were not significant.

Parental Top HPV Vaccination Concerns: PreSurvey and HPVVaxFacts Data Log

Only the HPVVaxFacts mobile web app allowed parents to take the quiz and confirm or change their top concerns produced via an existing algorithm. Parents in the HPVVaxFacts intervention arm were asked to identify and select their top 3 beliefs or concerns for HPV vaccination on the web app. We determined the frequency with which a concern was selected as a top 3 concern for parents. Based on the web app data, the majority of parents identified the vaccine could cause serious health problems (20/27, 74%), too many vaccines (17/27, 63%), and questioned HPV vaccine safety (12/27, 44%). Refer to Table 5 for a summary of the top 3 concerns selected for the HPVVaxFacts intervention arm participants.

Table . Top 3 selected concerns for HPVVaxFacts intervention arm participants.

Concern	WebApp (HPVVaxFacts[a] program), n (%)
Too many vaccines could cause harm to child	17 (63)
Natural Immunity against HPV[a] is better	7 (26)
HPV vaccine could cause serious health problems	20 (74)
Wonder if HPV vaccine is effective in preventing genital warts and cancer	8 (30)
Wonder if the HPV vaccine is safe	12 (44)
Wonder if child needs HPV vaccine to prevent cancer	6 (22)
Wonder if my child needs the HPV vaccine to prevent genital warts	1 (4)
I wonder if my child should wait until older	6 (22)
Worry that getting vaccine might make my child think it is okay to have sex	3 (11)

Feasibility: Study Procedures Implementation Into Clinic Workflow

Data Collection and Data Availability

At Clinic Site 1, quantitative data were collected between June and September 2023. At Clinic Site 2, data collection occurred 1 week in August 2023 for back-to-school immunization week.

The data needed for study evaluation were available with less than 5% missing data from the survey, EHR for child's age and vaccine status, and HPVVaxFacts data log tracking of parent concerns and selected top 3 HPV vaccine concerns. In total, 94% of parents completed the pre-post survey. One year post study, vaccination rates were manually pulled again by a clinic staff member to identify that 3 children in the active control group were already vaccinated when the parent enrolled in the study; these children had no record of HPV vaccination upon study enrollment, which reflects interoperability across EHRs. While these parents were excluded, it demonstrated they were interested in learning more about HPV vaccination.

Conceptual and Psychometric Adequacy of Measures

Psychometric measures for concerns, knowledge, and intervention acceptability were considered reliable. Cronbach α was 0.80 and higher, which is considered exceptionally good for internal consistency reliability. See measures in Methods for psychometric results.

Parental Acceptance of HPVVaxFacts

Parents who received the HPVVaxFacts (n=27) had consistently prominent levels of acceptability for the program across all the items. Over two-thirds agreed or strongly agreed that they liked the program (mean 4.1, SD 0.7), the program met their approval (mean 4.2, SD 0.8), and it was appealing (mean 4.2, SD 0.8), and they perceived that parents should use the tool for HPV vaccine education (mean 4.2, SD 0.7). Additionally, parents perceived that HPVVaxFacts was helpful and should be used to discuss the HPV vaccine with their child (mean 4.1, SD 0.7; Table 6).

Table . Intervention acceptability by parents (n=27).

Item	Mean (SD)
Meets approval	4.2 (0.8)
Appealing	4.2 (0.8)
Like program	4.1 (0.7)
Favor of tool being used by parents	4.2 (0.7)
Helpful to discuss HPV[a] vaccine with child	4.1 (0.7)

[a]HPV: human papillomavirus.

Qualitative

A total of 19 parents completed the interviews, 9 from the HPVVaxFacts intervention arm and 10 from the nutrition attention control arm. In the HPVVaxFacts intervention arm, the mean age of the parent was 38.9 (SD 5) years. All participants were female (9/9, 100%) and non-Hispanic White (9/9, 100%). For the nutrition attention control arm, all were female (10/10, 100%), with the majority being non-Hispanic White (7/10, 70%) and almost half had an education level of GED or High School Diploma (4/10, 40%; Table S1 on parent sociodemographics in Multimedia Appendix 2).

Themes

Overview

Based on participant responses, we identified 4 themes related to the study protocol. We identified one theme related to intervention acceptability using participants' responses in the HPVVaxFacts intervention arm only. Each theme is briefly described below.

Theme 1: Study Protocol Acceptability and Recommendations for Improvement

Acceptability

Parents across both study arms perceived the study protocol as acceptable and manageable. They commented on how the clinic staff were welcoming and provided clear study enrollment information. Mobile-based delivery of each study step—consent, enrollment, presurvey, view of nutrition or education program, postsurvey—was intuitive for participants, especially those in the nutrition education arm. One nutrition program parent stated,

> *So, with that said, it [steps of study protocol] was fairly easy to navigate, to read through, and to get it completed, and to gain that information in a short amount of time, um, despite what I was doing.*

However, receiving multiple texts for each study step posed a challenge, particularly for those in the HPVVaxFacts intervention arm. A few parents noted how clinic staff availability was helpful when questions arose. A parent in the HPVVaxFacts intervention arm stated,

> *The only hiccup I remember having was like, I feel like, to get from point A to point Z in the process, like it required the coordinator coming in and helping me get to where I needed to go.*

Finally, parents appreciated receiving education prior to their clinic visit, which allowed them to engage with study materials without the time constraints of an in-clinic visit appointment.

Parents in the HPVVaxFacts intervention arm did not use all the mobile web app features. Three stated they did not use the videos, citing personal preference. Four did not access the kid's corner, perceiving their child would not understand, was too

XSL•FO
RenderX

young, or lacked time to view or discuss with the child. A parent in the HPVVaxFacts intervention arm stated,

> *Maybe when they got a little bit older, I would, but my son would, it would go right over his head. Um, but, uh, my daughter, now that she's like 13, I hopefully would share it with her.*

Parents in the nutrition attention control arm found the nutrition webpage easy to navigate and comprehensible. One parent highlighted the survey was simple, and the webpage provided immediate feedback with explanations for both correct and incorrect answers.

Recommendations

To optimize the study protocol, parents from both study arms identified the need to improve logistics, particularly reducing the number of text messages containing links for each step. Regarding content delivery timing, parents across study arms acknowledged their busy schedule noted the night before or day of (at home or in clinic before the visit) is an ideal time to review materials. A parent in the HPVVaxFacts intervention arm stated:

> *I think the day before would be good just because then they have the information to make an informed decision at the actual doctor's visit.*

However, one HPVVaxFacts parent offered a different perspective, noting an optimal window of 2 weeks before the clinic visits to get more informed about the HPV vaccine. She stated,

> *I would say no more than two weeks before. That's kind of what we have found to be the sweet spot when we give deadlines for something because if you give them too much time, they're gonna forget about it because they're like, Oh, I've got plenty of time. And then if you don't give them enough time, I mean, you know, everybody's busy and it's like, well, I've got two days and I plan I can't get this done in two days.*

Other suggestions related to expanding the study protocol to address all vaccines and identify alternative content delivery mechanisms. A parent in the nutrition attention control arm stated the study protocol should address all vaccines.

> *My honest opinion would be that every vaccine needs to be treated this way, because a lot of emphasis is given into this one vaccine…If parents are given more information, I mean if a parent wants to educate themselves and they take the initiative, they educate themselves on all the vaccines.*

Another parent in the nutrition attention control arm highlighted,

> *I think maybe having the option of either you can get it beforehand on the phone or maybe you have it there for the provider to give to a parent to look over… I think that way you just kind of open it up to, you kind of cater to everyone that way because not everybody's tech savvy and wants it on their phone. Some people do still like to have a piece of paper to hold and look at.*

Theme 2: Acceptability of and Recommendations to Improve HPVVaxFacts

Acceptability

Parents who participated in the HPVVaxFacts intervention arm perceived the program as user-friendly, and the layout was easy to navigate. One parent stated,

> *I mean, I thought the whole thing was easy to use. I mean, I texted back our primary care. They got us set up with the links and everything was very easy.*

One even appreciated that the program asked targeted questions to narrow parental concerns and delivered tailored content. Parents found the content comprehensible and accessible, particularly on the mobile phone.

> *I thought it was good information. I liked that it was easily accessible and pretty quick to read through and understand.*

Another parent noted,

I think everything was pretty, pretty easy to understand and follow.

However, program completion was unclear for 2 parents. One parent stated,

> *A little unclear, like, I even messaged him and I was like, I think I finished everything, but I'm not sure that I did. And they were like, we think you did too, but we're not sure either.*

Recommendations

Parents suggested improving the web app and adding parent testimonials to demonstrate how others made vaccination decisions. One parent stated,

> *I think it's always good, especially for people who are, who have reservations to see. Stories of others who say, Hey, you know, I was really on the fence about this because I thought this, but, you know, I got this information and it may be understand that that wasn't the case because of whatever.*

Parents also requested more detailed information on "extreme" side effects and misinformation. One parent preferred links to research articles over the videos that discussed each concern.

Two parents highlighted the need for the app to be multilingual for greater reach. Parents wanted a reminder via text or email from providers to use the mobile web app to help prepare questions in advance. A few parents suggested increasing mobile web app availability for use by health care agencies, schools, and provider-led public service announcements (PSAs) to extend reach to parents. A parent stated,

> *I mean, my initial reaction is things like schools, but I know you have to be so careful with what kind of stuff you put out in schools nowadays.*

Another parent recommended,

> *If it became if it was, like, adopted by the state, the health department would be a really good channel,*

XSL•FO
RenderX

> *like, maybe the website through the health department.*

Two parents recommended that this program should be applied across all vaccines for parents to understand the benefits of vaccination. Specifically, the parent stated,

> *I think that if they had it for more vaccines that people would have a better understanding as to what it is that they are subjecting their child to by having the vaccinations, the benefits.*

Theme 3: Perceived Benefits of HPVVaxFacts

Parents described 4 benefits from participating in the HPVVaxFacts intervention arm. We summarize these benefits below.

Confirmed or Improved Knowledge for Decision-Making

Parents commonly reported that HPVVaxFacts improved or reaffirmed their knowledge of HPV and the vaccine, regardless of their baseline knowledge level. One parent stated,

> *It reaffirmed kind of what I already knew, and it did give me additional information that I might not necessarily have had or even have thought to ask the doctor about.*

Another parent described,

> *I thought it was very informative. A lot of the stuff I already knew, but I could see how, especially with new parents or parents who aren't as hypervigilant, could benefit from having that information if they didn't already know it.*

Some parents felt better equipped to make an informed decision after reviewing the program. A parent stated,

> *I feel like the information was clear and straightforward, and I think it was presented in a way to help parents more understand the vaccine and make an informed decision.*

Preclinic Information Improves Appointment Efficiency

All parents valued receiving HPV vaccination information preclinic visit and found it feasible. The majority of parents had adequate time to review the information and form a decision. A parent stated,

> *I liked having it ahead of time because then by the time I got in there, I had all the information that I needed in order to make the decision on whether or not we were going to do it.*

Several parents noted that information prior to the clinic visit allowed appointments to be more efficient with fewer questions. One parent emphasized,

> *I think that with the program, it gave me all the information that was needed to be able to just make the appointment smoother and just be able to like go in there and have our doctor's appointment and not have to worry so much about any of the questions. Because I felt like it was there for me to be able to know all the things before, I got there.*

Other parents noted HPVVaxFacts helped facilitate the discussion with the child's provider. A parent stated,

> *Honestly, it makes the appointment go faster. I mean, I know that the doctors are busy, so it's good to just have before so you just know what, what exactly it is before you, you know, you end up doing it if you do decide to do it or whatever.*

However, 2 parents wreported no provider recommendation or discussion on the HPV vaccination during the clinic visit, making previsit information particularly helpful in their decision-making.

Trust in Provider-Delivered Information

All parents appreciated that the program was delivered by their child's provider, who was deemed a trusted information source. A parent stated,

> *Yeah, I think it [HPVVaxFacts] was provided by his pediatrician. That's probably the best thing about it. In my opinion.*

Parents acknowledged widespread misinformation on vaccines and identified how this app could address those concerns. One parent stated,

> *Yeah, I definitely trust information provided through his pediatrician more so than just something you find online because I feel like it's easy to find supporting information for your bias ideas online. I can find something from the pediatrician. I'm going to trust that further than whatever I research on the Internet.*

Furthermore, they valued the credibility of provider-sourced information. One parent lauded,

> *There is way too much out there, and you don't know what you can trust and what you can't trust. Um, so definitely coming from a clinic and a trusted place is very comforting.*

Facilitates Parent-Child Discussion on HPV Vaccine

One parent used the kid corner to guide discussion with her child, while another found the information "lay" enough to discuss the HPV vaccine with her child. A parent shared,

> *I remember, thinking that it had good information for me to be able to explain it to my children in a way that they would understand better.*

Parents valued the program to facilitate parent-child conversations on vaccines such as HPV, with some preferring to use their older children who could benefit from these open discussions. A parent stated,

> *I think for older children, especially and where they are having conversations that are more open with their children about vaccines.*

Theme 4: Perceived Barriers to HPVVaxFacts Use

Most parents reported no barriers to using the program. A parent stated,

> *"I don't think so. I don't recall having anything that was, that I would consider a barrier."*

XSL•FO
RenderX

Three parents highlighted potential barriers that were not program-specific. One barrier was that some parents may lack access to the mobile web app. Another barrier older or not technologically "savvy" parents may have difficulty with web app navigation. A parent stated,

> *That [navigating a technology] would be a little bit more difficult, like later 50s, because I know I'm I had my daughter when I was 22, but I know a lot of parents aren't having them until like they're in their, you know, early to late 30s.*

Finally, one parent noted that some parents may not trust their health care provider and the research team or the information provided. It was further recommended to use alternative distribution channels (eg, media, social media, PSA) to reach these individuals.

Clinic Staff Consultation: Provider Feedback

Overall, providers perceived the program as beneficial for their clinic. Particularly, the top benefit was offering preclinic education visits to their patients. This complemented their recommendations and lessened clinic time for education. Another perceived benefit was the increased vaccination rates in the clinic because of the intervention. Regarding barriers, providers and clinic staff highlighted the need to improve logistics for large-scale implementation. Because the intervention was manual and required efforts from clinic staff and the research team to aid in recruitment and retention, providers questioned the feasibility of recruitment and retention procedures but still perceived offering preclinic information in general as feasible. However, providers and staff stated they understood this was a pilot study and hoped their suggestions improved future implementation.

Discussion

Principal Findings

Our study assessed feasibility, acceptability, and preliminary efficacy of the theory-informed, mobile web app HPVVaxFacts designed to decrease concerns and increase knowledge, intentions, and uptake of the vaccine among children aged 9 to 17 years. This study is one of the first to use a multimethod evaluation to assess mHealth interventions to increase HPV vaccination. More importantly, HPVVaxFacts is one of the first mobile web apps to identify and tailor information to parental concerns while supporting autonomy in both parental decision-making and educating their child using an optional kid's corner on the web app.

Feasibility

Our study reported feasibility across multiple metrics. The enrollment rate was 84%, and the random allocation achieved 100% recruitment. The retention rates in both study arms were 75% in the HPV program and 94% in the nutrition program. Notably, approximately 4 out of 5 (81%) parents in the intervention arm viewed HPVVaxFacts. These rates are considered good, especially with the sensitive context surrounding HPV vaccination and typical survey response rates. The engagement of clinic staff and parents in the development of the study protocol, a known factor in improving study outcomes (eg, logistics and behavior) [51], partly attributes to this success.

Additionally, the Cronbach α for concerns, knowledge, and intervention acceptability scales were considered reliable, further supporting study feasibility and potential deployment of these scales in a larger study. However, because one clinic had vaccination rates substantially increase prior to study implementation, this underscores the importance of conducting a feasibility assessment at multiple checkpoints before and during study implementation. Furthermore, both providers and participants highlighted the logistical barrier of study steps being manual, a factor which may have affected response rates at different steps in the research process. This supports the need to automate these steps for future efficacy trials to improve recruitment and retention.

Interestingly, parents identified factors that could influence use of HPVVaxFacts long-term in research and in clinical practice. For protocol application, improving the study logistics was commonly mentioned by both parents and providers, though not reflective of app functionality. This suggests that the tool alone could be applied in real-world settings with minimal human involvement, a major advantage for sustainability. Similar to past studies [52], parents identified limited access to technology (eg, mobile web app) as a potential barrier reflecting the "digital divide" in America [53]. Some parents, particularly older parents or non–English-speaking parents, may struggle to navigate the mobile web app, which has been identified as a barrier previously [54]. Some parents may mistrust a provider who delivered resources because of broader mistrust in health care. This demonstrates how mistrust can extend beyond the individual to tangibles perceived to be associated with the individual [55]. These findings suggest that feasibility of HPVVaxFacts can be improved using multilingual languages and addressing the digital divide (eg, physical infrastructure expansion, training, and tech support). Also, alternative strategies for providing health care information should be considered, including multiple dissemination channels and provider-led initiatives to build support and trust.

Acceptability

Acceptability was considered good with a rate of 74% or higher with room for improvement. Of interest, acceptability of HPVVaxFacts centered around the ability of the app to tailor to the parents' needs. Particularly, parents were able to access the app when available (previsit information), identify their top vaccine concerns, and view the modality that best served their need to get their concerns addressed. This suggests the importance of a multilevel, tailored approach that is cost-effective to target parent decision-making processes for vaccination, creating a unique opportunity for this tool to have broad reach. Other acceptable components of the mobile web app, though deemed unsurprising, were its comprehensible content, ability to navigate, and being time-friendly for use. Previsit information has been supported by past studies [26], but its use in the context of a mobile app has been underexplored. Parents lauded it for reasons such as lessened time in clinic or improved preparation for the visit, an acceptable

XSL•FO
RenderX

strategy we add to the literature. Our findings also support that increased acceptability of mobile web apps for parent-child discussion could be achieved via provision of parental autonomy to share select information or allow parents to use information to guide a discussion with the child without direct access. This should be further explored as mHealth continues to evolve to expand the reach of health information for caregivers and/or their children.

Not only did parents view HPVVaxFacts to improve feasibility through content being multilingual, but it was also viewed to increase acceptability. Particularly, the suggestion to expand this app content to different languages and its use in alternative settings that provide vaccination to increase acceptability reflects the altruism of these parents. Walker et al [56] found that parents with higher interpersonal altruism had higher odds of agreeing with HPV-specific state vaccine requirements, a confirmation of our qualitative findings. These findings suggest the need for inclusivity when developing strategies and tools that promote HPV vaccination among children. Exploring the app's use in alternative immunization settings supports the HPV National Roundtables' goal to increase HPV vaccination in these settings.

Preliminary Efficacy

Similar to other mHealth studies [26], HPVVaxFacts increased HPV vaccine initiation rates among children at significantly higher rates compared to the nutrition program. Interestingly, this increase occurred despite no significant differences in knowledge, concerns, or intentions between the study arms. Because knowledge and attitudes had a positive trajectory through the increase in effect size in the intervention arm compared to the control arm, this could reflect the pilot study being underpowered for these secondary outcomes. This is a common outcome, as many pilot studies are powered for testing feasibility and not proving an intervention's efficacy [57]. Also, it remains unclear whether, and to what extent, this effect was mediated through provider engagement or indirect engagement via app delivery through the EHR. Nevertheless, our qualitative findings support that parental willingness to get vaccinated was due to receipt of the information from the provider. Because parents' most trusted information source [55,58] is providers and their recommendation is critical for uptake [59], future studies should explore in-depth whether and how provider communication modalities can be leveraged to complement provider recommendations and communication in-clinic with a goal to increase HPV vaccination compliance. Finally, these findings could also reflect a ceiling effect in which a significant portion of participants in both the HPV and nutrition programs already had positive intentions to vaccinate [60]. Future studies could either recruit parents who are "not likely" or "somewhat likely" only or use baseline status to stratify analysis, both strategies to better capture intervention effects [61]. Finally, it was not surprising that the top 3 concerns identified by these parents centered around vaccine safety, the leading barrier to vaccine hesitancy and suboptimal rates [62].

Limitations

First, this study was conducted in 2 pediatric urban clinics in Tennessee in which the primary clinic for recruitment was predominantly female and non-Hispanic White. Collectively, this may limit generalizability to other populations, including those living in different geographical regions and settings along with racial and ethnic groups. Second, selection bias may have occurred if some parents with low mobile app literacy or who did not have a mobile app did not participate, which should be explored in future studies. However, we have begun to take steps to improve inclusion through the provision of HPVVaxFacts in Spanish. Third, this study had a small sample size, which limited our ability to detect a difference for some of the study outcomes (eg, concerns and intention) and whether those outcomes are a result of clinic demographics and protocol. Also, the small number of parents recruited at Clinic Site 2 made it impossible to assess whether clinic-level differences influenced results. Fourth, there were updates on the app during the feasibility study; however, study implementation metrics, including recruitment and retention, improved over time. Fifth, because parents agreed to be in the study and the invite mentioned HPV vaccination, parents may be more engaged or interested in receiving information. This should be explored in a larger study.

Sixth, some parents were lost due to their child already being vaccinated during study participation and study logistics, in which we could not recruit additional participants due to the study duration ending at both clinics. However, this reflects EHR interoperability, a commonly cited issue confirmed by clinic staff [63]. Seventh, we only studied the impact of HPVVaxFacts on initiation rates. The impact on completion rates (ie, 2 doses of HPV vaccine among children younger than 15 years old and 3 doses among those older than 15 years old) [64] will be explored in a future study, as we are exploring reasons for noncompliance and informational needs of parents to inform the update of messaging on the mobile web app to be more comprehensive. Eighth, for the interviews, there may be potential for recall bias, which increases due to the variable time between parent participation and the interview due to demanding study logistics. Ninth, some mobile web app components (ie, average session length) could not be tracked due to financial constraints. However, it is currently being updated to address this limitation. Tenth, small discrepancy between the HPVVaxFacts website content and knowledge scale could have led to a lack of significant improvement in knowledge. We were also unable to track participants' engagement within the website that may have varied from full review to partial or no interaction with the content. It is possible that the nutrition education within the attention control arm could have influenced parents to accept and/or obtain the first dose of the HPV vaccination for their child. Finally, the nutrition attention control arm did not select their top concerns as this was not an option on the app. Therefore, we are unable to compare parental top concerns by study arm.

Conclusion

Our pilot study suggests HPVVaxFacts is feasible and acceptable to provide tailored information to parents' preclinic visits to aid parent decision-making for HPV vaccination and ultimately increase uptake. This study's outcomes, both unclear yet offer a positive trajectory, lay the foundation for a full RCT to test the efficacy of HPVVaxFacts being offered preclinic visit to increase HPV vaccine initiation and completion rates.

XSL•FO
RenderX

Future studies can explore the mediating (eg, provider recommendation and communication) and moderating factors for successful intervention effects with a large sample size. Findings also reinforce that provider modalities such as mHealth are acceptable and can complement provider communication to address parental HPV vaccine concerns.

Acknowledgments

The authors would like to thank the participating clinics who offered their insights on how to enhance the study protocol and their participation in the study recruitment and retention. We also thank the parents who took part in the study, from either informing the study protocol or being a participant in the study. Collectively, this study's success can be attributed to these individuals. The authors would also like to thank 233 Analytics, experts who provide complex technical litigation and corporations, who developed and maintained the intervention. AI was not used to generate manuscript content.

Funding

This work was supported by the National Cancer Institute of the National Institutes of Health (NIH; award Number: K01CA237748-01), and the National Center for Advancing Translational Sciences (NCATS) Clinical Translational Science Award (CTSA; award number: 5UL1TR0002243). The funding sponsors had no role in the design and conduct of the study, collection, management, analysis, or interpretation of the data; preparation, review, or approval of the manuscript or decision to submit the manuscript for publication. Abstract

Background: Despite the human papillomavirus (HPV) vaccine being available to males for the past 12 years, adolescent males continue to lag in HPV vaccine uptake due to a variety of factors. With the ubiquitous nature of social media use among this population, further research is needed to improve HPV vaccine confidence among young adolescent males using these platforms.

Objective: Using the Elaboration Likelihood Model (ELM), this study sought to better understand knowledge, attitudes, and beliefs about HPV and HPV vaccination among male adolescents aged 14-17 years and examine how social media messaging influences vaccine perceptions and explore the characteristics of persuasion and trustworthiness of digital content narratives across age and vaccination status.

Methods: The study team recruited 18 adolescent males to participate in a series of online focus groups and interviews stratified by age (14-15 years and 16-17 years) and HPV vaccination status. The study team worked with our in-house national probability survey panel, AmeriSpeak Teen Panel, to recruit for the discussion groups and interviews. All discussions were recorded, transcribed, and coded using NVivo 14 (Lumivero). ELM was used to develop discussion guides, codebook, and analysis. Emergent themes were identified, and the full team participated in double-coding and analysis. Data were analyzed using rigorous thematic analysis to identify patterns across groups.

Results: Knowledge of HPV varied by age and vaccination status. Older, vaccinated adolescents were more likely to understand that HPV affects both genders and is sexually transmitted, whereas younger, unvaccinated adolescents often had little to no prior awareness. Parents—especially mothers—were the primary decision-makers for vaccinated adolescents, with older adolescents more likely to be engaged in that decision. Trust in social media health messages was low overall, with participants relying on perceived source credibility over content format or style. Trusted sources included parents, physicians, and well-known health organizations. Younger adolescents were more influenced by personal anecdotes, whereas older adolescents preferred statistics, facts, and reliable sources.

Conclusions: Our findings highlight the importance of tailoring HPV vaccine messaging by age and developmental stage. Trusted messengers, clear factual content, and platform appropriateness are critical for engaging adolescent males. ELM provides a useful lens for interpreting these findings: younger adolescents were more influenced by peripheral cues, personal stories, or visual appeal, whereas older adolescents engaged in more central processing, evaluating the credibility of the source and the factual content of the message. This underscores the need to match message strategies with adolescents' cognitive and motivational readiness. Future interventions should consider dual strategies targeting both youth and parents, especially for younger adolescents. As the digital landscape continues to evolve, further research should also examine how generative artificial intelligence (AI) may serve as a trusted source or tool for communicating accurate, engaging health information to adolescent audiences.

Introduction

Human Papillomavirus Vaccine Uptake Among Adolescents and Slow Adoption of HPV Vaccination Among US Adolescent Males

Human papillomavirus (HPV) remains the most common sexually transmitted infection in the United States despite vaccine availability to prevent many of the infection's strains in both young women and men [1]. Recent data from the CDC (Centers for Disease Control and Prevention) indicate that HPV vaccine uptake among US adolescents remains suboptimal, with notable gender disparities. In 2023, approximately 72% of adolescents aged 13-17 years initiated the HPV vaccine series, but only 49% completed it [2]. Although the CDC recommends routine vaccination at ages 11-12 years, initiation and completion rates remain consistently higher among females than males. For instance, from 2011 to 2020, the vaccination rate among males increased from 8% to 36%, whereas among females, it rose from 38% to 49% [3]. Studies suggest factors contributing to higher uptake among females include greater health awareness, proactive health care engagement, and stronger recommendations from health care providers [4]. These findings underscore the need for better understanding of the facilitators and barriers to vaccination to ensure equitable access to HPV prevention measures for adolescent males.

While efforts to vaccinate adolescent females for HPV have made strides in reducing HPV infections among this group, HPV vaccination delay, hesitation, and rejection continue to be prevalent among adolescent males [5]. Research suggests that if vaccination levels among adolescent males aged 14-17 years continue to dwindle, rates of HPV-related diseases will rise, continuing to widen vaccination disparities among this population [6]. Numerous interventions to promote HPV vaccination uptake among females exist [7-9], as well as interventions for parents and providers to promote HPV vaccination among younger males [10,11]; however, additional catch-up opportunities are needed for adolescent males aged 14-17 years. Various factors may contribute to the low uptake of HPV vaccination among adolescent males. For example, some health care providers have expressed reluctance to recommend the vaccine to males, citing perceived low risk and concerns about cost-effectiveness [12]. Parents may also be less aware of the vaccine's benefits for males due to an overall lack of communication about the HPV virus, therefore perceiving HPV-related diseases as less of a concern for their sons [13]. Furthermore, misconceptions that the vaccine promotes promiscuity and general vaccine hesitancy contribute to lower uptake [13].

Adolescents' HPV Vaccine Confidence and Health-Related Decision-Making Capabilities

Adolescents aged 14-17 years are developing greater autonomy and self-efficacy, which shape not only their health-related decision-making but also how they engage with health information on social media. Research shows that better knowledge of vaccine-preventable diseases such as HPV, higher confidence in vaccines, and active involvement in the decision-making process may explain a positive relationship with adolescents' vaccine uptake [14]. Similarly, adolescent maturity and self-efficacy play a role in HPV vaccination decision-making and overall vaccine confidence [15]. Theoretical models of health behavior suggest a role for self-efficacy (one's belief in one's ability to perform a certain behavior) in explaining why individuals do or do not engage in health behaviors, and these models have been applied in the context of HPV vaccination [16]. Social media platforms support self-efficacy by allowing adolescents to seek information independently, observe peer norms, and form attitudes outside of parental or clinical settings [17]. Recognizing that this age group prefers to be involved in decision-making, additional information is needed to understand what factors influence communication and messaging about health-related decision-making and vaccine confidence.

Effective communication strategies, particularly those initiated by health care providers, have been shown to increase vaccine uptake. However, given adolescents' high engagement with digital platforms, social media now plays a critical role in shaping health beliefs and behaviors. Platforms like TikTok, Instagram, and YouTube serve as both information sources and social influence networks. Through these platforms, digital storytelling has emerged as a promising approach; studies have shown the importance of tailored, evidence-based messaging in promoting HPV vaccination among adolescent males and how the evolving digital landscape can help engage this vulnerable age group [18]. This study will add critical information to understanding adolescent males' motivation and confidence in vaccination decision-making and the role social media plays in vaccine decision-making.

Social Media Messaging and Influence on US Adolescent Males

Social media plays a pivotal role in shaping adolescent males' health decisions, including HPV vaccination knowledge, attitudes, and beliefs. Male adolescents often seek health information on platforms like Instagram, TikTok, and YouTube, where content is frequently shared by peers, influencers, or health care professionals [19]. Studies have shown that social media channels can act as positive conduits of message delivery for adolescents if messages are considered interesting, their privacy is protected, and the source is credible [20].

The credibility of these messages is influenced by factors such as the perceived trustworthiness of the source, message framing, and platform-specific features. A systematic review identified 3 key domains affecting adolescents' trust in health information on social media: trust in the platform, trust in other users, and trust in the content itself [21]. Adolescents tend to trust content that aligns with their social identity, is presented in an engaging manner, and comes from sources they perceive as authentic or relatable [21]. For example, messages delivered by peers or influencers with whom adolescents identify may be more

XSL•FO
RenderX

persuasive than those from traditional health authorities. However, other studies suggest that messages developed and delivered by health care organizations or professionals provide reliable and factual information, providing higher believability and trustworthiness of a social media post [22,23].

The rapid evolution of platforms and the constant influx of new content can create an environment in which adolescents are continuously exposed to health-related messages. Studies have shown that exposure to vaccine misinformation on social media is associated with increased vaccine hesitancy, particularly when individuals rely solely on social media for health information without consulting trusted sources such as health care providers [24]. Additionally, the persuasive power of social media is heightened when messages are tailored to resonate with the audience's values and concerns. For instance, content that emphasizes peer experiences or addresses specific concerns about HPV vaccination may be more effective in influencing adolescent males' attitudes and behaviors. Therefore, understanding the factors that contribute to trust and engagement on social media is crucial for developing effective health communication strategies aimed at increasing HPV vaccination confidence among adolescent males. Research has yet to show how message characteristics and believability of social media messages targeting adolescent males impact vaccine confidence.

Theoretical Framework

This study used a qualitative descriptive design grounded in the Elaboration Likelihood Model (ELM), which is well suited for examining how adolescents perceive, interpret, and make meaning of health-related messaging in real-world contexts and social media. ELM posits that when an individual encounters various forms of communication, they process the communication with varying levels of elaboration ranging from low to high [25]. There are multiple factors that contribute to the elaboration of the messaging, requiring the individual to take 2 different routes, peripheral or central. Engaging in lower elaboration, or the peripheral route, results in the individual having lesser ability to process the message and having little or no interest in the subject. By contrast, engaging in higher elaboration, or the central route, results in higher motivation and ability to think about the message and its topic and to react.

More recently, ELM has been adopted to understand attitudes toward COVID-19 vaccination and intention to obtain the vaccine [26]. One study applied ELM to explore the characteristics of COVID-19 vaccine messages that may appeal to Twitter users, with findings suggesting that content-related messaging played a role in shaping decisions regarding whether to retweet antivaccine messages [27]. ELM has also been previously used to understand HPV vaccine messaging on social media to examine intentions and decision-making among parents. One study found that the central route, represented by information quality, affected parents' perceptions of HPV severity and susceptibility; the peripheral route, represented by source credibility, influenced their perceptions of HPV severity, HPV susceptibility, and vaccine response efficacy [28]. Another study with young girls found that recommended HPV vaccine messages should include focusing on cancer prevention rather than sexual transmission, routinization of the vaccine, and highlighting risks and costs of getting HPV [29]. Lastly, one study found that among college students, the use of hybrid messages containing both statistical and narrative descriptions of HPV resulted in greater perceived risk of getting HPV than either message type alone [30]. However, there has yet to be a study assessing believability of messaging impacting adolescent males aged 14-17 years in their decision-making to obtain HPV vaccines.

Study Design and Aims

This is an observational study that used qualitative methods to explore the knowledge, attitudes, and beliefs, along with the believability, persuasion, and influence of social media messaging on adolescent males' HPV vaccine confidence among those aged 14-17 years. Using the ELM framework [31,32], a dual-process communication and psychological framework, as our foundation, we examined how adolescent males process social media messaging (exploring the characteristics and persuasion of various narratives) and how such messages influence believability and adolescent males' confidence in HPV vaccine uptake.

The purpose of this study was to better understand the characteristics of social media narratives and their impact on adolescent males' perceptions about and confidence in receiving the HPV vaccine among those aged 14-17 years. ELM guided our protocol development and analysis, focusing on what this group believes and ways they are persuaded, based on social media influence. The study had two aims: (1) to understand knowledge, attitudes, and beliefs about HPV vaccination among male adolescents aged 14-17 years; and (2) to explore the characteristics and persuasive nature of social media (Facebook, TikTok, Twitch, YouTube, etc) narratives to which adolescent males are exposed and whether messaging plays an active role in impacting vaccine confidence among adolescent males.

Methods

Study Overview

A qualitative descriptive approach was selected to capture participants' perspectives in their own words and to generate findings with direct relevance for public health communication practice. The original study design included conducting 4 online focus groups with adolescent males aged 14-17 years to address the 2 key objectives. Using AmeriSpeak (Nation Opinion Research Center [NORC]'s the nationally representative probability panel of more than 30,000 US households) and AmeriSpeak Teen Panel (NORC's nationally representative sample of US adolescents aged 13-17 years), a group of male adolescents were recruited into the study [33]. The groups were stratified by age and HPV vaccination status: vaccinated males aged 14-15 years, unvaccinated males aged 16-17 years, vaccinated males aged 16-17 years, and unvaccinated males aged 14-15 years. However, due to recruitment challenges with participants aged 14-15 years, the study design was adapted to include a combination of focus groups and individual interviews. This revised approach maintained stratification by age and vaccination status and ultimately improved recruitment outcomes, particularly for the younger age group, through successful scheduling of individual interviews.

XSL•FO
RenderX

Study Eligibility and Recruitment

To be eligible for this study, parents must have (1) had a male child or male children aged 14-17 years and (2) not expressed strong antivaccine views to the following three questions: (1) "Overall, how hesitant about childhood shots would you consider yourself to be?"; (2) "To what extent do you agree with the following statement: I believe my son should be vaccinated against HPV?"; and (3) "Have you ever spoken with your son about the HPV vaccine?" Additional parental demographics were also collected, which were not part of the eligibility criteria.

Eligibility for adolescent males included (1) being aged 14-17 years and (2) HPV vaccination status ("Yes, I have received both HPV shots and I am fully vaccinated," "Yes, I have received one HPV shot but I have not received my second dose yet," "Yes, but I'm not sure if I received both doses," and "No"). Additional items such as demographics and social media usage were also captured, not part of eligibility criteria. Recruitment and data collection spanned from October 2024 to January 2025.

The panel invited 464 parents, and 326 consented for their adolescent to be offered the study opportunity. Among the 326 male adolescents aged 14-17 years invited to the recruitment screener survey, 111 adolescents were eligible and assented to be contacted for scheduling into a focus group or interview. To ensure homogeneity within each focus group or interview, we stratified participants based on the adolescents' age and vaccination status.

Study Procedures

The research team was composed of investigators with training and experience in public health, health communication, qualitative research methods, and vaccine confidence research. Several team members have prior experience designing and evaluating adolescent-focused health communication interventions, which informed the development of the discussion guide and the selection of social media stimulus materials.

The research team developed the focus group discussion guide using ELM to ask questions about knowledge, attitudes, and beliefs around HPV vaccination and to assess the believability of social media messaging on adolescent males' decision-making and vaccine confidence through message testing. We examined how adolescent males process social media messaging (exploring the characteristics and persuasion of various narratives) and how such messages influence believability and adolescent males' confidence in HPV vaccine uptake. The discussion guide (Multimedia Appendix 1) was constructed with specific topics (Textbox 1).

Textbox 1. Discussion group section topics.

Section topic
• Knowledge of the human papillomavirus (HPV) and HPV vaccine
• Attitudes and beliefs toward HPV vaccination
• Barriers and motivators to HPV vaccine uptake
• Social media platform use
• Trust/distrust in messages/sources on social media
• Believability of vaccine messages on social media

We also visually presented 4 social media posts on HPV vaccination for discussion. The research team created a social media HPV vaccine media scan protocol to gather a sample of media on HPV vaccination to which adolescent boys may be exposed or that they may actively seek online. Queries were created based on platforms (eg, TikTok, Reddit, X [formerly known as Twitter], Twitch, Facebook, Instagram), time period (eg, past year), content, narrative format, and messenger. TalkWalker [34] and CrowdTangle [35] (before it was obsolete) were used to pull and analyze media posts. Posts were analyzed and discussed as a team for inclusion based on the factors within the query. A matrix was created based on the query terms, and the research team discussed which posts were available and relevant to the study. We compared posts selected from both individuals and organizations, platforms, and messages, including facts compared with narratives (Multimedia Appendix 2). One member of the study team moderated the discussion, while another member was the notetaker. Each focus group lasted approximately 1 hour, whereas interviews lasted approximately 30 minutes.

Analysis

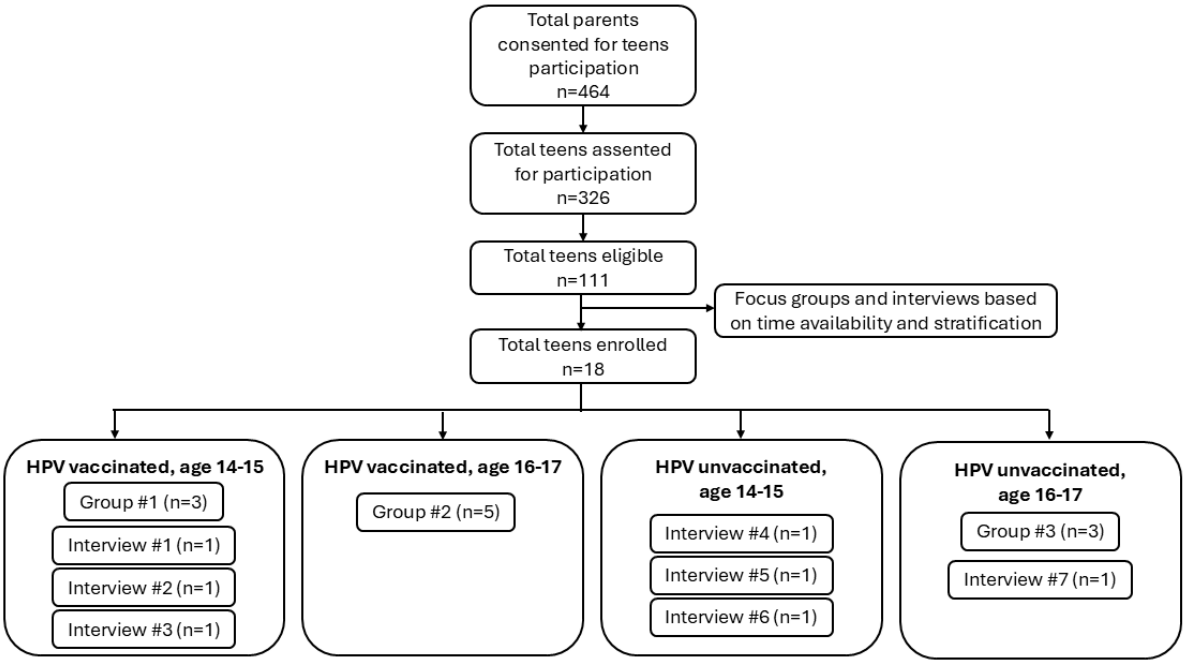
Multiple strategies were used to ensure the trustworthiness and rigor of the qualitative findings. Credibility was enhanced through the use of verbatim transcripts, double coding of a subset of interviews and focus groups, and regular analytic debriefings among the research team to discuss emerging themes and resolve discrepancies. Upon completion of the discussion groups and interviews, the transcripts were reviewed, updated by inserting moderator questions for clarity, and deidentified. A codebook was developed using a mix of a priori codes based on the discussion guide along with themes that emerged from each discussion group and interview that were relevant to the research questions [36]. Two independent coders from the research team double-coded 4 transcripts (based on the stratification of the groups by vaccination status and age) using NVivo 14 (Lumivero) [37] to conduct qualitative analysis. Following the first round of coding, discrepancies were discussed and addressed, and the codebook was updated where needed. Data saturation was assessed iteratively during analysis, with no new themes emerging across later focus groups and interviews, suggesting that thematic sufficiency was achieved.

XSL•FO
RenderX

In addition to double coding by the research team, regular team debriefings, and the use of a structured codebook helped ensure analytic consistency and credibility of findings. Interrater reliability [38] was calculated in MAXQDA using the Cohen κ metric. Using the 4 transcripts, double coding yielded an interrater reliability of 0.74. Codes were then applied to the remainder of the transcripts. Once coding was complete, we structured the presentation of results by themes.

Ethical Considerations

This study was reviewed and approved by the NORC at the University of Chicago Institutional Review Board (IRB; protocol number 24-07-1895). NORC operates its own IRB, which is registered with the US Department of Health and Human Services Office for Human Research Protections. For projects that are federally funded, the research protocol and accompanying documents have been approved under the expedited review procedure in accordance with HHS Regulations at 45 CFR 46.110 expedited review categories, by the NORC IRB (IRB00000967), under its Federalwide Assurance Number FWA00000142 (FWA 00000142). NORC's IRB follows a formal process for reviewing all research projects to assure human participants' protections and minimize respondent burden.



Due to the sensitive nature of the study topic, parents of eligible adolescents provided consent for their adolescent to participate. Both the parent consent language and the adolescent recruitment screener and assent were offered only in English and were self-administered online by the respondent. Consent and assent materials were provided in English and were self-administered online via the AmeriSpeak and AmeriSpeak Teen Panel. No waivers of consent or assent were requested or granted. All discussions were audio-recorded and transcribed. Transcripts were deidentified before analysis (eg, removal of names and other direct identifiers), with moderator questions inserted for clarity without introducing identifying information. Access to deidentified data was restricted to the research team, and results are reported in aggregate to further reduce reidentification risk. Participants received AmeriPoints in the amount of US $50 for participating in the focus group discussion and US $20 for an interview.

Results

Study Flow and Participant Distribution

Figure 1 provides the study flow and final distribution of participants across data collection methods.

Figure 1. Study flow diagram and recruitment.

Sample Characteristics

A total of 18 male adolescents aged 14-17 years participated in either a focus group discussion or an interview.

Table 1 presents the overall characteristics of the adolescent male participants. A total of 9 males were aged between 14-15 years, while 9 males were aged 16-17 years old. Participants were primarily White, non-Hispanic (n=10), and varied in terms of state of residence. The majority (n=11) reported receiving the HPV vaccination, whether 1 dose or both. YouTube (n=15) and Instagram (n=13) were the most used social media platforms.

Thematic Analysis

Findings from this study map clearly onto the core constructs of ELM, which posits that individuals process persuasive information along either the central or peripheral route depending on their motivation and ability to engage with the message. During analysis, transcripts were coded using ELM. ELM codes included central route processing (ability to process, motivation to process, emotional cues, personal relevance, motivation to process, and message quality) and peripheral route processing (familiarity or visual cues, heuristic processing, and source credibility). Social media post text vs source reliability were analyzed to determine how different message features influenced adolescents' engagement and vaccine-related attitudes. This approach allowed us to explicitly link participants' reactions to theoretically defined ELM pathways and assess how message characteristics may differentially shape HPV vaccine decision-making.

Table 2 presents results from the thematic analysis and is organized by knowledge, attitudes, and beliefs about HPV and HPV vaccine, barriers and motivators to HPV vaccine uptake, social media use, and trust and believability of vaccine messages on social media. Sample quotes are provided to support findings, based on ELM, and are identified by age and vaccination status of the focus group participant or interviewee (Table 2).

XSL•FO
RenderX

Table 2. Thematic analysis of focus group and interview data.

Theme and subtheme (if applicable)	Related ELM[a] construct	Illustrative quote
Knowledge, attitudes, and beliefs about HPV[b] and HPV vaccine	• Ability to process • Motivation to process	• I knew boys should get the vaccine from school, so my mom took me to get it, and my aunt had cervical cancer so knew it was something that affects men and women. [FG participant, 16yo, vaccinated]
Barriers and motivators to HPV vaccine uptake	• Emotional cues • Personal relevance	• I'm just cautious of what I put in my body, like any medication. I'm always concerned with side effects. My parents are cautious too. What are the fertility implications? [FG participant, 16yo, unvaccinated]
Social media use	• Motivation to process • Central route processing • Message quality	• I don't really use [social media] for anything research related, I only really use it for talking to my friends or communication because I would rather take some more time using Google or some other website rather than looking on a social media app, because misinformation on there spreads like wildfire and I don't want to be misinformed about something that I'm trying to learn. So I don't really use it much for things that are political or medical. [FG, 15yo, vaccinated]
Social media use for health information	• Motivation and ability to process • Central route processing	• We are interested to learn about the risks and the contents of it and eligibility. [FG participant, 17yo, vaccinated] • I would like to see more of the health concerns. And maybe the risk, because they usually have that really quick. So people don't hear about it very much. People need to talk about how you can get it. [FG, 14yo, vaccinated] • I'd like it to tell the risks about if you got the vaccine and if you didn't, like the pros and cons to each. And what is HPV, and more about the risks of that. [IDI, 14yo, unvaccinated]
Trust and believability of vaccine messages on social media	• Peripheral route processing (familiarity/visual cues), • Heuristic processing • Source credibility	• It looks relatively believable because it shows a picture of Robert F. Kennedy Jr. The 5thlawsuit he has filed against Merck, challenging the company's dangerous and defective HPV vaccine for causing severe and life-changing injuries. Now, obviously, in the second picture you can see that he is not in good health. Like he might be smiling there but he does not look happy. Yeah, I'm pretty sure it's real, but since there is a picture of when he was young and a picture of when he is older sometimes those pictures can be not always right, could be a different person, but I'm pretty sure this is real. [FG, 15yo, vaccinated] • Some of these social media messages are old, this one [RFK] is even older, a lot of things can change in a vaccine, modern medicine advances.I don't know if it's true, anyone can get hospitalized – that's a lot of likes but don't know if that matters that much. [IDI, 14yo, vaccinated] • Since Elon bought it [Twitter], it's filled with misinformation- blue check marks are bot accounts to farm likes for cash, account doesn't seem like genuine, would be paid bot account. [FG, 17yo, vaccinated] • The TikTok video is less believable because anyone can dance with scrubs on. I have no idea if she's a real doctor. [IDI, 14yo, vaccinated]

[a]ELM: Elaboration Likelihood Model.

[a]HPV: Human papillomavirus.

Knowledge, Attitudes, and Beliefs About HPV and HPV Vaccine

Adolescents' knowledge, attitudes, and beliefs about HPV and the vaccine varied notably by age and vaccination status. All vaccinated adolescents aged 16-17 years (n=5) demonstrated the most comprehensive understanding, often recognizing that HPV affects both males and females and that the vaccine is recommended for all adolescents regardless of gender. In contrast, two-thirds of unvaccinated adolescents aged 14-15 years (2/3) held the misconception that the HPV vaccine is only for girls, and several reported hearing about it for the first time during the study.

All vaccinated adolescents aged 14-15 years (n=6) were aware that they had received the vaccine but lacked clarity about what HPV is, how it is transmitted, and what symptoms it causes. They described vaccination as something that happened during a routine physician visit, without detailed explanation. Approximately 80% of the vaccinated and unvaccinated adolescents aged 16-17 years (7/9) generally knew that HPV is a sexually transmitted infection and could name potential consequences of infection, including warts and cancer. These older participants had also heard about methods of prevention beyond vaccination, such as using protection during sex. Overall, knowledge was limited among younger adolescents, particularly those who were unvaccinated, whereas older participants—regardless of vaccination status—were more

XSL•FO
RenderX

informed and engaged in thinking critically about HPV and its risks.

Barriers and Motivators to HPV Vaccine Uptake

Among all vaccinated adolescent males, parental influence—notably that of their mothers—was a consistent motivator for HPV vaccine uptake. A total of 80% (4/5) of the vaccinated adolescents aged 16-17 years described shared decision-making with their parents before receiving the vaccine, during which they discussed the benefits of the vaccine, asked questions, and ultimately agreed to get vaccinated. Some recalled learning about HPV from their parents or pediatricians, reinforcing their confidence in the decision. In contrast, 80% (5/6) of vaccinated adolescents aged 14-15 years did not have conversations with their parents or physicians before receiving the vaccine. Despite limited involvement in the decision-making process, most expressed trust in their parents' choices regarding their health.

Unvaccinated adolescents identified several barriers to vaccination. Across age groups, concerns about adverse effects and parental skepticism were prominent. All unvaccinated adolescents aged 14-15 years (n=3) believed that vaccination was not necessary because they were not engaging in sexual activity through which HPV could be contracted, reflecting a perception that the vaccine is only needed once someone becomes sexually active. Many felt that "if you're safe, you will be fine." All unvaccinated adolescents aged 16-17 years (n=4) were more cautious about vaccine uptake because of adverse effects commonly associated with vaccine, which was often influenced by parental concerns. Despite hesitancy, many unvaccinated adolescents from both age groups expressed interest in learning more and emphasized that they would want to conduct their own research before deciding whether to be vaccinated.

Social Media Use

Overview

Across vaccination status and age groups, adolescent males noted that they were on social media daily, primarily for entertainment and to chat with friends. Instagram was reported as the most popular platform for everyday social media use. TikTok, YouTube, and X (formerly known as Twitter) were also noted as platforms used across age groups. Among older adolescents aged 16-17 years, platforms such as Snapchat and Discord were especially prevalent and were often used for direct messaging, gaming-related conversations, and school-related group chats. Reddit was more commonly mentioned by younger adolescents aged 14-15 years, who used it to follow specific interests and read anonymous discussions. While social media was part of everyday life, few participants reported using it intentionally for health information.

Social Media Use for Health Information

Across vaccination status and age group, adolescent males indicated that they do not seek health information on social media because of concerns regarding the reliability of information circulating online. When asked what types of information they would want HPV social media content to address, many noted that they would like to understand the risks of contracting HPV, how the vaccine would mitigate those risks, and where to obtain the vaccine. Similarly, many adolescents noted that they wanted to understand the risks associated with vaccination and how vaccination might affect their future health if they were to receive the vaccine (eg, fertility issues in the future).

Trust and Believability of Vaccine Messages on Social Media

Across all age groups and vaccination statuses, adolescent males noted that social media is not their first source for accurate, reliable health information. Most participants said they would not trust HPV vaccine content on social media, with some saying they would trust it if the content was from a trustworthy source. A total of 67% (12/18) of participants said they would do more research to understand which social media posts are accurate and trustworthy and would seek multiple sources for health information given the spread of misinformation on social media.

When asked about trusted sources, older male adolescents noted that they would turn to their parents or personal physician for reliable and accurate information about HPV. Approximately 60% (3/5) of vaccinated older adolescents also said they trust health information from organizations such as the World Health Organization, Mayo Clinic, or another major hospital. About 40% (2/5) of older adolescents also said they would trust content that their peers, classmates, friends, or family members shared on social media.

When shown the 4 social media narratives, adolescent males, regardless of age, noted that the Maryland Department of Health post was trustworthy because it provided facts and was from a reliable source. There were mixed results, leaning to not trustworthy, about the InfoWars post because the source cited its own article, and many adolescents did not know the source. All adolescents noted that the TikTok narrative was not believable because messaging with singing and dancing was deemed unserious. A little over 80% (15/18) of participants noted that the narrative from Robert F Kennedy Jr would warrant a conversation with their physician or parent about the adverse effects of the HPV vaccine. However, two-thirds of unvaccinated adolescents aged 14-15 years (n=3), believed that narrative because they knew Robert F Kennedy Jr and had heard about risks associated with vaccination.

Participants found that the persuasiveness of a message was influenced by 3 key factors: content format, the substance of the message, and the source's credibility. Most participants found the dancing doctor video on TikTok to be "unprofessional," saying that it does not convey the seriousness of the issue and the content did not seem reliable as presented. On the other hand, the images from the Robert F Kennedy Jr post made it compelling through emotional appeal. Unvaccinated adolescents aged 14-15 years were more likely to believe social media messaging that included personal anecdotes, whereas the adolescents aged 16-17 years were more persuaded by statistics and facts.

Older adolescents also emphasized the importance of examining the account that posted the content. Source credibility emerged

XSL•FO
RenderX

as a salient factor for adolescents aged 16-17 years, highlighting that respondents were more likely to evaluate the reliability and validity of health information based on the authority, expertise, and affiliations of the poster. For example, the Maryland Department of Health post was widely considered credible because of its factual tone and clear institutional affiliation. The majority of respondents had heard of the Maryland Department of Health and found that this source would be credible for health information. In contrast, the InfoWars post was largely dismissed, with participants citing unfamiliarity with the source and concerns about its legitimacy.

Some participants said that the platform on which the narrative was posted impacted believability, suggesting that Instagram and Facebook are more trustworthy than TikTok and X. Participants also noted that other post characteristics, such as the date of the post and engagement metrics (eg, likes and reposts), impacted believability.

Discussion

Overview

This study underscores the significant role of social media in shaping adolescent males' knowledge and attitudes toward HPV vaccination. Consistent with the study aims, we found that adolescent males' engagement with HPV vaccine messaging on social media varies by age and vaccination status. Notably, unvaccinated and younger adolescent males exhibited lower awareness of HPV and the vaccine, rendering them more susceptible to misinformation prevalent on social media platforms. This aligns with findings from a systematic review indicating that adolescents often distrust online health information but continue to use it, using various heuristics to assess credibility, such as the source's perceived trustworthiness and the content's presentation [39]. The preference for information from familiar or relatable sources, including personal physicians and mothers, highlights the need for targeted health communication strategies that resonate with this demographic.

Furthermore, our research revealed that the believability of social media messages was predominantly influenced by the source rather than the content or format of the post. Older adolescent males demonstrated a higher propensity to trust messages from credible sources, such as health care providers and reputable organizations, and were more likely to engage with authoritative websites such as the CDC and Mayo Clinic for health information. Conversely, younger, unvaccinated males were more inclined to believe anecdotal messages featuring personal stories, which can be compelling but may not always present accurate or comprehensive information. This finding is consistent with studies showing that adolescents' trust in health information on social media is complex and influenced by factors such as platform trustworthiness, user identity, and content credibility [21]. Additionally, while parents and personal physicians were universally trusted sources of information for all adolescent males, social media posts featuring unrecognizable physicians were found to be unpersuasive, underscoring the importance of source credibility in health communication. These insights contribute to the growing body of research on the influence of social media on health-related decision-making and highlight the necessity for public health interventions to navigate the evolving digital landscape effectively.

Alignment With ELM

Our findings align with ELM, which posits that individuals process persuasive messages through either the central or peripheral route depending on motivation and ability to engage with the content. Older adolescent males aged 16-17 years, especially those vaccinated, appeared to engage more often through the central route, processing information thoughtfully, evaluating arguments, and preferring content from trusted, authoritative sources. Their critical evaluation of message credibility, preference for fact-based content, and desire to consult external sources (such as physicians or reputable websites) are all hallmarks of central-route processing.

In contrast, younger adolescents were more likely to engage through the peripheral route, relying on emotional cues, personal anecdotes, and familiarity rather than systematic analysis. They tended to be more receptive to personal narratives from public figures or peers, relying on heuristic processing. These distinctions underscore the importance of tailoring message design not only by age but also by presumed level of cognitive engagement, which ELM helps conceptualize effectively. This theoretical grounding offers a valuable lens for public health practitioners aiming to design persuasive health messages based on audience readiness, message processing style, source credibility, and story-telling content.

Strengths and Limitations

This study has many strengths. First the research team's ability to engage directly with adolescent males through a nationally representative probability panel was a major strength. This group is often a difficult-to-reach population in health communication research; however, we were able to explore their nuanced perspectives on vaccine messaging and social media use through innovative recruitment efforts. Second, the use of a nationally representative, probability-based recruitment panel enhances the generalizability of findings to US adolescent males by capturing perspectives across diverse geographic regions and vaccination statuses rather than relying on convenience samples. Lastly, by using real-world examples of social media narratives, we captured insights grounded in participants' lived experiences, increasing the validity of our findings.

However, this study is not without limitations. First, despite using a nationally representative panel for recruitment, the final participant pool was relatively homogenous in terms of race/ethnicity and socioeconomic background, which may limit generalizability. Our sample was predominantly White and non-Hispanic. This homogeneity in our adolescent sample may have resulted in greater trust in clinicians and well-known public health agencies than would be observed among individuals with differing racial/ethnic and socioeconomic backgrounds. Similarly, participants described low reliance on social media for health decisions and a preference for "official" sources, noting that their information-seeking behaviors may not be the norm. Evidence suggests that Black, Hispanic/Latine, immigrant,

XSL•FO
RenderX

and economically disadvantaged communities can experience higher medical mistrust toward government, pharmaceutical companies, and, at times health care systems, rooted in historical and ongoing inequities; such mistrust is associated with lower HPV vaccine uptake and different messenger preferences (eg, family networks, faith leaders, and community-based organizations).

Second, while the original study design emphasized focus groups to encourage peer discussion, recruitment challenges, particularly among adolescents aged 14-15 years, necessitated a pivot to individual interviews. As a result, we were not able to fully explore group dynamics or peer influence, which may have provided additional regarding social norms and vaccine attitudes. It is important to note that this transition may have limited the ability to capture peer-to-peer influences that are particularly salient during adolescence. Group discussions may have revealed additional insights into how social norms, shared beliefs, and peer reinforcement shape perceptions of vaccine-related content. While individual interviews allowed for a safe space to discuss this sensitive topic and were effective in eliciting personal reasoning and decision-making processes, the absence of group interaction may have obscured how peer discussions and perceived norms influence older adolescents' confidence in, or resistance to, vaccine messaging.

Lastly, although the study leveraged the AmeriSpeak parent–teen panel to reduce recruitment bias, reliance on parental consent may still introduce some degree of selection bias. Parents and adolescents were consented into the AmeriSpeak panel before learning about individual study topics, which helps mitigate overrepresentation of parents with particularly strong provaccine views. Additionally, both parents and adolescents completed vaccine-related screener items that allowed us to capture a range of vaccine attitudes.

Future research should explore alternative strategies to better engage younger adolescents, including school-based recruitment partnerships, collaboration with pediatric practices, and integration of research activities into youth-centered digital environments such as moderated online communities or gamified platforms. In addition, incorporating parent-adolescent dyadic designs may also enhance participation while capturing the shared decision-making dynamics that are central to HPV vaccination at this age.

Implications for Future Communication Efforts

The distinct differences in how younger and older adolescent males engage with and interpret vaccine messaging on social media suggest that a one-size-fits-all approach would be ineffective. Instead, interventions should be tailored by age group, vaccination status, and other key factors such as health information seeking behaviors and use of digital tools (social media, generative artificial intelligence [AI], etc). For younger adolescents, messaging should likely target both the adolescent and their parents, given the significant influence of parental decision-making in this age group and the limited health literacy among adolescents aged 14-15 years. Messaging for this audience should use emotionally engaging content that includes personal stories and encouragement for younger adolescents to have conversations with their parents and physicians when engaging with social media health information posts that need further context. A testable hypothesis for future research while using the principles of ELM, could examine whether, among younger adolescents with lower baseline knowledge, brief narrative posts paired with visible peripheral cues of credibility (eg, verified badges and institutional logos) would increase perceived relevance and discussion with parents more than statistics-heavy posts.

Messaging for older adolescents should be grounded in facts and delivered by highly credible sources, such as pediatricians or well-known public health agencies. Delivery platforms that are familiar and accessible to both youth and parents, such as Instagram and Facebook, may be more effective than TikTok or X. For older adolescents, who are increasingly autonomous in their health decisions, messaging should include more fact-based content with direct appeals to logic, data, and the consequences and risks of not vaccinating. This audience showed a higher likelihood of engaging in their own research with reputable websites or posts from verified sources, indicating a preference for content that satisfies a need for accurate, actionable information. A testable hypothesis for future research, while using the principles of ELM, could examine whether older adolescents with higher motivation who receive fact-forward messages from identifiable health care professionals would demonstrate higher message credibility and intent to vaccinate compared with entertainment-style narratives without evidence-based content. These findings suggest future HPV vaccine campaigns should develop parallel message strategies for different developmental stages: one focusing on emotional resonance and parental influence for younger adolescents and the other emphasizing autonomy, scientific rationale, and source credibility for older adolescents.

Conclusion

Summary of Key Findings

This study sought to explore how adolescent males engage with and interpret HPV vaccine-related messaging on social media, with a focus on differences by age and vaccination status. Findings indicate that younger and unvaccinated adolescents demonstrate lower HPV awareness and greater susceptibility to misinformation, whereas older adolescents are more likely to engage critically with health information and seek content from credible, authoritative sources. Social media plays a central yet complex role in shaping perceptions, with message credibility often hinging on the source rather than the content or format. Trust in personal physicians and parents remains strong, and different age groups exhibit distinct preferences for how and from whom they receive health information.

Public Health Implications and Practical Applications

These findings have important implications for both HPV vaccination efforts and the broader field of adolescent health communication. Public health practitioners should consider age-segmented strategies tailored to developmental stages and align message framing, emotional tone, and source credibility with adolescents' decision-making autonomy when designing campaigns. For younger adolescents, practical applications include developing social media content that encourages

XSL•FO
RenderX

parent-adolescent conversations and uses emotionally resonant narratives while clearly directing families to trusted health care providers for follow-up information. For older adolescents, campaigns may be more effective when they emphasize factual content, transparent risk-benefit information, and messages delivered by identifiable, reputable health professionals or organizations.

Health care providers and public health agencies can also apply these findings by strategically integrating social media into vaccine counseling, using trusted platforms to reinforce in-clinic conversations rather than replace them. Training clinicians and public health practitioners to recognize how youth interpret social media narratives may enhance their ability to address misinformation and tailor recommendations during clinical encounters. Additionally, vaccine campaigns should prioritize platforms familiar to both adolescents and parents to maximize reach and credibility.

Future Research Considerations

As the digital ecosystem continues to evolve rapidly, it is also important to explore emerging technologies, such as generative AI, as potential tools for delivering reliable, factual vaccine content to youth. Understanding how adolescent males interact with AI-generated information, alongside traditional social media, will be critical for designing future interventions that keep pace with their digital footprint. Studies incorporating parent-adolescent dyads, peer-based interactions, and more diverse populations are also needed to better understand shared decision-making processes and social influences on HPV vaccine uptake. Longitudinal designs may further clarify how adolescents' message processing and trust in digital health information change over time.

Abstract

Background: Screening for clinical trials is challenging for clinicians due to its time-consuming and repetitive nature. The rise of artificial intelligence (AI) offers an opportunity to improve screening productivity and reproducibility. Pancreatic cancer is characterized by increasing incidence, poor survival outcomes, and an urgent need for improved management strategies.

Objective: This study aimed to assess the performance of AI in evaluating clinical trial inclusion and exclusion criteria, compared to a double-blind human gold standard, using a retrospective cohort.

Methods: In the PANCR-AI (Pancreatic Cancer Retrospective Screening with Artificial Intelligence) pilot study, we retrospectively reviewed cases from our institutional database of patients with advanced pancreatic cancer presented at tumor board meetings between January 2018 and December 2023. Each patient was screened for clinical trials open for inclusion at the time of the multidisciplinary meeting. Manual screening of eligibility criteria for each patient-trial pair was performed by 2 blinded oncologists to determine potential eligibility (gold standard), with a third oncologist resolving discrepancies. Potential eligibility was also assessed using 3 large language models (ie, GPT-4.5, Claude 3.7 Sonnet, and Mistral-7B-Instruct v0.3). Their performance was compared to the human gold standard using standard evaluation metrics (eg, sensitivity, specificity, precision, recall, and F_1-score). Correlations between the risk of failure and the number of words and characters in the criteria were analyzed. The time required to complete the screening was recorded for both human and AI assessments. The number of trials open for enrollment at the time of the tumor board meeting was also recorded as a variable for analysis.

Results: Across 341 patient-trial pairs, the AI models demonstrated high sensitivity, ranging from 83.3% to 92.2%. Analysis of the criteria showed a correlation between the risk of failure and the number of words and the number of characters in the criteria. Overall screening time for manual assessment was significantly longer for the human gold standard (44.70 hours) assessment than for AI (2.53-3.15 hours). Patients were more likely to have been included in a clinical trial if the number of trials open for enrollment was higher at the time of the tumor board meeting (P=.02).

Conclusions: Our study highlights the promising performance of AI in clinical trial screening. Future work should explore integration with structured clinical data, such as laboratory values or radiological findings, to improve multimodal comprehension. Expanding the evaluation to a broader range of tumor types and multicenter datasets would improve generalizability. Finally, real-time prospective validation and workflow integration with electronic health records will be critical to assess the feasibility and clinical impact of large language model–assisted screening in daily oncology practice. Addressing these challenges will be essential to move from proof of concept to scalable clinical implementation.

Introduction

Pancreatic cancer is a leading cause of cancer-related mortality, and its incidence continues to rise [1]. In advanced and metastatic cancer, therapeutic options are often limited, with poor results for overall survival in comparison with other malignancies [2,3]. There is a critical need to gather knowledge about the different subtypes of the disease and to adopt new approaches to improve patient outcomes. Clinical trials are the preferred option to ensure access to innovation. Screening patients for clinical trials is a complex and time-consuming procedure. Screening electronic patient records requires reviewing all inclusion and exclusion criteria for each potential clinical trial for which a patient might be eligible. This effort becomes obsolete as soon as new elements are added to the patient medical record. This assessment at a given moment does not predict short- or medium-term clinical evolution, particularly in the case of patients with locally advanced and metastatic pancreatic adenocarcinomas. The multidisciplinary tumor board meeting is held at a critical moment in the therapeutic decision-making process and represents an opportunity to suggest the inclusion of a patient in a clinical trial before treatment begins.

Promising artificial intelligence (AI) tools, such as assistant agents, are increasingly being incorporated into hospital information systems, and their applications now cover a wide range of needs expressed by health care professionals [4]. The emergence of generative AI could help physicians to screen patients by performing automated, real-time analysis of their electronic medical records to determine whether the inclusion and exclusion criteria for a clinical trial are met. This real-time screening would increase the chances of offering the patient a relevant clinical trial.

Screening for clinical trials at the time of the pretherapeutic tumor board meetings is of major interest for the prognosis of pancreatic malignancies. Current efforts in this area are hampered by a lack of human resources. Among the possible factors leading to the failure of clinical trials, the small number of patients included is one of the main causes of trial discontinuation [5]. Only an estimated 2% to 4% of all patients with cancer participate in clinical trials. Although multiple factors explain this low enrollment rate, a significant benefit has been observed with the employment of dedicated medical resources to screen patients, leading to an increase in enrollment. However, this possibility is limited by the availability of human resources [6]. Manual review of patient records for clinical trial eligibility represents a significant burden on research teams and medical oncologists. The manual extraction of this information is time consuming, labor-intensive, expensive, and error prone.

The information contained in electronic medical records is heterogeneous and complex. Extracting meaningful information from medical records presents significant challenges owing to the unstructured nature of these data, which limits their immediate applicability for clinical research [7]. As with other malignancies, information about patients with pancreatic cancer is primarily available in free-text form, which requires sophisticated processing. Rule-based extraction techniques are limited by their rigidity and the need for postprocessing. Machine learning and deep learning techniques show promise for recognizing word relationships; however, they require postprocessing for complex data and do not understand implicit or semantic information [8].

To address these limitations and challenges, we propose the use of a strategy for medical text mining with the help of large language models (LLMs) to convert text into structured computerized data using informatic extraction technologies. LLMs are high-performance technologies for classifying, filtering, and clustering information, enabling the direct extraction of information without additional postprocessing. These technologies can extract textual data from medical records and reorganize them for use in oncology research [9,10]. These technologies could also improve access to clinical trials in secondary centers or pediatric settings, with the expectation of improving health care democracy [11].

In PANCR-AI (Pancreatic Cancer Retrospective Screening with Artificial Intelligence) study, we assessed the performance of 3 different LLMs (GPT-4.5, OpenAI; Claude 3.7 Sonnet, Anthropic; and Mistral-7b-Instruct v0.3, Mistral) for clinical trial screening using a retrospective cohort of patients with metastatic or locally advanced pancreatic cancer [12-14].

Methods

Study Context and Population

The Institut de Cancérologie de Lorraine Comprehensive Cancer Center prospectively maintains a database of pancreatic malignancies. This database was queried to identify patients with newly diagnosed locally advanced, unresectable, or metastatic pancreatic adenocarcinoma. All patients with a pretherapeutic tumor board meeting report available in their electronic medical records between January 2018 and December 2023 were included in the study. Patients with other subtypes of pancreatic malignancies, such as intraductal papillary mucinous neoplasms or neuroendocrine tumors, were excluded. Each patient had a pretherapeutic tumor board meeting report summarizing their clinical and pathological status. For each patient, “candidate trials” were defined as all clinical trials open for enrollment in advanced or metastatic pancreatic cancer at the time of the tumor board meeting. Each possible match between a patient and a candidate trial constituted a patient-trial pairing, representing one evaluation of eligibility according to the trial’s inclusion and exclusion criteria. Clinical and pathological variables were extracted from the database and analyzed, including demographic characteristics, tumor pathology features, treatments received, and follow-up information. The study was registered with the French Health Data Hub on February 3, 2025 (22286214).

Study Design and Data Source

This retrospective single-center analysis was based on pretherapeutic tumor board meeting reports, which provided a structured summary of each patient’s clinical condition and characteristics as documented in their medical records. These reports served as a common database for both oncologists and LLMs.

XSL•FO
RenderX

The inclusion and exclusion criteria were extracted from the sponsor's trial protocol and reformatted into standardized textual items for analysis. Criteria related to biological samples, life expectancy, contraceptive use, or ethical consent were removed from the screening process due to the absence of corresponding data in the pretherapeutic tumor board meeting reports. The remaining criteria were independently reviewed and categorized according to their type (eg, clinical, pathological, or demographic) and analyzed for their textual characteristics, including word and character counts. The number of inclusion criteria ranged from 1 to 7, and the number of exclusion criteria ranged from 2 to 19. The characteristics of the 12 clinical trials are summarized in Table 1. Each criterion was evaluated for its number of characters, nature, and category of variables.

Table . Characteristics of the 12 candidate clinical trials open for recruitment (January 2018 to December 2023) and associated patient-trial pairs (N=341).

[a]N/A: not applicable.

The inclusion and exclusion criteria for each candidate trial were evaluated on a criterion-by-criterion basis using information extracted from the pretherapeutic tumor board meeting reports. For each patient-trial pairing, fulfillment of every inclusion and exclusion criterion was assessed independently by the human gold standard and by each LLM. When the available clinical information in the reports was insufficient to assess a given criterion, or when it was not possible to reach a conclusion due to insufficiently consistent or contradictory information based on the tumor board meeting report, that criterion was considered to be met if it was an inclusion criterion and to be unmet if it was an exclusion criterion. This conservative assumption ensured that such patients were classified as eligible, reflecting a sensitivity-oriented approach consistent with the intended practical use of LLM-derived outputs. At the patient-trial level, the individual criterion assessments were then aggregated to determine the overall eligibility decision for each pairing.

Performance Evaluation of LLMs

Three LLMs (ie, GPT-4.5, Claude 3.7 Sonnet, and Mistral-7B-Instruct v0.3) were evaluated for their ability to assess patient eligibility for each inclusion and exclusion criterion of all candidate trials based on the information contained in the pretherapeutic tumor board meeting reports. LLMs were queried through the online interfaces and respective application programming interfaces of OpenAI, Anthropic, and Mistral. The LLMs' unique prompt design was developed according to European Medicines Agency guidelines and contextual prompt engineering methodology (role assignment, step-by-step reasoning, and constrained outputs) to ensure the reproducibility of the output for the same input. The input prompt is available in Multimedia Appendix 1 [15,16]. All

XSL•FO
RenderX

LLMs were given the same instructions and data to be analyzed as the medical oncologists (for the human gold standard). Results are displayed in a dedicated radar plot. The screening time for each LLM was determined between the time each tumor board meeting was submitted and the time of completion of the output for each trial-patient assessment, measured using digital tools.

Gold Standard Assessment

AC, AS, AM, LD, and CL are medical oncologists who participated in establishing the gold standard and volunteered to collect the data. Participation was proposed to a panel of physicians who were not involved in the care of the patients whose records were analyzed in this study to minimize potential bias in their assessments. The information provided for analysis included the inclusion and exclusion criteria for clinical trials and the deidentified tumor board meeting reports. The data were collected in a deidentified database stored on a secure internal server at the Comprehensive Cancer Center. All reports were reviewed by 2 medical oncologists to ensure reproducibility of the human assessment. Each oncologist was blinded to the evaluation of the other. In case of disagreement, a third medical oncologist independently reviewed the case to reach a consensus. Interrater reliability was assessed using Cohen κ coefficient. The screening time was reported by each medical oncologist for the determination of the gold standard and measured using digital tools. This duration was compiled and allocated to each corresponding candidate trial.

Statistical Analysis

Data analyses were performed using SAS (version 9.4; SAS Institute Inc). $P<.05$ was considered statistically significant. Given the exploratory nature of the study, no adjustment for multiple testing was applied.

Quantitative data are reported as median values unless otherwise specified. Comparisons between 2 groups were performed using the Mann-Whitney test, and comparisons among more than 2 groups were performed using the Kruskal-Wallis test. Categorical variables were compared using the chi-square test. Survival was estimated using the Kaplan-Meier method, and survival curves were compared with the log-rank test.

For each inclusion and exclusion criterion, and subsequently at the patient-trial level, the LLM outputs were compared with the human gold standard. The results were classified as true positives when both methods identified eligibility; true negatives when both identified noneligibility; false positives when the LLM indicated eligibility, whereas the human gold standard did not; and false negatives when the LLM indicated noneligibility, whereas the human gold standard indicated eligibility. Cases in which the LLM and the human reviewers provided divergent results were considered as discordant.

LLM performance was evaluated using standard metrics (eg, recall, sensitivity, specificity, precision, and F_1-score) to assess their ability to determine patient eligibility both at the level of individual inclusion criteria and across all clinical trials screened; sensitivity and specificity were computed with 95% CIs. Pairwise comparisons of LLM sensitivities (or specificities) were performed using McNemar test among cases identified as eligible (or ineligible) by the human gold standard.

Statistical analyses were conducted at the criterion level to assess factors associated with LLM-human discordance. Variables with $P<0.1$ in bivariate analyses were included in the multivariate logistic regression model.

Ethical Considerations

The PANCR-AI study was conducted at the Institut de Cancérologie de Lorraine (Vandœuvre-lès-Nancy, France). It complies with the French reference methodology MR-004 of the French Data Protection Authority (Commission Nationale de l'Informatique et des Libertés) for research involving human data. According to the MR-004 regulatory framework, ethics committee approval and individual informed consent were not required, as the study involved retrospective analyses of deidentified clinical data and had no impact on patient care or management. For trial involvement, patients were evaluated using the standard manual screening process at the Institut Cancérologie de Lorraine. The reports were deidentified by retaining only age and gender, modifying dates to preserve the temporal relationship with the tumor board meeting, and implementing measures to ensure patient anonymity. The physicians who volunteered to collect the data were medical oncologists practicing at a comprehensive cancer center, and thus consent was implied.

Results

Study Population

Among the 141 patients initially identified from the Institut de Cancérologie de Lorraine Comprehensive Cancer Center database, 85 (60%) patients with locally advanced or metastatic pancreatic adenocarcinoma were included in this analysis; 46 (32.6%) patients were excluded due to unavailable pretherapeutic data in the tumor board meeting report, and 10 (7%) patients were excluded from the analysis based on histological type (all neuroendocrine tumors). The flowchart of eligibility is available in Multimedia Appendix 2. Overall, 30 (35.2%) patients of this cohort were historically included in a clinical trial. The median age was 68 (IQR 32 - 89) years, and 49% (42/85) of patients were male. At the time of the tumor board meeting, 66 (78%) patients presented with metastatic disease, while 19 (22%) patients had locally advanced unresectable tumors. Patients were more likely to have been included in a clinical trial if the number of trials open for enrollment was higher at the time of the tumor board meeting ($P=.02$). Overall survival did not differ according to patients' participation in clinical trials ($P=.34$). No significant association was observed between clinical trial inclusion and age ($P=.09$) or personal history of previous malignancy ($P=.25$). The baseline characteristics of the study population are summarized in Table 2.

Table . Characteristics of patients from the cohort of locally advanced and metastatic pancreatic cancer, according to inclusion or noninclusion in a clinical trial (N=341).

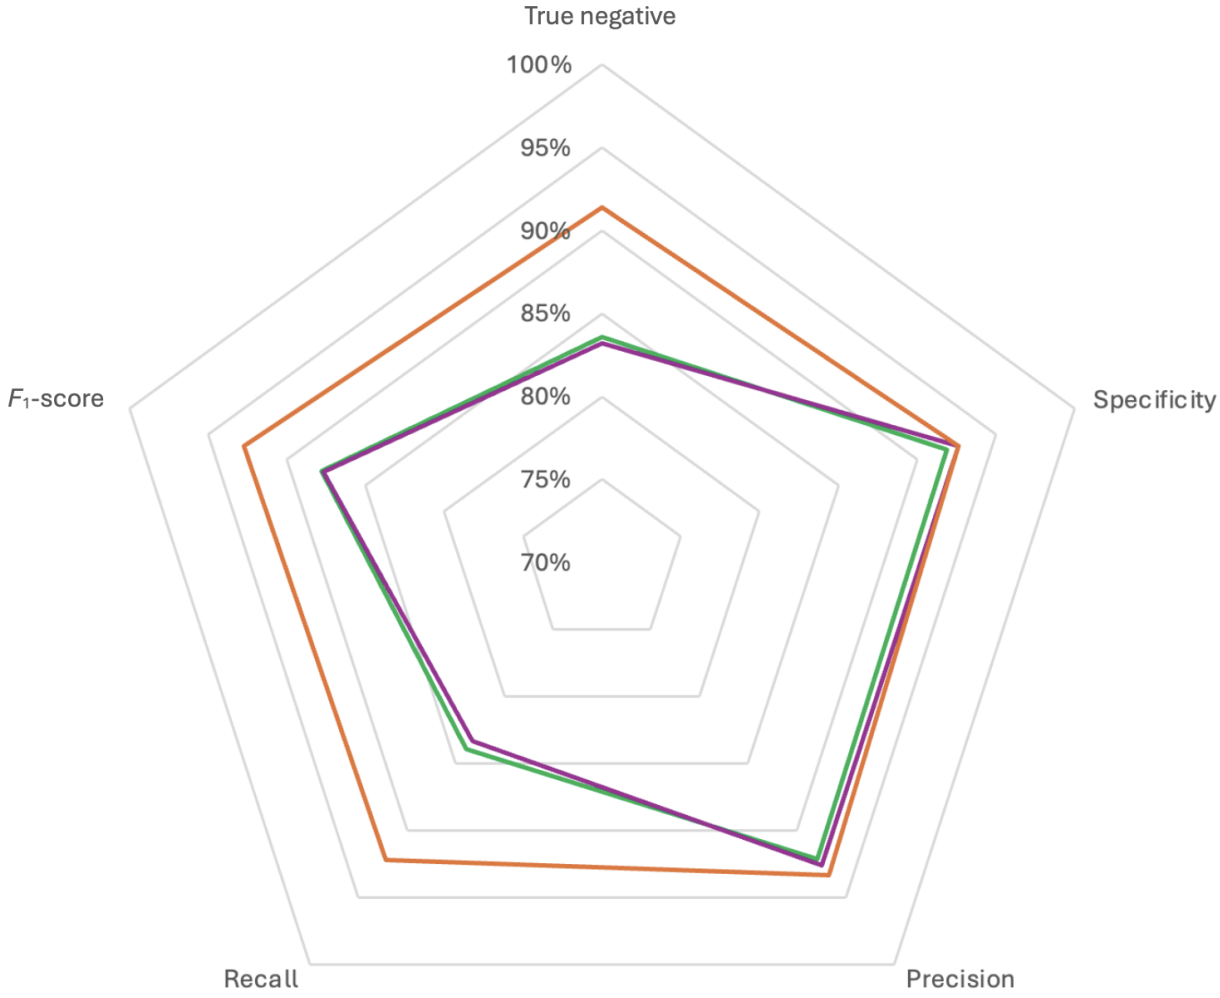
Characteristics, baseline, and demographics	All patients (n=85)	Patient historically included in the clinical trial (n=30)	Patient not included in the clinical trial (n=55)	*P* value
Age (years), median (IQR)	68 (60 - 73)	62 (56 - 67.25)	70 (61.25 - 77.5)	.09
Female, n (%)	43 (51)	16 (53)	27 (49)	.82
Overall survival (months), median (95% CI)	9 (7-15)	14 (8 - 18)	7 (5-13)	.34
Locally advanced pancreatic cancer, n (%)	19 (22)	5 (16)	14 (25)	.49
Candidate trials per patient, median (IQR)	4 (3 - 5)	5 (4-6)	4 (2.5 - 5)	.02
ECOG[a], median (IQR)	1 (1 - 2)	1 (1 - 2)	1 (1 - 2)	.86
History of malignancies, n (%)	7 (0.08)	1 (0.03)	6 (0.11)	.25
Cardiovascular comorbidities, n (%)	40 (47)	16 (53)	24 (43)	.53
BMI at diagnosis (kg/m^2), median (IQR)	23.53 (20.96 - 25.88)	24.01 (20.53 - 27.12)	23.20 (21.36 - 25.29)	.58

[a]ECOG: Eastern Cooperative Oncology Group Performance Status Scale.

Gold Standard Assessment

Manual assessment of eligibility was performed as the gold standard for this analysis. Interrater reliability for manual assignment was substantial, with a Cohen κ value of 0.83 between reviewers (95% CI 0.81-0.84). Seven (0.06%) discordant cases required the intervention of a third reviewer to reach consensus.

Performance of LLMs



With a median of 4 (IQR 3-5) candidate trials per patient among the 85 patients analyzed, a total of 341 patient-trial pairs were identified. The overall performance of the 3 LLMs in evaluating patient eligibility for clinical trials is presented in Table 3. Detailed performance results of all LLMs for each trial are provided in Multimedia Appendix 3. Mistral-7b-Instruct v0.3 demonstrated the highest sensitivity, followed by GPT-4.5 and Claude 3.7 Sonnet (92.2%, 83.9%, and 83.3%, respectively), with a statistically significant difference between the Mistral-7b-Instruct v0.3 and the other 2 models (P<.01 for both comparisons). Overall performance metrics for each LLM are reported in Figure 1.

In clinical trials, analysis of the criteria revealed that the frequency of discordance between LLMs and human reviewers increased with the number of words and the number of characters in the criteria (P=.02 and P<.01, respectively). Both associations remained significant in a multivariable logistic regression model. The other characteristics of the criteria were not significantly associated with the risk of LLM error.

The total screening time for the gold standard manual assessment was 2682 minutes (ie, 44.70 hours). The total screening time using LLMs ranged from 152 minutes (2.53 hours) for Mistral-7B-Instruct v0.3 to 189 minutes (3.15 hours) for Claude 3.7 Sonnet. Screening time was significantly shorter for all LLMs compared to the gold standard assessment. Detailed screening time data are reported in Multimedia Appendix 4.

Discussion

Main Findings

This study shows promising performance of LLMs for the prescreening of patients with locally advanced or metastatic pancreatic cancer based on pretherapeutic tumor board meeting reports. Screening for clinical trials assisted by LLMs would be appropriate in cases where there are a large number of inclusion and exclusion criteria or in peripheral centers with a view to referring patients to expert centers for a specific condition, thereby offering them the best chance of benefiting from therapeutic innovation.

The disparities in results between clinical trials using LLMs are difficult to interpret because of the small number of patients analyzed per trial, but overall, the risk of LLM error was correlated with the number of words or characters contained in a single inclusion or exclusion criterion. LLMs displayed poor performance in interpreting data, such as identifying clinically relevant past medical events or recent but resolved medical conditions. This aspect represents a major area for improvement in these technologies. No errors were observed in terms of timing between the discussion of the case in tumor board meetings and an event of particular interest. The identification of characteristics such as age, personal (rather than family) history of cancer, pregnancy status, or metastasis location was not a major cause of failure for LLMs. This is reassuring regarding the feasibility of using LLMs for the purpose of prescreening patients for clinical trials.

Mistral-7b-Instruct v0.3 is an LLM trained using multiple French-language databases and does not require translation when generating responses in French, unlike Anglo-Saxon models. Its optimization for Latin languages enables it to understand complex syntactic structures and semantic nuances. This characteristic may help explain the superior results obtained by this LLM, which outperformed the other 2 solutions tested.

Comparison to Prior Work

Recent developments in AI and the rise of LLMs have offered promising opportunities to address these challenges. The ability of these models to process large quantities of complex patient data quickly and reliably has already demonstrated benefits in the field of oncology research [17]. Studies have shown that AI-based approaches significantly reduce the time required for screening eligibility, without compromising the consistency of trial-patient identification [18,19]. By integrating AI into clinical workflows, physicians could spend more time on direct patient interactions, complex medical decision-making, and personalized care, thereby enhancing overall health care quality and potentially improving patient outcomes [20,21]. Our study concurs with previous research, demonstrating the clear relevance of these tools in this setting [22]. A recent review focusing on the application of AI to clinical trial recruitment demonstrated several positive outcomes, including increased efficiency and improved recruitment or accuracy. It also emphasized various technical and ethical issues, including privacy, data security, transparency, and selection bias [23]. The first recent multicenter study using AI to streamline screening processes in patient medical records, conducted on a cohort of patients with lung cancer, found that LLMs achieved promising performance across 28 points of interest, including metastatic status and comorbidities. This study also highlighted that LLMs trained for screening make fewer errors than humans, although the contribution of humans to complement automated screening in cases where LLMs returned results with lower levels of confidence reduced the risk of error. The use of AI would also reduce variability between centers in identifying key features for clinical trial inclusion [24].

Strengths and Limitations

Although the reasoning capabilities of generative AI models for clinical trial screening have shown impressive results, their implementation in clinical practice remains a challenge. The heterogeneity of software, data formats, extraction methods, and ethical considerations poses challenges to the routine use of these tools by health care providers.

Furthermore, because the analysis is based on a snapshot of the patient's disease history, it is possible that some information may evolve over time, leading to misjudgment of certain inclusion or exclusion criteria for clinical trial screening. A significant number of tumor board meeting reports were missing due to the recent digitization of patient records. This study was also unable to use certain scanned documents of poor quality.

Given the limited number of patients and clinical trials, as well as the retrospective and single-center design of this study, the results should be interpreted with caution. However, they suggest a potentially valuable contribution of generative AI tools in screening patients with locally advanced or metastatic pancreatic cancer for their eligibility for clinical trials.

Future Directions

Refining prompt engineering and fine-tuning models with domain-specific datasets could further enhance the accuracy and specificity of LLMs. Future work should explore integration with structured clinical data, such as laboratory values or radiological findings, to improve multimodal comprehension. Expanding the evaluation to a broader range of tumor types and multicenter datasets would improve generalizability.

The next step is to ensure outputs with clinical-grade standard requirements. Establishing a robust data governance framework to safeguard patient privacy, ensure data security, and maintain traceability of LLM actions could help to enhance acceptance of LLMs by regulatory agencies for real-time screening within electronic health records systems.

Finally, real-time prospective validation and workflow integration with electronic health records will be critical to assess the feasibility and clinical impact of LLM-assisted screening in daily oncology practice. Addressing these challenges will be essential to move from proof of concept to scalable and ethically sound clinical implementation.

Abstract

Background: Surveillance is noted to be an important part of survivorship to detect recurrence and/or second primary lung cancer (SPLC) at a curable stage. However, current surveillance guidelines remain controversial, and the factors providers consider in clinical decision-making are neither well-defined nor consistently applied.

Objective: In order to inform the qualitative protocol for a larger national study, this pilot study aimed to understand the factors that influence lung cancer surveillance and how providers view risk stratification as a potential tool to inform surveillance practices.

Methods: Semistructured interviews were conducted between October 2023 and July 2024 with purposively sampled providers involved in treating and surveilling patients with lung cancer from the US-based Palo Alto Veterans Affairs Medical Center and Stanford Medicine and its affiliate clinics. Providers were recruited through both email outreach and in-person invitations. Interviews were transcribed by an external transcription service and analyzed through a qualitative inductive content analysis approach to identify themes.

Results: In total, 11 physicians and 2 advanced practice providers (N=13) participated in interviews. The majority were from medical specialties (n=8, 61.5%), and the average number of years of practice as a provider was 9 years. A total of 3 themes were identified that describe the clinicians' sentiments about current surveillance practices and how a risk stratification tool could be used in screening for recurrence and/or SPLC. Clinicians consider a variety of clinical and nonclinical factors (category 1: factors that influence clinical decision making) and highlighted limits of a risk stratification tool, including concerns about generalizability, accuracy, and validity (category 2: sentiments toward a hypothetical risk stratification tool). Finally, concerns were raised about how delivering risk stratification data might impact patient anxiety, misinterpretation, and adherence to surveillance plans (category 3: delivery of risk stratification data to patients).

Conclusions: This qualitative analysis highlights the complexity of lung cancer surveillance decision-making and provider concerns about tool accuracy and delivery. While risk stratification tools may support surveillance decisions, their further development must address data quality, accuracy across diverse clinical and nonclinical risk factors, and effective patient-level data delivery. Doing so will facilitate the practical implementation of risk stratification tools to improve surveillance of SPLC and recurrence.

KEYWORDS

surveillance; lung cancer; risk stratification; second primary lung cancer; patient-provider relationship; clinical decision-making

Introduction

Surveillance is widely accepted to be an important part of lung cancer survivorship to help early detection of local recurrence and second primary lung cancer (SPLC) at a more curable stage. Guidelines by the American Society of Clinical Oncology, the National Comprehensive Cancer Network, and the European Society of Medical Oncology recommend surveillance imaging every 6 months for the first 2 years and then annually after those 2 years [1-3]. Despite these universal guidelines around

XSL•FO
RenderX

surveillance, not all survivors receive surveillance imaging. One study found that two-thirds of 1288 patients did not receive recommended surveillance imaging [4], while another study reported that less than 1 in 5 patients out of 1537 at Veterans Health Administration received recommended surveillance imaging [5].

Current variability in imaging receipt may be due to a complex mix of factors, including uncertainty about the optimal frequency of surveillance, duration of surveillance, which findings warrant continued surveillance, or who would be a good candidate for surveillance, considering other comorbidities. Although surveillance imaging is a widely accepted and guideline-recommended practice, there is limited clinical trial evidence that increased surveillance improved survival, especially for patients with advanced non-small cell lung cancer (NSCLC) [6]. Moreover, patients' comorbidities and overall life expectancy compel providers to balance the potential benefits of surveillance against its harms, including complications from biopsies of false positives and reduced quality of life from anxiety around scans [7,8]. How clinicians navigate these competing considerations remains unclear and may vary inconsistently across patients.

Tailored approaches to surveillance may benefit low-risk patients by reducing the frequency of surveillance, while focusing surveillance efforts on high-risk patients [6]. Risk calculators, developed using factors considered in retrospective evidence, can guide clinical judgment when current guidelines lack clear recommendations. For example, risk stratification based on malignancy risk is already used in primary lung cancer screening to identify high-risk patients and improve adherence to screening [9]. Applying a similar strategy to surveillance decision-making in survivors of lung cancer could help reduce variability and promote more consistent clinical practices.

Our study objective was to explore clinicians' clinical decision-making practices around surveillance and to assess the acceptability of risk stratification tools to guide surveillance.

Methods

Study Design

This pilot qualitative interview study was designed to gather insights and perspectives from providers who treat lung cancer. The aim of this study was to identify the array of factors that providers consider for risk of recurrence and/or SPLC and to explore provider perceptions of a hypothetical risk stratification tool that would evaluate the risk of recurrence and/or SPLC.

To contextualize clinician feedback, the hypothetical risk stratification tool referenced in interviews was modeled after the validated Second Primary Lung Cancer–Risk Assessment Tool (SPLC-RAT) developed by Stanford Medicine [10]. SPLC-RAT generates a 5-year SPLC risk estimate using regression-based modeling of clinical and smoking history inputs (eg, age at diagnosis, cancer stage, histology, surgical resection, smoking status, pack-years, and time since cessation). In practice, such a tool could integrate with the electronic health record to automatically pull structured data (eg, age, gender, and race) and combine it with manually entered variables, similar to the integration of analogous tools for primary lung cancer screening [11]. While modeled after SPLC-RAT, the hypothetical risk stratification tool was unnamed to study participants to collect their broader perceptions of risk stratification tools.

Recruitment

Providers were purposively identified and recruited from the Palo Alto Veterans Affairs (VA) medical center and Stanford Medicine and its affiliate clinics, all located within the United States. Eligibility criteria included licensed providers who are involved in treating and surveilling patients with lung cancer at these 2 health care systems. Eligible clinicians were invited to participate in the study through both email and in-person outreach. Initially, 1 provider from a thoracic oncology department was contacted, who then introduced the researcher (JMW) to other oncology providers in that department who were invited to be interviewed in person. The remaining providers were introduced by the study principal investigator (PI) (a thoracic oncologist; JTW) and were invited to participate via email.

Interview Process

The interview guide was modeled on a previous study on machine learning prognostic algorithms and adapted to fit the research questions for this study [12]. The interview guide contained 9 questions surrounding provider surveillance practices in evaluating risk of recurrence and perspectives on a hypothetical risk stratification tool (Textbox 1). Mock interviews were conducted among the research team (JMW, JTW, and SC), and the interview guide was subsequently adjusted for clarity. Research questions asked to providers aimed to explore their clinical decision-making practices around lung cancer surveillance and to assess their perspectives on a hypothetical risk stratification tool to guide surveillance.

XSL•FO
RenderX

Textbox 1. Interview questions.

1. When considering stopping surveillance for a lung cancer survivor, some clinicians stop once a certain timeframe has passed (ie, five y), while others may prefer to continue surveillance indefinitely. When do you think clinicians should consider stopping surveillance indefinitely? When do you think clinicians should consider stopping surveillance imaging for a survivor?

a. If they do not mention, ask: What are the reasons behind your opinion?

b. Follow up: What events or circumstances prompt you to order a surveillance scan?

c. If prompted for clarification or if the subject only discusses the time of diagnosis, mention that some clinicians are prompted by certain events or circumstances, such as multiple negative surveillance scans or declining functional status due to non-cancer-related causes.

2. How do you define risk of recurrence? Numerical risk? Or context of relative risk?

a. Do you think about risk in concrete terms, as in quantitative numbers or relative terms (ie, this pt is higher risk than someone else)?

3. What factors do you use in assessing the risk of recurrence and/or second malignancy in the context of the patient's overall health?

a. I understand guidelines say to screen regularly, but in practice, there are other co-morbidities that can change your decision. Does this come to mind apart from the guidelines regarding quantitative risk assessment?

    i. Do you use clinical intuition to modify guidelines?

4. What information about risk of recurrence and/or second malignancy do you usually share with a patient? [Do you have a discussion with a lung cancer survivor about whether or not to continue surveillance imaging?]

a. If they do not describe this, ask: Some clinicians frame surveillance in terms of general risk, such as the high risk of recurrence for lung cancer. Others specifically tailor it to patient-specific factors, such as ongoing smoking and advanced stage at diagnosis. Where along that spectrum do you fall?

5. We are developing a computer program that can use a patient's medical record data to estimate the patient's risk of developing a second primary lung cancer. If you had access to a score that accurately estimated a 5-year risk of each of your patients -- for example, a 0.1% risk of cancer or a 6% risk of cancer -- how would you use this information in the care of the patient, if at all?

a. If prompted for clarification of specific scenarios, specify: For example, a 60y patient diagnosed with early stage resected lung adenocarcinoma with a history of prior cancer before lung cancer and a 20 pk-yr smoking history has ~6% 5-year risk of SPLC. If that same patient did not receive resection and does not have a prior history of cancer, the risk reduces to 1.3%.

b. If they do not mention, ask: Do you think it would prompt a discussion about surveillance practices?

6. Who on the care team should be the primary recipient of this information and how should it be incorporated into the clinical workflow? [Are you comfortable with the primary recipient of this information being a designated screening coordinator?]

a. If prompted for clarification, mention that lung cancer screening has dedicated coordinators who triage patients based on risk assessment of lung nodule findings and that surveillance follow-up could follow a similar model

7. No prediction model will ever be perfect. A model could have many false positives, which in this case would be patients who are erroneously flagged as having a high risk of cancer. Alternatively, a model could have many false negatives, which in this case would be patients who are high risk of cancer but not flagged by the model. With that in mind, would you prefer to have a model that has more false negatives or more false positives? Why?

a. If prompted to define "high risk of cancer," it is whatever the clinician would consider high risk.

8. What concerns, if any, do you have about using computer-generated cancer risk predictions in the clinical care of your patients?

9. Do you have any current or prior experience using computer-generated models or cancer risk prediction tools to inform clinical decision-making?

a. If the person answers "Yes," ask: How does your experience impact the way you view the utility of computer-generated cancer risk predictions in clinical care?

After the main interview questions, demographic information including their years practicing in their specialty, specialty, age, gender, and race were collected.

Semistructured interviews with providers were conducted on Microsoft Teams by 2 trained female researchers (JMW and SC) and the female study PI (JTW). At each interview, verbal consent was obtained before the audio recording. Some study participants knew the PI before interviews, given her role as a thoracic oncology clinician at the health care systems participants were based. Some participants also had previous exposure to a previously developed SPLC risk stratification tool (SPLC-RAT) from Stanford Medicine, including as coauthors on the model development publication, which may have informed their responses to the hypothetical tool described in the interview guide. Interviews were conducted between October 2023 and July 2024, and audio files were transcribed by an external transcription service. The interviewers reviewed all

XSL•FO
RenderX

transcriptions to verify accuracy. Participants were not contacted following the initial interview.

Our research team consists of oncology and surgical clinicians, along with health services researchers, including experts in qualitative methods and oncology. We value a comprehensive understanding of current health system landscapes and the importance of engaging with providers directly involved in patient care before developing future interventions and tools to enhance the quality of health services.

Data Collection and Analysis

The research team aimed to interview at least 12 providers to support preliminary pilot findings; this has similarly been found sufficient for reaching a general level of saturation, or repetition of basic themes or findings [13]. When creating our participant sample, we also considered the concept of information power, which is defined as the capacity of a study's sample size to effectively capture the unique experiences and insights of participants, particularly when the sample is specifically aligned with the research objectives [14]. Since the eligibility criteria created a smaller, well-defined sample of eligible participants, a smaller sample size was sufficient to provide exploratory pilot data that addressed our research questions. Moreover, since interview questions were highly specific, with multiple follow-up probes, and there was depth to the answers, a wide array of insights was captured despite a smaller sample.

Interview transcripts were uploaded to Microsoft Excel. Data analysis was completed through an inductive content analysis approach. First, familiarization with the data was conducted by 2 researchers (JMW and JTW), after which a list of initial codes was identified. During this process, the researchers met weekly to discuss and determine consensus, creating the initial codebook, which contained preliminary codes and definitions, and to adapt the codebook as needed. The finalized codebook was further reviewed externally by the qualitative methods methodologist (CG), providing expert validation and addressing potential biases that may have arisen from the internal coding team. Once the codebook was agreed upon, the rest of the interviews were coded (JMW and SC). Finally, codes were analyzed and organized into groups to identify overarching themes. Themes were defined, and supporting data that were already analyzed were summarized into these larger themes.

Ethical Considerations

The study was approved by the Stanford University Institutional Review Board (IRB #67922) as an expedited review with a waiver of documentation of informed consent. VA Local Union Notification was obtained for VA employees. Oral information about the study was given before verbal informed consent. This included details about the study's purpose, risk, and benefits of participation, confidentiality protections, and participants' rights to withdraw at any time. All participants provided verbal consent for participation before audio recording. All data were deidentified before transcription using a coding system. Only the interviewers (JMW, SC, and JTW) had access to the code key. Transcriptions and audio recordings were stored in a secure and access-restricted folder on a server behind the VA firewall, accessible only to the research team. Participants did not receive any compensation for their participation.

Results

Participants

Of the 29 eligible providers recruited to participate, 11 physicians and 2 advanced practice providers (N=13) who were specifically involved in treating and surveilling patients with lung cancer were interviewed. The interviews ranged from 14 to 30 minutes. The average number of years the participants have been practitioners was 9 (SD 5.52, range 3 - 20) years. The majority of participants were medical specialists (n=8, 61.5%), while the remaining 38.4% (n=5) were interventional specialists. Additional demographic information is provided in Table 1.

Table . Demographic characteristics of providers (N=13).

Characteristics	Value
Age (y), mean (SD; range)	42.5 (5.75; 34-50)
Sex, n (%)	
Female	9 (69.2)
Male	4 (30.8)
Race, n (%)	
White	6 (46.1)
African American	1 (7.8)
Asian	6 (46.1)
Ethnicity, n (%)	
Hispanic, Latino/a/x, or Spanish Origin	0 (0)
Specialty, n (%)	
Interventional	5 (38.4)
Medical	8 (61.5)
Average time as a practitioner (y), mean (SD; range)	9 (5.52; 3-20)

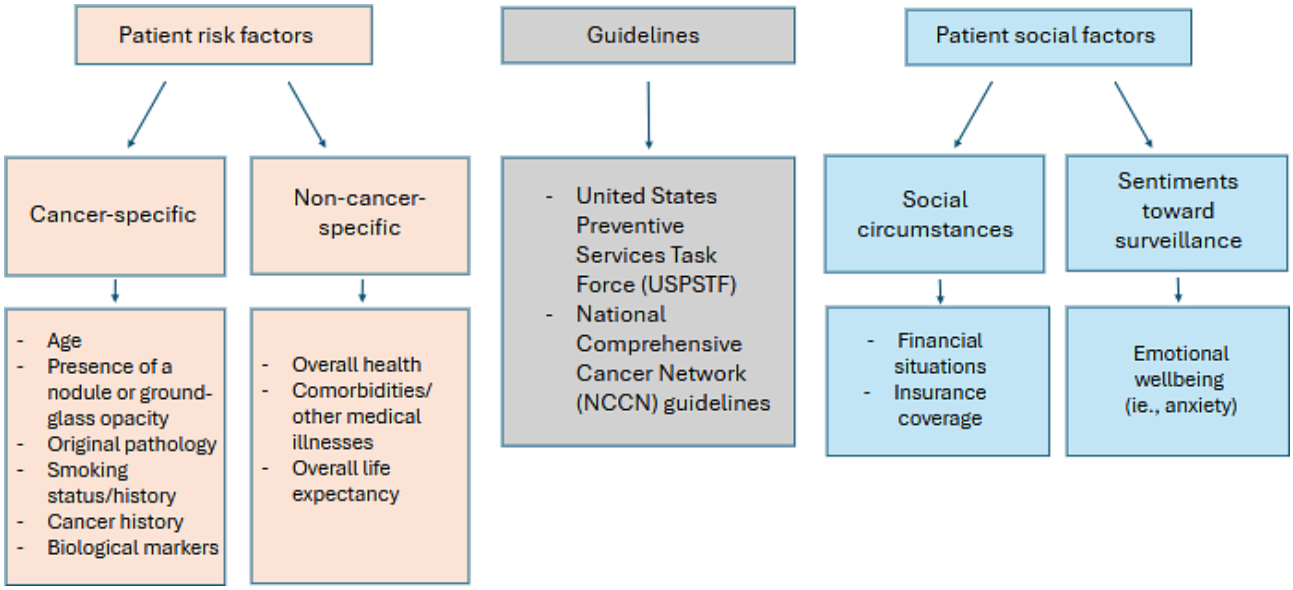
Themes

Findings clustered around three main themes: (1) factors that influence clinical decision making, (2) sentiments toward a hypothetical risk stratification tool, and (3) delivery of risk stratification data to patients. Themes and illustrative quotes are displayed in Table 2.

XSL•FO
RenderX

Table . Themes and representative quotes.

Overarching theme and subcategory	Definition	Representative quotes
Factors that influence clinical decision-making (for surveillance)		
Clinical risk factors	Clinical risk factors providers consider for surveillance, including cancer-specific and non–cancer-specific factors.	• "I would probably consider smoking history in addition to the patient's medical history. Maybe other medical illnesses we need to consider, different types of cancers and pathologies" [Interventional Specialty, practicing for 10 y] • "What the patient's overall life expectancy is in respective to the diagnosis" [Medical Specialty, practicing for 1.5 y] • "With older people over the age of 75, they have competing risks. Not just their lung cancer recurrence but also dying from other causes so we certainly take that in account and a patient's ability to continue coming in. It's really a shared decision making with the patient" [Medical Specialty, practicing for 12 y]
Nonclinical risk factors	Nonclinical risk factors that providers consider such as patients' social circumstances and sentiments toward surveillance. Some social circumstances include differing emotional capacities, financial situations, and insurance coverage.	• "[There's] still a lot of anxiety result[ing] from living as a cancer survivor" [Medical Specialty, practicing for 21 y]
Sentiments toward a hypothetical risk stratification tool		
Positive sentiments	Providers' positive sentiments toward a hypothetical risk stratification tool	• "I think these risk calculators could be very helpful because it gives us concrete idea of the risk level and if it tells us of a very low risk level, it can give us some confidence in doing less surveillance imaging" [Medical Specialty, practicing for 8 y]
Provider concerns	Concerns providers have toward a hypothetical risk stratification tool. This includes concerns about the tool's generalizability, accuracy, and validity.	• "I'd have to trust the model and have to trust the data that is going into it to make sure I would be convinced that the information would be helpful to me" [Medical Specialty, practicing for 15 y] • "I think a computer-generated model will certainly have more pitfalls in poor and less fortified areas. You're going to have a lot of data for the rich folks and not so much data on the poor folks. This might be a serious social justice element to that – who gets screened for cancer, people who can afford a house in Palo Alto? If you live in Nevada, maybe not so." [Interventional Specialty, practicing for 10 y]
Views on false positives versus false negatives	Provider views on which error (type I or type II) they would choose between in a model setting.	• "The repercussions of missed opportunity to diagnose recurrence earlier is worse than the risk of overtreating" [Interventional Specialty, practicing for 14 y] • "Could do some Markov modeling to see ideal threshold. There could be downsides to over biopsying benign things. I would err on the side of flagging people" [Medical Specialty, practicing for 4 y]



XSL•FO
RenderX

Overarching theme and subcategory	Definition	Representative quotes
Provider concerns about delivery of risk stratification data to patients	Providers' concerns about how patients would receive the risk stratification data.	• "Making sure that they understand the importance of coming back for their scans regularly" [Interventional Specialty, practicing for 5 y] • "I think it would be valuable to speak to that patient about the risk of radiation, risk of recurrence of cancer, and really put the numbers in front of them" [Interventional Specialty, practicing for 10 y]

Factors That Influence Clinical Decision Making

There are a multitude of factors that providers consider that can influence their clinical decision making, falling into 2 categories, clinical factors (patient risk factors and guidelines) and nonclinical factors (patients' social factors; Figure 1).

Figure 1. Factors that influence provider decisions on surveillance. This figure describes a summary of the factors mentioned that influence provider decisions on lung cancer surveillance. The first row of headings is different overarching groups of factors. Following each heading ("patient risk factors," "guidelines," and "patient social factors") are arrows pointing to further specific categories under the respective headings. For the "patient risk factors" and "patient social factors" sections, there is a second set of arrows that are pointing to specific examples of factors that were noted by the participants.

Clinical Factors (Patient Risk Factors and Guidelines)

When providers were asked about what factors they consider for surveillance, they first mentioned cancer-specific factors (patient's age, presence of a nodule or ground-glass opacity, original pathology, smoking status and history, and medical history). They also explained that they consider cancer history (stage of cancer, history of lung cancer, family history of cancer, and time from treatment) as well as biological markers (presence of mutations, molecular markers, and lymph node status) when considering surveillance for a specific patient.

Besides these factors, they also described how they consider guidelines and published data. Many providers mention a 5-year cutoff for surveillance unless there is a presence of a nodule, while others stated they screen every year indefinitely. The United States Preventive Services Task Force and National Comprehensive Cancer Network guidelines were mentioned as resources they use as well. When asked if they currently use a risk stratification tool for risk of recurrence and/or SPLC, the providers denied using one.

Beyond the guidelines and published data, providers listed other non–cancer-specific clinical factors, such as the patient's overall health, comorbidities, other medical illnesses, and overall life expectancy. One provider expressed how:

> *...with older people over the age of 75, they have competing risks. Not just their lung cancer recurrence but also dying from other causes so we certainly take that in account and a patient's ability to continue coming in. It's really a shared decision making with the patient.* [P04]

One provider mentioned how they look at life expectancy tables to help decide if focusing on lung cancer surveillance is in the patient's best interest.

Nonclinical Factors (Socioeconomic and Patient Sentiments)

Factors such as patient social circumstances and patient sentiments toward surveillance were highlighted. One provider stated,

XSL•FO
RenderX

> *People have a certain bandwidth for their healthcare, and I think they should be able to put their energy on what specific condition they should focus on [ie, heart condition or diabetes].* [P01]

They explained that patients' factors, such as differing emotional capacities, financial situations, and insurance coverage, all play a role in their clinical judgment on whether surveillance is beneficial. For instance, it was mentioned,

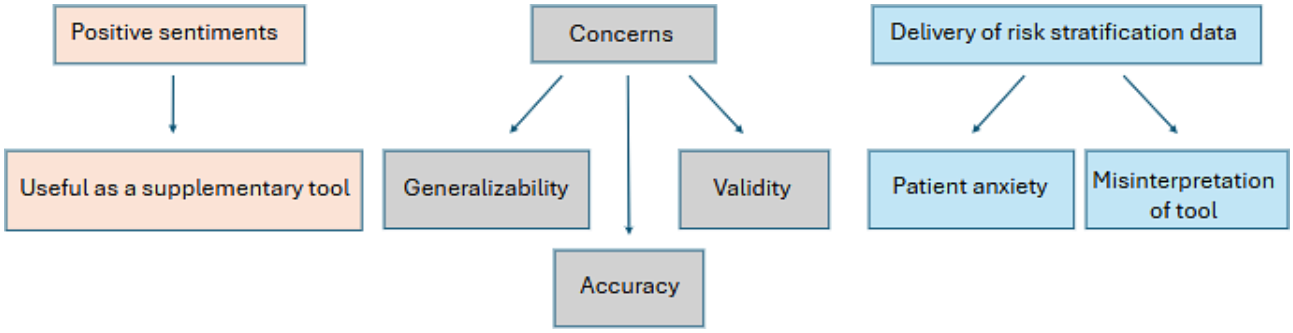
> *I also tell them things like I don't know if their insurance will cover surveillance after five years and things like that and then generally if they want to, then I'll order the scan.* [P08]

The provider explains that financial capability is also a part of the shared decision-making process in considering surveillance. Another provider described how they consider "healthcare spending [and] patients' bank accounts" (P10) as well.

Emotional well-being, particularly patient anxiety, was stated a few times. One provider explained how there's "still a lot of anxiety result[ing] from living as a cancer survivor" (P07). They noted there are significant emotional challenges that patients face as survivors of lung cancer and expressed great caution with how they bring up the topic of risk of recurrence and/or SPLC with their patients. One provider shared how "...many of them have anxieties, of course, some of them won't want the scans sooner and then some people don't want to know" (P11).

Another provider brought up a similar sentiment, stating:

> *There is a lot of anxiety about just having nodules knowing that one of them turned into a lung cancer group [in the past].* [P08]



The providers explained how this is a shared decision-making process with their patients, acknowledging patients' socioeconomic and emotional bandwidths. One provider acknowledged that at times, they'll need to follow how the patient feels and stated:

> *If the patient decides that they don't want to do surveillance anymore then it is a discussion and then we will stop.* [P11]

Sentiments Toward a Hypothetical Risk Stratification Tool

When asked about a hypothetical risk stratification tool that can use a patient's medical record to estimate a 5-year risk of recurrence and/or SPLC, providers were generally positive, but did express concerns surrounding a risk stratification tool (Figure 2).

Figure 2. Provider sentiments on a risk stratification tool. This figure describes a summary of the provider sentiments on a hypothetical risk stratification tool. The first row of headings is different overarching groups of sentiments. Following each heading ("positive sentiments," "concerns," and "delivery of risk stratification data") are arrows pointing to further explanations and examples of sentiments that were noted by the participants. For the "delivery of risk stratification data," the arrows are pointing to outcomes providers expressed concerns of in relation to how the risk stratification data is delivered to patients.

Positive Sentiments

Many providers expressed interest in the hypothetical risk stratification tool, especially its role in surveillance practices past the 5-year mark, which they consider the cutoff for surveillance in survivors of lung cancer without a nodule as it would be "useful for determining whether [they] should keep surveying after 5 years" (P08). Having a risk stratification tool could be beneficial for providers,

> *...because it gives [a] concrete idea of the risk level and if it tells of a very low risk level, it can give some confidence in doing less surveillance imaging.* [P10]

While these providers expressed positive attitudes toward this hypothetical risk stratification tool, the majority stated that although it could be useful as a supplementary tool to clinical decision making, they would not rely solely on it due to various concerns outlined below.

Provider Concerns

Many providers expressed concerns about the generalizability, accuracy, and validity of the tool. They questioned the data the model would be using, with 1 provider suggesting:

> *...[they would] have to trust the data that is going into it to make sure [they] could be convinced that the information would be helpful.* [P13]

They expressed hesitancies if a tool could consider all the factors they consider and how representative of the patient population the data would be.

Regarding generalizability, 1 provider mentioned the potential shortcoming in the data surrounding socioeconomic status, stating:

> *...[the] model will certainly have more pitfalls in poor and less fortified areas. You're going to have a lot of data for the rich folks and not so much data for poor folks. That might be a serious social justice element*

XSL•FO
RenderX

> *to that – who gets screened for cancer, people who can afford a house in Palo Alto? If you live in Nevada, maybe not so.* [P02]

Not only that, underrepresentation of racial and gender disparities was also highlighted as a concern, with 1 provider expressing that,

> *...[they] worry a bit about racial or gender disparities in terms of information that models are given and whether that will actually apply to all patients.* [P08]

Due to the concerns that the data may not be representative and comprehensive enough, the providers suggested that the model may not be generalizable to their patients and thus may not be a tool they can fully rely on in their clinical decision-making.

Concerns with the accuracy and validity of the input data for the tool were also shared. A participant explained,

> *...as you do this [with] large amounts of data, things that might not be apparent otherwise can come forward. That's where we have the challenge of, is it really there or is it not really there, but you know you're not going to have most people though there will be some who ask about all those little details.* [P07]

Other concerns providers highlighted were the limitations of relying on data from electronic medical records. A provider stated that "there is lots of variability in the patient data like the dates of diagnoses" (P09) and how "the date of diagnosis is not discrete and consistent" (P09). One provider illustrated that,

> *...many patients have incomplete follow-up and survival data which could bias your observed outcomes and could result in an inaccurate model.* [P10]

Therefore, instead of being a primary tool to depend on, the providers emphasized that this tool should have a "disclaimer that of course [is] not predictive" (P12) of whether a patient has a recurrence and/or SPLC and should be used as a supplementary check.

Views on False Positives Versus False Negatives

Providers also discussed their perspectives on false positives and false negatives in a tool, with most providers preferring a model threshold that errs on the side of more false positives. One provider explained,

> *The repercussions of missed opportunity to diagnose recurrence earlier is worse than the risk of overtreating.* [P03]

Other providers, while still agreeing that false positives were better than false negatives, shared that there should be "some Markov modeling to see [an] ideal threshold" (P06) to help minimize the difference. Many providers illustrated that this approach of more false positives would be useful in flagging patients and then verifying if the finding is accurate, but false positives would falsely worry patients who did not have lung cancer, and that "there could be downsides to over biopsying benign things" (P06).

Delivery of Risk Stratification Data to Patients

When asked whether patients should directly receive the risk stratification tool data, most of the providers emphasized that patients should not directly receive it due to the potential for misinterpreting the numbers and developing anxiety about their health status. Many of the providers explained that they generally do not give quantitative values involving risk prediction as they want to avoid worrying their patients. They also worry that if they gave specific numbers, it would not truly resonate with the patient, as they would not understand the numbers in depth. One provider puts it as sharing enough in "making sure that they understand the importance of coming back for their scans regularly" (P08). There were a few providers who stated that they would share exact numbers to patients if the patients pushed for those numbers or used the numbers "...to speak to that patient about the risk of radiation, risk of recurrence of cancer, and really put the numbers in front of them" (P02).

Discussion

Principal Findings

This qualitative pilot study interviewed specialists from 2 medical systems about their current practices surrounding surveillance for risk of recurrence and/or SPLC, their attitudes toward a hypothetical risk stratification tool, and how they would deliver risk stratification data to their patients. Surveillance decisions were found to incorporate diverse clinical and nonclinical factors beyond current guidelines, which may explain variability in imaging receipt observed in population-based studies [15]. While participants showed interest in risk stratification tools to systematize decision-making, they raised concerns about the tool's generalizability, accuracy, validity, and content delivery. These concerns highlight key areas for future tool and intervention development. These pilot findings will also inform the development of a future national survey study of physician attitudes and perspectives of an adapted risk stratification tool for SPLC and lung cancer surveillance.

Providers emphasized how their surveillance plans go beyond following current guidelines, incorporating both clinical and nonclinical risk factors. They consider patients' overall well-being, comorbidities, and sentiments toward surveillance, tailoring efforts to reduce adverse outcomes, such as complications or reduced quality of life [7,8]. Most participants highlighted the importance of shared decision-making, which has been shown to improve knowledge surrounding lung cancer screening and be positively associated with intentions to go through screening again [16]. This personalized approach allows providers to create comprehensive patient-centered surveillance plans.

With innovations, such as computer models and artificial intelligence (AI) in cancer care, understanding provider acceptance and opinions toward a computer-generated risk stratification tool is important [17]. This feedback provides risk stratification tool developers with the necessary elements and concerns clinicians are likely to have. Given the complexity of factors in lung cancer recurrence and SPLC, such models could

XSL•FO
RenderX

guide and standardize surveillance by identifying high-risk patients while reducing unnecessary low-dose computed tomography scans for low-risk individuals.

Providers expressed interest in a hypothetical risk stratification tool for improving clinical care, but stated it was not robust enough to be used independently and emphasized they trust their clinical intuition above all. They viewed it as a supplemental tool that could provide additional validation to their clinical decision-making, citing limitations such as the data quality and model accuracy. Providers emphasized the importance of inclusive input data, particularly for underrepresented groups based on income, race, and gender. This has been shown to be a significant barrier to the widespread adoption of AI models in cancer care [18]. Accuracy concerns were also raised, such as overestimating risk in low-risk individuals or failing to identify high-risk patients. Given these limitations, most providers viewed such tools as secondary to clinical intuition. They stressed that the tool's output should not drive decisions independently, and that providers should understand the input factors and rely on their expertise to override the tool if inaccuracies arise.

Delivery of risk information was another key concern. Most providers indicated that they would avoid sharing exact risk stratification numbers with their patients, citing concerns about potential misinterpretation and anxiety. Studies have shown that patients with cancer already have scan-associated anxiety, and adding to this underlying anxiety could negatively influence their adherence to getting necessary surveillance scans [19,20]. Instead, providers have suggested that they could use the risk stratification tool to initiate conversations about risk without focusing on specific numbers. These sentiments from providers shed light on the importance of considering how patients will receive risk stratification tool information before sharing it, and in response, sharing enough information to ensure that the patient can continue to pursue the best care in a well-informed manner. Although providers viewed this tool as supplementary, they agreed that it could be a helpful double-check for their own clinical judgment and prompt alternative surveillance strategies, such as adjusting scan frequency. Ultimately, providers emphasized that with a tool or not, their goal for patients is to adhere to the most clinically accurate and effective plan to prevent recurrence and/or SPLC.

Limitations

First, the small sample size limits the transferability of findings to lung cancer survivorship specialists nationwide. However, as a pilot study, it gathered perspectives across various settings, including academia, the VA, and satellite clinics, which may have broadened the findings beyond a single clinic or hospital. Nonetheless, these results will inform our planned national study, which will produce more transferable findings. Second, participants were from an affluent, research-focused region, and providers may be more receptive to technology and innovation than those at other locations. This initial pilot study was also limited by recruitment reach. Future work would benefit from the inclusion of a more diverse group of lung cancer providers from various geographic locations, institutions, and hospital settings across the United States, particularly those in rural areas where access to new technology and innovation may be limited or less emphasized. Third, some participants knew the PI before interviews, given her role as a thoracic oncologist, and some participants had previous exposure to SPLC risk stratification tools. Due to narrow eligibility criteria and the interconnectedness of these 2 health care systems, this was inevitable and had the potential to impact study participants' responses. Future work will gather perspectives from a national sample of providers to broaden findings and make them more transferable. Fourth, providers' perceptions were reported based on a hypothetical tool, rather than one they have used or trialed, limiting the applicability of findings. While the hypothetical risk stratification tool concept was explained to providers and some had previous knowledge of risk stratification tools, participants were still inferring what the tool could or could not do. Future work should provide a detailed explanation of a developed risk stratification tool, outlining its exact functionality within surveillance.

Conclusions

This study illustrates the complexity of lung cancer surveillance decision-making, which may contribute to variability in surveillance imaging among survivors. While risk stratification offers a systematic approach to guide decisions, uptake is limited by concerns about data quality, tool accuracy, and delivery and applicability to individual patients. Addressing these issues can inform the development and implementation of more acceptable and effective risk stratification tools.

Abstract

Background: Lung cancer is one of the most commonly diagnosed cancers worldwide and the leading cause of cancer-related mortality. Global studies have highlighted the importance of awareness of lung cancer signs and symptoms, as it influences health care seeking, diagnosis timing, and treatment outcomes. Despite the high prevalence of both lung cancer and smoking in Jordan, no studies have assessed lung cancer awareness among the Jordanian population. This study is the first in Jordan to reveal the levels of awareness of lung cancer signs and symptoms, risk factors, and screening and to identify factors associated with the awareness level.

Objective: This study aimed to explore the awareness of lung cancer risk factors, signs and symptoms, and screening in the Jordanian population and the factors determining the levels of awareness.

Methods: A cross-sectional survey was conducted across all 12 governorates of Jordan, including 498 adult participants. Data were collected using a structured questionnaire covering sociodemographic characteristics and awareness about lung cancer signs, symptoms, risk factors, and screening. Items were derived from the Lung Cancer Awareness Measure Toolkit, version 2.1, 2011. Awareness scores for lung cancer risk factors, signs and symptoms, and overall lung cancer awareness were calculated. Multivariate linear regression was used to identify significant predictors of awareness scores. Multivariate logistic regression was used to determine significant predictors of lung cancer screening awareness.

Results: The mean lung cancer signs and symptoms awareness score was 5.4 (SD 4.9) out of 14, while the mean risk factor awareness score was 33.0 (SD 5.6) out of 45. The most recognized symptoms were coughing up blood (n=297, 59.6%) and pain upon breathing (n=237, 47.6%), while cigarette smoking (n=403, 80.9%) and exposure to air pollution (n=339, 68.1%) were the most recognized risk factors. Only 41.6% (n=207) of the participants had heard of lung cancer screening, while 79.3% (n=395) believed that screening improves survival. Being a smoker was predictive of lower awareness of lung cancer signs, symptoms, and risk factors, while a higher educational level and having a friend or relative previously diagnosed with lung cancer were associated with higher levels of awareness.

Conclusions: This study revealed a low level of awareness of lung cancer signs and symptoms, risk factors, and screening in the Jordanian population. Further studies are needed to identify effective strategies for improving awareness, especially among high-risk populations.

KEYWORDS

lung cancer awareness; lung cancer risk factors; lung cancer signs and symptoms; lung cancer screening; Jordan

Introduction

According to recent statistics, lung cancer is one of the most commonly diagnosed cancers worldwide and the most common cause of cancer-related mortality [1]. Thus, it remains an extremely significant global health problem. In the Hashemite Kingdom of Jordan, lung cancer is also one of the most commonly diagnosed cancers and the most common cause of cancer-related mortality [1], which could be attributed to the very high tobacco smoking prevalence in the country [2]. Multiple studies have shown that low awareness of lung cancer signs and symptoms may be associated with longer delays in diagnosis [3-5], which in turn can lead to worse treatment outcomes and higher mortality rates [6]. In addition, research suggests that better awareness of lung cancer signs and symptoms and risk factors may lead to better attitudes toward smoking and alcohol habits [7]. This highlights the importance of promoting lung cancer awareness in different populations.

Several studies have evaluated awareness of lung cancer signs and symptoms and risk factors across various populations. In high-income nations, studies conducted in the United Kingdom, Australia, and Estonia revealed a low level of awareness. In all 3 studies, smoking was the most recognized risk factor, while shortness of breath and coughing up blood were the most recognized signs and symptoms. High socioeconomic status was predictive of higher awareness of signs, symptoms, and risk factors, while smokers had lower awareness levels than nonsmokers. Contradictory results were found regarding age and sex. In the United Kingdom and Australia, female participants had better awareness, while in Estonia, male participants demonstrated higher awareness. In the United Kingdom, older participants had better awareness, while in Australia and Estonia, younger people had better awareness [8-10]. Awareness of lung cancer signs, symptoms, and risk factors was also investigated in many low- and middle-income countries, including Nepal, Malaysia, India, and Nigeria. In concordance with results from high-income nations, tobacco smoking was the most commonly recognized risk factor, while other risk factors were poorly acknowledged, and coughing up blood was the most commonly recognized symptom [7,11-14].

Recently, research on awareness of lung cancer signs, symptoms, and risk factors has been conducted in several countries in the Middle East. In nations such as Syria, Saudi Arabia, and Palestine that are geographically and culturally similar to Jordan, results were also consistent with studies in other low- and middle-income nations. Overall levels of awareness were low, and higher levels of education and socioeconomic status were associated with higher levels of awareness [15-17]. The lack of such data in Jordan highlights the need for similar studies that explore the degree of awareness among the Jordanian population.

Considering the high prevalence and high mortality rate of lung cancer, along with the propensity for patients to seek medical attention at an advanced stage when treatment becomes more challenging [18], many resource-rich countries have implemented national screening programs for early detection of asymptomatic lung cancer using low-dose chest computed tomography scans. The survival benefit of lung cancer screening in populations at risk was confirmed by multiple randomized controlled trials, notably among individuals aged 50 to 80 years with a ≥20-pack-year smoking history [19-21], highlighting the importance of lung cancer screening as a public health measure.

Many research efforts were directed toward investigating lung cancer screening awareness among both smokers and nonsmokers. In low- and middle-income nations, research in China found that only approximately 25% of high-risk individuals participated in lung cancer screening. Additionally, awareness of lung cancer screening benefits was low, with 72.1% of participants perceiving it as unnecessary [22]. Notably, Lin et al [23] reported that a higher level of awareness of lung cancer signs and symptoms was predictive of more positive lung cancer screening behaviors. Studies in Malaysia and Saudi Arabia revealed high rates of willingness to undergo screening (78.8%-94.7%) among high-risk individuals [17,24]. Despite the high rate of willingness to undergo lung cancer screening, significant barriers, including a lack of medical insurance or awareness of lung cancer risk factors, might limit participation in screening programs. In a high-income nation such as the United States, studies have also reported low levels of lung cancer screening awareness [25,26]. Various strategies designed to enhance awareness of lung cancer screening and perhaps increase participation rates in lung cancer screening programs have been examined. Multiple studies found that various educational programs successfully raised awareness of lung cancer screening and improved participation rates for lung cancer screening [27,28].

As per our knowledge, studies exploring awareness of lung cancer signs, symptoms, risk factors, and screening have not been conducted in Jordan, despite the high incidence of this cancer and the very high smoking prevalence. In addition, very few studies have investigated the factors associated with lung cancer screening awareness. The main aims of this study are to explore the levels of awareness of lung cancer signs and symptoms, risk factors, and screening in the Jordanian population and to explore the factors that predict these levels of awareness.

Methods

Study Design

This cross-sectional study was conducted across all 12 governorates of the Hashemite Kingdom of Jordan, covering both rural and urban regions, from March 2024 to September 2025. In total, 498 adult Jordanian citizens participated in the

XSL•FO
RenderX

study. Due to limitations in time and resources, participants were recruited using convenience sampling. Data were collected through an online self-administered questionnaire distributed via Google Forms, which was shared on various social media platforms, including Facebook (Meta Platforms Inc) groups and WhatsApp (Meta Platforms Inc) channels. Only adult Jordanian citizens were eligible to complete the study. Individuals who were studying or working in health care–related fields were excluded from the study to reduce potential bias related to prior knowledge.

Ethical Considerations

Ethics approval for this study was obtained from the institutional review board ethics committee at the University of Jordan (JU-2024/32). All participants provided electronic informed consent prior to completing the questionnaire. They were informed that all collected data would be collected anonymously, kept confidential, and stored securely in a nonidentifiable format. They were also informed that participation was voluntary and that they could withdraw from the study at any time. This study was conducted in accordance with institutional and national ethical standards and the Declaration of Helsinki (1975, updated 2013). Participants did not receive any compensations or financial incentives.

Study Tool

Participants completed a questionnaire administered through Google Forms. The form consisted of 3 sections.

Section 1: Socioeconomic and Demographic Characteristics

This section gathered data on participants' age, sex, place of residence, level of education, marital status, job, and smoking status.

Section 2: Awareness of Lung Cancer Signs, Symptoms, and Risk Factors

Items were adapted from the Cancer Research UK Lung Cancer Awareness Measure Toolkit, version 2.1. 2011, which had shown good validity and reliability [10]. The Arabic translation of the questionnaire followed the Chapman and Carter translation procedure [29], which included expert forward translation, review by bilingual experts, and cultural adaptation to ensure clarity and appropriateness.

The signs and symptoms awareness subscale included 14 items, with responses scored as 1 for "yes" and 0 for "no or don't know." Those who answered "yes" were deemed to recognize the sign or symptom. Included signs and symptoms were unexplained weight loss, persistent chest infection (≥3 weeks), persistent cough (2 to 3 weeks or longer), persistent tiredness or lack of energy, persistent shortness of breath, persistent chest pain, persistent shoulder pain, coughing up blood, ache or pain when breathing, loss of appetite, painful cough, finger or nail changes, a high-pitched sound when breathing, and progression or new development in an existing cough. The signs and symptoms awareness score was calculated by summing the scores across all 14 items. Cronbach α for the lung cancer signs and symptoms awareness subscale in this study was 0.936.

The lung cancer risk factor awareness subscale consisted of 9 items scored on a 5-point Likert scale (1="strongly disagree," 2="disagree," 3="neutral or uncertain," 4="agree," and 5="strongly agree"). Participants who responded with "strongly agree" or "agree" were deemed to recognize the risk factor. Included risk factors were exposure to radon gas, exposure to passive smoking, previous cancer treatment, having a close relative with lung cancer, exposure to chemicals such as asbestos fibers, having a previous history of another cancer, such as head and neck cancer, exposure to air pollution, smoking, and having a history of chronic lung diseases such as chronic obstructive lung disease. A total risk factor awareness score was calculated for each participant by summing the scores across all 9 items, with higher scores indicating a higher level of awareness. Cronbach α for the lung cancer risk factors awareness subscale in this study was 0.901.

A total lung cancer awareness score was calculated by summing the total signs and symptoms awareness score and the total risk factors awareness score.

Section 3: Awareness of Lung Cancer Screening

Participants were asked whether they had ever heard about lung cancer screening and whether they believed that early detection of lung cancer improves cure and survival rates.

Data Analysis

Statistical analysis was performed using SPSS (version 27.0.1; IBM Corp). Descriptive statistics were used to summarize the characteristics of the study population. Inferential statistical tests, including 2-tailed independent samples *t* tests and 1-way ANOVA, were used to compare mean awareness scores across demographic subgroups. Multivariate linear regression was conducted to identify significant predictors of awareness scores related to lung cancer signs, symptoms, and risk factors, while multivariate logistic regression analysis was used to determine the predictors of awareness related to lung cancer screening. A *P* value of <.05 was considered statistically significant for all analyses.

Results

Descriptive Statistics

Table 1 summarizes the descriptive statistics of the study participants. The mean age of participants was 35.2 (SD 13.2) years. Most participants resided in an urban area, and most had completed either high school or a bachelor's degree or diploma. Overall, 39.6% (n=197) of participants were active smokers. The mean lung cancer risk factors awareness score was 33.0 (SD 5.6, range 9-45). The mean lung cancer signs and symptoms awareness score was 5.4 (SD 4.9, range 0-14). The mean total lung cancer awareness score was 38.4 (SD 8.4, range 9-59). In total, 41.6% (n=207) of the study participants had ever heard of lung cancer screening, while 79.3% (n=395) believed that lung cancer screening for early detection improves survival.

[a]Range for possible lung cancer risk factors awareness scores was 9-45.

[b]Range for possible lung cancer signs and symptoms awareness scores was 0-14.

[c]Range for possible total lung cancer awareness scores was 9-59.

Recognition of Lung Cancer Signs and Symptoms and Risk Factors

Table 2 summarizes the frequencies of recognition of the different lung cancer signs, symptoms, and risk factors. The most recognized signs and symptoms were coughing up blood (n=297, 59.6%) and pain when breathing (n=237, 47.6%), while the least recognized signs and symptoms were persistent shoulder pain (n=108, 21.7%) and changes in the shape of fingers or nails (n=122, 24.5%). The most recognized risk factors were being a smoker (n=403, 80.9%) and exposure to air pollution (n=339, 68.1%), while the least recognized risk factors were receiving treatment for a previous cancer (n=175, 35.1%) and having a past history of cancer (n=204, 41%).

Painful cough	228 (45.8)
Changes in the shape of the fingernails	122 (24.5)
High-pitched sound when breathing	205 (41.2)
Change in existing cough	203 (40.8)
Risk factors	
Exposure to radon gas	233 (46.8)
Passive cigarette smoke exposure	326 (65.5)
Past cancer treatment	175 (35.1)
Close relative with lung cancer	219 (44)
Exposure to chemicals (eg, asbestos)	249 (50)
Past history of cancer (eg, head and neck cancer)	204 (41)
Exposure to air pollution	339 (68.1)
Being a smoker	403 (80.9)
History of lung disease (eg, chronic obstructive pulmonary disease)	337 (67.7)

Association Among Risk Factors Awareness Score, Signs and Symptoms Awareness Score, Total Lung Cancer Awareness Score, and Demographic Characteristics

Table 3 summarizes lung cancer risk factors awareness score, signs and symptoms awareness score, and total lung cancer awareness score across the different demographic categories. Participants aged <35 years had a significantly higher level of awareness of lung cancer signs and symptoms (P=.04). Smokers had a significantly lower level of awareness of both lung cancer risk factors (P<.001) and signs and symptoms (P=.003). No significant differences in awareness of lung cancer risk factors and symptoms were observed across sex, place of residence, level of education, and marital status categories.

XSL•FO
RenderX

Table 3. Comparison of risk factors awareness scores, signs and symptoms awareness scores, and total lung cancer awareness scores across demographic categories.

Variable	Risk factors awareness score[a]		Signs and symptoms awareness score[b]		Total lung cancer awareness score[c]	
	Mean (SD)	*P* value	Mean (SD)	*P* value	Mean (SD)	*P* value
Age (years)		.34		.04		.06
≥35	32.7 (4.6)		5.0 (5.0)		37.7 (7.9)	
<35	33.2 (6.5)		5.9 (4.8)		39.1 (8.9)	
Gender		.18		.54		.19
Female	33.3 (4.7)		5.5 (4.7)		38.8 (7.7)	
Male	32.5 (6.9)		5.2 (5.4)		37.7 (9.4)	
Place of residence		.74		.15		.28
Rural	33.2 (6.5)		6.4 (5.2)		39.6 (9.3)	
Urban	32.9 (5.5)		5.3 (4.9)		38.3 (8.3)	
Level of education		.49		.17		.14
Elementary school	31.7 (6.4)		3.9 (5.2)		35.6 (9.6)	
High school	32.8 (4.9)		5.0 (5.1)		37.8 (8.2)	
Bachelor’s degree or diploma	33.1 (5.7)		5.7 (4.9)		38.8 (8.2)	
Postgraduate	33.3 (5.7)		5.6 (4.9)		38.9 (8.6)	
Marital status		.73		.33		.42
Single	33.1 (6.7)		5.7 (4.9)		38.8 (9.1)	
Married	32.9 (4.7)		5.2 (5.0)		38.1 (7.9)	
Smoking status		<.001		.003		<.001
Nonsmoker	33.9 (5.1)		6.0 (4.7)		39.9 (7.8)	
Smoker	31.6 (6.1)		4.6 (5.2)		36.2 (8.9)	

[a]Range for possible risk factors awareness scores was 9-45.

[b]Range for possible signs and symptoms awareness scores was 0-14.

[c]Range for possible total lung cancer awareness scores was 9-59.

Linear Regression Analysis

Table 4 summarizes the results of linear regression analysis used to predict risk factors awareness score, signs and symptoms awareness score, and total lung cancer awareness score. Having a bachelor’s degree or diploma level of education was significantly associated with a higher lung cancer signs and symptoms awareness score (β=1.89, 95% CI 0.23-3.55; *P*=.03). Being a smoker was significantly predictive of a lower total lung cancer awareness score (β=−3.74, 95% CI −5.29-−2.19; *P*<.001) as well as lower scores in both the risk factors (β=−2.23, 95% CI −3.29-−1.17; *P*<.001) and signs and symptoms (β=−1.51, 95% CI −2.42-−0.59; *P*<.001) domains. Having a friend or relative diagnosed with lung cancer was significantly predictive of higher symptom awareness scores (β=2.74, 95% CI 1.79-3.68; *P*<.001) and total lung cancer awareness scores (β=3.69, 95% CI 2.08-5.29; *P*<.001). There was no significant association between age, gender, place of residence, educational level, marital status, or having friends or relatives working in the health care sector, and total lung cancer awareness score.

[a]Range for possible risk factors awareness scores was 9-45. R^2=0.054; adjusted R^2=0.034; $F_{10,485}$=2.75; *P*=.003. All variance inflation factor values were <5, indicating an acceptable degree of collinearity.

[b]Range for possible signs and symptoms awareness scores was 0-14. R^2=0.093; adjusted R^2=0.074; $F_{10,485}$=4.96; *P*<.001. All variance inflation factor values were <5, indicating an acceptable degree of collinearity.

[c]Range for possible total lung cancer awareness scores was 9-59. R^2=0.095; adjusted R^2=0.076; $F_{10,485}$=5.05; *P*<.001. All variance inflation factor values were <5, indicating an acceptable degree of collinearity.

Logistic Regression Analysis

Table 5 summarizes the results of logistic regression analysis used to determine the factors predictive of the odds of recognition of lung cancer screening and believing that screening for early detection improves survival. Having a friend or relative diagnosed with lung cancer (odds ratio 2.90, 95% CI 1.87- 4.48; *P*<.001) and a higher symptom awareness score (odds ratio 1.10, 95% CI 1.06-1.15; *P*<.001) were significantly associated with higher odds of recognition of lung cancer screening. Having a higher educational level (Bachelor's degree or diploma: odds ratio 2.73, 95% CI 1.23-6.07; *P*=.01 vs postgraduate odds ratio 3.96, 95% CI 1.28-12.25; *P*=.02), a higher symptom awareness score (odds ratio 1.14, 95% CI 1.07-1.21; *P*<.001), and a higher risk factor awareness score (odds ratio 1.08, 95% CI 1.03-1.13; *P*<.001) were significantly associated with higher odds of believing that lung cancer screening is effective for early diagnosis and improving survival.

[a]Yes=1 and no=0. Hosmer-Lemeshow test: *P*=.82.

[b]Yes=1 and no or do not know=0. Hosmer-Lemeshow test: *P*=.05.

[c]Range for possible risk factors awareness scores was 9-45.

[d]Range for possible signs and symptom awareness scores was 0-14.

No significant association was found between age, gender, residence, marital status, smoking status, or having friends or family in the health care profession and the recognition of lung cancer screening or believing that screening is effective for enhancing survival through early diagnosis.

Discussion

Principal Findings

The primary objective of this study was to assess population-level awareness of lung cancer signs, symptoms, risk factors, and screening in Jordan. Our study revealed a lung cancer signs and symptoms awareness score of 5.4, indicating that, on average, participants could recognize approximately 5 to 6 signs or symptoms of lung cancer, reflecting a low level of awareness despite the relatively high incidence of lung cancer in Jordan. This score is comparable to the score observed in Nigeria (5) [13] but is significantly lower than the scores reported in the United Kingdom (8.78) [10] and Syria (8.63) [15]. This could be attributed to the lack of national awareness initiatives focused on lung cancer in Jordan and the nonspecific nature of lung cancer signs and symptoms, which could be easily

XSL•FO
RenderX

confused with symptoms or signs of other lung diseases that are prevalent in the country (eg, chronic obstructive pulmonary disease). The mean risk factor awareness score was 33.0 (SD 5.6), which is comparable to that reported in the United Kingdom (35.6) [10].

Smokers had a significantly lower level of awareness of both lung cancer risk factors (P<.001) and signs and symptoms (P=.003), aligning with most existing literature [8-10,15]. This association might reflect multiple factors. Smokers might be more likely to avoid or disengage from health awareness–promoting programs due to perceived threat or denial. In addition, tobacco smoking may be more common in populations with lower socioeconomic status and educational attainment, which might also limit their awareness. This finding elucidates the importance of focusing awareness programs on smokers due to their increased susceptibility to lung cancer.

Younger participants had greater awareness of lung cancer signs and symptoms, consistent with studies from Australia [8], Estonia [9], and Saudi Arabia [17], but divergent from findings from the United Kingdom [10], where older individuals exhibited greater awareness. This could be attributed to younger populations having greater access to social media and online information platforms, which promote their health awareness. However, in other countries, cancer awareness programs might focus on older populations due to their increased susceptibility.

Having a friend or relative diagnosed with lung cancer was significantly associated with a higher lung cancer signs and symptoms awareness score (β=2.74; P<.001), highlighting the influence of personal connections on an individual's perception of their own signs and symptoms.

Consistent with studies from high-, low-, and middle-income countries, smoking was the most recognized risk factor for lung cancer in Jordan, reflecting the global success of antitobacco campaigns in raising awareness of smoking as the leading preventable cause of lung cancer. Other risk factors (eg, exposure to asbestos fibers, radon gas, and receiving treatment for a previous cancer) were much less recognizable, likely due to their relative rarity compared to tobacco smoking. This highlights the importance of focusing health awareness programs on the most overlooked risk factors, particularly in populations with distinct exposures (eg, individuals whose occupations involve asbestos exposure).

Signs and symptoms recognition was variable across different countries. In Jordan and the United Kingdom, the most recognized symptom was coughing up blood [10], while shortness of breath was the most recognized symptom in Syria [15], Saudi Arabia [17], and Australia [8]. Change in a pre-existing cough and prolonged cough were the most commonly recognized in Palestine and Estonia, respectively [9,16]. This variability could be attributed to the varying prevalence of other respiratory diseases across the globe. In populations with a high prevalence of tuberculosis, for example, coughing up blood may be less recognized as a symptom of lung cancer, while in populations with a high prevalence of chronic obstructive pulmonary disease, shortness of breath and a change in a pre-existing cough may be less perceived as serious.

The least recognized lung cancer signs and symptoms in our study were persistent shoulder pain and changes in the shape of the nails. Unlike the more prominent respiratory symptoms (eg, coughing up blood), these symptoms may be seen as unrelated to the lungs in common perception; rather, they might be linked to the musculoskeletal system.

A small proportion of participants (n=207, 41.6%) in our study recognized the concept of lung cancer screening, while the majority (n=395, 79.3%) believed that screening improves survival. These results are comparable to findings from the United States [25], where 44% of participants had heard of and were aware of lung cancer screening, and 93% believed that catching it early results in better outcomes. The high proportion of participants believing that screening for early detection improves survival despite the low level of lung cancer screening recognition might be due to the common misconception that early diagnosis improves outcomes in all cancers, while the low level of recognition of lung cancer screening might be due to its relative novelty compared to screening for other cancers (eg, breast cancer). Having a friend or relative diagnosed with lung cancer was associated with higher odds of recognition of lung cancer screening, again highlighting the importance of close people's experiences in perceptions of an individual's own health.

Higher lung cancer awareness scores were significantly associated with higher odds of recognizing lung cancer screening and believing that it improves survival, highlighting the potential role of improving lung cancer awareness in promoting positive attitudes toward lung cancer screening.

To the best of our knowledge, this is the first study to assess population awareness of lung cancer symptoms, risk factors, and screening in the Hashemite Kingdom of Jordan, and this is the first study to identify and quantify that having a relative or friend diagnosed with lung cancer increases awareness of lung cancer signs, symptoms, and screening. Further research should be done to identify effective interventions to improve knowledge and awareness of lung cancer, minimize diagnostic delay, and improve early detection and participation rates in lung cancer screening, especially among high-risk groups. In addition, further studies are warranted to explore characteristics of patients with lung cancer in Jordan, including involvement in screening programs, stage at diagnosis, and unique exposures.

Limitations

Several limitations should be acknowledged when considering the findings of our study. The use of an online form to collect data excludes individuals with no access to social media or the internet, which might induce selection bias, resulting in an overestimation of awareness levels. This approach may also have introduced bias toward younger participants, as they are more likely to use social media, thereby limiting the representation of older adults who are at higher risk of developing lung cancer. The small sample size limits the generalizability and the representativeness of our sample. Participants' governorates of residence were not recorded, limiting the ability to determine geographic representativeness and identify potential regional variation in lung cancer awareness across Jordan. The reliance on a self-administered

XSL•FO
RenderX

questionnaire and the lack of concise explanations limited deeper exploration of participants' understanding. Moreover, the inability to completely exclude health care professionals might bias the results toward higher awareness levels. Our study had a pure quantitative design and lacked a qualitative approach to evaluate lung cancer awareness, depended on recognition rather than recall, and used closed-ended rather than open-ended questions. Our study included Jordanian adults of all ages, with no focus on older people despite their higher susceptibility.

Conclusions

Our study revealed a low level of awareness of lung cancer signs and symptoms, risk factors, and screening. Higher awareness was associated with younger age, having a friend or relative diagnosed with lung cancer, while smoking was linked with a lower level of awareness. These findings underscore the importance of implementing targeted, age-inclusive public health strategies to improve lung cancer awareness and promote early detection, particularly among high-risk groups.

Abstract

Background: Telehealth use expanded rapidly during the COVID-19 pandemic and has since become integrated into routine oncology care. However, clinician experiences and confidence with telehealth may vary across oncology subspecialties, and these differences remain incompletely characterized.

Objective: This study aimed to evaluate telehealth perceptions, decision-making factors, and confidence across oncology clinicians from multiple specialties at a single academic cancer center.

Methods: We conducted a cross-sectional survey of oncology clinicians at the University of California San Diego Moores Cancer Center. A 27-item Qualtrics questionnaire was distributed by email to attending physicians, fellows, and advanced practice providers across surgical, medical, radiation, and palliative oncology. Survey domains included telehealth coordination, technical quality, communication effectiveness, confidence in remote physical examination, and factors influencing visit modality selection. Quantitative responses were summarized descriptively, and open-ended responses underwent thematic analysis.

Results: Among 114 invited clinicians, 57 (50%) complete responses were analyzed. Among 57 respondents, 86% (n=49) were physicians. Specialties included surgical oncology (n=21, 36.8%), medical oncology (n=18, 31.6%), radiation oncology (n=16, 28.1%), and palliative care (n=2, 3.5%). Telehealth coordination was rated easy or very easy by 78.9% (n=45) of clinicians. Audio and video quality were rated good or very good by 71.9% (n=41) and 57.9% (n=33), respectively. Technical issues prompted at least occasional conversion to audio-only visits for 86% (n=49) of respondents, and 17.5% (n=10) of clinicians reported frequent conversion. Communication satisfaction was high (n=48, 84.2%), yet only 50.9% (n=29) reported moderate or high confidence in performing a virtual physical examination. The need for physical examination (n=53, 93%) and patient travel distance (n=45, 78.9%) were the most influential factors in offering telehealth visits. Confidence varied by specialty and clinical phase: moderate or high confidence was reported by surgical oncology clinicians in 52.4% (11/21) of preoperative and 71.4% (15/21) of postoperative responses, by medical oncology clinicians in 77.8% (14/18) of prechemotherapy and 76.5% (13/17) of during chemotherapy responses, and by radiation oncology clinicians in 87.5% (14/16) of preradiation and 93.8% (15/16) of during radiation responses.

Conclusions: Oncology clinicians reported generally positive experiences with telehealth, although confidence and use patterns varied across specialties and phases of care. Telehealth is viewed as a complementary modality when physical examination is not essential. Improvements in technical reliability and interpreter integration may enhance equitable access and support continued telehealth use in oncology care.

Introduction

Telehealth use expanded rapidly during the COVID-19 pandemic and has remained integrated into many areas of routine clinical care [1-3]. In oncology, telehealth has particular appeal because patients often require longitudinal care, frequent follow-up, multidisciplinary coordination, and review of laboratory, imaging, pathology, and treatment-related information. For selected visits, virtual care may reduce travel burden, decrease time away from work or caregiving responsibilities, and improve access for patients who live far from cancer centers [1,2].

Despite these advantages, telehealth in oncology is not uniformly applicable across all clinical settings. Cancer care often depends on physical examination, assessment of treatment toxicity, symptom evaluation, shared decision-making, and coordination across medical, surgical, radiation, and supportive care teams. The relative importance of these factors may differ substantially by oncology subspecialty and by phase of care. For example, surgical oncologists may have different levels of confidence in telehealth before versus after an operation, whereas medical and radiation oncologists may use telehealth differently during treatment planning, treatment monitoring, and survivorship care. Prior studies have described telehealth implementation in cancer centers, transition to telehealth in surgical practice, and clinician attitudes toward telehealth in multidisciplinary cancer care, but specialty-specific clinician confidence across different phases of oncology care remains incompletely characterized [4-6].

Understanding clinician experience is important because clinicians play a central role in determining whether telehealth is offered, whether it is considered clinically appropriate, and how technical or communication barriers are managed. Clinician confidence may be shaped by visit type, need for physical examination, institutional technology, interpreter availability, patient age, and other patient-specific factors. Broader telehealth use data also suggest that adoption and experience may be shaped by patient characteristics, clinical setting, and health system infrastructure [7]. These issues are especially relevant because telehealth may improve access for some patients while potentially widening disparities for others if language, technology, or workflow barriers are not addressed.

However, limited data describe how oncology clinicians across different specialties perceive telehealth, what factors influence their decision to offer virtual visits, and how confident they are using telehealth during different phases of cancer care. To address this gap, we conducted a cross-sectional survey of medical, surgical, radiation, and palliative oncology clinicians at a single academic cancer center. We evaluated clinician experiences with telehealth, factors influencing visit modality selection, perceived barriers and facilitators, and confidence in telehealth across specialty-specific clinical scenarios.

Methods

Study Design and Setting

We conducted a cross-sectional survey study of oncology clinicians at the University of California San Diego Moores Cancer Center, a National Cancer Institute–designated academic cancer center. The survey was designed to assess clinician experiences with telehealth across multiple oncology subspecialties, including perceived visit quality, technical challenges, communication, confidence in remote assessment, and factors influencing visit modality selection.

Participants and Recruitment

Medical, surgical, palliative, and radiation oncology physicians, fellows, and advanced practice clinicians were invited to participate by email. The survey was distributed using a combination of individual provider email lists and specialty or institutional email distribution lists. A total of 114 providers were invited, including 32 (28.1%) surgical oncology clinicians, 49 (43%) medical oncology clinicians, 26 (22.8%) radiation oncology clinicians, and 7 (6.1%) palliative care clinicians. The survey was open from October 1, 2024, through January 31, 2025. Participation was voluntary, and no incentive was provided. Responses were treated confidentially and reported in aggregate. The primary analytic cohort included respondents with complete survey data for the main telehealth experience items. Blank or incomplete survey records were excluded from the primary analysis.

Telehealth Context

At the time of the survey, telehealth visits at our institution were primarily conducted through Epic or MyChart video visits. Telephone visits were used when audiovisual connection could not be established or when technical issues required conversion from video to audio-only care. Survey items therefore focused primarily on video-based telehealth, while also capturing the frequency of conversion to audio-only visits due to technical difficulties.

Survey Instrument Development

The survey instrument was developed by the study investigators and was administered using Qualtrics. The survey was generally inspired by previously published surveys evaluating telehealth experiences, satisfaction, communication, and technology use [8-11]. Items were newly adapted for oncology-specific workflows, including visit modality decision-making, perceived adequacy of remote physical examination, and clinician confidence across phases of cancer care, such as preoperative and postoperative care, chemotherapy, and radiation treatment. The final instrument included 27 closed- and open-ended items and is provided as Multimedia Appendix 1. The survey was reviewed by study investigators with expertise in oncology, telehealth, and cancer care delivery for face validity, clinical relevance, and clarity before distribution. Formal pilot testing, cognitive interviewing, psychometric validation, and reliability testing were not performed.

Quantitative Analysis

Descriptive statistics were used to summarize respondent characteristics and survey responses. Categorical variables were reported as counts and percentages. Continuous variables were summarized using mean and SD or median and IQR, as appropriate. For key proportions, 95% CIs were calculated using the Wilson method. Likert-scale responses were collapsed for selected analyses to improve interpretability; responses

XSL•FO
RenderX

indicating at least moderate confidence were grouped as moderate or high confidence.

Exploratory chi-square tests were used to compare collapsed confidence proportions across specialty groups, McNemar tests were used for paired within-specialty comparisons across phase-of-care items, and a Friedman test was used to evaluate clinician likelihood of offering telehealth across increasing patient age categories. Given the modest sample size and exploratory design, statistical comparisons were interpreted cautiously.

Qualitative Analysis

Open-ended responses were analyzed using manual inductive coding informed by grounded theory principles. Two investigators independently reviewed and coded the open-ended responses. Codes were compared, and disagreements were resolved through consensus.

Recurring concepts related to telehealth decision-making, barriers, facilitators, and clinician experience were grouped into themes when similar concepts were identified across responses from at least 2 clinicians. Themes were then reviewed and refined to ensure that they reflected the underlying responses and were clinically interpretable. Representative quotations were selected to illustrate major themes. Qualitative analysis was conducted using exported survey responses rather than dedicated qualitative analysis software.

Ethical Considerations

This study was approved by the University of California San Diego Institutional Review Board (IRB 810808). Consent information was included within the survey, and respondents were required to proceed through the consent portion before accessing the survey. Participation was voluntary, no incentive was provided, and responses were treated confidentially and reported in aggregate.

Results

Respondent Characteristics

A total of 114 clinicians were invited to participate, including 32 (28.1%) surgical oncology clinicians, 49 (43%) medical oncology clinicians, 26 (22.8%) radiation oncology clinicians, and 7 (6.1%) palliative care clinicians. Overall, 65 (50%) survey records were captured, of which 57 (87.7%) were complete and included in the primary analysis, yielding a complete response rate of 50% (57/114). Eight blank or incomplete records were excluded.

Among the 57 respondents, 49 (86%) were physicians and 8 (14%) were advanced practice clinicians. Respondents included surgical oncology clinicians (21/57, 36.8%), medical oncology clinicians (18/57, 31.6%), radiation oncology clinicians (16/57, 28.1%), and palliative care clinicians (2/57, 3.5%). Specialty-specific complete response rates were 65.6% (21/32) for surgical oncology, 36.7% (18/49) for medical oncology, 61.5% (16/26) for radiation oncology, and 28.6% (2/7) for palliative care. Mean respondent age was 46.3 (SD 8.7) years. Most respondents were male (34/57, 59.6%) and non-Hispanic (54/57, 94.7%). Full demographic and professional characteristics are shown in Table 1.

Medical oncology	18 (31.6)
Palliative care	2 (3.5)
Radiation oncology	16 (28.1)
Surgical oncology	21 (36.8)

Experience With Telehealth

Clinician experience with telehealth is summarized in Figure 1 and Table 2. In Figure 1, responses were reported on 5-point Likert scales. For coordination, audio quality, video quality, communication, and physical examination confidence, higher scores indicated more favorable responses. For audio-only conversion, higher scores indicated more frequent conversion. Most respondents reported that coordinating a telehealth visit was easy or very easy (45/57, 78.9%; 95% CI 66.7% - 87.5%). Audio quality was rated good or very good by 41 of 57 (71.9%; 95% CI 59.2% - 81.9%) respondents, while video quality was rated good or very good by 33 of 57 (57.9%; 95% CI 45.0% - 69.8%) respondents. Technical issues were common: 49 of 57 (86%; 95% CI 74.7% - 92.7%) clinicians reported at least occasional conversion to audio-only visits due to audiovisual problems, including 10 (17.5%; 95% CI 9.8% - 29.4%) clinicians who reported frequent conversion.

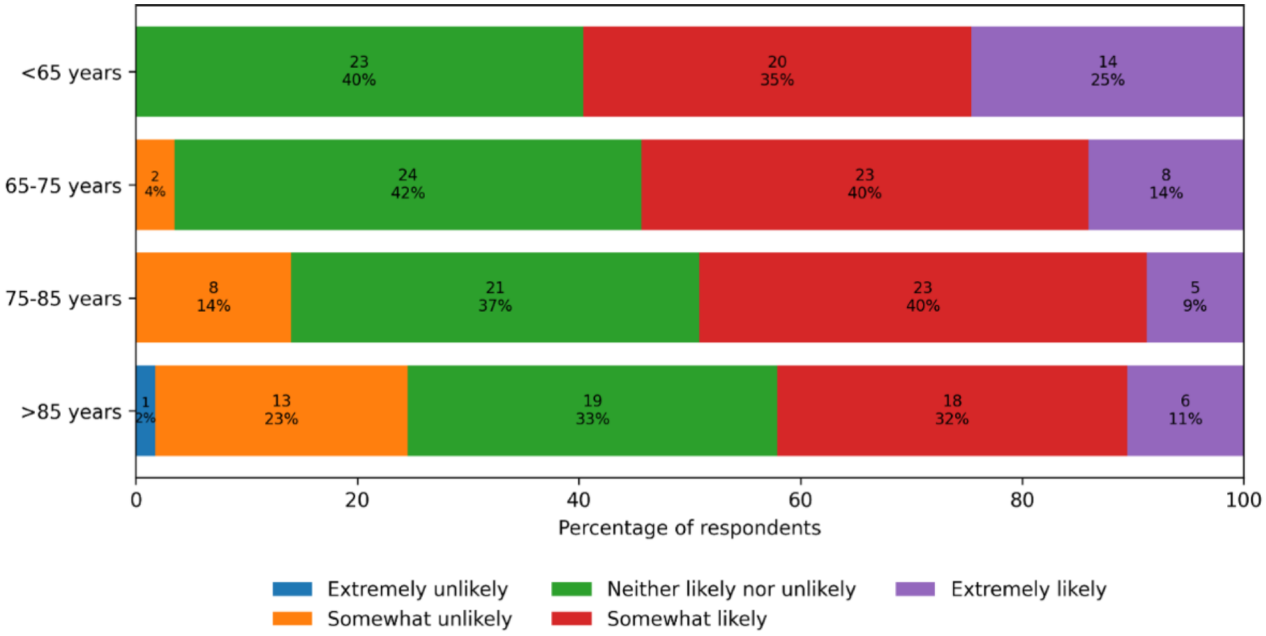
Table . Detailed survey responses for telehealth experience and visit modality decision factors[a].

Domain or survey item	Response summary	Responses, n (%)	95% CI
Telehealth experience (n=57)			
Telehealth coordination	Easy or very easy	45 (78.9)	66.7 - 87.5
Audio quality	Good or very good	41 (71.9)	59.2 - 81.9
Video quality	Good or very good	33 (57.9)	45.0 - 69.8
Audio-only conversion due to technical issues	Occasionally, frequently, or very frequently	49 (86)	74.7 - 92.7
Patient communication by telehealth	Somewhat or extremely satisfied	48 (84.2)	72.6 - 91.5
Confidence in telehealth physical examination	Moderate or high confidence	29 (50.9)	38.3 - 63.4
Visit modality decision factors (n=57)			
Reviewed patient address before visit	Yes	22 (38.6)	27.1 - 51.6
Patient distance influenced decision to offer telehealth	Yes	45 (78.9)	66.7 - 87.5
Need for physical examination influenced decision to offer telehealth	Yes	53 (93)	83.3 - 97.2
Race or ethnicity influenced decision to offer telehealth	Yes	0 (0)	0.0 - 6.3
Primary language influenced decision to offer telehealth	Yes	25 (43.9)	31.8 - 56.7
Interpreter availability and coordination for telehealth	Somewhat or extremely satisfied	12 (21.1)	12.5 - 33.3
Interpreter availability and coordination for telehealth	Somewhat or extremely dissatisfied	31 (54.4)	41.6 - 66.6
Likelihood of offering telehealth by patient age (y), (n=57)			
Patients younger than 65 years	Somewhat or extremely likely	34 (59.6)	46.7 - 71.4
Patients aged 65-75 years	Somewhat or extremely likely	31 (54.4)	41.6 - 66.6
Patients aged 75-85 years	Somewhat or extremely likely	28 (49.1)	36.6 - 61.7
Patients older than 85 years	Somewhat or extremely likely	24 (42.1)	30.2 - 55.0
Specialty-specific confidence in telehealth[b]			
Surgical oncology: preoperative (n=21)	Moderate or high confidence	11 (52.4)	32.4 - 71.7
Surgical oncology: postoperative (n=21)	Moderate or high confidence	15 (71.4)	50.0 - 86.2
Medical oncology: prechemotherapy (n=18)	Moderate or high confidence	14 (77.8)	54.8 - 91.0
Medical oncology: during chemotherapy (n=17)	Moderate or high confidence	13 (76.5)	52.7 - 90.4
Radiation oncology: preradiation (n=16)	Moderate or high confidence	14 (87.5)	64.0 - 96.5
Radiation oncology: during radiation (n=16)	Moderate or high confidence	15 (93.8)	71.7 - 98.9

[a]Percentages may not total 100 due to rounding. 95% CIs were calculated using the Wilson method. Moderate or high confidence includes responses indicating at least moderate confidence.

[b]For specialty-specific confidence items, “not applicable” responses were excluded from denominators.

XSL•FO
RenderX



Despite these technical limitations, communication satisfaction was high. Of 57 respondents, 48 (84.2%; 95% CI 72.6% - 91.5%) were somewhat or extremely satisfied with patients' ability to communicate questions and concerns by telehealth. In contrast, confidence in the remote physical examination was more limited: 29 of 57 (50.9%; 95% CI 38.3% - 63.4%) respondents reported moderate or high confidence in performing a physical examination by telehealth, while 28 of 57 (49.1%; 95% CI 36.6% - 61.7%) respondents reported being not confident or not very confident.

Decision Factors for Offering Telehealth

Factors influencing clinicians' decisions to offer telehealth are summarized in Table 2. The need for a physical examination was the most frequently reported factor influencing visit modality selection, cited by 53 of 57 (93%; 95% CI 83.3% - 97.2%) clinicians. Patient distance from clinic also strongly influenced modality selection, cited by 45 of 57 (78.9%; 95% CI 66.7% - 87.5%) clinicians. Although distance influenced decision-making for most respondents, only 22 of 57 (38.6%; 95% CI 27.1% - 51.6%) clinicians reported reviewing a patient's address before a scheduled visit.

Patient age also influenced telehealth decision-making (Figure 2). The proportion of clinicians reporting that they were somewhat or extremely likely to offer telehealth declined across increasing age categories: 34 of 57 (59.6%; 95% CI 46.7% - 71.4%) for patients younger than 65 years, 31 of 57 (54.4%; 95% CI 41.6% - 66.6%) for patients aged 65 to 75 years, 28 of 57 (49.1%; 95% CI 36.6%-61.7%) for patients aged 75 to 85 years, and 24 of 57 (42.1%; 95% CI 30.2% - 55.0%) for patients older than 85 years. This decline across age categories was statistically significant in exploratory ordinal analysis (Friedman test: $P<.001$). No clinician reported that race or ethnicity influenced their decision to offer telehealth. In contrast, 25 of 57 (43.9%; 95% CI 31.8% - 56.7%) clinicians reported that a patient's primary language influenced their decision to offer telehealth.

Figure 2. Likelihood of offering telehealth by patient age group. Bars show the distribution of clinician responses across likelihood categories for each patient age group. Numbers within bars indicate respondent counts and percentages. Percentages may not total 100 due to rounding.

Interpreter-related responses were less favorable than other telehealth domains. Only 12 of 57 (21.1%; 95% CI 12.5% - 33.3%) respondents reported being somewhat or extremely satisfied with obtaining an interpreter for telehealth visits, while 31 of 57 (54.4%; 95% CI 41.6% - 66.6%) respondents reported being somewhat or extremely dissatisfied. Open-ended responses emphasized that interpreter integration into telehealth visits was technically and logistically challenging and that in-person interpretation was often preferred for complex conversations.

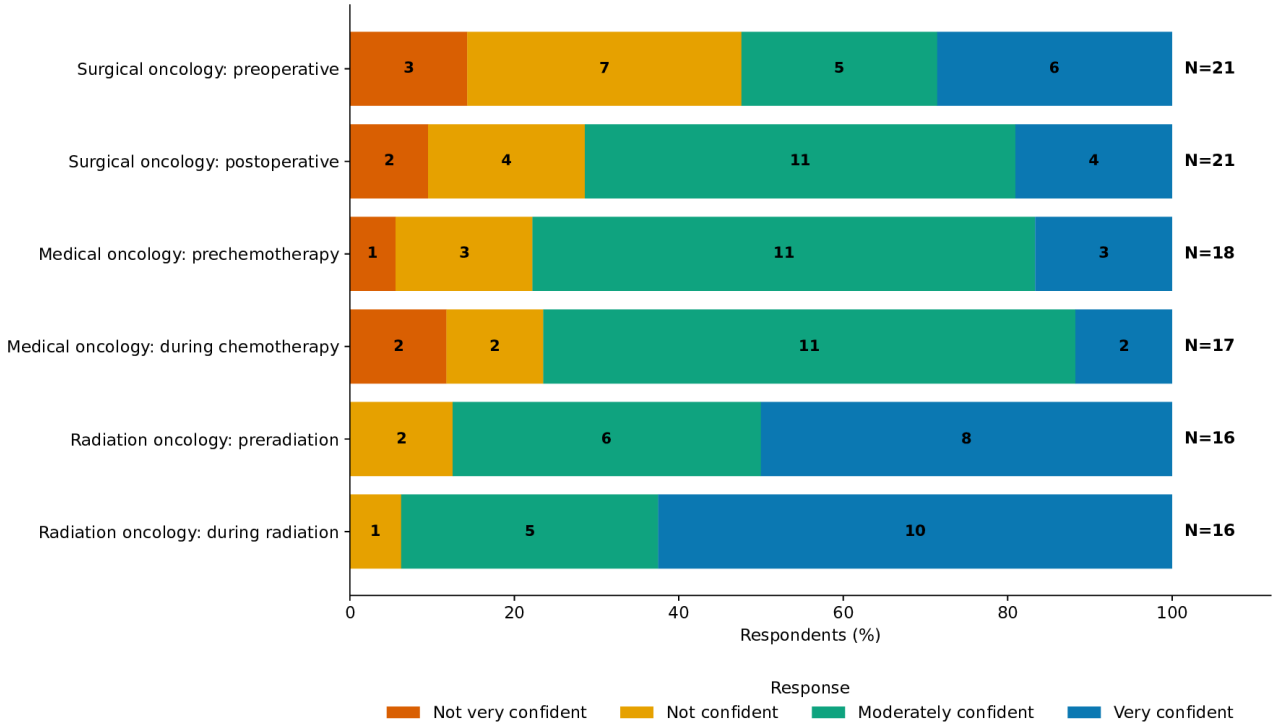
Qualitative Themes

Thematic analysis of open-ended responses identified several recurring themes related to telehealth decision-making. When discussing patient distance from the clinic, clinicians emphasized travel burden, cost and time toxicity, access to care, patient preference, and clinical appropriateness. Telehealth was viewed as particularly useful when the visit involved review of laboratory results, imaging, treatment planning, routine follow-up, or postoperative care without a need for physical examination. Representative comments included that telehealth can reduce unnecessary travel and improve follow-up access for patients who live far from the cancer center.

When discussing primary language, clinicians described interpreter use during telehealth visits as cumbersome, time-consuming, and technically unreliable. Several respondents stated that communication was easier when interpreters were present in person, particularly for visits requiring complex counseling or visual explanations. These themes are summarized with representative quotations in Table 3.

XSL•FO
RenderX

Table . Thematic analysis of qualitative responses regarding patient distance and primary language as factors influencing the decision to offer telehealth.



Theme summary	Representative quotes
Does a patient's distance from your clinic influence your decision to offer a telehealth visit?	
Cost, time, and financial toxicity	• "Telehealth avoids the ridiculous parking fee the university charges our patients." • "Unnecessary time spent in a car or bus can be avoided."
Clinical judgment and visit type	• "I feel more confident in-person for breast patients but will offer telehealth for initial consults if travel is difficult." • "A physical exam is not necessary and they live far away, I offer a telehealth visit."
Access, compliance, and equity	• "I want their distance to not be a barrier for follow-up care." • "It allows better access to care and increases patient compliance."
Legal and geographic considerations	• "I was informed that the patient needs to legally be in California at the time of telehealth visit."
Patient preference and flexibility	• "Patients often try to switch their visit to telemed due to distance or traffic." • "If patient mentions travel time, I consider telehealth."
Does a patient's primary language influence your decision to offer a telehealth visit?	
Interpreter use is challenging via telehealth	• "Translation services are spotty for telehealth visits at best, and rates of technical difficulties are much higher." • "I need a translator for telehealth so find it very difficult to do that."
Preference for in-person interpretation	• "Interpreters are best in person with actual live humans." • "Understanding each other is much easier if at least some of the people involved are in person."
Communication barriers and patient comprehension	• "I often like to draw figures/pictures for my patients which help them better understand certain concepts." • "More difficult to coordinate translator on video. Communication and connection issues make it hard."
Impact on visit quality and duration	• "It takes longer. Difficult to use an interpreter via telehealth." • "It is cumbersome to request an interpreter over telephone and/or video."
Workarounds and limitations	• "If the patient has a family member who is willing/able to translate, then I am more keen on using a telehealth visit." • "I have not found a good way to do video telehealth with interpreters."

Experience by Specialty and Phase of Care

Confidence in telehealth varied across specialty-specific clinical scenarios (Figure 3). Among surgical oncology clinicians, 11 of 21 (52.4%; 95% CI 32.4% - 71.7%) reported moderate or high confidence in assessing patients by telehealth in the preoperative setting, compared with 15 of 21 (71.4%; 95% CI 50.0% - 86.2%) in the postoperative setting. This within-specialty increase was descriptive and was not statistically significant in paired exploratory analysis (McNemar test: P=.39).

XSL•FO
RenderX

Figure 3. Clinician confidence in telehealth by oncology specialty and phase of care. Bars represent the distribution of provider responses for each specialty-specific clinical scenario. Numbers within bars indicate respondent counts, and denominators on the right indicate the number of applicable respondents for each scenario. “Not applicable” responses were excluded from denominators.

Among medical oncology clinicians, 77.8% (14/18; 95% CI 54.8% - 91.0%) reported moderate or high confidence in assessing patients by telehealth before chemotherapy. For assessment while receiving chemotherapy, 76.5% (13/17; 95% CI 52.7% - 90.4%) of respondents with nonmissing and applicable responses reported moderate or high confidence. Among radiation oncology clinicians, 87.5% (14/16; 95% CI 64.0% - 96.5%) reported moderate or high confidence before radiation therapy and 93.8% (15/16; 95% CI 71.7% - 98.9%) reported moderate or high confidence during radiation therapy.

In exploratory comparisons across specialty-specific pretreatment scenarios, moderate or high confidence differed across surgical, medical, and radiation oncology clinicians (11/21, 52.4% vs 14/18, 77.8% vs 14/16, 87.5%; chi-square test: P=.049). Differences across postoperative, during chemotherapy, and during radiation therapy scenarios were not statistically significant (15/21, 71.4% vs 13/17, 76.5% vs 15/16, 93.8%; chi-square test: P=.23).

Overall Experience

Overall, clinicians viewed telehealth as a useful adjunct to in-person oncology care when used for clinically appropriate visits. Commonly cited advantages included improved access, reduced travel burden, greater flexibility, and support for longitudinal follow-up. Commonly cited areas for improvement included audiovisual reliability, interpreter integration, patient preparation and expectations, and improvements to the clinician-facing telehealth platform. Clinicians consistently emphasized that telehealth should complement rather than replace in-person care, particularly when physical examination or complex communication is required.

Discussion

Principal Findings

In this cross-sectional survey of oncology clinicians at an academic cancer center, telehealth was generally viewed as a useful adjunct to traditional in-person care. Clinicians reported high satisfaction with visit coordination and patient communication but identified audiovisual reliability, interpreter integration, and limitations of remote physical examination as important barriers. Confidence in telehealth varied by specialty and phase of care, reflecting differences in clinical workflows and the role of physical examination across surgical, medical, and radiation oncology.

Our findings suggest that clinician confidence with telehealth is context dependent rather than uniform across oncology care. Surgical oncology clinicians reported greater confidence in postoperative than preoperative telehealth assessment, which likely reflects the greater need for physical examination, procedural planning, and initial treatment counseling before surgery. In contrast, medical and radiation oncology clinicians reported relatively high confidence across treatment-related scenarios, where telehealth may be particularly useful for counseling, reviewing laboratory or imaging results, symptom assessment, and longitudinal follow-up. These findings support the concept that telehealth is best viewed as a modality matched to visit type rather than a universal replacement for in-person oncology care.

XSL•FO
RenderX

Telehealth Decision-Making and Workflow Implications

The need for physical examination and patient distance from the clinic were the most influential factors in clinicians' decisions to offer telehealth. This reflects a practical balance between clinical appropriateness and patient access. Clinicians described telehealth as a way to reduce travel burden, time toxicity, parking and transportation costs, and barriers to follow-up for patients living far from the cancer center. However, only a minority of respondents reported routinely reviewing a patient's address before a scheduled visit, suggesting that opportunities exist to make distance-informed telehealth triage more systematic.

Institutions could use these findings to develop clearer workflows for identifying visits that are well suited for telehealth. Examples include standardized visit-type criteria, previsit screening for the need for physical examination, workflows that identify patients with long travel distances, and patient-facing instructions to improve technical readiness before the visit. Embedding these processes into scheduling and electronic health record workflows may help reduce variability in how telehealth is offered while preserving clinician judgment.

Equity Considerations

Although telehealth has the potential to improve access, our findings also highlight equity concerns. Clinicians were less likely to favor telehealth for older patients and reported substantial difficulty using interpreter services during telehealth visits. These findings are consistent with prior work showing that telehealth adoption may vary by patient characteristics, language, technology access, and health system infrastructure [7,12]. Without intentional workflows, telehealth could inadvertently widen disparities among patients who already face barriers to cancer care.

Several practical interventions may mitigate these risks. Institutions could improve interpreter integration into video visit platforms, develop workflows for previsit interpreter scheduling, provide technical support before visits, and offer patient education materials in multiple languages. For older patients or patients with limited digital access, previsit test calls, caregiver inclusion, simplified login processes, and hybrid models that combine in-person and telehealth visits may help preserve access without compromising care quality. These strategies may be especially important in oncology, where complex counseling and shared decision-making are common.

Comparison With Prior Literature

Our results align with prior studies demonstrating broad acceptance of telehealth in cancer care while also identifying persistent technical, communication, and patient safety concerns [8,12,13]. Similar to prior work, we found that telehealth use depends on clinical context and specialty-specific workflows [6,13]. Our study adds to this literature by comparing clinician experiences across oncology subspecialties and by evaluating specialty-specific confidence across phases of cancer care. This provides a more nuanced view of where providers perceive telehealth to be most clinically useful and where in-person visits remain important.

Limitations

This study has several limitations. First, it was conducted at a single academic cancer center, and findings may not generalize to community practices, nonacademic settings, or institutions with different telehealth infrastructure. Second, although we were able to calculate an overall complete response rate of 50% (57/114), response rates varied by specialty, and nonresponse bias remains possible. Third, although the survey was reviewed by investigators for face validity and clinical relevance, it did not undergo formal psychometric validation, cognitive testing, or reliability testing. Fourth, subgroup sizes were modest, particularly for palliative care and for specialty-specific phase-of-care analyses, and exploratory statistical comparisons should therefore be interpreted cautiously.

Fifth, the study focused on clinician experience and did not include patient perspectives, objective visit outcomes, completion rates, or measures of clinical quality. Sixth, tumor-site specialty was not collected. This is important because the role of physical examination and perceived appropriateness of telehealth may differ by disease site, such as breast, genitourinary, gastrointestinal, thoracic, or central nervous system malignancies. Finally, telehealth workflows and reimbursement policies continue to evolve, and clinician experiences may change as technology, interpreter integration, and institutional practices improve.

Future Directions

Future studies should validate these findings in larger, multi-institutional cohorts and should include both clinician and patient perspectives. Additional work should evaluate disease site–specific telehealth appropriateness, identify visit types that can be safely and effectively conducted virtually, and test interventions to improve interpreter integration, technical reliability, and equitable access. As telehealth reimbursement policies and digital infrastructure continue to evolve, understanding clinician-level experiences across oncology specialties may help guide workflows that maintain care quality while improving patient access.

Conclusions

Telehealth is a useful adjunct to in-person oncology care across medical, surgical, and radiation oncology, but clinician confidence and perceived utility vary by specialty and phase of care. Our findings support using telehealth as a complementary care modality when physical examination is not essential and when virtual visits can reduce travel burden or improve access. Further integration of telehealth into oncology care will require intentional workflows, improved audiovisual reliability, better interpreter integration, and attention to equitable access for all patients.

We sincerely thank the authors [1] for their thoughtful engagement with our article [2] and for raising important questions regarding the clinical accuracy of AI-generated health information. We welcome this opportunity for scientific dialogue.

Clinical accuracy is unquestionably an essential dimension of generative AI in health care. The letter and our original article illuminate different dimensions of the same phenomenon. The letter examines the clinical validity and completeness of AI-generated information, whereas our study examined how that information is framed, enacted, and experienced within a situated interaction concerning sexual health after prostate cancer. These perspectives are complementary because they address different dimensions of AI-mediated supportive care.

This distinction was fundamental to the design of our study. As stated in the original article [2], the study was "not designed to evaluate clinical effectiveness, safety, or generalizable performance of chatbots," but instead sought to examine "how responses are framed and experienced in sexual minority contexts." Consistent with contemporary netnographic scholarship, our analytical interest, therefore, lies in the interaction itself rather than in validating the medical correctness of individual chatbot responses [3-5].

The observations presented in the letter [1] illustrate this distinction. The authors note, for example, that none of the chatbots challenged the hypothetical assumption that both radical prostatectomy and radiotherapy would likely include hormonal therapy. We agree that this represents an important clinical observation and precisely the type of finding that a benchmarking study is designed to identify. Within our study [2], however, the hypothetical patient scenario functioned as a standardized interactional prompt rather than a test of guideline concordance. It also highlights an important feature of real-world human-AI interaction: people seeking health information may formulate prompts from incomplete or inaccurate understandings of their condition or treatment. Whether generative AI identifies, challenges, or reproduces such assumptions represents an important question for future research.

Similarly, the observations concerning contextual inaccuracies reflect these complementary perspectives. Our study reported such observations descriptively because they formed part of the interactional experience under investigation rather than constituting outcome measures of clinical reliability.

We, therefore, do not view the letter as challenging the central contribution of our study. Rather, it complements that contribution by examining another important dimension of AI-mediated supportive care. Clinical benchmarking establishes whether AI-generated information is medically reliable. Interpretive inquiry examines how that information becomes meaningful through interaction. Together, these perspectives provide a more comprehensive understanding of generative AI as a digital adjunct in supportive cancer care.

Christiansen and colleagues [1] make a welcome contribution by shifting attention from correctness to interactional framing in a group whose informational needs remain underaddressed. The authors state clearly that they did not set out to assess clinical effectiveness or safety, and they caution in their limitations that the absence of obvious fabrication should not be read as evidence of accuracy. Reading the published outputs from a urological perspective, we offer three observations that may refine future work.

First, the initial prompt states that both radiotherapy and surgery would likely include hormonal therapy. This is a patient utterance, not a claim by the authors, and patients do hold such beliefs. Androgen deprivation is standard in combination with radiotherapy for intermediate- and high-risk disease, but neoadjuvant androgen deprivation around radical prostatectomy is not recommended [2]. What is notable is the response: none of the four systems queried or corrected it, and all four built counseling based on it. Silent acceptance of a premise that is not guideline-concordant is, in our view, among the most consequential failure modes in patient-facing use, and it falls outside the pragmatic accuracy definition used here.

Second, the two treatment arms differ categorically for receptive anal intercourse: after prostatectomy, the gland is absent and prostate-mediated pleasure is permanently lost [3], whereas after radiotherapy, the gland remains in situ and rectal toxicity becomes the limiting factor. Comparative data bear this out: climacturia is far commoner after prostatectomy and anodyspareunia after radiotherapy [4]. Only one output made this explicit. Another described treatment as affecting the sensitivity and function of the prostate, which does not apply once the gland has been removed. The passage quoted twice as an exemplar of compassionate precision proposes a 4‐ to 6-week interval for resuming receptive anal intercourse without reference to anodyspareunia, mucosal fragility, or proctopathy after irradiation.

Third, the statement that no hallucinated content was identified sits alongside a reported support group link misattributed to a Swedish service. We would classify that as a contextual hallucination rather than as a separate category, and the platform responsible is not named. A further unflagged example appears in Multimedia Appendix 2 in Christiansen et al [1], where a hereditary cancer organization is presented as a resource for LGBTQ+ (lesbian, gay, bisexual, transgender, queer) individuals with cancer.

These observations do not undermine the authors' interpretive aim but indicate where a complementary design would add value. We suggest three additions: (1) a prespecified urology-anchored content checklist scored independently by two clinicians, covering the prostatectomy versus radiotherapy distinction, anodyspareunia and rectal toxicity, climacturia, penile length change, and the expected duration and reversibility of androgen deprivation; (2) deliberate inclusion of premises that are not guideline-concordant, with correction rate as an explicit end point; and (3) per-model reporting of every identified error, with exact query dates, session conditions, and repeated generations, as the CHART (Chatbot Health Advice Reporting Tool) statement the authors followed recommends [5].

Communicative warmth and clinical adequacy are separable qualities. This study measures the first with care, and we would welcome a companion study that measures the second.

KEYWORDS

palliative; hospice; home care; cancer; meta-synthesis

The recent meta-synthesis by Deng et al [1] on the experiences of family caregivers in home-based cancer hospice care was read with great interest. The authors presented a precise summary of their needs and perceptions and, in doing so, highlighted a critical gap in tailored interventions for supporting this vulnerable group. This is a gap that warrants further consideration.

This gap, while concerning, is understandable. The time and physical confinement inherent in home hospice care limit caregivers' ability to participate in research or access traditional in-person support. Deng et al's [1] review emphasized the dual challenges of this role: the immense burden of being "physically and emotionally present" and the critical need for "sharing responsibility" with palliative care teams, community partners, and family. While this shared support makes caregivers feel less isolated, the home hospice care setting creates logistical barriers to effective collaboration. To make this sharing of responsibility more accessible for home hospice caregivers, we should leverage innovative technology to connect the caregivers with their external support network. This is where we can adopt proven therapies like mindfulness-based stress reduction, delivering them through flexible digital methods that fit the specific constraints of the home hospice setting.

Encouragingly, some recent studies have validated this approach. For example, a pilot study using virtual reality demonstrated that technology can provide homebound caregivers with much-needed individual psychological respite through immersive nature scenes [2]. On a larger scale, a randomized controlled trial of the "Symptom Care at Home" intervention proved that an automated digital coaching system could significantly reduce caregiver burden by connecting them to their care team when symptoms escalated [3]. These studies illustrate the potential of novel ways of delivering support to overcome the practical barriers of home hospice care.

The work of Deng et al [1] should be a catalyst for action. To translate these promising findings into real-world practice, robust collaboration is essential for adapting and testing such interventions. An ideal model would involve researchers and developers co-designing digital tools with caregivers, an approach shown to improve the usability and adoption of digital health interventions [4]. This also calls for a partnership between hospice providers and community organizations to bring these tools into routine care, creating hybrid support models that combine scalable technology for both individual coping and shared care. Through such collaborative efforts, we can deliver interventions that truly empower caregivers to navigate one of life's most profound challenges.

Abstract

Background: Patients with cancer often face significant financial challenges, known as financial toxicity (FT), which is associated with reduced quality of life. Patients with hematologic malignancies (HMs) are especially vulnerable due to intensive and prolonged treatments, frequent hospital visits, and a high risk of complications. While FT affects many in the general population, it is particularly severe among racial and ethnic minorities, especially those below the poverty line. To our knowledge, no studies have specifically examined FT in this vulnerable group in the United States.

Objective: This study aimed to evaluate the severity of FT in patients receiving treatment for HMs in a socioeconomically underserved population, explore sociodemographic factors that may predict the severity of FT, and evaluate the subjective experiences of these patients as they relate to FT.

Methods: We conducted a prospective, observational, longitudinal study at the Montefiore Cancer Center's outpatient department in the Bronx, New York, from October 1, 2022, to October 30, 2023. Participants included either adult patients newly diagnosed (ND) with HMs or those already diagnosed, undergoing cellular therapy (CT). The severity of FT was assessed using the validated Comprehensive Score for Financial Toxicity–Functional Assessment of Chronic Illness Therapy (COST-FACIT) questionnaire. Additionally, an investigator-designed questionnaire was developed to gather sociodemographic data and evaluate the subjective effects of financial burden on patient care. Patients in both the ND and CT groups were followed for 90 days. Data collection occurred at their initial presentation, as well as on days 30 and 90.

Results: Ninety patients participated in the study (ND=52 and CT=38). The median age was 59 (IQR 44-66) years, with 27% (n=24) African American and 55% (n=48) Hispanic. Overall, 75% (n=67) of participants experienced some degree of FT, most with mild FT at baseline (day 0, median COST-FACIT score=19.4). In the CT group, FT worsened significantly over time, with a decline in median COST-FACIT scores from 19.9 at day 0 to 15.5 on day 90 (P=.02). In a multivariable linear regression model, race and ethnicity were a significant predictor of FT burden: identifying as African American or Hispanic was associated with a significantly lower COST-FACIT score (ie, higher FT) compared to non-Hispanic White participants (B=−3.08, P=.04, 95% CI −6.05 to −0.12). Additionally, over half of ND and CT participants reported difficulty affording basic necessities (ND: 28/52, 54%; CT: 23/38, 61%) and concerns regarding transportation access and costs (ND: 26/50, 52%; CT: n=18/38, 47%).

Conclusions: FT is prevalent among patients with HMs receiving care in underserved populations, and the burden is significantly higher among African American and Hispanic populations.

Introduction

Cancer continues to be a significant public health concern in the United States. According to the American Cancer Society, in 2022, there were nearly 2 million new cancer cases and over 600,000 cancer-related deaths in the United States [1]. Receiving a new cancer diagnosis brings untold physical, emotional, and psychological distress to the patient and their caregivers. Although survival rates of patients with cancer have improved over the years due to advances in diagnosis and treatment, the rising cost of cancer care has become a significant challenge for patients and their providers in the US health care system. Financial toxicity (FT) has emerged in oncologic care to describe the psychological, material, and behavioral hardships arising from the economic burden of cancer [2].

Indeed, several studies have reported a close association between FT and reduced quality of life, delays in seeking medical care, nonadherence with treatment, emotional and psychological distress, and reduced overall survival in patients with cancer [3-5]. The impact of FT is particularly pronounced in patients with hematologic malignancies (HMs) as they must deal with the high cost of therapy, especially with the shift from conventional chemotherapy to immunotherapy, multiple infusion visits, prolonged hospitalizations due to life-threatening presentations, long duration of intensive treatment, and treatment-related complications [6,7]. In 2014, the average cumulative costs of hematologic cancer care in the United States ranged from approximately US $200,000 for chronic leukemias to greater than US $800,000 for acute leukemias within the first 3 years of treatment. In comparison, the cost for lung cancer was around US $250,000 and that for colorectal cancer was approximately US $150,000 [8].

The severity of FT is also determined by the patient's sociodemographic and socioeconomic factors. Extremes of age, Black race, lower income level, limited ability to provide basic household needs, unemployment, and insurance status are associated with worse FT [2,9-11]. The factors associated with worse FT are predominant in households living below the federal poverty line. This population primarily comprises Native American, Black, and Hispanic individuals [11].

Despite growing attention to FT, most studies were conducted predominantly on the White population, who are often insured. To the best of our knowledge, no similar studies in the United States have specifically targeted racial and ethnic minorities with HM in underserved areas in the United States. This study aims to assess the severity of FT, examine relevant sociodemographic factors influencing FT, and explore the subjective experience of FT among patients with HMs.

This study was conducted in a large academic hospital in the Bronx, where more than 25% of the population lives below the federal poverty line [12].

Methods

Study Design and Setting

This prospective observational study was conducted over 12 months, from October 1, 2022, to October 30, 2023, at Montefiore Medical Center in Bronx, New York. The study took place in both outpatient and inpatient hematologic oncologic units of the Montefiore Cancer Center, a quaternary academic center serving a predominantly low-income, racially and ethnically diverse population.

Participant Eligibility and Recruitment

Eligible participants included adults over 18 years old with a HM (ie, acute or chronic leukemia, Hodgkin lymphoma, non-Hodgkin lymphoma, or multiple myeloma) who either received a new diagnosis or were being evaluated for cellular therapy (CT), such as autologous or allogeneic stem cell transplantation (SCT) or chimeric antigen receptor T-cell (CAR-T) therapy.

Patients were excluded if (1) they were being seen for conditions other than HMs, (2) they were seeking a second opinion after treatment at a different institution, (3) they presented after recurrence ineligible for autologous or allogeneic SCT and CAR-T therapy, (4) they were being evaluated for a second autologous SCT as part of tandem autologous transplantation or for recurrent myeloma, or (5) they lacked capacity or were non-English or non-Spanish speakers.

Recruitment took place during routine clinical visits and on the oncology floors. Eligible patients were identified by treating providers or study personnel and were invited to participate on a rolling basis. Participants were divided into two cohorts: (1) newly diagnosed (ND) and (2) undergoing CT (SCT or CAR-T).

Data Collection and Measurements

Data were collected in person at three time points: baseline (day 0), day 30, and day 90. At each time point, the participants completed two instruments:

1. Sociodemographic and Subjective Impact Questionnaire: The research team developed an investigator-designed, bilingual (English and Spanish) questionnaire to gather information on demographics (age, sex, race and ethnicity, income, education, employment, and insurance), cancer type, and subjective experience of financial burden, including effects on basic needs and access to care.
2. Comprehensive Score for Financial Toxicity–Functional Assessment of Chronic Illness Therapy: FT was assessed using the validated Comprehensive Score for Financial

XSL•FO
RenderX

Toxicity–Functional Assessment of Chronic Illness Therapy (COST-FACIT) tool [13]. It is categorized into grades 0 to 4, based on the level of FT severity, with scores ranging from 0 to 44. A score of 0 represents grade 0 or *severe toxicity*; 1 - 13, grade 2 or *moderate toxicity*; 14 - 25, grade 3 or *mild toxicity*; and >25, grade 4 or *no toxicity*. Hence, higher scores indicated less severe FT. The patients were assessed at three different time points: day 0, the initial visit time, day 30, and day 90.

Statistical Analysis

Data analysis was performed using SPSS version 29 (IBM Corp). Descriptive statistics summarized demographic characteristics and COST-FACIT scores. Frequencies and percentages were calculated for categorical variables, while medians and IQRs were used for continuous variables. Comparison of the severity of FT across the timelines was determined using the Friedman test. The Mann-Whitney *U* test and Kruskal-Wallis *H* test were used to examine significant differences in FT with respect to sociodemographic groups. Linear regression analysis identified sociodemographic predictors of FT. A two-tailed *P* value of <.05 was considered statistically significant. No adjustment for multiple comparisons was made due to the exploratory nature of the study.

Ethical Considerations

Study Approval

This study was conducted in accordance with ethical standards and received approval from the IRB at Albert Einstein College of Medicine and Montefiore Medical Center (approval number: IRB 2022 - 13798, approval date: 09/13/2022). The research involved human participants and adhered to the principles outlined in the Declaration of Helsinki.

Informed Consent

The provider (MD or nursing practitioner) or study personnel obtained informed consent during the initial visit at the HM clinic or for auto/allo SCT and CAR-T evaluation. All participants gave written informed consent before enrollment. The consent process included explaining the study's objectives, procedures, risks, and benefits and the fact that participation is voluntary. For patients unable to give written consent, verbal consent was obtained in the presence of a trained research coordinator, per institutional policy.

Privacy and Confidentiality

All collected data were deidentified prior to analysis to protect participant confidentiality. Study data were stored in secure, password-protected databases accessible only to authorized personnel. No identifiable personal health information was used in any publication or presentation.

Compensation

Participants were not financially compensated for their involvement in this study.

Results

Sociodemographic Characteristics

Over a period of 12 months, we recruited 90 patients who met eligibility criteria and consented to the study. The sociodemographic characteristics of these participants are shown in Table 1. Fifty-two of 90 (57%) patients were ND, whereas the rest (n=38, 43%) were either currently receiving or preparing to receive CT. The median age was 59 (IQR 44-66) years. There were more male patients (n=56, 62%), 24 (27%) patients were African American, and more than half (n=48, 55%) were Hispanic. Over 60% (n=55, 63%) of the participants were not employed, and over a third (n=33, 37.1%) were on Medicaid. Regarding HMs, most patients had plasma cell dyscrasias (n=33, 37%) compared to other HMs.

Severity of Financial Toxicity Across Time

Overview

Table 2 and Figure 1 depict the median FT scores at various periods. Over 75% (n=67) of patients experienced some degree of FT, with a median COST score of 19.4 at baseline (day 0). While the median COST score indicates mild FT, many patients experienced moderate FT at the individual level. The CT group demonstrated significant changes in FT scores over time (day 0: 19.9; day 30: 19.0; day 90: 15.5; *P*=.02). When comparing FT severity between the ND and CT groups, as shown in Table 3, no statistically significant differences were observed at any period (day 0: *P*=.88; day 30: *P*=.54; day 90: *P*=.75).

Financial Toxicity and Sociodemographic Factors

Table 4 summarizes the difference in FT by race and ethnicity, diagnosis, and employment status at day 0, day 30, and day 90. We examined the association between FT and sociodemographic factors such as race, ethnicity, type of HM, and employment status (employment status was recategorized as employed vs unemployed for ease of analysis). Differences in FT across racial groups were marginally significant, with White patients experiencing relatively milder FT at day 0 (median FT: 27.0 for White patients, 16.5 for African American patients, and 14.0 for other racial groups; P=.08) and at day 90 (median FT: 37.0 for White patients, 13.5 for African American patients, and 15.0 for other racial groups; P=.06).

P value	.25	.45	.66

Within the ND cohort, White patients had significantly less severe FT than other racial groups at day 0 (median FT: 33.5 for White patients, 15.4 for African American patients, and 14.0 for other racial groups; *P*=.04). However, the significance was not maintained at day 30 or day 90.

A similar trend was observed in the CT group at day 90 (median FT: 39.5 for White patients, 33.0 for African American patients, and 13.0 for other racial groups; *P*<.001).

Predictors of Financial Toxicity

A linear regression analysis was performed (Table 5) to identify potential predictors of FT, as measured by the continuous COST-FACIT score. The model incorporated sex, race and ethnicity, insurance status, employment, and type of malignancy as independent variables. Among individual predictors, race and ethnicity were the only statistically significant predictors, which were associated with a 3.08-point lower COST-FACIT score, indicating higher FT in this group (B=−3.08, *P*=.04, 95% CI −6.047 to −0.121). The other variables—sex, insurance status, employment, and malignancy type—were not significantly correlated with FT.

Table . Linear regression predicting financial toxicity using the COST-FACIT[a] score.

Predictor	B (95% CI)	SE	β	*t*	*P* value
Sex	3.521 (−1.136 to 8.177)	2.337	.169	1.507	.14
Race/ethnicity	−3.084 (−6.047 to −0.121)	1.487	−.232	−2.074	.04
Health insurance	0.357 (−2.697 to 3.411)	1.533	.027	0.233	.82
Type of malignancy	0.185 (−2.711 to 3.080)	1.453	.014	0.127	.90
Employment	3.724 (−2.711 to 3.080)	2.511	.173	0.127	.90
Intercept	14.317 (−1.272 to 29.906)	7.824	—	1.830	.07

[a]COST-FACIT: Comprehensive Score for Financial Toxicity–Functional Assessment of Chronic Illness Therapy.

Subjective Experience of Financial Toxicity

Our social workers evaluated more than 75% of the patients in our survey at the time of diagnosis. Over a third (n=32, 37%) of our patients were employed, while more than 60% were retired, disabled, or unemployed (Table 1). Table 6 and Figure 2 show the results of our investigator-based questionnaire. Most patients reported financial difficulties in carrying out their daily activities, such as paying for food, heating/air-conditioning, or warm clothes over the past 6 months (ND group: n=28, 54%; CT group: n=23, 61%). Additionally, over half of the patients experienced some degree of emotional distress in their daily

XSL•FO
RenderX

lives (ND group: n=29, 57%; CT group: n=18, 48%). About 15% in the ND group and 26% in the CT group delayed seeking medical care due to financial constraints, and only about 10% missed appointments due to caregiver issues.

Figure 2. Box-plot graph showing frequencies of parameters assessing subjective experience from financial toxicity by treatment group. CT: cellular therapy; ND: newly diagnosed.

Regarding transportation, the median distance from patients' homes to the treatment center was 5.8 km in both groups. Although fewer than 20% missed appointments due to lack of transportation, many expressed concerns about the cost and accessibility of transportation to their medical appointments (ND group: 52% on day 0; CT group: 47% on day 0). Interestingly, many patients showed interest in telemedicine alongside in-person visits (ND group: 53% and CT group: 40% at day 0). We examined differences in social factors and subjective experiences of FT by ethnicity, and no statistical difference was found at day 0 in either cohort.

Discussion

Principal Findings

Our pilot study highlights a high prevalence of FT within the study population, affecting over 70% of participants. While no significant differences in FT were observed between patients

XSL•FO
RenderX

ND and those undergoing CT, those in the CT group had significantly worse FT at day 90 compared to baseline (day 0). Race and ethnicity emerged as significant predictors of FT, with African American and Hispanic patients experiencing greater FT compared to non-Hispanic White counterparts. Although most patients could attend their oncology appointments and receive treatment, over one-third expressed concerns regarding access to transportation and associated costs.

Comparison to Prior Work

Our findings are consistent with a growing body of literature that identifies FT as a persistent and complex challenge in cancer care [14]. Our patients in the CT group experienced worse FT over time, similar to a previously published study on CAR-T therapy [15]. The study by Maziarz et al [16] on health care costs in patients receiving allogeneic transplants reported that the median cost of health care for a patient receiving a transplant was over US $300,000. Apart from the high cost of SCT and CAR-T, prolonged hospital stays and multiple hospitalizations from treatment-related toxicities add to the burden of FT in these patients [17,18].

In addition to direct medical costs, indirect expenses—such as transportation, loss of employment from poor productivity due to illness, or switching to low-income jobs because they are less physically demanding—also add to the burden of FT [19,20]. Our study confirms these findings. In our study, although most patients made their oncology appointments, over a third were worried about access and the cost of transportation to attend them. Patients undergoing scheduled chemotherapy infusions need to make multiple visits to the clinic, which can be burdensome, especially for those in the CT group who must travel long distances to a FACT (Foundation for Accreditation of Cellular Therapy)-accredited center. This increases gas and public transportation costs, ultimately increasing the overall treatment cost burden [21,22]. Insurance coverage, while protective, may be insufficient to offset the rising costs. Increased deductibles, co-payments, and coinsurance have shifted much of the burden to patients, leading to substantial out-of-pocket expenses for their cancer care. Our study did not assess these out-of-pocket costs directly, nor did it quantify medical debt, areas that merit further investigation.

We found that race and ethnicity are significant predictors of FT, with African American and Hispanic patients experiencing worse FT than non-Hispanic White patients. Our results do not differ from studies on race and cancer-related FT in the literature [23-25]. Most of our patients are essentially racial and ethnic minorities and immigrants, and some are undocumented. They are likely to have lower incomes compared to their White counterparts, to be in the lowest socioeconomic tier, and have access only to public health insurance with limited coverage or even be uninsured [26-28]. Additionally, these patients are likely to have lower health literacy, leading to late disease presentation, increasing the intensity and cost of treatment. These findings underscore the structural inequities that contribute to FT among racial and ethnic minorities and immigrant populations. The convergence of social, economic, and health care–related factors amplifies financial strain and perpetuates disparities in outcomes. Addressing FT in these populations will require more than individual-level solutions; it demands systems-level change.

Beyond the direct effects of FT, it also encompasses the subjective financial distress—the emotional and psychological toll of economic strain [2,29]. This includes the depletion of household wealth and nonmedical budgets, as well as worries about the effectiveness of coping strategies [30]. In our study, over half of the patients experienced financial difficulty in paying for basic needs such as food, and more than 50% experienced emotional distress in their daily life, aligning with findings from Yu et al [31]. Although our results indicate a substantial emotional burden, further research is needed to determine whether this stems from receiving devastating news of a cancer diagnosis, the financial burden of treatment, or a combination of both. In our study, where over 50% of patients are unemployed, most of them will likely have to adjust their monthly budget and spend less on basic needs to pay for their cancer treatment. As their cancer treatment progresses, which is often prolonged in HM, they may face increasing financial burdens, leading them to adopt coping strategies such as relying on retirement savings, selling valuables, or borrowing from friends, family, or financial institutions [32]. In some cases, patients may resort to maladaptive strategies such as missing hospital appointments, medication nonadherence, or even stopping treatment entirely [33]. In our study, though a few patients missed or delayed treatments due to financial constraints, we see a decrease in the number of patients when followed up on day 30 and day 90. Although only a few patients in our study reported missing or delaying treatment due to financial constraints, we observed a decline in patient follow-up at 30 and 90 days. While the reasons for this attrition are not fully elucidated, the inability to afford ongoing treatment remains a plausible factor. These strategies may temporarily mitigate the financial impact of cancer care but ultimately lead to reduced quality of life, emotional distress, and devastating clinical outcomes.

Limitations

Our study certainly has limitations. First, we had a low sample size, especially at the 90-day time point, as many of our patients were lost to follow-up, deceased, or chose not to continue with the study. Second, although our study was observational, the follow-up period may not have been long enough to detect a significant change in FT across time. Third, we did not collect data on the participants' monthly income and the number of cycles of chemotherapy received at each survey time. This may have provided additional insights into assessing the severity of FT in our patient population. With our pilot study, we aimed to capture some of the barriers to cancer care in a unique patient population.

Potential Solutions and Future Directions

Mitigating the burden of FT will involve developing and implementing intervention strategies at multiple levels, from the state/national level to the health insurance/payer, hospital, and provider levels [34]. In our study, many patients were worried about the transportation cost to their oncology appointments but were open to telemedicine visits. Therefore, incorporating telemedicine visits as an option in the care of our

XSL•FO
RenderX

patient population could offer more flexibility for patients, reducing the travel burden and lost income from missed work [35]. Most of our patients were assessed by a social worker. While they play a role in identifying patients at high risk of financial distress, their assistance may not be sufficient, and they may not have the expertise to provide solutions to mitigate the severity of FT. A dedicated financial navigator, especially in a quaternary academic medical center, is required to help patients understand the economic aspects of their cancer care, budget appropriately, and maximize their employment and disability benefits in the context of ongoing financial commitment [36]. A larger cancer center–wide study is underway to evaluate the social determinants of health and better understand their implications on patient outcomes.

Conclusions

This study highlights the significant and far-reaching impact of FT experienced by patients with cancer, particularly those from socioeconomically disadvantaged and ethnic and racial minority backgrounds. Our findings underscore the need for early FT screening and multilevel interventions to protect vulnerable populations from economic harm during cancer care.

Acknowledgments

This manuscript is dedicated to the exceptional life and work of Karen Wright, an oncology nurse and a dedicated patient advocate for patients at Montefiore Medical Center.

Part of this study was presented at the American Society of Hematology Annual Meeting in San Diego, California, 2023 (abstract presentation and online publication) and the American Society of Clinical Oncology Annual Meeting in Chicago, 2023 (online publication).

Generative artificial intelligence (ChatGPT-5, OpenAI, 2025) was used to (1) generate Figure 2 based on the data presented in Table 6, (2) assist with the interpretation of the linear regression analysis performed using SPSS version 29, and (3) improve grammar and clarity of the text.

Data Availability

The datasets underpinning this study are securely stored on a restricted institutional server and are not publicly accessible, safeguarding participant confidentiality. Access may be granted upon formal request to the corresponding author, contingent upon ethical and legal approvals.

Abstract

Background: Reliance on telehealth increased dramatically during the COVID-19 pandemic, introducing new opportunities to consider the use of telehealth across the cancer control continuum. However, patient, clinician, and staff perspectives about the types of cancer care appointments that are considered appropriate and the clinical care needs to support expanded remote care services are limited. Understanding older adults' diverse technology needs and perspectives is especially important given that they comprise a large and growing proportion of patients with cancer.

Objective: This study aimed to describe the perceptions and experiences of older patients with cancer and their clinical care team members regarding the expansion of telehealth use across the cancer control continuum and to solicit suggestions about how to support telehealth use for cancer care delivery.

Methods: Using a convergent mixed methods design, we surveyed and interviewed patients aged ≥60 years, clinicians, and staff at a comprehensive cancer center in the southern United States between December 2020 and November 2021. Interview questions were rooted in the sociotechnical model, which proposes 8 interrelated dimensions representing factors influencing the design, use, and outcomes associated with health information technologies. Patient survey domains included telehealth experience and satisfaction and factors affecting telehealth perceptions and use; clinician survey domains included contexts of telehealth appropriateness, training, and barriers and facilitators to telehealth service provision. Survey data were analyzed using descriptive statistics. Qualitative data were thematically analyzed using a combined deductive and inductive approach.

Results: We received completed surveys from 128 patients (567 invited) and 106 clinicians and staff (146 invited). We completed 14 patient (29 invited) and 20 clinician and staff (22 invited) interviews. Across all participants, most agreed or strongly agreed that multiple cancer care appointment types should be offered via telehealth, including discussing treatment side effects (75/102, 73.5% of patients and 66/94, 70.2% of clinicians and staff), results communication (71/102, 69.6% of patients and 65/94, 69.1% of clinicians and staff), and treatment follow-up (67/102, 65.7% of patients and 52/93, 55.9% of clinicians and staff). In interviews, participants elaborated on factors influencing the appropriateness of telehealth versus in-person appointments, including symptom severity, type of cancer, and purpose of the appointment. Many patient and staff suggestions focused on ways to address digital literacy gaps, while clinicians recommended improving clinic workflows, infrastructure, and training.

Conclusions: Overall, clinicians, staff, and older patients with cancer all responded positively toward expanding telehealth use across multiple cancer and appointment types across the cancer control continuum. Older adults with cancer are generally interested in telehealth for cancer care, especially if strategies to address digital literacy gaps are incorporated. Clinicians and staff members expressed specialized training and infrastructure needs to optimize telehealth uptake and service delivery.

KEYWORDS

telemedicine; video visits; remote technology; older adults; remote cancer care; cancer prevention; cancer treatment

Introduction

Synchronous video visits, or telehealth, have transformed the way cancer care is delivered, accelerated in large part due to the COVID-19 pandemic [1-4]. Avoiding infection due to COVID-19 was particularly important for patients with cancer, who were twice as likely to contract the SARS-CoV-2 virus and 8 times as likely to die from it compared to individuals without cancer [5,6]. In the pre-COVID era, telehealth services for patients with cancer primarily focused on the survivorship phase of the cancer control continuum [7-10] (see Figure 1), addressing issues like long-term monitoring and rehabilitation [11,12]. Among cancer survivors, telehealth had been shown to increase independence, convenience, quality of life, and patient satisfaction with care [13-16]. However, patient and clinician attitudes toward broader implementation of telehealth across other phases of the cancer control continuum, detection, diagnosis, and treatment, for example [17,18] are limited.

Figure 1. Cancer control continuum, adapted from the National Cancer Institute [17].

During the COVID pandemic, health care systems rapidly developed and deployed new remote care protocols and processes for patients across the cancer control continuum, with little time to assess patient and clinician needs and preferences. Cancer centers reported between 33% and 50% of patient visits occurring via telehealth, compared to rates formerly in the single digits [19]. Given that approximately 65% of cancer cases occur in patients aged 65 years and older [20,21], as well as the potential for this age demographic to face disparities in technology use, we had anticipated the need to examine the impact of the rapid expansion of telehealth on older patients specifically. Before the pandemic, a growing body of literature had begun to assess digital health literacy and technology preferences among older adults. Attitudes were diverse and multiple factors affected inequities in health literacy in addition to age, including socioeconomic status, level of education, and rural residence, particularly in the delivery of health care services [22-27]. The transition to telehealth use beyond the survivorship phase created an opportunity to understand shareholder perspectives on both the types of appointments and clinical needs that would be appropriate for remote care, and what could be done to bridge the digital health disparities facing older adults.

The objective of this study was to explore patients' and clinicians' pandemic-era experiences and perceptions of the appropriateness of telehealth expansion for different encounter types across the cancer control continuum. We also solicited suggestions for enhancing access to telehealth in the current era of increasing remote cancer care delivery.

Methods

Study Design

Using a convergent mixed methods design [28], we conducted surveys and semistructured interviews with patients, clinicians, and staff at a National Cancer Institute-designated comprehensive cancer center ("Cancer Center") located at a large academic medical center in the southern United States. We conducted a small number of interviews as a preliminary step to inform the question items and domains included on subsequent survey instruments and to capture participant perceptions and experiences in more depth than could be captured through surveys alone. Concurrently, we used surveys to measure the robustness of experiences and perceptions with a larger sample than could be accomplished in interviews.

XSL•FO
RenderX

Instrument Design

We selected survey domains by drawing on the literature and the sociotechnical model [29], which proposes 8 interrelated dimensions that represent the range of factors that can influence the design, use, and outcomes associated with health information technologies. The patient survey addressed a range of domains relevant to perceptions of and experiences with telehealth, including access and use, challenges encountered, perceived usefulness, and satisfaction. The clinician and staff survey similarly addressed a range of domains, including extent of experience with telehealth, perceived appropriateness of telehealth in different clinical contexts, training, and barriers and facilitators to use. In all, the patient survey comprised 89 unique questions and the clinician staff survey 124 unique questions, including Likert scale ratings, categorical items, and open-ended responses. We pilot tested the survey and interview guides with clients, caregivers of patients with cancer, and staff members of a local community-based organization for seniors in 4 focus groups prior to launching data collection. Their insights helped us optimize the content, wording, and length of instruments.

In addition to exploring some of the survey domains in greater depth, interview guides for clinicians and staff reflected their unique roles (eg, patient care, administrative leadership, and front-line clinical and administrative staff). Additionally, interviews with patients, clinicians, and staff included questions soliciting suggestions about how to improve telehealth services and the role of telehealth in cancer care in the future.

Sampling

Surveys

We sampled patients for surveys from the Adult Cancer Patient Registry at the Cancer Center (n=4037) (Multimedia Appendix 1). Eligible patients were ≥60 years of age, had completed at least one telehealth encounter since March 15, 2020 (approximately the start of the COVID-19 pandemic), were English- or Spanish-speaking, were open to contact for research through the portal, and were diagnosed and received treatment for breast, prostate, colorectal, and/or hematological cancer (in order to achieve a diverse sample by cancer type; n=2464). Of these individuals, we identified n=580 patients for survey recruitment, first stratified by cancer organ site in proportion with the Adult Cancer Patient Registry, then randomly selected within each organ category by date of telehealth appointment, age, gender, and race and ethnicity to achieve a diverse sample. We invited all employees across the Cancer Center to participate in the electronic survey.

Interviews

Patients recruited for semistructured interviews followed the same eligibility criteria as those for the survey but additionally were identified as being in active cancer treatment (defined as receiving chemotherapy, radiation, or being within 6 months postsurgery) at the time of recruitment. We also purposefully recruited 3 patients for interviews who met all criteria except that they had not completed a telehealth encounter in an effort to understand possible reasons for nonengagement or barriers to telehealth.

The primary investigators (RTH and TPH), who are nonphysicians with expertise in qualitative methods, worked with Cancer Center leaders and clinical co-investigators (SC and JM) to create a purposive sample of clinicians and staff given the diversity of cancer care services available. We jointly identified individuals with expertise across various organ sites (breast, colorectal, prostate, and heme), roles (medical oncologists, surgical oncologists, radiation oncologists, clinical staff, and administrative staff), and levels of telehealth proficiency.

Recruitment

Surveys

Because our objective was to survey patients who had completed telehealth appointments, and because telehealth appointments require the use of a patient portal account at the Cancer Center where we conducted our work, we first contacted patients through a messaging function within the patient portal with an invitation to complete the survey. Patients who did not respond to the portal message within one week were sent the same message to their personal email on file in the electronic health record. Those who did not respond to the first email inviting them to complete the survey, or who did not decline to participate, were sent a reminder email one week later, and those who did not respond to both emails within 2 weeks were sent an opt-out invitation letter by postal mail before they were called twice and offered the option to complete the survey by telephone, online through REDCap (Research Electronic Data Capture; Vanderbilt University; RRID:SCR_003445), or on paper via postal mail.

We recruited Cancer Center clinicians and staff via email for both surveys and interviews. The survey invitation included a link to take the survey in REDCap [30]. Clinicians and staff invited to participate in interviews were provided the option to schedule the interview via video conferencing or telephone. Two additional emails were sent if a survey response was not logged or if no reply was received to the interview invitation.

Interviews

Patients who completed a survey and who indicated in the survey a willingness to be contacted for interview participation were in turn recruited for interviews. We conducted semistructured telephone interviews with 14 patients, 11 of whom completed at least one telehealth appointment since March 15, 2020; we also purposefully recruited 3 patients who had never completed a telehealth appointment to provide contrasting perspectives. Patients who had completed telehealth appointments were recruited the same way as survey participants. The 3 patients who did not complete a telehealth appointment were mailed an opt-out letter, then contacted by phone. Up to two attempts were made to contact each of these participants.

Data Collection

Surveys

We conducted patient surveys between July and October 2021 and clinician and staff surveys between April and June 2021. Patient surveys took approximately 20 minutes to complete,

XSL•FO
RenderX

while clinician and staff surveys took approximately 10 minutes to complete.

Interviews

We conducted patient interviews between August and November 2021 and clinician and staff interviews between December 2020 and September 2021. Patient interviews lasted 24 - 78 minutes (average 51 minutes) and were conducted via telephone in English or Spanish by bilingual, qualitatively trained nonphysician research staff (RTH and Ana Belen Conrado). Clinician and staff interviews lasted 29 - 54 minutes (average 41 minutes) and were conducted via telephone or videoconferencing per individual preference by nonphysician investigators (RTH and TPH). Interviewers recorded brief field notes following each interview, which were reviewed and discussed in weekly meetings with members of the research team to determine when thematic saturation had been reached and thus data collection ended.

Data Analysis

Survey data were analyzed using descriptive statistics. Audio-recorded interviews were transcribed by a professional vendor and data were managed using NVivo 12.0 (QSR International; RRID:SCR_014802). Interviews were analyzed using a thematic content analysis approach. Two qualitatively trained researchers (RTH) first developed an initial, deductively driven codebook corresponding to the semistructured interview guide domains and sociotechnical model. They jointly coded the first 20% of transcripts, sampling from a diverse set of clinician and staff roles to refine codebook definitions and add and define codes as needed based on emergent findings. The codebook was then finalized, and researchers independently coded the remaining 80% of transcripts, meeting weekly to resolve discrepancies. The lead qualitative analyst (RTH) then reviewed thematic code reports and selected representative quotes and findings for discussion and interpretation with the research team. In line with our mixed methods design, to assess areas of convergence between the survey and interview findings, the team used a joint display approach [31] to systematically integrate findings from the interviews corresponding to survey questions that we had chosen to explore in greater depth (eg, preferences for appointment type, perceptions of the telehealth implementation process, and training or preparedness for telehealth use).

We engaged the Cancer Center leaders and clinical co-investigators in 2 small group meetings to review the data and discuss their interpretations of the findings.

Ethical Considerations

This study was approved by the Institutional Review Board at the University of Texas Southwestern Medical Center. All participants provided verbal informed consent to participate in interviews in accordance with the approved protocol (STU 2020 - 0919). Participants who completed the survey received a $10 gift card. All patients who completed an interview received a $20 gift card. Clinicians and staff did not receive remuneration per institutional policy. Consent included recognition that identifiable information about participants would not be included in any publications or reports resulting from the research.

Results

Overview

Of 567 patients and 146 clinicians and staff invited to participate in the survey, 128 patients (23% recruitment rate) and 106 clinicians and staff (73% recruitment rate) completed the survey. For interviews, we contacted 29 patients who completed the survey and had indicated they were willing to be contacted for interviews; 3 people were unavailable after the maximum 3 attempted calls, 12 declined to participate ("not interested after all"), and 14 patients consented and were interviewed. We invited 22 clinicians and staff to participate in interviews; 2 did not respond, and 20 consented and participated in an interview. Demographic characteristics of survey and interview participants are shown in Table 1.

The qualitative and quantitative findings converged across multiple domains. In this analysis, we focus on two principal thematic findings: (1) agreement in patients' and clinicians' openness toward expanding cancer care via telehealth beyond the survivorship phase of the cancer control continuum, and (2) comparison between patients' and clinicians' recommendations about how to enhance telehealth in the future. Representative quotes from semistructured interviews are documented by theme in Multimedia Appendix 2.

Theme #1: Perceptions Toward Expanding Telehealth to Other Phases of the Cancer Control Continuum

Patients

Both patient and clinician and staff participants responded positively toward questions about the future use of telehealth during other phases of the cancer control continuum. A majority of surveyed patients indicated they would be "willing to have a video visit with a member of their cancer care team" for discussing treatment side effects (75/102, 73.5%), results communication (71/102, 69.6%), and treatment follow-up (67/102, 65.7%), as shown in Table 2. Of note, less than 6% (6/102) of our sample indicated that telehealth should not be used for any types of cancer care appointments.

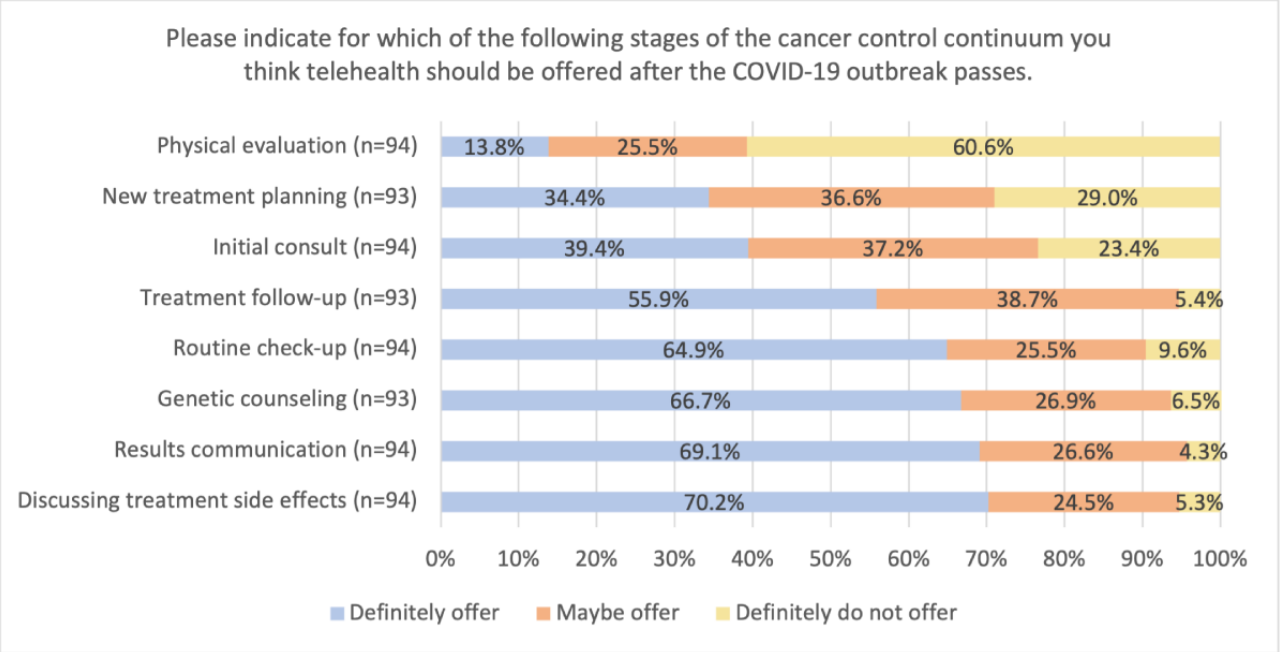
Table . Patient perceptions regarding appointment types for which telehealth should be offered (n=102).

Appointment type (check all that apply)	Value, n (%)
Discussing treatment side effects	75 (73.5)
Results communication	71 (69.6)
Treatment follow-up	67 (65.7)
New treatment planning	48 (47.1)
Routine check-up	32 (31.4)
Planning the end of cancer treatment	32 (31.4)
Postoperative surgical follow-up	28 (27.5)
Genetic counseling	26 (25.5)
Physical evaluation	13 (12.7)
None	6 (5.9)
Other appointments	3 (2.9)
Total	102 (100)

In semistructured interviews, patients cited various reasons why they would feel comfortable having certain types of appointments via telehealth versus in-person, including how they were feeling physically, whether the appointment was routine, whether they had extensive questions, or whether the appointment was with a new clinician. Patients also mentioned that, regardless of appointment type, telehealth was often a convenient option for purely logistical reasons. Some had small children, others had mobility impairments, and still others noted that an easy public transportation system was unavailable to them.

Clinicians and Staff

Clinician and staff survey findings mostly mirrored patients', but there was recognition of the potential role for telehealth in an even greater range of appointment types. A majority of clinicians and staff felt telehealth should "definitely" be offered for discussing treatment side effects (66/94, 70.2%), results communication (65/94, 69.1%), genetic counseling (63/94, 66.7%), routine check-ups (61/94, 64.9%), and treatment follow-up (52/93, 55.9%), as shown in Figure 2.



In semistructured interviews, clinicians elaborated on the multiple considerations that would determine whether they would offer a telehealth versus in-person appointment. One clinician felt that appointments scheduled to discuss laboratory results were an appropriate opportunity to use telehealth because the primary purpose of such appointments is to support conversation as opposed to gathering more laboratory data or providing other treatment. Similarly, another clinician felt that patients on infusion could be followed adequately via telehealth appointments, provided they are in a stable place with their treatment.

XSL•FO
RenderX

Some clinicians indicated that the appropriateness of telehealth depended on the type of cancer the patient has. A urology oncologist commented that telehealth was appropriate for his patients with prostate cancer, whose treatment comprised only hormone shots every 6 months. A hematologist noted there were varying circumstances in which patients with leukemia required in-person visits; lymph node checks required a physical exam, whereas discussing lab results did not.

Other factors included the complexity of a patient's care, with one clinician noting that the immediate perioperative period for surgical patients could influence the appropriateness of the modality of care delivery. Further, the stage of a patient's disease was also an important consideration in the eyes of some clinicians, with advanced-stage disease requiring more aggressive monitoring and treatment. Not surprisingly, a majority of clinicians felt physical exams still required in-person visits. One clinician, for example, noted that an in-person exam would be crucial when determining what type of breast surgery was most appropriate for a patient with breast cancer because the breast size, shape, tumor size, and tumor location all factored into her surgical strategy.

Figure 2. Clinician and staff perceptions regarding appointment types for which telehealth should be offered.

Theme #2: Suggestions to Enhance Remote Cancer Care in the Future

Patients

The Cancer Center dedicated significant resources to patient education and technical assistance during the COVID-19 pandemic to facilitate rapid conversion of patient appointments to telehealth. Surveyed approximately one year after the height of the pandemic, fewer than 20% of patients reported experiencing specific challenges with initiating or preparing for telehealth appointments. Specifically, 18% did not understand the video visit setup process, 19% did not feel it was easy to join the video visit session, and 17% did not have enough technical support. But while the vast majority (88%) of the surveyed patients felt sufficiently prepared for their telehealth appointment, less than a third (31%) of surveyed clinicians and staff agreed or strongly agreed that the Cancer Center did a good job of preparing patients for their first telehealth encounter.

Importantly, in semistructured interviews, patients still offered various suggestions about how telehealth care could be enhanced in the future. One participant recommended improving the quality of educational materials pertaining to telehealth, noting they often assume patients have better digital literacy than they actually do. Another patient felt that in-person education for older patients, particularly when initiating or preparing to use telehealth, would be helpful. One individual, who was initially opposed to having telehealth appointments before the pandemic but became a strong supporter of the technology after completing telehealth appointments during the pandemic, suggested offering testimonials to convince patients who may be apprehensive about trying telehealth.

Other patients indicated that telehealth appointments needed to be offered to patients on a more regular basis, acknowledging that they sometimes ask if telehealth is possible when scheduling.

Clinicians and Staff

Administrative leaders, clinicians, and front-line staff offered various suggestions based on the different challenges they faced and the telehealth workarounds they devised. During the early part of the pandemic, clinical and administrative staff were assigned to assist patients with initiating their telehealth appointments. This process involved first logging on through a patient's portal account, and during this step, some patients discovered problems with their portal login credentials. In such cases, knowing what level of familiarity patients already had with the portal was key to triaging a high volume of technical assistance requests. Other staff suggestions to assist patients with limited digital literacy included establishing "fake

XSL•FO
RenderX

appointments" for patients to practice online connections and hiring a dedicated employee like a digital health navigator to provide on-call technical assistance and setup of the online portal.

Whereas front-line staff suggestions tended to focus on digital literacy assistance for patients, clinician, and administrator suggestions tended to focus on the need to enhance workflows and infrastructure to improve privacy, efficiency, and clinician training. Multiple clinicians expressed the need for dedicated physical spaces with sufficient privacy for them to conduct telehealth appointments. From a technical standpoint, some clinicians noted that it would also greatly improve efficiency to implement consenting for surgical procedures and clinical trials via telehealth. Some clinicians felt that additional training was needed, for example, to show patients images over telehealth using the "share screen" function.

Despite the challenges they experienced, a majority of both patients (65.7%) and clinician and staff (76.9%) survey respondents reported that they intended to continue using telehealth in the postpandemic era.

Discussion

Principal Findings

In this mixed methods study, patients, clinicians, and staff reported an openness toward expanding telehealth-based cancer care across the cancer control continuum. Participants recognized that some situations still favored in-person visits, including appointments in which a physical exam would be necessary and appointments for patients who required more aggressive surveillance due to the stage of their disease. However, both patients and clinicians agreed that telehealth would be convenient and efficient for appointments to discuss treatment side effects, lab results, and treatment follow-up. Clinicians also noted that genetic counseling and consenting patients for surgery or clinical trials could be effectively performed over telehealth. Participants also offered multiple recommendations for health care systems to establish the infrastructure to support these specific opportunities for telehealth-based cancer care delivery.

Comparison to Prior Work

Despite the reported willingness of older patients to engage in telehealth, literature indicates that older adults are often offered telehealth appointments and patient portal registration at lower rates than younger patients, partly due to health care clinicians' assumptions that older patients may be less interested in or capable of using digital health tools [32-34]. Such assumptions can inadvertently limit older patients' access to telehealth, even though many are both willing and able to engage with these technologies when provided adequate support. Such ageist biases highlight the need for intentional strategies to encourage telehealth use among older adults, ensuring that they are not inadvertently excluded from the potential benefits of the technology. Further, given that approximately 65% of cancer cases occur among patients aged 65 years and older [20,21], addressing such inequities among older patients could expand the role of telehealth in cancer care.

Several strategies to improve digital engagement for older adults may serve to address inequities in telehealth service delivery and outcomes for older adults [22-24]. These include technical modifications in portal interfaces to simplify the sign-in process, changes to size or color of text or icons, and incorporation of more pictures as opposed to text, which may improve user experience and capability [35,36]. Other recommendations include patient portal adoption campaigns targeting older adults, task-specific training, support for proxy users, challenging assumptions about older adults and technology, and alternative workflows to allow for communication between patients and personnel to review personal health information within patient portals [22,37]. Clinical and administrative staff may benefit from having policies and procedural guidance detailing when and for whom telehealth appointments should be offered.

Our findings contribute evidence that educational materials must be tailored to older adults or other patients with lower digital health literacy, such as through in-person educational sessions and testimonials from those who have benefited from telehealth. Clinicians and staff on our study also suggested the idea of establishing "fake appointments" for patients to practice using telehealth interfaces and hiring a dedicated employee such as a digital health navigator for technical assistance. The use of digital navigators—trained individuals who assist patients in accessing and using digital health resources—has been found to be effective in enhancing digital literacy and reducing barriers to telehealth access, especially for socioeconomically disadvantaged populations [38-41]. These programs could be particularly beneficial for older adults with cancer, who may face additional challenges due to their complex care needs.

Increasing the use of telehealth for older adults with cancer has the potential to increase independence, patient satisfaction, and quality of life [13-16,42-44]. Studies have found that older adults who learned to use new technology were over twice as likely to adopt telehealth during the pandemic compared to those who did not [45]. In light of the "gray tsunami" phenomenon, where an increasing number of older adults are anticipated to require health care services, and the overwhelming burden of cancer among patients aged 65 years and older [20,21], it is important to recognize the urgency of addressing digital health literacy to minimize health disparities.

Strength and Limitations

This study has several limitations that impact the potential transferability of our findings to other settings. First, the sample was drawn from a single Cancer Center, with most participants being White and English-speaking, thereby limiting applicability to more diverse populations. Second, data collection for this study occurred during the latter half of 2021, and as such, should be considered within the context of the COVID-19 pandemic. Third, attitudes toward patient portals and telehealth use were evolving during the pandemic, and remote cancer care delivery was a necessity for some patients with cancer during this time. Fourth, by recruiting participants through the portal to sample patients who could adequately comment on telehealth experiences, we may have introduced a bias toward patients who are already more technologically proficient or feel positively about telehealth. This may have limited insights into

XSL•FO
RenderX

the experiences of older adults with lower digital literacy, potentially underrepresenting the experiences of those with significant barriers or negative perceptions. Anticipating this limitation, we purposefully recruited 3 individuals without telehealth experience to participate in an interview; however, the small overall patient sample size may also be a limiting factor. Similarly, by recruiting our patient interview sample from our survey sample, we may have introduced a potential response bias toward the inclusion of individuals who felt strongly toward telehealth (positively or negatively). Our recruitment for clinician and staff interviews could also have introduced bias given our reliance on suggestions by our clinician co-investigators. Strengths of this study include its use of the sociotechnical model as a guiding framework for the instrument design and analysis plan, and our inclusion of both patients and clinicians and staff. Finally, our approach of conducting a small number of targeted, preliminary clinician and staff interviews enabled us to assess the appropriateness and representativeness of our survey question items prior to launching our full surveys with patients and other clinicians and staff.

Future Directions

If telehealth expands across the cancer control continuum, it will be critical that health care organizations prioritize digital equity and inclusion of populations with lower digital literacy. This includes racial and ethnic minorities and older adults and their care partners, to ensure that the needs of these growing populations are adequately met and to provide a more balanced view of the challenges they may face. Future research would benefit from exploring the relative impacts of various interventions, such as digital navigator programs and tailored educational materials, on telehealth engagement and health outcomes.

Conclusions

This study contributes new evidence that older patients and their clinical care members welcome the expansion of telehealth use across the cancer control continuum. This is an important finding given the fact that digital health technologies, including but not limited to synchronous telehealth visits, are already integral components of health care delivery. It suggests that, as the population ages, health care systems will have the potential to reach a greater share of their patients by enhancing access to cancer services through telehealth and other digital health technologies.

Acknowledgments

The authors thank Ms Suzanne Ouyang and Ms Jessica L Lee for coordinating the study, and Ms Ana Belen Conrado for conducting interviews.

Funding

This study was funded by a Community-Engaged Research Pilot Award from the Office of Community Outreach, Equity & Engagement at Simmons Comprehensive Cancer Center, 2020-2022. The study was also supported by the National Center for Advancing Translational Sciences (NCATS) of the National Institutes of Health (UL1 TR003163). Funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Data Availability

Data are presented in the main manuscript; additional data may be available upon reasonable request from the authors.

Authors' Contributions

RTH and TPH contributed to conceptualization and methodology. RTH, BE, SC, JCM, and TPH conducted the investigation. RTH, JL, and AZ drafted the original manuscript. All authors contributed to manuscript review and editing. RTH and TPH were responsible for funding acquisition.

Abstract

Background: Social media is a common source of cancer information for patients, caregivers, and survivors. Factors influencing engagement with oncology nutrition content on social media are not well-defined, despite the high prevalence of social media use for health information. The impact of bilingual content strategies on that engagement is also poorly understood.

Objective: This study aims to describe changes in postlevel engagement on a Facebook page used to disseminate evidence-based cancer nutrition information during the period before and after the implementation of a bilingual, multiformat content strategy and to identify creative and linguistic features associated with audience engagement at the post level.

Methods: This cross-sectional study analyzed 306 Facebook posts from Cook for Your Life over 12 months, comprising 9 months before the strategy change (T1) and 3 months after (T2). Postlevel engagement metrics (likes, comments, shares, and link clicks) and aggregated user demographics were obtained from Meta Business Suite. Trained coders annotated visual and creative features, including branding, post shape, and infographics, as well as topical categories. Linguistic Inquiry and Word Count characterized language features. Group differences across time periods were tested using *t* tests and chi-square tests. Generalized linear models estimated associations between post characteristics and engagement, adjusting for the time period.

Results: Users who engaged with oncology nutrition Facebook content (N=10,196) were mostly female (n=9500, 93.2%) participants, over 35 years of age (n=9311, 91.4%), based in the United States (n=6708, 71.4%), and English-language users (n=9419, 93.4%). Engagement tripled from T1 (mean 5.3, SD 4.2) to T2 (mean 17.7, SD 37.9; *P*<.001). Creative features such as branding and format were positively associated with engagement. Linguistically, there was a shift toward longer sentence structures, simplified vocabulary, increased analytical language, and a decline in emotionally charged and cognitive language in posts during T2. In models controlling for time period, posts that used bilingual content had 1.72-fold higher odds of audience engagement than English-only posts (95% CI 1.05 - 2.80).

Conclusions: Implementing a bilingual, multiformat content strategy may promote engagement with oncology nutrition information on Facebook and enhance the equitable dissemination of health information. The use of creative visual design elements in combination with language that is more analytical and emotionally neutral was associated with higher engagement with educational public health content. Future research should test bilingual language presentation more directly and examine whether exposure to such content influences health beliefs and downstream behaviors across additional platforms.

Introduction

Emerging Health Communication on Social Media

The pervasive use of the internet, driven by the emergence of social media platforms, has revolutionized communication patterns, particularly within health-related contexts [1]. Social media, ranking as the third most frequent online activity, has become an integral part of human interaction, facilitating the exchange of ideas, information sharing, and the creation of online communities [2,3]. With the increasing prevalence of personal wireless devices, the popularity of social media applications continues to grow worldwide [4-6]. This

XSL•FO
RenderX

observation has prompted health communication experts to explore innovative opportunities for using social media to enhance population health [3,7-11].

Social media platforms are powerful tools for health communication interventions and offer opportunities to improve outreach and impact [12-14]. Notably, cancer organizations have increasingly embraced social media for outreach and patient support and have promoted technology-based interventions that use social media to support patients and caregivers in the period after a cancer diagnosis [15]. Studies across multiple scientific disciplines have highlighted the potential of social media to improve health through the efficient exchange of user-generated health information, increased perceived social support, and the facilitation of public health programs such as dietary interventions [16-23].

It is valuable to study the language organizations use in online cancer communities related to oncology nutrition education, considering the rapid transformations in the communication landscape brought on by participative internet use and social media alongside the potential for social media to amplify misinformation [24]. Research studying the association between engagement and the language used within social media aligns with the National Cancer Institute's focus on bringing cancer research studies to individuals in their communities [25]. The first step in this effort is to identify the characteristics of current social media users. *Facebook* is a social media platform that allows users to share and interact with stories, images, and videos. In the United States, Facebook is widely used within the adult population, more commonly by females than males [26]. On this platform, *engagement* is defined as any action users take on a Facebook page or post [27]. The most common examples of Facebook engagement actions are reactions (eg, likes), comments, and shares, but engagement can also include video views, link clicks, or post saves. Understanding social media usage and how people engage with information online will support health communication efforts aiming to use social media effectively to promote the dissemination of trusted, evidence-based oncology nutrition content online. This may inform the work of health science institutions to design effective population health campaigns that use digital technology.

Cook for Your Life

Cook for Your Life (CFYL), a website based at Fred Hutchinson Cancer Center (FHCC), stands out as a pioneer in promoting healthy cooking for individuals with cancer [28]. Founded in 2007 by a 2-time cancer survivor as a community-based nonprofit in New York City teaching in-person culinary and nutrition courses to cancer survivors, CFYL launched its website in 2012 to address the unmet need for culinary and nutrition education in the field of oncology. In 2019, the website was transferred to FHCC to continue serving as a bilingual (English/Spanish) research platform and community resource under their institutional support. The content produced by CFYL, which is grounded in science and supported by 2 advisory boards composed of FHCC leaders and experts—Scientific & Medical Advisors and Clinical Oncology Nutrition Advisors—caters to patients with cancer, survivors, individuals interested in cancer prevention, as well as health care professionals and oncology societies. Disseminated through social media platforms such as Facebook, X (formerly known as Twitter), Pinterest, YouTube, and Instagram, CFYL's library comprises a rich collection of science-based recipes, articles, and videos.

In a strategic move in September 2021, CFYL implemented a bilingual multiformat social media strategy, producing content in both English and Spanish. This targeted approach, grounded in evidence-based communication techniques, aimed to enhance engagement and broaden the audience for oncology nutrition content. This strategy was executed on the CFYL Facebook page, and the content produced from the strategy is publicly available for review online. The evidence for implementing this content strategy drew on visual communication and health communication research that links visuals and branding to higher social sharing, greater engagement, and improved persuasive impact for health information. The incorporation of bilingual content into CFYL's social media strategy serves as a unique opportunity to investigate linguistic changes in Facebook content and their influence on engagement.

With that being said, the importance of using social media to communicate science-based information to people affected by cancer warrants further research on this topic, and few studies have examined which bilingual, visual, and linguistic features of oncology nutrition Facebook posts are associated with engagement. We hope to unravel the characteristics of social media posts that promote engagement with the CFYL content on Facebook, focusing on nutrition and cancer, before and after integrating targeted bilingual, multiformat content into their social media approach. Our objective is to describe changes in postlevel engagement on the CFYL Facebook page in the period before and after the implementation of this content strategy and to identify creative and linguistic features associated with audience engagement at the post level. We aim to deepen our understanding of the factors influencing user engagement with health information via social media platforms, specifically within online cancer communities.

Methods

Study Timeline

This descriptive cross-sectional study uses linguistic content analysis to examine textual data from Facebook posts about nutrition and cancer prevention and to describe (1) indicators of social engagement, (2) valence (ie, positive/negative terms), and (3) linguistic content (eg, emotional terms/pronouns). The study analyzes CFYL Facebook content over a 12-month period during the COVID-19 pandemic. We divided the 12-month observation window into 2 prespecified periods based on the implementation of a revised social media strategy in September 2021. Time point 1 (T1) represented 9 months before implementation (January 1-September 30, 2021; n=202 posts), and time point 2 (T2) represented the first 3 months after implementation (October 1-December 31, 2021; n=104 posts). T2 was intentionally restricted to the immediate postimplementation period to capture early changes in posting practices while minimizing contamination from later programmatic changes or cultural events. This temporal division

XSL•FO
RenderX

facilitated the examination of post characteristics associated with engagement, linguistic content, and other factors in the introduction of a bilingual, multiformat social media strategy by CFYL.

Facebook Metadata and Sampling

The analytic sample comprised 306 original posts published by the official CFYL Facebook page during the 12-month observation period from January 1, 2021, through December 31, 2021. Each post was created and published by CFYL page administrators as part of the organization's dissemination of evidence-based oncology nutrition content, including links to CFYL recipes, articles, videos, and branded educational graphics. The unit of analysis was the individual CFYL-authored Facebook post. User-generated comments and posts from non-CFYL accounts were not included as analytic units; engagement with CFYL posts was captured through platform-generated metadata.

Postlevel reach, impressions, engagement, and other key metrics (post type: photo, link, video, or albums) were exported for each CFYL-authored post from Meta Business Suite, the standard analytics interface for Facebook pages. Reach reflects the number of unique accounts that saw a post; impressions reflect total on-screen displays, and engagement aggregates user interactions such as reactions/likes, comments, shares, and link clicks. These are widely used reporting metrics and serve as a data source for digital health research. Meta Business Suite also provided aggregate demographic information describing the audience that interacted with the CFYL Facebook page. Demographic variables extracted from Meta Business Suite include gender, age group, language spoken, and country. Access to this Facebook Metadata is limited to the administrators of the CFYL Facebook account and is not publicly available.

Qualitative Content Analysis

Certain variables of interest were not available directly from Meta Business Suite (branding, post shape, image content, and topic). Content codes were manually collected from the CFYL Facebook page by a research assistant. This manual extraction included the post text in both English and Spanish, the number of comments and emojis, and image content data. Each post was assigned a unique identifier to enable linkage to Meta Business Suite variables. Additional data included postpublication dates and hyperlinks. These manual content codes were used to construct independent variables for analysis to contextualize observed pre-post shifts in creative strategy and topical focus. To ensure data accuracy, another investigator quality-checked this manually collected data. Next, to analyze how the content of posts was associated with engagement, we performed qualitative content analysis. A codebook from prior social media research was adapted and implemented to code the visual and topical content of posts [29]. Discrepancies and inconsistencies were discussed among the research team, and the codebook was refined over time (Multimedia Appendix 1). User data were grouped according to categorical coding units with adequate variation for statistical comparisons. Manual content codes (branding, post shape, and topic) were used to construct independent variables for quantitative analyses and to contextualize observed pre-post shifts in creative strategy and topical focus.

Linguistic Variables

To analyze the linguistic content of CFYL Facebook posts, Linguistic Inquiry and Word Count (LIWC) was used. LIWC is a widely recognized content analysis platform that provides valuable insights into the linguistic characteristics of textual content [30]. It includes various dimensions such as emotional tone, positivity, negativity, pronouns, and numerous other linguistic attributes. The selection of specific LIWC dimensions was based on the research questions, hypotheses, and preliminary findings, aligning with the study's objectives. LIWC's "Analytic" summary dimension reflects formal, logical, and hierarchical thinking styles, with higher values indicating more analytic language. "Tone" summarizes overall emotional tone, and "Big Words" reflects the use of longer words (commonly operationalized as words with 6 or more letters).

There are also more specific index variables used to assess distinct linguistic processes. For example, the "Cognitive" dimension indicates reasoning and stance-taking, "Authentic" indicates the use of a more personal, self-disclosing, first-person style, and "Perceptual" notes the presence of sensory language. Informal language indicators such as "Conversational" and "Netspeak" capture a more chat-like style and internet shorthand. Social orientation is captured by "Social processes" and related subcategories (eg, "Social referents," "Family," and gender references), whereas "Affect," "Emotion," "Positive emotion," and "Negative emotion" quantify the proportion of emotion-laden words. Topic-oriented categories such as "Health" and "Illness" index the extent to which posts reference health and disease experiences. The "Netspeak" dimension describes internet-specific language such as emojis and internet acronyms (eg, LOL [laughing out loud] and OMG [oh my god]).

A stop list was applied to exclude noncontent words, ensuring that the analysis focused on meaningful language. Textual data from hashtags were also omitted from the analysis, as they were considered irrelevant and repetitive content. Then, LIWC was applied to estimate the percentage of terms in each post containing different language types (with scores ranging from 0 to 100). Higher values indicate a greater proportion of words in the post belonging to that category (or higher scores on LIWC summary dimensions), and lower values indicate less frequent use of that linguistic feature.

Engagement Outcomes

Our primary outcome variables were indicators of social engagement within online cancer communities, defined as the number of likes, comments, and shares on each CFYL Facebook post. This definition using postlevel engagement was selected based on its prior use in digital health research and the presence of these features across other social media platforms [23,31]. We also extracted postlevel engaged user metrics from Meta Business Suite, which reflect the number of users who performed one or more engagement actions on the post. Outcomes of engagement included postlevel summary statistics (mean, SD) for each time period. High engagement indicated that posts were relevant to the target audience. Reach and

XSL•FO
RenderX

impressions were also extracted to characterize post exposure. We integrated platform analytics (Meta Business Suite), manual content coding of post features and topics, and LIWC text analysis to characterize how changes in post design, topic focus, and linguistic style aligned with changes in engagement across time periods.

Statistical Analysis

To facilitate statistical comparisons, textual data were grouped based on categorical coding units with sufficient variation. We descriptively summarized post characteristics, engagement metrics, and aggregate audience demographics obtained from Meta Business Suite using both total counts and postlevel distributional summaries. Bivariate analyses were used to compare postlevel characteristics between the preimplementation (T1) and postimplementation (T2) periods. Independent-samples *t* tests were used for continuous variables, including engagement metrics and LIWC summary measures, whereas chi-square tests were used for categorical variables such as post format, branding, bilingual presentation, and topic categories. To examine associations between post characteristics and engagement while accounting for differences between time periods, we fit generalized linear models, treating the number of total engaged users as a continuous postlevel outcome, and reported odds ratios (ORs) with 95% CIs. In these models, the time period was included as a covariate to account for temporal differences between T1 and T2. All statistical tests were 2-sided, and $P<.05$ was considered statistically significant. This regression model provides insights into the dynamics of engagement and linguistic content on the CFYL Facebook page while controlling for temporality.

Ethical Considerations

This study analyzed CFYL's public Facebook posts and aggregated, deidentified engagement metrics exported from Meta Business Suite at the post level. Manual coding was limited to CFYL-owned post text and images, not user comments or profiles. No direct identifiers (eg, names, usernames, and profile links) were collected, and no individual user content from private accounts or direct messages was accessed. Analyses were conducted on deidentified, aggregated data; demographic information (eg, age group, country, and language) was available only in platform-provided summary form. The FHCC determined the project exempt from institutional review board approval, and no individual consent was required. FHCC provides funding for CFYL and supported research activities. Procedures for data use complied with ethical expectations for internet-based research and did not involve automated scraping or circumvention of platform protections.

Results

Characteristics of Individuals Who Engaged With CFYL Content on Facebook

The final analytic dataset included 306 original CFYL-authored Facebook posts published between January 1 and December 31, 2021. Of these, 202 posts were published during T1 (preimplementation) and 104 posts during T2 (postimplementation). Posts disseminated CFYL oncology nutrition content, including recipes, educational articles, visual graphics, and links to CFYL web content. According to aggregate demographic summaries provided by Meta Business Suite, users who engaged with CFYL content during the 12-month monitoring period were predominantly female (n=9500, 93.2%) and over 35 years of age (n=9311, 91.4%), with the highest engagement present in the group of people aged 55 to 64 years (n=2708, 26.6%). These findings are consistent with broader platform usage patterns for Facebook among midlife adults. The majority of the CFYL audience is based in the United States (n=6708, 71.4%) and identified by the platform as English-language users (n=9419, 93.4%). A smaller proportion of engaged users were identified as Spanish-language users (n=311, 3.1%) with an even lesser number of users residing in a Spanish-speaking country (n=101 from Mexico, 1.1%), indicating that there is also a community of Spanish-speaking individuals residing in the United States who engaged with the CFYL content during this time period (Table 1). Because these demographic data were available only in aggregate platform-provided categories, they describe the engaged audience at the page level rather than post-specific audiences.

Post Characteristics Associated With Engagement With CFYL Content on Facebook

The overall engagement with posts increased from T1 (mean 5.3, SD 4.2) to T2 (mean 17.7, SD 37.9; *P*<.001; Table 2). Similar increases were observed across engagement components, including likes (T1: mean 2.5, SD 2.0 vs T2: mean 12.5, SD 33.5; *P*<.01), shares (T1: mean 0.4, SD 0.7 vs T2: mean 0.8, SD 1.1; *P*<.01), comments (T1: mean 0.1, SD 0.6 vs T2: mean 0.5, SD 1.3; *P*<.01), and link clicks (T1: mean 2.2, SD 2.6 vs T2: mean 3.9, SD 7.5; *P*=.003; Table 2), underscoring a surge in user interaction with the content. The magnitude of change in user engagement metrics can be visualized in Figure 1. Post format and creative features shifted over time, with a decrease in photography posts (T1: 98.5% vs T2: 67.3%) and increases in text-dominant posts (T1: 1.5% vs T2: 32.7%), infographics (T1: 0.0% vs T2: 7.7%), and branding (T1: 19.8% vs T2: 94.2%; all *P*<.01; Table 2). Similarly, the qualitative content analysis results indicate that the presence of specific content topics within the posts exhibited significant changes during T2. For instance, there were higher proportions of posts focused on cancer (T1: 25.7% vs T2: 58.6%; *P*<.01), nutrition and diet (T1: 64.4% vs T2: 84.6%; *P*<.01), health care support (T1: 18.3% vs T2: 40.4%; *P*<.01), and breast cancer–specific content (T1: 0.5% vs T2: 9.6%; *P*<.01), suggesting a strategic focus on these themes to enhance engagement and promote actionable oncology nutrition information online (Table 2). Bilingual content presentation was also rare in the preimplementation phase but nearly universal after applying the new content strategy (T1: 0.5%, T2: 99.0%; *P*<0.1, Table 2).

Figure 1. Changes in user engagement with Cook for Your Life (CFYL) across the implementation period.

Engagement by Lexical Content

The results from the natural language processing analysis using LIWC produced a large number of linguistic and semantic dimensions, which may be interpreted as an exploratory descriptive comparison of language style across time periods before and after the implementation of the targeted social media content strategy. T2 posts showed higher Analytic scores, longer sentences, and lower rates of affect- and cognition-related terms, indicating a shift toward more formal, informational language. The average number of words per sentence increased from mean 13.83 (SD 3.84) at T1 to mean 16.81 (SD 3.85) at T2 (P<.01; Table 2), demonstrating a shift toward longer sentence structures. The linguistic analysis revealed that posts in the latter time period (T2) exhibited a substantial increase in the use of "analytical" language from mean 80.04 (SD 18.05) at T1 to mean 87.70 (SD 5.66) at T2 (P<.001; Table 3), along with greater use of "Big Words" from mean 32.85 (SD 7.48) at T1 to mean 39.66 (SD 5.27) at T2 (P<.01; Table 3), suggesting a shift toward evidence-based logic and the use of complex medical terminology related to health science, oncology, and nutrition. Conversely, the use of words included in the LIWC dictionary declined from mean 64.92 (SD 8.34) at T1 to mean 37.23 (SD 5.76) at T2 (P<.001; Table 3), suggesting the use of a scientific vocabulary with uncommon words appearing more frequently in the text of T2 posts. Other linguistic style indices such as Linguistic (mean 44.84, SD 8.49 to mean 19.10, SD 3.49; P<.001) and Function words (mean 31.18, SD 8.48 to mean 12.36, SD 3.02; P<.01) also declined from T1 to T2 (Table 3).

Informal language markers such as the use of conversational language (mean 2.18, SD 1.36 to mean 1.47, SD 0.69; *P*<.001) and netspeak (mean 2.14, SD 1.33 to mean 1.45, SD 0.68; *P*<.001) decreased significantly from T1 to T2 (, Table 3), along with a decrease in the Authentic summary score (mean 19.03, SD 21.64 to mean 1.12, SD 0.60; *P*<.001; Table 3). Affect-related categories revealed significant changes in emotional tone, including affect (mean 6.11, SD 3.83 to mean 3.76, SD 1.50; *P*<.001), positive emotion (mean 0.59, SD 1.38 to mean 0.24, SD 0.42; *P*=.01), and negative emotion (mean 2.15, SD 1.26 to mean 1.34, SD 0.64; *P*<.001), with decreases in both positive tone (mean 3.59, SD 3.25 to mean 2.07, SD 1.25; *P*<.001) and negative tone (mean 2.44, SD 1.54 to mean 1.65, SD 0.83; *P*<.001; Table 3). These findings signify a shift toward less emotionally charged language in T2 posts.

Cognition-related categories were lower at T2, including cognitive processes (mean 6.65, SD 4.47 to mean 2.64, SD 1.59; *P*<.001), tentative language (mean 2.38, SD 2.22 to mean 0.50, SD 0.61; *P*<.001), discrepancy (mean 1.00, SD 1.48 to mean 0.49, SD 0.76; *P*<.001), and certitude (mean 0.43, SD 1.00 to mean 0.08, SD 0.25; *P*<.001; Table 3), suggesting a shift toward certainty and scientific reasoning. There was also less perception-related language used in T2 posts, indicating that the content shifted away from describing subjective experiences with sensory terms and toward promoting objective scientific evidence (mean 7.26, SD 4.30 to mean 2.09, SD 1.46; *P*<.001). Additionally, the use of physical language related to health (mean 1.96, SD 3.57 to mean 6.69, SD 3.29; *P*<.001) and illness terms (mean 0.83, SD 2.08 to mean 5.64, SD 3.09; *P*<.001) was greater at T2, suggesting a shift in content topics toward cancer-centered language.

Several characteristics of posts were associated with engagement in univariate regression analyses controlling for the time period (Table 4). First, posts that used the bilingual multiformat content strategy were associated with higher engagement (OR 1.72, 95% CI 1.05 - 2.80; *P*=.03). The presence of CFYL branding (OR 1.08, 95% CI 1.04 - 1.13; *P*<.001) and square-formatted images (OR 1.11, 95% CI 1.06 - 1.17; *P*<.001) was also associated with higher engagement, whereas rectangular-formatted posts were associated with lower engagement (OR 0.90, 95% CI 0.86 - 0.94; *P*<.001; Table 4). Only bilingual content was associated with increased odds of engagement after adjusting for the time point (data not shown). These findings underscore the influence of linguistic and thematic elements on user engagement with CFYL content on Facebook, even when adjusting for variations in the time period of the posts.

Survivorship	0.98 (0.96 - 1.12)	.77

[a]Indicates statistical significance at $P<.05$.

Changes observed in engagement metrics during T2 coincided with co-occurring shifts in post design and language. Specifically, the increase in branded and square-formatted creative (manual coding; Table 2) aligned with positive associations between these features and engagement in regression analyses (Table 4). Similarly, increases in posts coded as cancer, health care support, and nutrition-focused (Table 2) aligned with LIWC shifts showing more health and illness language and less food language (Table 3), suggesting that posts increasingly framed nutrition within cancer and treatment contexts during the strategy period.

Discussion

Principal Findings

This study analyzed 306 original CFYL-authored Facebook posts published over 12 months and described both overall engagement volume and postlevel engagement patterns before and after the implementation of a bilingual, multiformat content strategy. Across the observation window, engagement with CFYL content was concentrated among women, adults aged 35 years and older, and predominantly English-language users based in the United States, according to aggregate platform demographic summaries. These demographic results are in contrast to the epidemiology of cancer in America, where there is a much broader distribution of demographics across patients and survivors. One reason for this finding may be that younger adults are more likely to engage with social media platforms and have demonstrated high rates of digital health literacy. This distinct cohort could also be interpreted as the population of female caregivers who provide the invisible labor of seeking and implementing health information within their home and community. The demographic data might suggest that women act as the primary drivers of health-related caregiving and nutrition management within their social support networks.

In analyses controlling for the time period, bilingual posts had higher odds of engagement, and creative features, including CFYL branding and formatted images, were also positively associated with engagement. Linguistically, posts produced with this content strategy used more analytical language and longer sentences, with fewer conversational, authentic, affective, and cognitive terms in T2 than T1. These results amount to more formal, scientific language and less emotionally charged vocabulary used in T2, aligning with best practices for organizational evidence-based messaging. Content-related lexical categories also shifted, with increases in health and illness terms, indicating a greater emphasis on nutrition in the context of cancer and treatment-related concerns. Metrics of engagements per post increased over time, and in models that adjusted for the time period, bilingual posts had higher odds of engagement.

Creative features such as institutional branding and purpose-designed visual content were also positively associated with engagement. Visual branding implementation associated with CFYL and the Fred Hutch Cancer Center may have the potential to drive higher credibility among the target content audience. Given the observational design and co-occurring changes to content and format, these results should be interpreted as associations rather than causal effects. However, these findings emphasize the importance of strategic social media approaches in increasing user interaction with high-quality cancer information on social media platforms [32-34].

XSL•FO
RenderX

Comparison to Prior Work

Widespread access to the internet has drastically shifted the sources of health information from health care providers to user-generated online content. Simultaneously, access to high-quality cancer information online may not be equitable. This is especially true in a global online community where the source and credibility of cancer information are not always transparent. Incorporating bilingual cancer content on the CFYL Facebook page extended accessibility for Spanish-speaking individuals. Bilingual social media strategies have been documented to promote user engagement with online health promotion content in other settings as well, with Latino Facebook users tending to show more engagement with either Spanish or bilingual posts compared to English posts [35]. This suggests that cancer centers, hospitals, and cancer advocacy groups that intend to promote accessible cancer information online should strongly consider a bilingual approach, matching the linguistic needs of the target population.

Differences in health literacy on a global scale also emphasize the need for cancer information to be delivered at an appropriate literacy level, particularly given our current digital age where people worldwide have access to social media content [36]. The observed rise in the use of complex language elements represents a conscious effort to make the content more informative and scientifically accurate. However, the longer sentence structure and use of more complex, analytical language may present comprehension challenges for diverse audiences, such as individuals with varying levels of health literacy. Simplifying language in health communication is a recognized strategy to ensure that information is easily understood and accessible to a wider spectrum of readers. It may be valuable for CFYL to assess the health literacy of their audience and tailor social media content in order to make critical information about cancer nutrition more accessible and understandable to a broader public.

Moreover, the shift toward less emotionally charged language, as evidenced by the decrease in language that uses both positive and negative tones, aligns with the expected findings observed in organizational communication. Previous research has indicated that organizations, especially those in the health domain, tend to use fewer emotionally charged words compared to individual users [37]. This strategic approach aims to maintain a professional and informative tone, avoiding potential misinterpretations that emotionally charged language might introduce. It is also plausible that less emotional, more objective language is interpreted as being more credible and scientifically accurate. We also observed declines in perceptual processes (see/hear/feel), which likely reflect fewer sensory descriptors and a more didactic, informational tone used in the new content strategy. The decline of conversational and internet-specific language suggests fewer informal linguistic markers, which aligns with the educational content strategy used by cancer research institutes. This can increase credibility for an audience seeking trustworthy nutrition guidance.

We found that visual content such as photo media, branding, and infographics are useful tools to improve engagement with cancer nutrition information on social media, which is supported by prior literature on the topic within the field of health information and cancer research [32-34]. Visual content is commonly used across social media platforms, and social media posts with visual content are more frequently shared with other users and are associated with engagement metrics (including likes and comments) [34]. In addition to its impact on user engagement, visual content improves persuasive impact [38]. Other factors associated with higher engagement across time points were branding, square-shaped posts, and bilingual content. Square-shaped posts represent purposively selected photos that were identified by the CFYL content creators as opposed to rectangular-shaped posts, which represent preselected images that are input automatically when adding an external link into a Facebook post. Therefore, this finding does not imply an attraction to a specific geometrical shape but it suggests a preference for intentional photos over simple links. Institutions and researchers aiming to improve engagement with their social media content may use these strategies.

Strengths and Limitations

Strengths of this study design include the integration of platform analytics with manual content coding and the addition of linguistic analysis to characterize message features. There are also limitations of this approach that should be considered in the interpretation of our results. First, we cannot attribute engagement changes solely to bilingual content due to the multiple changes that occurred around the same time as the bilingual strategy (eg, more branding, more square images, and topic shifts). Because exposure varied and multiple changes occurred alongside the strategy, causality cannot be inferred. We attempted to mitigate this by comparing post characteristics across periods and by including the time period in regression models; however, residual confounding by unmeasured time-varying factors likely remains. Future studies should use longer, balanced observation windows, staggered rollouts, or interrupted time-series designs to strengthen causal inference.

Second, we could not directly compare engagement by language because nearly all posts after implementation were bilingual. This limits inferences about the relative contribution of Spanish vs English content. Although we examined overall engagement changes and the presence of bilingual formatting, this approach cannot isolate language-specific effects. Future work could stratify analyses by audience language segments when platform analytics allow it. Another factor to consider is that engagement counts are influenced by audience exposure (reach and impressions), which can vary by post and over time. Our primary analyses did not explicitly model exposure as an offset to normalize engagement rates for delivery. As a result, posts with wider distribution of engagement may appear to perform better independent of their content.

Third, there are threats to the generalizability of these findings in other settings and online communities. The data reflect a single oncology nutrition platform and an engaged audience that was predominantly female and largely based in the United States, although demographic granularity was limited to platform-provided aggregates. These findings are limited to Facebook, and characteristics may not represent other populations or platforms with distinct content formats and algorithms. Replication across additional cancer centers,

XSL•FO
RenderX

community organizations, and other social networks (eg, Instagram, YouTube, and TikTok) would strengthen the external validity of these findings.

We acknowledge that the asymmetric time windows to assess preimplementation and postimplementation of this content strategy may also introduce seasonality and exposure differences into our results. Additionally, changing temporal, cultural, and algorithmic dynamics may have altered engagement patterns independent of content during the observation period. We partially addressed this by incorporating time period comparisons, but more granular controls (eg, calendar month, day of the week, or platform policy change markers) would better account for temporal and algorithmic shifts. Extending monitoring across multiple years in future studies may also help separate strategy effects from seasonality.

Future Directions

In the future, novel digital media and technological tools (eg, eye-tracking and web-monitoring) may be useful for determining how individuals evaluate the quality of cancer nutrition information and the features that promote online engagement with cancer nutrition information. This technology has been previously implemented in research to record users' viewing patterns on web-delivered information and provides a physiological measure linked to cognitive processing that may indicate the presence of active or passive engagement [39,40]. Data from eye-tracking can assess how users process online information such as social media content [41,42]. In the context of public health research, eye-tracking technology improves the understanding of how online health promotion content attracts attention from users [39,41,43].

The association between social media use and oncology nutrition knowledge is another topic that should be explored further, particularly because engaged social media users are more likely to be aware of other prevention measures, such as cancer screening [44,45]. Similarly, improving engagement with oncology nutrition content on social media may promote healthy dietary choices for cancer prevention and patients with cancer. The dietary needs of patients with cancer undergoing treatment such as chemotherapy are different from those of cancer survivors or caregivers aiming to reduce cancer risk. Therefore, oncology nutrition interventions through social media may benefit from addressing these individualized needs through targeted social media content. Importantly, future work should assess how exposure to online cancer information influences users' health beliefs, perceived cancer risk, trust in nutrition recommendations, and subsequent health behaviors.

It is also relevant to examine how these findings translate to other social media platforms with distinct audiences, content formats, and engagement algorithms such as Instagram, TikTok, and Snapchat. Each of these platforms reaches different demographic groups and prioritizes different types of content, particularly short-form video, visual storytelling, and creator-driven posts. Studying oncology nutrition messaging across these environments may help determine whether bilingual strategies, visual elements, or linguistic elements operate similarly on platforms that emphasize rapid, algorithm-driven content exposure. Understanding these mechanisms will be essential for identifying which platform features most effectively support evidence-based cancer prevention and nutrition education and for ensuring that such content reaches diverse communities that may not engage with Facebook.

Going forward, providers and staff can leverage cancer nutrition websites and social media to guide patients to high-quality cancer information by incorporating visual content such as photos, branding, and infographics, which improve social engagement, as well as including more analytical language and a neutral emotional tone within a multilanguage content strategy. It is important for providers to be aware of disparities in accessing information and to make cancer information available in different languages and at varying literacy levels. Another area with clinical relevance is to consider the specific dietary needs of patients with cancer undergoing treatment and provide targeted social media content to address these dietary needs both during treatment and across the cancer control continuum.

Conclusion

This study describes how CFYL, an online cancer nutrition community, disseminates information about nutrition education and cancer prevention. The results of this analysis demonstrate that implementing a dedicated bilingual, multiformat social media content strategy is associated with higher audience engagement with oncology nutrition posts. We describe strategies to increase engagement with online social media content disseminating nutrition-related cancer prevention and survivorship information. In models adjusted for the time period, posts that were bilingual, branded, and formatted performed better, and the language profile shifted toward more analytical, emotionally neutral text.

These associations were observed alongside concurrent changes in creative elements and content delivery, and exposure varied across posts. As such, causal inferences cannot be made. Even so, these findings suggest practical signals for designing bilingual, branded, multiformat content to support the equitable dissemination of evidence-based cancer nutrition information. Studying online language use may help cancer organizations strengthen the rationale for investing in bilingual social media cancer communication initiatives tailored to the language needs of the communities they serve. Future work should test language presentation more directly and evaluate how exposure to such content influences health beliefs and downstream behaviors across multiple social media platforms. Overall, these findings provide an initial context for communicating about nutrition with patients with cancer, survivors, and caregivers on Facebook and other social media platforms. These results are a step toward implementing more supportive interventions for the quality dissemination of cancer nutrition information on social media.

Abstract

Background: Precision oncology (PO) improves and extends the lives of patients living with cancer, but multiple studies have documented its underuse in practice. Specifically, studies note a significant lack of PO use within the Veterans Affairs (VA) medical system. A paucity of implementation of PO in oncologic practice poses a significant barrier to providing the most up-to-date guideline-based care.

Objective: While several studies have explored determinants of PO use, we sought to contribute to the body of knowledge by additionally focusing on the unique perspectives of patients, as well as conducting a comprehensive study within the VA medical system, the United States' largest single-payer health care system. We conducted interviews with both patients and providers at multiple VA sites to identify and characterize barriers and facilitators of PO use in clinical care.

Methods: Using a qualitative descriptive approach, we conducted semistructured interviews with 17 patients with cancer and 16 oncology providers recruited from multiple VA sites. Cancer types included prostate, gastrointestinal, and lung. Data were analyzed via a team-based coding approach using directed content analysis. Data were coded and then aggregated into themes and mapped to the Theoretical Domains Framework (TDF) and Behavior Change Wheel sources of behavior (Capability, Opportunity, and Motivation) based on the consensus of the study team.

Results: The patient sample consisted of 17 all-male veterans seen at VA oncology clinics in 2022. Participants predominantly self-identified as White (n=9, 52.9%) or Black (n=6, 35.3%), and the majority (n=11, 64.7%) held a high school degree or a higher level of education. The provider sample consisted of 16 physicians, all of whom held MD degrees and practiced oncology. The provider sample represented 6 states, was 50% (8/16) female, and participants averaged 14 years in their current position. The overarching theme was the "Precision Oncology Feedback Loop," which captured the essence of the complex processes involved in facilitating PO care in the VA system. The TDF and Behavior Change Wheel helped categorize findings to identify where issues in the feedback loop could facilitate or generate barriers to care.

Conclusions: Our findings expand on the current literature by highlighting both patient and provider experiences across key TDF domains (Environmental Context and Resources, Knowledge, Memory, and Attention). The conceptual model produced by the analysis illustrates the complexities associated with the implementation. Our findings support the design of multilevel interventions that target increased knowledge or education, improved workflow, and ease of communication to enhance PO delivery.

oncology; precision oncology; health services; qualitative; health equity

Introduction

Precision oncology (PO), the identification of tumor-specific abnormalities as targets for personalized therapy, has revolutionized cancer care over the last several decades by extending survival and minimizing treatment-related toxicities [1]. Despite the benefits established in clinical trials, extensive studies by our group and others document that up to 50% of patients do not receive guideline-recommended PO treatment. For example, molecular testing of colon cancer biopsy tissue for clinically targetable alterations in patients with advanced colon cancer has been recommended by expert consensus guidelines since 2010 [2]. Studies of this population in the Veterans Affairs (VA) health system established that such

XSL•FO
RenderX

testing was completed in only 28% of eligible patients with advanced colon cancer by the year 2015 [3]. This hinders the ability of clinicians to use the cancer mutational profile to determine therapy, which is standard care for patients with advanced colon cancer. Similarly, among patients with non-VA colorectal cancer included in the Surveillance Epidemiology and End Results database, molecular testing was completed for only 31% of eligible patients [4,5].

Consistent with ecological models of health behaviors, barriers and facilitators to PO exist at many levels (eg, patient, provider, and system) and steps in the process of care [6,7]. At the patient level, older patients and those with Medicaid insurance are less likely to receive PO [3,8]. Furthermore, Black and Latino patients have been consistently underrepresented in the practice and study of PO [9]. Furthermore, at the provider level, quantitative and chart review data suggest that providers do not always act upon PO testing results [10]. Facility and systems-level barriers have also been identified in multiple studies, including lower testing rates in lower-volume cancer centers, difficulty coordinating testing, financial barriers, and lack of clear protocols for test indications and use [10,11].

A recent review of qualitative research on barriers and facilitators to PO suggests that barriers often involve insurance or reimbursement as well as a lack of certainty with regard to clinical utility, while facilitators include the incorporation of PO into clinical guidelines. Notably, this review included only 5 qualitative studies, with very limited representation of oncology clinicians and patients with cancer [12]. One study included no clinicians, another included only 1 clinician, and a third included only 3 clinicians [13-15]. The final 2 studies included 10 and 14 clinicians, respectively, but did not include clinicians in the VA [16,17]. Only one study specified the inclusion of patients and included 16 [16]. While this suggests that there is active investigation in the space, there are relatively few studies, with small sample sizes, and no prior VA representation.

The Veterans Health Administration is the largest integrated health system in the United States, and the VA National Oncology Program cares for approximately 43,000 veterans newly diagnosed with cancer annually [18]. We designed a qualitative study of patients with cancer and providers based on the Theoretical Domains Framework (TDF) [19] to explore barriers and facilitators to PO care in this population. We know that molecular testing, essential for the standard of care in cancer treatment, is being underused. The reasons for the underuse of molecular testing remain unclear, and we are conducting a qualitative investigation to facilitate an in-depth exploration of the patient and provider experiences of PO and identify areas in which interventions to increase guideline-concordant PO can be effectively used.

Methods

Design

We used a qualitative descriptive approach with directed content analysis to structure the study. The goal of qualitative descriptive studies is to describe the experiences of those participating in the health-related behavior or process under consideration [20]. When used for health services research, this approach can identify and differentiate common and unique factors experienced by patients and clinicians when engaging with health services.

Theoretical Underpinning

The TDF is a widely used behavior change framework, consisting of 14 domains that are used in the identification of determinants of change [21]. TDF categories are then mapped to the Behavior Change Wheel (BCW) components of Capability, Opportunity, and Motivation. The BCW is an evidence-based framework for understanding drivers of behavior and translating that understanding into actionable change [22]. Both TDF and BCW were chosen for this analysis over other frameworks, such as the Consolidated Framework for Implementation Research. The TDF can be more useful for the design of qualitative research interview guides by specifying discrete domains, which are applicable at the individual level as well as at the systems level. Our focus was predominantly on the behaviors and experiences of the patients and providers, which is best suited to TDF and BCW over the more process-oriented Consolidated Framework for Implementation Research.

Reflexivity

The research team comprised 4 researchers: one senior qualitative PhD researcher who is a nurse (AS) and three MD researchers board-certified in internal medicine (KC, DB, and AB). Of the MD researchers, one was a practicing oncologist, and two were oncology fellows in the third year of their training. The nurse researcher had no oncology background and brought methodological expertise. All identify as having White European heritage.

Sample and Setting

Adult patients seen in oncology clinics between January and June 2022 at participating VA medical centers (VAMCs) in Pittsburgh and New York with a histologically confirmed prostate, gastrointestinal, or lung cancer were included in the study. We chose these 3 cancers as they together represent more than 60% of all patients with cancer within the VA, and PO is well established in all 3 cancers. We chose common cancers to understand practice patterns in patients with relatively common oncologic diseases. Patients with other cancers were excluded. The US Department of Veterans Affairs includes both VAMCs with inpatient and outpatient care as well as VA Community–Based Outpatient Care Centers with outpatient care only. Our study was conducted only at VAMCs. The VA is a single-payer health care system that serves 9 million American veterans and veteran family members.

Recruitment

Prospective patient participants were recruited by either letter or flyer. A letter was mailed to patients at the Veterans Affairs–New York Harbor Health Care System (VA-NYHHS), whereas a flyer was used at the Pittsburgh VAMC. At the Pittsburgh VAMC, flyers were placed in highly visible locations in the oncology clinics, such as the front desk at registration and in patient examination rooms. Providers were encouraged

XSL•FO
RenderX

to inform patients that the study was available. The recruitment of provider participants was email-based. Emails were sent to oncology physicians at the VA-NYHHS, Greater Los Angeles Area (GLA), Pittsburgh, Michigan, and Seattle VAMCs. Informed consent was obtained from all participants, with all study methods approved by the local VA institutional review board (IRB). Patients were eligible for this study if they were receiving medical care at one of the participating VAMCs and were receiving treatment for prostate, lung, or gastrointestinal cancer. Only English-speaking patients were eligible, as US military enlistment requires English proficiency. Providers were eligible if they provided care for patients with cancer in one of the participating VAMCs.

Data Collection

The semistructured interview guide was constructed through an expert review process by a multidisciplinary team of oncologists, qualitative health researchers, and patient representatives. All 14 TDF domains were represented by at least 1 question in the interview tool. Three patient and three provider interviews, not included in the sample population, were used to refine the interview guide and construct a draft code list. This was done to provide test samples for assessing the feasibility of the interview guide.

Two interviewers then conducted semistructured interviews with patients and providers that lasted between 30 and 60 minutes. All interviews were conducted via audio using patients' telephone numbers through Microsoft Teams. The interviews were transcribed using Microsoft Teams' automated transcription feature, with verification by study personnel. Interviews continued until data saturation was achieved.

Data Analysis

Directed content analysis using the TDF categories guided the analytical process. Directed content analysis allows for codes dictated by a preanalysis identified list, as well as purely descriptive codes, to emerge during the process [23].

AS provided coding training to the physician team and reviewed findings as they emerged. A team-based coding approach structured the consensus-based process [24]. Based on guidance from Cascio et al [24], we drew from principles of team-based coding to generate intercoder consensus throughout the analytic process. The consensus process was documented throughout the study to record the process of data review, idea generation, and analytical technique. The consensus process was conducted in person through meetings with the entire coding group.

Atlas TI.web (version 9.24.3; Lumivero) was used to code interviews. Each interview, whether from a patient or clinician, was coded independently by 3 research staff members (DB, KC, and AB). Initial codes came from the theoretical framework to start the process, and others emerged iteratively during the coding process. All team members met after 3 interviews were coded to harmonize code names and conceptual definitions. The codes were then compared and reviewed to achieve consensus on any coded data about which study staff disagreed. Disagreements regarding code application were discussed among the study team until a consensus was reached. A common codebook was then generated, and the team members checked in periodically to continue coding harmonization throughout the process.

The team then met to finalize categories and themes that emerged independently from the data as well as to evaluate how coding aligned with the TDF theoretical framework. Similar code groups were aggregated and mapped to related BCW sources of behavior (Capability, Opportunity, and Motivation) based on the consensus of the study team.

Ethical Considerations

A determination of minimal risk and approval was granted by the VA-NYHHS IRB for our protocol (1605219‐1). We received subsequent approval from the Research and Development Committee and the Research Safety and Security Subcommittee. Consent forms were reviewed and approved by each committee and subcommittee. Informed consent was obtained from each participant in accordance with IRB-approved documents. Privacy and confidentiality were protected in accordance with data security specifications outlined in the IRB-approved protocol and were further reviewed by the institutional data security officer. Participant compensation consisted of US $25 gift cards for each participant.

Results

Overview

At the VA-NYHHS, letters were sent to 136 patients, of whom 10 (7.4%) enrolled. At the Pittsburgh VAMC, flyers were posted for patients attending the oncology clinic. Of these patients, 7 (1.8%) enrolled, from approximately 400 patients who passed through the clinic. A total of 17 patients and 16 providers (n=33) were interviewed.

Patient participants were predominantly aged 70 to 80 years, entirely male, and mostly White. Twenty-four providers received the email, of whom 16 (67%) participated. Of the 16 providers who were interviewed, 1 provider requested to reply to demographic questions by email but did not subsequently respond. Providers were mostly New York–based, predominantly aged 40 to 50 or 50 to 70 years, and predominantly White. Providers were mainly MDs. Patient and provider characteristics are further outlined in Tables 1 and 2 and include self-reported age, gender, race or ethnicity, as well as the state of the site from which the participant was recruited. For providers, additional information was collected regarding the number of years in position, type of professional degree, and leadership role status.

Overarching Theme: The Precision Oncology "Feedback Loop"

Our findings suggest that there is a cyclical feedback loop related to the delivery of PO. The feedback loop is driven by the opportunity for this kind of care, as dictated by the resources of the system where care is delivered. Satisfaction from the clinician and patient side is the result of technical process outcomes associated with the PO testing process. Motivation to engage with PO services is a product of clinician learning and success with the tool and the resulting success with patient treatments, which also generates happiness for the patient.

The following sections illustrate how the feedback loop occurs, with the TDF providing structure for the categories that shape it. Figure 1 illustrates the feedback loop of Capability, Opportunity, and Motivation on the part of both patients and providers, all of which contribute to patient and provider engagement leading to PO. Sections are organized by the framework's components.

Behavioral Regulation (TDF)–Motivation (BCW)

In the TDF, behavioral regulation is defined as the components aimed at managing or changing objectively observed or measured actions, while motivation aligned with the BCW is defined as brain processes that energize and direct behavior [21,22].

In our analysis, statements that referred to self-moderation of actions on the part of patients and providers fell into this category. Patients reflected on the importance of a sense of motivation and autonomy in navigating their care, while providers identified motivation and adaptability as components of effective action. Furthermore, positive feedback emerged as providers sensed that patients were motivated to pursue testing. As one clinician described:

> *I think most of the guys get it pretty good and are excited to hear that there's something beyond standard chemotherapy that they've heard all the horror stories about. They're excited about it so as you move from standard chemotherapy into immunotherapy, now into gene therapy, people are happy to hear that there's more knowledge, more options, more thinking, we're getting somewhere with cancer treatment.* [Provider 13]

Cognitive and Interpersonal Skills Capability: The Impact of Communication

This category captures the way in which respondents felt communication and coordination between various individuals affected PO and cancer care. Three key motifs emerged, centered on the intersections of multilevel aspects of communication.

Interdepartmental Communication

Participants noted the issues that arise, even with an electronic health record, when trying to coordinate departments involved in diagnosis, treatment, and management of care. For example, several respondents identified issues with delayed next-generation sequencing (NGS) results due to gaps in communication between different medical specialties (eg, proceduralists, oncologists, and pathologists):

> *It would be nice if pathology had a way to reflexively send the specimen. I guess it's hard for them. They don't know the whole situation and you kind of need somebody to oversee it, but that again is just another frustrating thing.* [Provider 2]

Conversely, several respondents cited regular interdepartmental meetings, such as tumor boards, as helpful in reducing delays.

Interdisciplinary Communication

Interactions between providers and nurses, between providers and trainees, and between providers and administrators were all identified as key elements of PO care. Multiple providers also praised an individual coordinator responsible for PO implementation.

Patient-Provider Communication

Overall, respondents on both the patient and provider sides expressed that communication with their counterparts was an effective and important facilitator of PO. "The doctors I went to, I think, were extremely thorough in describing what was going and what the treatments were, and answering my questions" (patient 51). On the other hand, a lack of patient understanding was reported as a barrier on the part of clinicians.

XSL•FO
RenderX

Emotions and Motivation

Emotions and motivation statements reflected the interactions between how patients and clinicians highlighted the role of emotions in influencing PO practice. Unsurprisingly, most of the negative patient-reported emotions reflected fear of their cancer, its progression, and death. Providers cited concerns about the emotional and practical implications of detecting germline mutations.

Nonetheless, finding an actionable mutation was in itself a significant provider motivator:

> *I think that there's kind of a sense of happiness when we find one of those really high yield variants, when you find the EGFR or the ALK in lung cancer. You feel really happy sharing that information with patients and obviously I think they understand that when the provider is happy with something that that's probably good news for their cancer.* [Provider 5]

Thus, the balance of emotions and motivations encapsulates the inherent rewards and challenges of the PO treatment process for both clinicians and patients.

Environmental Context and Resources Shaping Opportunity

Overview

Both providers and patients talked extensively about how the care environment and its resources were critical for treatment opportunities. The overall environment and the provider's ability to navigate the resources to get patients their treatment were essential for balancing patient-level factors that influenced care choices. How they described these aspects of the environment fell into two subcategories of "system-centered" and "patient-centered" descriptions.

System: Technical

The organizational structure of the PO process functions was extensively discussed by participants. This included challenges with ordering forms, a lack of dedicated communication channels between pathology and the ordering provider, and inconsistencies in how results are eventually uploaded and displayed. For example, one respondent noted:

> *We've had to overcome some issues because there is no ordering method within the electronic medical record […] So right now we're doing this by emails. So essentially, we identify patients in the clinic that need sequencing, and I have a coordinator that is in clinic with me each time I'm in clinic and she will send specimens for sequencing. It's kind of inefficient.* [Provider 7]

Among facilitators, patient consent and electronic ordering processes were cited as technical aspects of the system that functioned well and did not delay care delivery.

System: Personnel

Respondents cited understaffed provider departments as barriers and navigators and administrative assistants as facilitators. Noting the effectiveness of a nurse navigator working in the system, a provider offered an example of facilitated communication flows:

> *The nurse navigator does usually read the report and they will scan and send me an alert, an email, and say "this is someone who's got an actionable mutation" just to make sure that I've read the report.* [Provider 12]

Understaffing reflected vacancies, hiring processes, and other factors associated with operating within a government bureaucracy.

System: Practice Resources

Clinical and institutional guidelines were noted to help providers recognize PO testing indications. These were seen as important for quickly discerning treatment plans and managing patient responses to them. As one provider stated:

> *So my overall goals do align with guidelines, such as NCCN guidelines. So they just hopefully align with standard of care.* [Provider 4]

For some providers, these guidelines served as educational tools to update their practice.

Patient Factors

Logistics, financial challenges, and how patients were educated about their treatments and options were the patient-centered factors that influenced the progression of PO care. Transportation issues were the most frequently cited barrier to care. Many veteran participants were economically vulnerable and did not always have access to reliable public transportation as an alternative. For example, one patient participant stated "sometimes I'd have an appointment that was too early and I'd request transportation and it was hard" (patient 058).

Despite economic vulnerability, the low or no-cost care provided to VA patients was viewed as a significant facilitator that helped ensure veterans were protected from the financial toxicity that can be associated with cancer care outside the VA system. Finally, patients reported a variety of strategies to educate themselves about their diseases and treatments. While some patients mentioned receiving educational materials from their doctor or other VA sources, many more reported using external resources, such as the internet or family members, to learn about their disease and treatment options. One patient stated:

> *My wife she goes online … that's where she learned about the endocarditis because she had to deal with it too. And she's had sepsis and cancer and she goes to all of the medical sites.* [Patient 056]

Educating themselves was a clear goal and motivator for patients, which highlights the value of patient engagement in the PO process. They wanted to understand the causes behind their cancer, including potential germline mutations, and to be informed about their testing results and treatment plans.

Goals: Motivation

Providers had clear goals for PO care that motivated them when working with patients throughout their cancer treatment. They formed into 2 categories focused on patient outcomes and quality of care. Both providers and patients shared a mutual outcome

XSL•FO
RenderX

goal of an increase in the length of life or a cure to their disease, as well as their desire to maintain a good quality of life. As one provider stated: "The goals of patient care would be to help people be on the best therapy with the lowest side effects that keeps them alive the longest" (Provider 010). Many provider respondents expressed the importance of the highest quality care, including safety, personalized care, and the ability to treat actionable mutations. They viewed this as inherently intertwined with a good patient outcome.

Knowledge: Capability

Overview

Patients and providers reflected on the role of knowledge in the implementation of PO. Among patients, knowledge of their disease and how it is treated was often broad, with a lack of information constituting a barrier. Conversely, among providers, a deep understanding of both the disease and its treatment facilitated greater engagement in PO.

Patient Disease

Although many patients expressed an awareness of genes and their contribution to cancer, more statements were identified in which patients specifically reported a lack of knowledge or understanding about the cause of their disease and its treatment as stated by a patient:

> *How it forms is I'm not sure. It's something to do with your cells.* [Patient 57]

Patient Treatment

Patients frequently expressed knowledge of their treatment in broad, overarching terms, with occasional confusion between modalities of treatment. A lack of familiarity with terms such as "precision medicine" and "targeted treatment" was prevalent. One patient stated:

> *I know that everyone has DNA and it's specific to each person and genes ... I've heard of gene therapy but I'm not sure if it apples to cancer.* [Patient 055]

Provider Understanding of Disease and Treatment

Providers expressed comfort with knowledge of the role of mutations in cancer pathogenesis and treatment. They also, however, pointed out the quickly changing PO landscape as a barrier and guidelines and peer-reviewed sources as facilitators. NGS reports themselves were felt to be "a little bit better in terms of outlining what's pathogenic and what's not" (provider 11).

Memory and Attention: Capability

Among both patient and provider participants, external distractors emerged as barriers to PO, with responses generally categorized as prioritization either within the clinic or outside the clinic.

Prioritization Within the Oncology Clinic

Some providers expressed difficulty with practicing PO in part because of competing oncologic concerns, such as complex treatment and comorbidity management. Furthermore, providers noted feeling overwhelmed by variable interpretations of PO testing, unclear clinical implications of certain mutations, and excessive extraneous information. Providers noted facilitators, including tumor boards and reflex testing.

Prioritization Outside the Oncology Clinic

For patients and providers, the COVID-19 pandemic and associated personal and professional distractions were noted:

> *I mean the hardest part is just always just doing too many things at once. Like sometimes Path will just call me and I'll be there in the middle of clinic. One time I was at softball practice for my 7-year-old and like they're like, "Oh yeah, we didn't get enough tissue" and my head is in a totally different place, I can't write that down.* [Provider 9]

Patients also noted the need to manage other conditions and social issues.

Skills: Capability

For the second least-frequently encountered domain, the reported "skills" involved in PO include the abilities to obtain tumor tissue, select the appropriate kit, and properly complete the ordering process:

> *They need to know the difference between the tissue sample kits and the liquid biopsy kits. And they need to make sure that the kits aren't expired.* [Provider 1]

The majority of difficulties reported were in the latter category, with convoluted and unstandardized ordering processes sometimes creating difficulties with PO.

Reinforcement: Motivation

As in the Goals domain, providers and patients noted an anticipated increase in the length or quality of life as a perceived positive consequence of PO, and providers feared missing this opportunity.

Treatment Outcomes

With regard to treatment outcomes, patients' stated goals typically pertained to survival, with one patient stating: "Well basically it's to stay alive" (Patient 51). Providers expressed similar goals as well as concerns about not meeting the goals. One provider stated:

> *I'm thinking about targeted therapy so it's a whole 15 to 17% of people you can deprive of potentially life prolonging medication. And the impact that you're doing by not testing it, can you take it? Being an oncologist, treating oncology patients, can you take it with you every night and go to sleep? I cannot, so test for it.* [Provider 3]

The negative consequences of treatment adverse effects were mentioned frequently in broad terms, but PO was seen as a way to potentially avoid these consequences.

Quality Outcomes

Respondents cited the benefits of selecting a more effective treatment as a positive outcome of PO and the detriment from the failure of PO.

XSL•FO
RenderX

Social Influences: Motivation

Sources of motivation for patients and providers came from similar and distinct sources. This relationship was always dyadic in nature.

Patient-Provider

Patients frequently mentioned their providers as their principal source of advice on treatment-related issues. For example, one respondent stated, "Yes, yes. Total trust in my doctor" (patient 073). Comfort with and deference to providers emerged as common themes, whereas instances of conflict between patients and providers were mentioned only twice.

Patient-Other

Additional relevant social influences on patients come from their community, including family and friends.

Provider-Colleague

The most important social influence between providers appeared to be their peers' consensus on the indications and use of PO:

> *I think we're constantly learning from each other. You know, we're seeing our colleagues order testing in this setting and so we're going to order.* [Provider 5]

Technical Challenges: Opportunity

How providers were able to operationalize PO treatments was the result of internal processes. These could facilitate or inhibit timely care delivery.

Ordering Process

This was the most frequently mentioned aspect of technical challenges. Providers noted frequent difficulties in completing the orders required to send testing and reported frequent breakdowns in communication with the pathology department related to initial processing. One respondent was quoted as saying:

> *Trying to get the stuff ordered is more difficult than just ordering standard tests like immunohistochemistry or flow cytometry. We have to jump through a bunch of hoops for that and also the retrieval of the information. Once it's done it requires a few phone calls, where's my stuff?* [Provider 13]

Specimen Acquisition or Processing

The expected procedural difficulties in obtaining a specimen were mentioned by several providers, and it was occasionally noted that tissue was available but at another institution. Knowing where kits were available and arranging for transport were also potential failure points, especially when dealing with peripheral blood NGS, obtained in the clinic.

Resulting Process

The principal issues with the resulting process were the long time it takes to generate a usable result and the inability to see the result once testing was completed.

Conceptual Model

To illustrate the intersections of our results, we offer a conceptual model in Figure 1. Under the auspices of our overarching theme of "The Precision Oncology Feedback Loop," the conceptual model illustrates the contribution of each of the areas of the BCW to the patient and provider interaction that ultimately influences PO implementation. Capability, opportunity, and motivation all influence and variously reinforce or negate each other, contributing to the implementation of PO.

Discussion

Principal Findings

Our study aimed to characterize the barriers and facilitators to PO. We found significant determinants of PO implementation at the patient, provider, and systems levels. In our analysis, the TDF provides a useful framework to conceptualize PO service implementation and, combined with the BCW, informs the design of interventions to improve PO implementation.

Our findings associated with system and operational issues are consistent with other studies. Prior research reported substantial structural or logistical issues in PO implementation, including coordinating or awaiting sample collection [25]. Our results add to previous work by presenting a more detailed analysis of specific factors associated with these problems, including interdepartmental communication–related barriers and the obstruction of interdepartmental communication via EHR ordering processes. Our data on the domains of Cognitive and Interpersonal Skills reiterated these challenges in communication. Furthermore, our finding about the role that staffing plays in PO care delivery, with a specific nod to the added benefit of patient navigators to help streamline test ordering, sample procurement, and results communication from pathology to providers, is novel.

From the patients' perspective, our findings are associated with the social determinants of health around patient financial, logistics, and education specific to the VA population. The existing literature reports concerns around insurance coverage, high copays, and overall costs associated with treatment, which contrasts with our findings because VA participants do not bear those financial burdens [26]. This discrepancy is likely related to the VA single-payer model, which minimizes patient costs and third-party payer interactions, thereby eliminating a barrier to PO. Notably, existing literature is concordant with our findings that logistical challenges outside of cost (eg, transportation) represent barriers [26,27].

Patient education was perceived as a facilitator in our population, but only some patients noted receiving materials from their physicians, with many others turning to external resources. Several prior studies note that education can facilitate precision medicine when available and appropriately disseminated because it promotes patient engagement with care [28]. Yet, information sources sought by patients outside of their clinical team also suggest there is a risk for patients around misinformation in understanding precision medicine [26]. Our findings are also consistent with previous work identifying

XSL•FO
RenderX

limited patient knowledge as a barrier to PO clinical trial accrual [28].

Regarding provider *Knowledge*, previous survey research reported that approximately 1 in 5 providers felt "low confidence" in their knowledge of clinical genomics and believed the tests would be used for less than 10% of patients [29]. Additional studies report that a lack of provider knowledge in genomic medicine may lead to delayed use [30]. Our findings reflect similar insecurities in providers regarding PO knowledge. Our data, however, build on previous literature by noting enthusiasm for systems-level educational interventions (ie, tumor boards noted as "immensely helpful") and increasing comfort in interpreting NGS results (ie, providers feel "better in terms of outlining what's pathogenic and what's not"). Our data suggest a role for educational initiatives at the provider and patient levels to mitigate perceived knowledge gaps. Taken together, our findings along with the existing literature suggest that a deliberately implemented educational initiative may help facilitate PO uptake while also ensuring that patients do not fall victim to misinformation.

We noted that findings regarding the domains of Memory and Attention have substantial interplay with the findings in physician *Environment*, insofar as both relate to the structural/logistical burden that physicians face when implementing PO. Our findings were concordant with previous work suggesting barriers to precision medicine in time investment by physicians reviewing records, coordinating or awaiting sample collection, determining patient eligibility, and resolving insurance-related issues [26].

With regard to the domains of Goals and Reinforcement, previous studies similarly found that patients sought the benefits of PO clinical trials over previous less-targeted approaches to cancer care [31]. Our results support similar findings not only among patients considering clinical trials but also among all patients considering PO as standard care.

Limitations

The limitations of our study include the following: (1) a small sample size comprising entirely of men, (2) VA-only study sites, (3) a risk of social desirability bias on the part of participants, and (4) bias in interpretation. Regarding sample size, our number of 33 (17 patients and 16 providers), although a relatively small cohort, was determined using theoretical saturation in which recruitment stopped when few additional new themes emerged. This approach increases efficiency while covering the majority of relevant themes. Of note, this is the largest sample of both patients and providers in any published work on the topic.

Regarding VA-only study sites, our study was conducted within the VA and represents viewpoints from a single, uniform health system. As such, external factors including insurance coverage, access to care, and access to trials are different from those in the private health care sector. Nonetheless, the VA setting does allow for geographic diversity and frequently samples patients with limited economic means, a population with well-reported underrepresentation in research [32,33].

A further consequence of VA-only sites is that our sample includes only male patients. The VA patient population is approximately 90% male, but the number of female patients is growing [34]. They may have unique PO treatment needs; thus, their perceptions may differ from those of their male counterparts. While we considered oversampling female patients, the cancers they are treated for are different from those of male patients and may change the PO oncology experience. Future research should focus specifically on female veterans to understand their needs with regard to PO.

We also chose to focus on the cancers that are most frequently treated in VA oncology clinics and to incorporate PO, that is, prostate, lung, and colorectal cancers, which yielded a predominantly male patient base. We made these decisions to focus on high-volume cancers, which can illuminate systemic challenges in a way that infrequently treated cancers cannot.

Finally, we recognize the constraints of social desirability bias along with biases in the interpretation of results. To mitigate social desirability bias, we maintained participant anonymity and confidentiality and used verbal and nonverbal cues to increase patient comfort [32]. To mitigate bias in interpretation, all interviews were coded independently by 3 reviewers, and disagreements on coding were resolved by discussion until consensus.

Conclusion

In conclusion, our interviews with patients and providers added essential data to an understudied and quickly growing area of cancer care. Patients and providers reported barriers to Knowledge, Environment, Goals, and Attention. When mapped to the TDF or BCW, these identified barriers facilitate the design of a multilevel intervention for patients, providers, and systems to educate and improve the implementation of PO. Future research should engage with broader populations of specific cancers and also examine geographic variation more closely.

Acknowledgments

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to the GAIDeT (Generative AI Delegation Taxonomy; 2025), the following tasks were delegated to GAI tools under full human supervision: data visualization to generate the conceptual model in Figure 1. The GAI tool used was Gemini 2.5 Nano Banana Image Generator. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes. Additionally, we used the Gemini image generator available within the NYU Langone Health closed AI system; thus, no data were fed into public models.

Abstract

Background: Preoperative nodal assessment in colorectal cancer (CRC) remains imperfect, and uncertainty regarding pathological lymph node metastasis (LNM) may persist despite conventional imaging. Machine learning using routinely available preoperative information may provide complementary patient-level risk estimates without requiring radiomic feature extraction or molecular testing.

Objective: This study aimed to develop and externally validate machine learning models for preoperative estimation of pathologically confirmed LNM risk in patients with newly diagnosed CRC undergoing direct radical surgery without preoperative anticancer treatment, and to assess whether multivariable prediction adds information beyond clinical tumor stage (cT) alone.

Methods: This multicenter retrospective study included 2725 patients from 2 hospitals. The internal cohort (n=1074) was split into training (n=753) and internal test (n=321) sets, while 1651 patients from a second center formed the external validation cohort. Candidate predictors were routinely available preoperative clinical, laboratory, tumor-marker, imaging-based, and endoscopic biopsy variables. Predictors were selected using univariable and multivariable logistic regression (LR). Seven algorithms were evaluated: random forest (RF), support vector machine (SVM), LR, decision tree (DT), extreme gradient boosting (XGBoost), naive Bayes (NB), and light gradient boosting machine (LightGBM). Performance was assessed using discrimination, threshold-dependent classification metrics, calibration, and decision curve analysis (DCA). Shapley additive explanations (SHAP) were used for interpretation. Sensitivity analyses compared the selected predictors with all candidate predictors and cT alone.

Results: Six predictors were retained: BMI, preoperative carcinoembryonic antigen, primary tumor site, cT, histological type, and tumor differentiation. RF was selected based on internal test performance. The area under the receiver operating characteristic curve (AUROC) was 0.803 (95% CI 0.756 - 0.849) in the internal test set and 0.776 (95% CI 0.755 - 0.797) in external validation. In external validation, accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were 0.687, 0.677, 0.693, 0.569, and 0.781, respectively. The Brier score was 0.190, and the calibration slope was 1.061. cT contributed most in SHAP analysis; however, the 6-predictor RF model showed significantly higher discrimination than cT alone in both the internal test set (AUROC 0.803 vs 0.712; ΔAUROC=0.091; P<.001) and external validation cohort (AUROC 0.776 vs 0.707; ΔAUROC=0.069; P<.001). Discrimination did not differ significantly between the 6-predictor and all-predictor RF models.

Conclusions: We developed and externally validated a 6-predictor RF model for preoperative LNM risk estimation in patients with newly diagnosed CRC undergoing radical resection with regional lymph node dissection without preoperative anticancer treatment. The model showed moderate external discrimination and provided predictive information beyond cT alone. It is intended for research-stage adjunctive risk stratification and should not replace imaging, pathological evaluation, or clinical judgment. Prospective validation in broader populations and clinical settings is required before implementation.

KEYWORDS

colorectal cancer; lymph node metastasis; machine learning; random forest; preoperative prediction; external validation; SHAP; risk stratification; shapley additive explanations

Introduction

Colorectal cancer (CRC) remains a major global health burden. According to Global Cancer Observatory (GLOBOCAN) 2024, more than 2.0 million new CRC cases and approximately 918,000 CRC-related deaths occurred worldwide in 2024, making CRC the third most commonly diagnosed cancer and the second leading cause of cancer death globally [1]. Regional lymph node metastasis (LNM) is a key component of CRC staging and an important prognostic factor [2]. Accurate preoperative assessment of nodal involvement is therefore important for defining disease extent and stratifying patient risk before surgery.

Conventional imaging is central to preoperative CRC staging and provides essential information on local tumor extent. However, radiological assessment of nodal involvement remains challenging because benign and metastatic lymph nodes may overlap in size and morphological appearance. A recent systematic review and meta-analysis found that size-based preoperative computed tomography (CT) achieved only moderate diagnostic performance for LNM in colon cancer [3]. Similarly, an updated review of rectal magnetic resonance imaging (MRI) identified nodal staging as a persistent challenge, with size and morphological criteria subject to substantial overlap and staging pitfalls [4]. Thus, although imaging provides indispensable anatomical information, uncertainty regarding pathological nodal status may remain before surgery. Integrating routinely available clinical, laboratory, and biopsy-derived information may therefore provide a more complete patient-level estimate of LNM risk.

Machine learning has increasingly been used to combine clinical, imaging, and pathological information for LNM prediction in CRC. However, existing models differ substantially in the populations studied, predictors included, and data modalities used, ranging from conventional clinical variables to radiomics and digital pathology, which complicates comparison across studies [5]. Models using high-dimensional imaging or pathological features may capture additional predictive information but also require more complex feature extraction and interpretation. Importantly, model performance observed during development may not be maintained in independent populations, and recent CRC-specific reviews have identified limited external validation as an important source of uncertainty in reported performance [6,7]. These issues are particularly relevant to preoperative LNM prediction, for which a useful model should provide reliable risk estimates using information that can be obtained consistently before surgery.

Accordingly, we aimed to develop and externally validate machine learning models for preoperative estimation of pathologically confirmed LNM risk in patients with newly diagnosed CRC undergoing direct radical surgery without preoperative anticancer treatment. Predictors were restricted to routinely available preoperative information, including clinical characteristics, laboratory and tumor-marker measurements, imaging-based clinical assessment, and endoscopic biopsy findings. We compared multiple machine learning algorithms, evaluated the selected model in an independent external cohort, and used model interpretation to characterize predictor contributions. We also assessed whether the multivariable model provided predictive information beyond clinical T stage alone. The intended use was adjunctive patient-level LNM risk stratification within the direct-surgery pathway.

Methods

Study Design, Setting, and Participants

This was a multicenter retrospective study for the development and external validation of a clinical prediction model. After ethics approval was obtained, investigators retrospectively collected data from patients with newly diagnosed CRC who underwent radical resection at the First Affiliated Hospital of Harbin Medical University or Shanxi Province Cancer Hospital between July 2023 and December 2025.

The inclusion criteria were as follows: (1) age ≥18 years; (2) a new diagnosis of CRC confirmed by postoperative pathology; (3) direct treatment with radical resection and regional lymph node dissection; and (4) ascertainable postoperative pathological regional LNM status. Patients managed with endoscopic resection, local excision, nonoperative treatment, or preoperative anticancer therapy were not eligible for the direct-surgery cohort. The exclusion criteria were as follows: (1) preoperative radiotherapy, chemotherapy, targeted therapy, immunotherapy, or other anticancer treatment; and (2) synchronous or metachronous malignant tumors other than CRC.

The sample size was determined by all consecutive eligible cases available during the prespecified study period, and no a priori sample size estimation was performed.

The First Affiliated Hospital of Harbin Medical University constituted the internal development cohort. Stratified random sampling based on LNM status was used to split the cohort into training and internal test sets at a 7:3 ratio. The random seed was fixed at one to ensure reproducibility. Shanxi Province Cancer Hospital constituted the independent external validation cohort.

Outcome Definition and Candidate Predictors

The primary outcome was regional LNM, confirmed by the postoperative pathological report. Patients were then classified as LNM-positive or LNM-negative according to the final pathological findings.

Candidate predictors were prespecified before model construction and were all obtainable through routine preoperative clinical assessment.

The candidate predictors included the following categories: Demographic and general clinical variables were age, sex,

XSL•FO
RenderX

ethnicity, residence, smoking history, drinking history, family history, comorbidities, and BMI. Laboratory indices were neutrophil percentage, systemic immune-inflammation index (SII), and albumin-to-globulin ratio (AGR). Tumor markers were preoperative carcinoembryonic antigen (pCEA) and preoperative carbohydrate antigen 19‐9 (pCA19-9). Tumor-related variables were clinical T stage, bowel obstruction, primary tumor site, maximum tumor diameter, gross tumor type, histological type, and tumor differentiation. Comorbidities were recorded as a binary variable (yes or no). Patients with a documented history of hypertension, diabetes mellitus, or coronary heart disease were classified as having comorbidities; patients without any of these conditions were classified as having no comorbidities.

Laboratory indicators were obtained from the most recent preoperative test results, and values measured within 1 week before surgery were used whenever available. SII was calculated as platelet count×absolute neutrophil count/absolute lymphocyte count. AGR was calculated as serum albumin/globulin, where globulin=total protein−albumin. Tumor differentiation and histological type were obtained from preoperative endoscopic biopsy pathology reports, whereas maximum tumor diameter and clinical T stage were obtained from preoperative imaging and/or endoscopic evaluation.

Missing Data Handling

Before data preprocessing, the number and proportion of missing values for each candidate predictor were calculated separately in the training, internal test, and external validation sets. Patients with missing postoperative pathological LNM status were excluded before cohort formation, and the outcome was not imputed. The internal development cohort was divided into the training and internal test sets before missing-data handling, and the external validation cohort remained independent throughout. For limited missingness in continuous predictors, multiple imputation by chained equations was performed with the R package *mice* (Stef van Buuren and Karin Groothuis-Oudshoorn), generating 3 imputed data sets with a maximum of 50 iterations per chain and a random seed of 123. Missing categorical predictor values were imputed using the training-set mode. The imputation model and derived preprocessing rules were estimated from the training data and then applied without refitting to the internal test and external validation sets. Variable-level missingness before imputation is reported in Table S2 in Multimedia Appendix 1; because missingness was summarized by variable, the same patient could contribute to more than one missing-value count.

Biopsy-Resection Agreement Analysis

Among patients with both preoperative endoscopic biopsy and postoperative resection specimen pathology results, the agreement in histological type and tumor differentiation was evaluated. This analysis included only patients with nonmissing preoperative and postoperative results for the corresponding pathological indicator, and no imputed values were used.

Histological type was uniformly classified as adenocarcinoma and special histological type, with the latter including mucinous adenocarcinoma and signet-ring cell carcinoma. Agreement was evaluated using a cross-classification table, the exact agreement rate, the proportion of special histological type missed on preoperative biopsy, the positive predictive value (PPV) of a preoperative diagnosis of special histological type, and the unweighted Cohen κ coefficient with its 95% CI. A missed special histological type was defined as a preoperative biopsy diagnosis of adenocarcinoma with a postoperative resection specimen diagnosis of special histological type, and its proportion was calculated with patients confirmed as having special histological type postoperatively as the denominator. Tumor differentiation was uniformly classified as G1, G2, and G3, G4. Concordance was assessed using cross-classification tables, the exact agreement rate, the proportion with underestimated grade, the proportion with overestimated grade, and the linearly weighted Cohen κ coefficient with its 95% CI. Underestimated grade was defined as a pathologic grade on preoperative biopsy that was lower than the pathologic grade on the postoperative resection specimen, indicating that the biopsy suggested a more favorable grade; overestimated grade was defined as a pathologic grade on preoperative biopsy that was higher than the pathologic grade on the postoperative resection specimen. The 95% CIs for all percentages were calculated using the Wilson method, and the 95% CI for the Cohen κ coefficient was estimated by 20,000 multinomial bootstrap resamples. Detailed results are presented in Table S3 in Multimedia Appendix 1.

Predictor Preprocessing and Encoding

After missing-data handling, predictors were encoded according to their variable type before model development. BMI and pCEA were retained as continuous variables without standardization. Primary tumor site was one-hot encoded, with right-sided colon as the reference category and separate indicator variables for left-sided colon and rectum. Histological type was binary encoded as adenocarcinoma=0 and mucinous adenocarcinoma or signet-ring cell carcinoma=1. Clinical Tumor stage (cT) and tumor differentiation were encoded as ordinal integers ([clinical Tumor1 stage] cT1=0, [clinical Tumor2 stage] cT2=1, [clinical Tumor3 stage] cT3=2, [clinical Tumor4 stage] cT4=3; G1=0, G2=1, and G3 or G4=2, respectively).

The same preprocessing and encoding scheme was applied across all candidate machine learning models. The preprocessing rules were defined using the training data and then applied unchanged to the internal test and external validation sets. Detailed predictor preprocessing and encoding rules are provided in Table S5 in Multimedia Appendix 1.

Predictor Selection

Predictor selection was performed exclusively in the training set to avoid information leakage. Prespecified candidate predictors were first evaluated using univariable binary logistic regression (LR). Variables associated with LNM at $P<.05$ were subsequently entered into a multivariable binary LR model. Variables remaining statistically significant at $P<.05$ in the multivariable analysis were retained as the final predictor set for subsequent machine learning model development. Associations were reported as odds ratios (ORs) with 95% CIs. The internal test and external validation sets were not used for predictor selection.

XSL•FO
RenderX

Model Development and Hyperparameter Tuning

Using the predictors retained through the prespecified selection procedure, 7 machine learning models were developed: random forest (RF), support vector machine (SVM), LR, decision tree (DT), extreme gradient boosting (XGBoost), naive Bayes (NB), and light gradient-boosting machine (LightGBM). All model development and hyperparameter tuning were performed exclusively using the training set. In the training set, LNM was present in 278 of 753 (36.9%) patients. RF therefore used class_weight=balanced to account for the moderate outcome imbalance. Final hyperparameter settings are provided in Table S5 in Multimedia Appendix 1.

For RF, SVM, DT, XGBoost, and LightGBM, hyperparameters were optimized using grid search with 3-fold cross-validation within the training set, with the area under the receiver operating characteristic curve (AUROC) as the optimization metric. LR and NB were fitted without hyperparameter tuning. The final hyperparameter settings for all candidate models are provided in Table S5 in Multimedia Appendix 1.

Model Performance Evaluation and Validation

Model performance was evaluated in the training, internal test, and independent external validation sets. Discrimination was assessed using receiver operating characteristic (ROC) curves and the AUROC with 95% CIs. Classification performance was evaluated using accuracy, sensitivity, specificity, F_1 score, PPV, and negative predictive value (NPV).

For each model, an evaluation operating point was determined by maximizing the Youden index in the training set and was then applied unchanged to the internal test and external validation sets to calculate threshold-dependent classification metrics. No operating-point reoptimization was performed using the internal test or external validation data. These training-derived operating points were used for model evaluation and were not considered validated clinical decision cutoffs.

Calibration was assessed using calibration curves, the Brier score, calibration intercept, and calibration slope. Clinical utility was explored using decision curve analysis (DCA) by estimating net benefit across a prespecified threshold-probability display interval of 0.05 - 0.80. The final model was selected based on prespecified overall performance in the internal test set, considering discrimination, classification performance, calibration, clinical utility, and the balance of sensitivity, specificity, and F_1 score. After model selection, the selected model was evaluated in the independent external validation cohort without further fitting, hyperparameter tuning, or threshold optimization. The DCA interval was descriptive and was not treated as a validated clinical decision threshold.

After selection of the final model, its AUROC was compared pairwise with those of the other candidate models in the internal test and external validation sets using the DeLong test. To account for multiple comparisons, *P* values were adjusted separately within each data set using the Holm method.

Model Interpretability

Shapley additive explanations (SHAP) analysis was performed for the model selected according to the prespecified evaluation framework to characterize the contribution of individual predictors to model output. Global feature importance was quantified using the mean absolute SHAP value for each encoded feature. A SHAP summary plot was used to visualize both the magnitude and direction of predictor contributions across patients.

Patient-level interpretation was performed using an individual SHAP explanation to illustrate how multiple predictors jointly contributed to a single prediction. SHAP dependence plots were additionally generated to examine the relationship between predictor values and their contributions to model output. For primary tumor site, the 2 dummy variables representing left-sided colon and rectum were interpreted separately, with right-sided colon serving as the reference category; the dummy-variable values were not interpreted as an ordinal risk gradient.

Sensitivity Analyses

Sensitivity analyses were performed to examine the robustness of the predictor-selection strategy and the incremental predictive value of the selected predictor set beyond clinical T stage alone. Using the algorithm selected as the final model, 3 models were constructed: a model based on the predictor set retained through the prespecified selection procedure, a model incorporating all prespecified candidate predictors, and a model using clinical T stage alone.

All models were developed using the training set and evaluated in the internal test and external validation sets. Their performance was compared in terms of discrimination, threshold-dependent classification performance, calibration, and clinical utility. Pairwise AUROC comparisons between the 6-predictor model and the 2 comparator models were performed using the DeLong test. Detailed sensitivity-analysis results are presented in Table S10 and Figure S4 in Multimedia Appendix 1.

Statistical Analysis and Software

Two-sided tests were used for all analyses. Statistical significance was defined at α=.05. We assessed normality of continuous variables with the Shapiro-Wilk test. Normally distributed data are presented as mean (SD). These data were compared with the independent-samples *t* test. Skewed data are presented as median (IQR). They were analyzed with the Mann-Whitney *U* test. We summarized categorical variables as frequencies and percentages. Group differences were examined with the chi-square test or Fisher exact test, as appropriate. When Fisher exact test was used, chi-square statistics were not reported.

Associations between candidate predictors and LNM were examined using univariable and multivariable binary LR models, with effect estimates reported as ORs and 95% CIs.

Statistical analyses and missing-data handling were performed using R version 4.5.1 (R Core Team). Machine learning model development, performance evaluation, and model interpretation were performed using Python (Python Software Foundation) version 3.12.3 with scikit-learn (scikit-learn developers) version 1.4.2, XGboost (Distributed Machine Learning Community)

XSL•FO

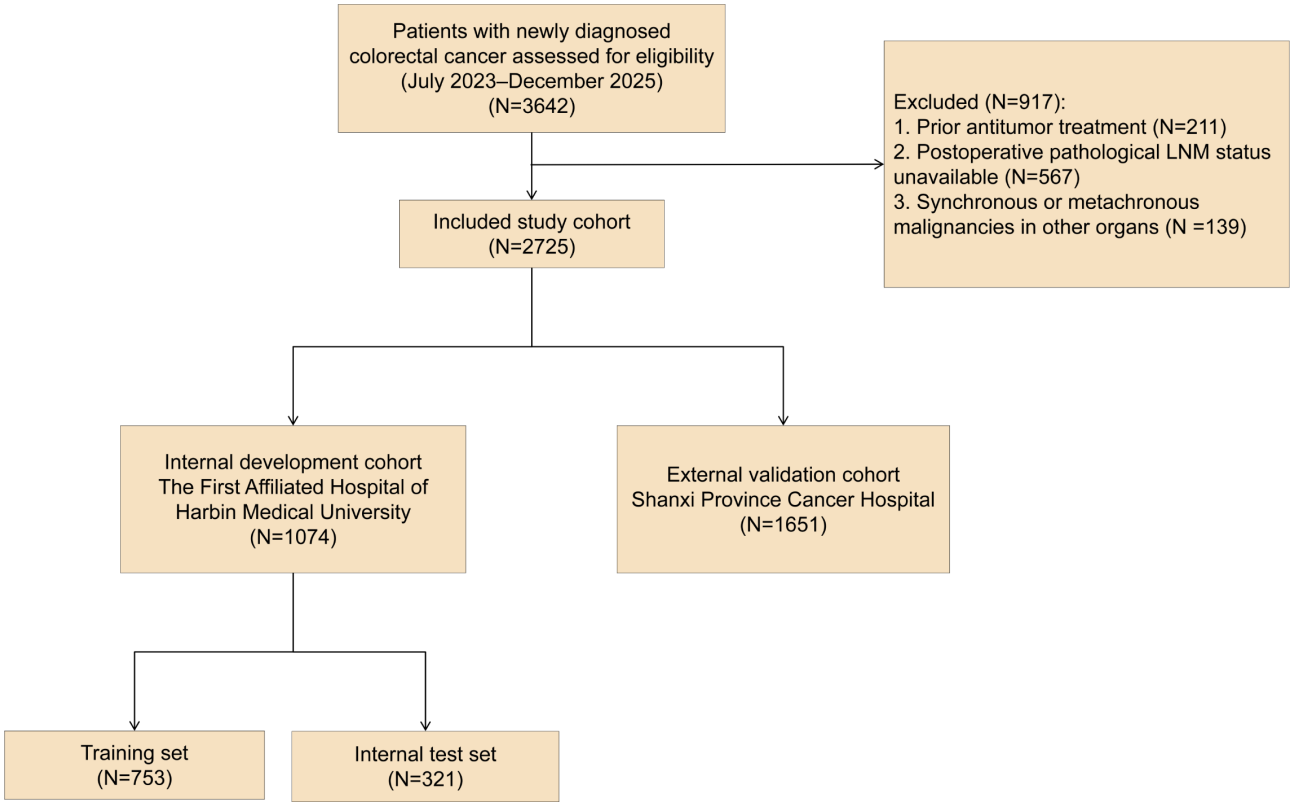
version 2.1.1, lightGBM (Microsoft Corporation) version 4.5.0, and SHAP (Scott Lundberg) version 0.45.1.

Ethical Considerations

This study was approved by the Ethics Committee of the First Affiliated Hospital of Harbin Medical University (approval No. 202452) and the Ethics Committee of Cancer Hospital, Chinese Academy of Medical Sciences, Shanxi Hospital (Shanxi Province Cancer Hospital; approval No. KY2024163). At the First Affiliated Hospital of Harbin Medical University, the requirement for informed consent was waived because of the retrospective study design. All patient-level data used for the present analysis were deidentified before analysis.

Results



Study Population and Data Characteristics

Patient Inclusion and Cohort Allocation

During the study period, 3642 patients with newly diagnosed CRC were screened for eligibility. Of these, 211 patients were excluded because they had received preoperative anticancer treatment, 567 because postoperative pathological LNM status could not be ascertained, and 139 because of synchronous or metachronous malignancies other than CRC. The final study cohort therefore comprised 2725 patients from 2 independent medical centers (Figure 1).

The internal development cohort included 1074 patients from the First Affiliated Hospital of Harbin Medical University. Stratified random splitting at a 7:3 ratio yielded 753 patients for model training and 321 for internal testing. The independent external validation cohort comprised 1651 patients from Shanxi Province Cancer Hospital.

Figure 1. Study flowchart for patient screening, cohort allocation, model development, and validation. LNM: lymph node metastasis.

Baseline Characteristics and Missing Data

The development and external validation cohorts differed significantly in pCA19-9 (P=.004), SII (P=.03), residence (P<.001), family history (P<.001), smoking status (P=.03), and the number of lymph nodes examined (P=.01). No significant differences were observed in the other baseline characteristics, including LNM status (Table 1). No significant differences were observed between the training and internal test sets (Table S1 in Multimedia Appendix 1). Missingness was low overall, with missing proportions below 5% for all prespecified candidate predictors across the 3 data sets. The maximum missingness was 35/753 (4.65%) in the training set, 14/321 (4.36%) in the internal test set, and 78/1651 (4.72%) in the external validation set (Table S2 in Multimedia Appendix 1).

[a]Values are median (IQR) or n (%) unless otherwise indicated. The Mann-Whitney U test was used for continuous variables, and the chi-square test or Fisher exact test was used for categorical variables, as appropriate.

[b]Values are median (IQR) or n (%) unless otherwise indicated. The Mann-Whitney *U* test was used for continuous variables, and the chi-square test was used for categorical variables. Z denotes the standardized test statistic from the Mann-Whitney *U* test. Z values are reported for continuous variables, whereas chi-square values are reported for categorical variables, with degrees of freedom given in parentheses.

[c]Z value.

[d]χ^2 (df).

[e]pCEA: preoperative carcinoembryonic antigen.

[f]pCA19-9: preoperative carbohydrate antigen 19 - 9.

[g]SII: systemic immune-inflammation index.

[h] AGR: albumin-to-globulin ratio.

[i]cT: clinical Tumor stage.

Biopsy-Resection Agreement

Agreement between preoperative biopsy and postoperative resection pathology was moderate for both histological type and tumor differentiation. For histological type, the exact agreement rate was 88.5% (2392/2703), with an unweighted Cohen κ of 0.616 (95% CI 0.577 - 0.653); 42.5% (248/583) of postoperative special histological types had been classified as adenocarcinoma on preoperative biopsy. For tumor differentiation, the exact agreement rate was 77% (2074/2692), with a linearly weighted Cohen κ of 0.521 (95% CI 0.488 - 0.552); undergrading and overgrading occurred in 13.9% (374/2692) and 9.1% (244/3692) of cases, respectively (Table S3 in Multimedia Appendix 1).

Predictor Selection

Univariable LR Analysis

Univariable analysis identified BMI, pCEA, bowel obstruction, maximum tumor diameter, gross tumor type, primary tumor site, clinical T stage, histological type, and tumor differentiation as significantly associated with LNM (Table S4 in Multimedia Appendix 1). Higher BMI and pCEA levels, bowel obstruction, right-sided colon or rectal location, mucinous adenocarcinoma or signet-ring cell carcinoma, and poorer tumor differentiation

XSL•FO
RenderX

were associated with higher odds of LNM, whereas protruding gross tumor type was associated with lower odds. Compared with cT1, cT3 and cT4 were associated with substantially higher odds of LNM (OR 8.238 and 11.520, respectively; both *P*<.001). cT2 showed a lower odds estimate than cT1 in the univariable analysis (OR 0.186, 95% CI 0.043 - 0.810; *P*=.03). The remaining candidate predictors were not significantly associated with LNM.

Multivariable LR Analysis

Multivariable LR identified BMI, pCEA, primary tumor site, cT, histological type, and tumor differentiation as factors independently associated with LNM (Table 2). Higher BMI (OR 1.154, 95% CI 1.095 - 1.216; *P*<.001) and pCEA (OR 1.005, 95% CI 1.001 - 1.010; *P*=.03) were associated with higher odds of LNM. Compared with left-sided colon tumors, right-sided colon tumors (OR 1.756, 95% CI 1.101 - 2.801; *P*=.02) and rectal tumors (OR 1.838, 95% CI 1.196 - 2.824; *P*=.005) also showed higher odds of LNM.

Clinical T stage showed the strongest associations: compared with cT1, cT3 and cT4 were associated with markedly higher odds of LNM (OR 11.798 and 17.743, respectively; both *P*<.001), whereas cT2 was not statistically significant (*P*=.10). Mucinous adenocarcinoma or signet-ring cell carcinoma was associated with higher odds than adenocarcinoma (OR 1.880, 95% CI 1.172 - 3.017; *P*=.009). Compared with G1 differentiation, G2 (OR 5.122, 95% CI 1.082 - 24.237; *P*=.04) and G3 or G4 (OR 13.593, 95% CI 2.755 - 67.070; *P*=.001) were associated with higher odds of LNM. Gross tumor type, bowel obstruction, and maximum tumor diameter were no longer statistically significant after multivariable adjustment.

Model Performance and Model Selection

Discrimination and Classification Performance

The discrimination and classification performance of the 7 candidate models is summarized in Table 3 and Figure 2. In the internal test set, AUROCs ranged from 0.708 to 0.809. The RF model achieved an AUROC of 0.803 (95% CI 0.756 - 0.849), with an accuracy of 0.720, sensitivity of 0.763, specificity of 0.695, and F_1 score of 0.667. In the external validation set, RF showed the highest AUROC among the candidate models (0.776, 95% CI 0.755 - 0.797), with an accuracy of 0.687, sensitivity of 0.677, specificity of 0.693, and F_1 score of 0.618.

Pairwise DeLong comparisons showed that, in the internal test set, the RF AUROC differed significantly only from that of the DT after Holm adjustment. In the external validation set, RF showed significantly higher AUROCs than SVM, LR, DT, and NB, whereas the differences versus XGBoost and LightGBM were not statistically significant after adjustment (Table S6 in Multimedia Appendix 1). Using the RF training-derived Youden operating point of 0.545, the PPV and NPV were 0.592 and 0.834 in the internal test set and 0.569 and 0.781 in the external validation set, respectively. The corresponding false-positive and false-negative counts were 62 and 28 in the internal test set and 317 and 200 in the external validation set. Threshold-dependent classification metrics are summarized in Table 3, while PPV, NPV, and full confusion-matrix counts are provided in Table S7 in Multimedia Appendix 1.

[a]Data set sizes were 753 for training, 321 for internal testing, and 1651 for external validation.

[b]AUROC: area under the receiver operating characteristic curve.

[c]Classification metrics were calculated using model-specific training-derived operating points selected by maximizing the Youden index in the training set: RF, 0.545; SVM, 0.316; LR, 0.343; DT, 0.429; XGBoost, 0.439; NB, 0.208; and LightGBM, 0.413. These operating points were applied unchanged to the internal test and external validation sets and were used for performance evaluation rather than as validated clinical decision cutoffs. Values are presented to 3 decimal places; full-precision values were used in the analyses. PPV, NPV, and full confusion-matrix counts are reported in Table S7 in Multimedia Appendix 1.

[d]RF: random forest.

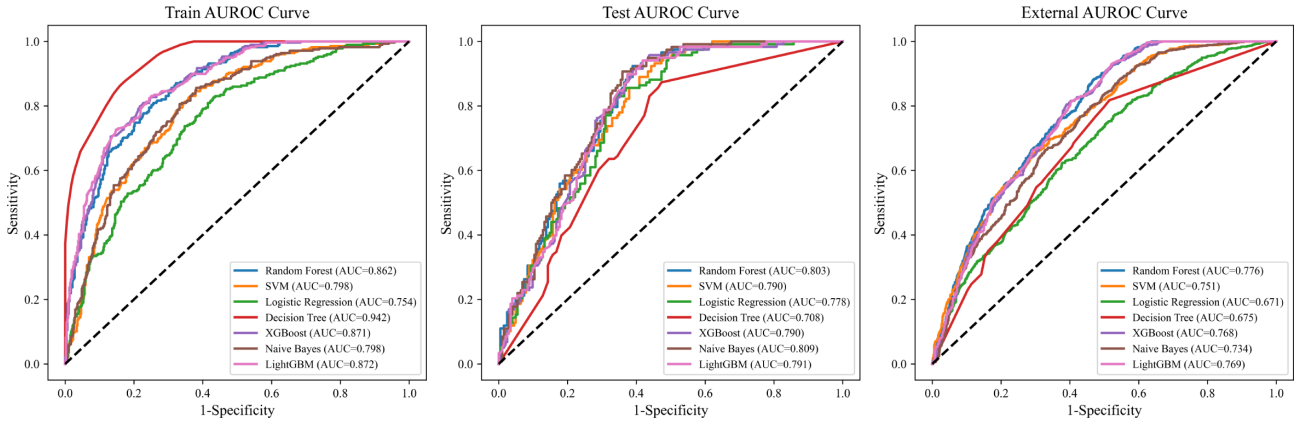
[f]LR: logistic regression.



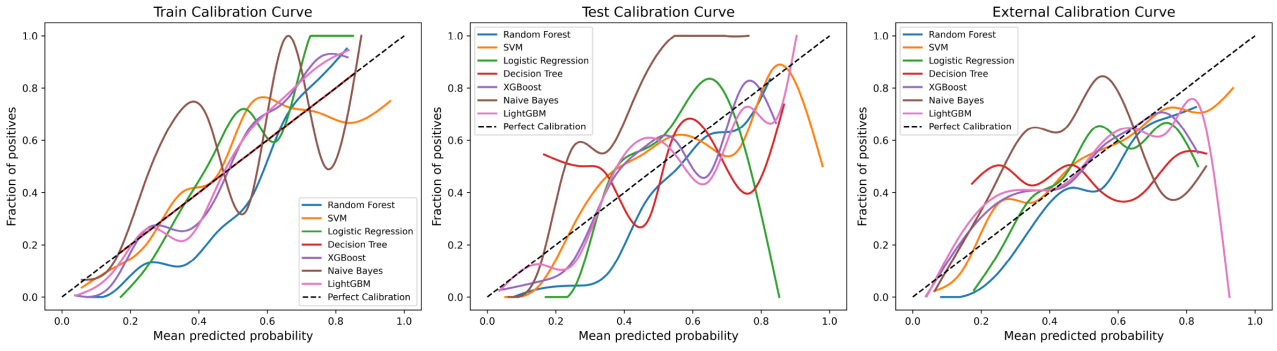
[g]DT: decision tree.

[h]XGBoost: extreme gradient boosting.

[i]NB: Naive Bayes.

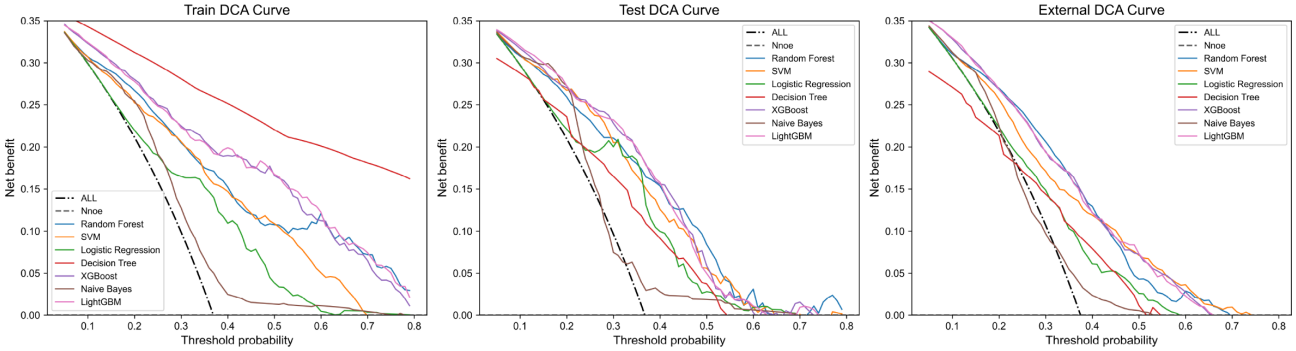
[j]LightGBM: light gradient boosting machine.

Figure 2. Area under receiver operating characteristic curves of the 7 candidate machine learning models in the training, internal test, and external validation sets. AUROC: area under receiver operating characteristic; LightGBM: light gradient boosting machine; SVM: support vector machine; XGBoost: extreme gradient boosting.



Calibration and Clinical Utility

Calibration curves are shown in Figure 3, and quantitative calibration statistics, including the Brier score, calibration intercept, calibration slope, and observed-to-expected ratio, are reported in Multimedia Appendix 1, Table S8 in Multimedia Appendix 1. Corresponding calibration results from the sensitivity analyses are provided in Table S10 in Multimedia Appendix 1. For the RF model, the Brier score was 0.179 in the internal test set and 0.190 in the external validation set. The calibration intercepts were −0.176 and −0.120, the calibration slopes were 1.161 and 1.061, and the observed-to-expected ratios were 0.806 and 0.803, respectively. These estimates indicated reasonably stable calibration across the 2 validation sets, although the CIs should be considered when interpreting precision.



DCA is shown in Figure 4, and the corresponding model-specific net-benefit threshold-probability ranges are summarized in Table S9 in Multimedia Appendix 1. The lower bound of 0.05 was the prespecified lower limit of the display interval; these ranges were exploratory and should not be interpreted as validated clinical decision thresholds.

Figure 3. Calibration curves of the 7 candidate machine learning models in the training, internal test, and external validation sets. AUROC: area under receiver operating characteristic; LightGBM: light gradient boosting machine; SVM: support vector machine; XGBoost: extreme gradient boosting.

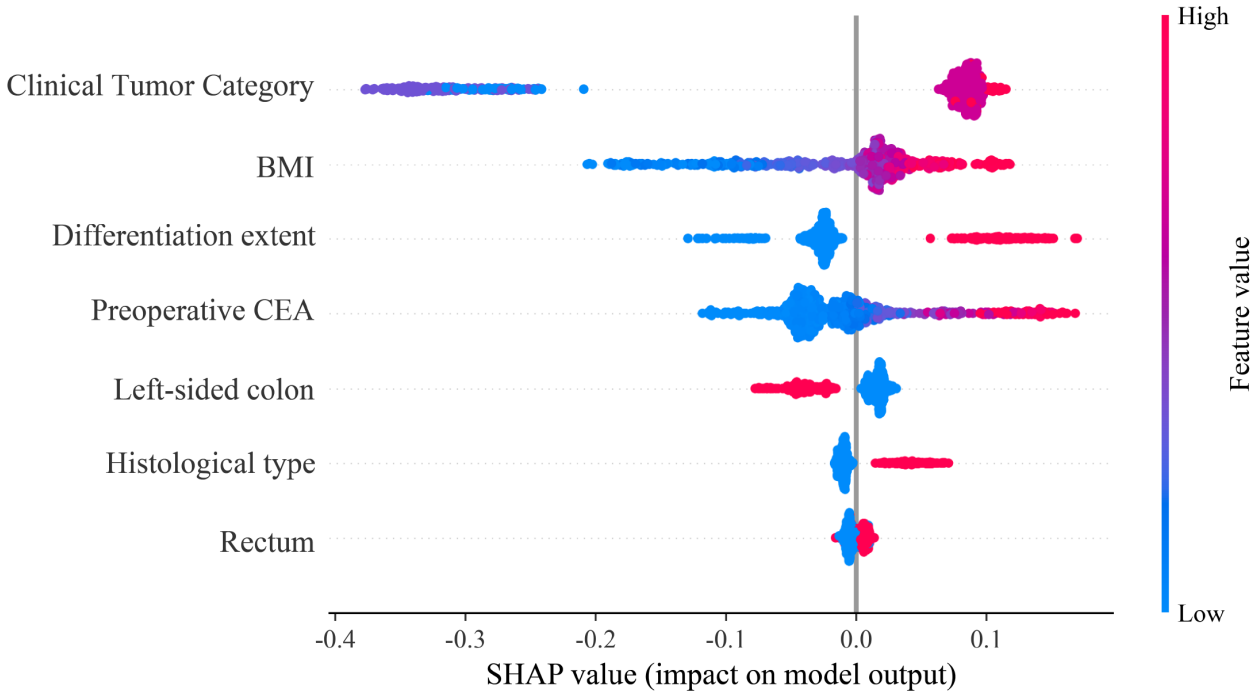
Figure 4. Decision curve analysis of the 7 candidate machine learning models in the training, internal test, and external validation sets. AUROC: area under the receiver operating curve; DCA: decision curve analysis; LightGBM: light gradient boosting machine; XGBoost: extreme gradient boosting.

Final Model Selection



Considering discrimination, classification performance, calibration, and clinical utility in the internal test set, RF was selected as the final model before external validation. RF achieved the highest AUROC in the external validation set (0.776), while maintaining relatively balanced sensitivity (0.677) and specificity (0.693). Its calibration slope was close to 1 in both the internal test (1.161) and external validation (1.061) sets. Although the external-validation AUROC differences between RF and XGBoost or LightGBM were not statistically significant after Holm adjustment, RF showed a favorable overall balance across the prespecified internal-test criteria and was therefore selected for subsequent external validation and interpretability analyses.

Model Interpretation

Global Feature Importance

SHAP analysis showed that clinical T stage had the greatest overall contribution to the RF model, followed by BMI, tumor differentiation, pCEA, the left-sided colon indicator, histological type, and the rectum indicator (Figure S1 in Multimedia Appendix 1). The SHAP summary plot further showed that higher clinical T stage, BMI, poorer tumor differentiation, higher pCEA, and special histological type generally shifted model predictions toward LNM positivity (Figure 5). In contrast, the left-sided colon indicator was predominantly associated with negative SHAP values relative to the right-sided colon reference category.

Figure 5. Shapely additive explanations summary plot of the encoded features in the final random forest model. CEA: carcinoembryonic antigen; SHAP: Shapely additive explanations.

Individual Prediction and Feature Dependence

For the representative patient shown in Figure S2 in Multimedia Appendix 1, the RF model estimated an LNM probability of 0.804, compared with a baseline probability of 0.504. G3 or G4 differentiation, cT3 stage, elevated pCEA (22.9 ng/mL), and higher BMI (25.9 kg/m²) contributed positively to the prediction, with tumor differentiation showing the largest individual contribution.

SHAP dependence plots further demonstrated distinct patterns across predictors (Figure S3 in Multimedia Appendix 1). Higher

XSL•FO
RenderX

BMI and pCEA were generally associated with increasingly positive SHAP values. cT1 and cT2 contributed predominantly toward LNM-negative predictions, whereas cT3 and cT4 contributed toward LNM-positive predictions. G3 or G4 differentiation and mucinous adenocarcinoma or signet-ring cell carcinoma also showed predominantly positive contributions. For tumor location, the left-sided colon indicator was associated with lower SHAP values when present, whereas the rectum indicator showed comparatively smaller and more variable contributions.

Sensitivity Analyses

Sensitivity analyses showed that the RF model based on the 6 selected predictors performed similarly to the model incorporating all prespecified candidate predictors. The AUROC differences were not statistically significant in either the internal test set (0.803 vs 0.833; *P*=.15) or the external validation set (0.776 vs 0.787; *P*=.22). The all-candidate-predictor model showed slightly higher accuracy and lower Brier scores, but the overall performance profiles of the 2 models were comparable.

In contrast, the 6-predictor RF model showed significantly better discrimination than the model using clinical T stage alone, with AUROC differences of 0.091 in the internal test set and 0.069 in the external validation set (both *P*<.001). Calibration and decision curve analyses were consistent with improved probabilistic accuracy and broader exploratory net-benefit ranges for the multivariable model than for clinical T stage alone (Table S10 and Figure S4 in Multimedia Appendix 1).

Discussion

Principal Findings

In this multicenter retrospective study, we developed and externally validated a machine learning model for preoperative estimation of LNM risk in patients with CRC using routinely available clinical information. Six preoperative predictors—BMI, preoperative carcinoembryonic antigen (CEA), primary tumor site, clinical T stage, histological type, and tumor differentiation—were retained through the prespecified predictor-selection procedure. Among the 7 candidate algorithms, RF was selected as the final model based on its overall performance in the internal test set, with particular consideration of discrimination and the balance of threshold-dependent classification performance. The model achieved an AUROC of 0.803 in the internal test set and maintained an AUROC of 0.776 in the independent external validation cohort. In external validation, sensitivity and specificity were 0.677 and 0.693, respectively, while the calibration slope was 1.061 and the Brier score was 0.190, indicating that the model retained moderate discrimination with relatively stable classification and calibration performance when transported to an independent center.

An important finding was that the predictive information captured by the final model extended beyond clinical T stage alone. Although clinical T stage was the most influential predictor in the SHAP analysis, the clinical T stage–only RF model showed substantially lower discrimination than the final 6-predictor model in both the internal test set (AUROC 0.712 vs 0.803) and the external validation set (AUROC 0.707 vs 0.776). The corresponding AUROC differences of 0.091 and 0.069 were statistically significant in both datasets (both *P*<.001). These findings indicate that clinical T stage provides an important foundation for LNM risk estimation, but that BMI, preoperative CEA, tumor location, histological type, and tumor differentiation contribute additional complementary information for distinguishing individual risk.

Conversely, expanding the RF model from the selected 6 predictors to all prespecified candidate predictors did not result in a statistically significant improvement in discrimination. The all-predictor model yielded AUROCs of 0.833 and 0.787 in the internal test and external validation sets, respectively, compared with 0.803 and 0.776 for the 6-predictor model; the corresponding differences were not statistically significant (*P*=.15 and *P*=.22, respectively). Although the expanded model showed small numerical improvements in some performance measures, the absence of a clear gain in discrimination suggests that substantially increasing the number of predictors added limited incremental predictive information. The selected 6-predictor model therefore represents a relatively parsimonious approach that preserves most of the predictive information available from the broader set of routinely collected variables.

The SHAP analysis showed that the final RF model used information from several predictor domains. cT contributed most strongly, followed by BMI, tumor differentiation, pCEA, primary tumor site, and histological type. Higher cT, poorer tumor differentiation, higher BMI, and elevated pCEA generally shifted predictions toward a higher probability of LNM. These patterns describe model associations and should not be interpreted as causal effects or as evidence that the model explicitly identifies causal interactions.

Interpretation of Key Predictors

This finding is consistent with previous studies identifying deeper tumor invasion as a strong correlate of LNM in CRC [2,8,9]. The strong contribution of cT in the present model is therefore consistent with its established relationship to local tumor invasion and regional nodal spread.

Tumor differentiation was also an important predictor in the model. In our study, differentiation was assessed on preoperative endoscopic biopsy. Poor differentiation has been associated with an increased risk of LNM, particularly in early CRC [10]. However, limited tissue sampling may prevent preoperative biopsy from fully representing the tumor's overall differentiation. Barresi et al [11] reported concordant grading in approximately 75% of CRCs using a grading system based on poorly differentiated clusters, and the biopsy-derived grade was associated with nodal involvement and pTNM stage. Although their grading system differed from that used in our study, these findings support the clinical relevance of adverse histological features identified on preoperative biopsy. In our biopsy-resection analysis, tumor differentiation showed 77.0% (2074/2692) exact agreement, with a linearly weighted Cohen κ of 0.521, and 13.9% (374/2692) of tumors were undergraded on preoperative biopsy. Biopsy-reported differentiation therefore provides useful preoperative information, although it may not fully capture the highest-grade component of the tumor. Poor

XSL•FO
RenderX

differentiation on biopsy may serve as a meaningful high-risk feature, whereas a more favorable grade should be interpreted with awareness of sampling limitations.

Histological type showed a similar pattern. Mucinous adenocarcinoma and signet-ring cell carcinoma have distinct clinicopathological characteristics and are generally associated with more aggressive disease than conventional adenocarcinoma [12]. In our cohort, histological type showed 88.5% (2392/2703) exact agreement between preoperative biopsy and resection pathology, with a Cohen κ of 0.616. However, 42.5% (248/583) of tumors ultimately classified as mucinous adenocarcinoma or signet-ring cell carcinoma on the resection specimen had not been identified as a special histological type on preoperative biopsy. Previous studies have also reported that mucinous colorectal adenocarcinoma may be missed on initial endoscopic biopsy, reflecting the limitations of tissue sampling [13]. Importantly, despite incomplete biopsy-resection agreement, biopsy-derived histological type remained independently associated with LNM and contributed to the RF predictions, supporting its value as a routinely available preoperative predictor.

pCEA was independently associated with LNM, consistent with previous studies identifying elevated CEA as a risk factor for nodal involvement in CRC [14]. Our findings support pCEA as a routinely available preoperative marker for LNM risk prediction.

We found that right-sided colon and rectal tumors were associated with higher odds of LNM than left-sided colon tumors. CRCs arising at different anatomical sites show distinct clinicopathological and biological characteristics [15,16], which may partly explain the observed differences in nodal involvement. Our findings suggest that primary tumor site provides additional information for preoperative LNM risk prediction.

BMI was independently associated with LNM and ranked highly in the SHAP analysis. Obesity-related phenotypes have been linked to CRC development and progression [17,18], although BMI is only a simple proxy for overall adiposity. The observed association should not be interpreted as causal; BMI may instead function as a readily available patient-level marker correlated with other biological or clinical factors.

Taken together, these routinely available preoperative features capture complementary information on tumor extent, morphology, circulating markers, anatomical site, and patient characteristics, providing a broader basis for individualized LNM risk estimation.

Comparison With Previous Studies

Conventional imaging remains the foundation of preoperative staging in CRC, with CT commonly used for colon cancer and pelvic MRI for rectal cancer. Imaging provides important information on local tumor extent, as also reflected by the strong contribution of cT in our model. However, direct assessment of nodal metastasis still relies largely on lymph node size and morphological characteristics, which have limited accuracy for distinguishing metastatic from benign nodes. A meta-analysis of MRI-based nodal staging in rectal cancer reported only moderate diagnostic performance across different size and morphological criteria [19], while a recent systematic review similarly found limited performance for preoperative N staging in colon cancer using MRI or 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) [20]. These limitations provide a rationale for complementing conventional imaging with additional preoperative clinical and pathological information when estimating patient-level LNM risk.

Previous CRC metastasis prediction models have commonly included cancer stage, tumor differentiation, histological type, CEA, and demographic factors [21]. However, external validation has been limited: only 4 of 12 models identified in an umbrella review had undergone external validation, and calibration was incompletely reported [21]. More recent meta-analytic evidence also found higher reported AUROCs in studies without external validation [5]. Our model used routinely available preoperative variables and was evaluated in a large independent external cohort.

Quantitative imaging approaches, including radiomics and deep learning, aim to extract information beyond conventional visual assessment. A recent systematic review and meta-analysis reported promising performance of radiomics for preoperative LNM prediction in CRC, although substantial heterogeneity across studies remains [22]. Multimodal models further combine imaging-derived features with clinical variables to capture complementary information. However, the added value of these features may not always persist in external validation. In a multicenter rectal cancer study, Li et al [23] found that a clinical-radiomics model outperformed the clinical model in the training and internal validation cohorts, but this advantage was not maintained in the external cohort.

Taken together, previous studies illustrate a trade-off between the amount of predictive information incorporated and the complexity of data acquisition and model implementation. Differences in study populations, predictor sets, imaging modalities, and validation strategies make direct comparison of reported AUROCs across studies difficult [5,21,22]. In this context, our study focused on routinely available preoperative information, including clinical staging, laboratory markers, and biopsy-derived pathological features, without requiring radiomic feature extraction or additional molecular testing. The selected model was evaluated in a large independent external cohort, and sensitivity analyses showed that the 6-predictor model provided additional discriminatory information beyond cT alone, whereas expanding the model to all candidate predictors did not significantly improve discrimination. These findings support a relatively parsimonious model for preoperative LNM risk estimation, but they do not establish superiority over every existing clinical model.

Clinical Implications and Intended Use

Preoperative nodal assessment remains imperfect in CRC, leaving uncertainty even after conventional imaging and clinical staging. Our model addresses this uncertainty by integrating routinely available clinical, laboratory, imaging-derived, and biopsy-based information into an individualized estimate of pathological LNM risk. Individualized risk estimation is an

XSL•FO
RenderX

important application of clinical prediction models because it translates multiple patient characteristics into a probability that can be interpreted at the patient level [24]. In our study, the 6-predictor model also provided additional discriminatory information beyond cT alone, suggesting that routinely collected features can complement conventional assessment of local tumor extent.

A practical advantage of the model is that all predictors are already available during routine preoperative assessment and do not require dedicated radiomic feature extraction, molecular assays, or additional specialized examinations. This may simplify future evaluation in routine-care settings, although the completeness and reliability of these inputs, as well as transportability across centers, must be confirmed before implementation [25,26].

The model was developed in patients with newly diagnosed CRC who proceeded directly to radical surgery without preoperative anticancer treatment, and its intended use is therefore preoperative LNM risk stratification in a similar direct-surgery population. Its performance has not been validated in patients being considered for endoscopic resection, local excision, neoadjuvant therapy, or nonoperative management. The predicted probability is not intended to function as an isolated treatment criterion. A possible future workflow would be to calculate the probability after routine preoperative data collection and initial imaging review, then use discordance between the model estimate and the clinical assessment to prompt verification of the input data, focused radiology or pathology review, or multidisciplinary discussion. This workflow is a proposed implementation scenario for prospective evaluation, not a validated decision rule.

Strengths and Limitations

This study has several strengths. It included a large multicenter cohort with independent external validation, and all predictors were routinely available before surgery without requiring radiomics, molecular testing, or additional specialized examinations. Model evaluation included discrimination, calibration, DCA, threshold-dependent performance, and SHAP interpretation. Biopsy-resection agreement and sensitivity analyses against cT alone and the full predictor set provided additional evidence regarding predictor reliability and model robustness.

Several limitations should be acknowledged. First, the retrospective design and inclusion of only 2 centers in China may limit generalizability. Second, eligibility was restricted to patients with newly diagnosed CRC who underwent direct radical resection with regional lymph node dissection without preoperative anticancer treatment; therefore, the findings should not be extrapolated to patients undergoing neoadjuvant therapy, endoscopic resection, local excision, or nonoperative management. Patients with unavailable postoperative pathological LNM status were excluded, which may have introduced selection bias. Third, clinical regional lymph node category (cN category) was not included in the prespecified predictor set; therefore, the model was not directly benchmarked against clinical regional lymph node category-based assessment. The model also depends partly on imaging-derived cT, and its performance may vary with imaging quality, reader expertise, staging protocols, laboratory measurement, pathology processing, lymph-node yield, and biopsy practices across centers. Biopsy-derived differentiation and histological type showed imperfect agreement with resection pathology and remain subject to sampling limitations. Comorbidities were available only as a binary clinical-record variable without harmonized disease-specific definitions across centers. Early-stage tumors, particularly cT1-cT2 disease, were relatively underrepresented, and subgroup or fairness analyses were not performed. Finally, the training-derived evaluation operating point, DCA ranges, and threshold-dependent classifications were exploratory; no decision-impact or patient-outcome benefit was established. These factors define the current validation boundaries of the model: it has been evaluated in a direct-surgery population from 2 centers in China, with limited representation of early-stage disease, and its performance has not been established in other treatment pathways or broader clinical settings. Prospective multicenter validation across diverse populations and settings is required.

Conclusions

We developed and externally validated a 6-predictor RF model for preoperative LNM risk estimation in patients with newly diagnosed CRC who proceed directly to radical resection with regional lymph node dissection without preoperative anticancer treatment. The model used routinely available clinical, laboratory, imaging-derived, and biopsy-based information and showed moderate discrimination in an independent external cohort, with predictive information beyond cT alone. Its intended role is adjunctive, research-stage risk stratification rather than replacement of imaging, pathology, or clinical judgment. Further prospective validation in broader populations, particularly patients with early-stage disease and those managed through different treatment pathways, is required before clinical implementation.

Data Availability

The fitted final RF model and a prediction script implementing the 6-predictor model are provided in Multimedia Appendix 2. The implementation is intended for patients with newly diagnosed CRC who proceed directly to radical resection with regional lymph node dissection without preoperative anticancer treatment and has not been validated for patients managed with endoscopic resection, local excision, neoadjuvant therapy, or nonoperative treatment. Complete values for all 6 predictors are required because the released implementation does not include the original training-time imputation object and does not perform missing-value imputation. Predictor definitions, units, accepted categories, encoding rules, and software requirements are provided in the accompanying README. The script returns the predicted probability of LNM and, for reproducibility of the reported threshold-dependent analyses, a binary classification based on the training-derived Youden operating point of 0.545. This operating point was used for performance evaluation and is not a validated clinical decision cutoff. Additional analysis code used for model development and evaluation is available from the corresponding author upon reasonable request.

Abstract

Background: Uninterrupted delivery of radiation therapy is critical to cancer treatment quality. Unplanned radiation treatment interruptions compromise tumor control and survival. Although previous studies have explored clinical and sociodemographic factors influencing treatment adherence, the role of psychosocial distress and related symptoms remains unclear.

Objective: This study aims to identify patient-reported psychosocial predictors of radiation treatment interruptions from patient-reported distress screening data integrated with clinical and socioeconomic correlates via traditional and machine learning–enhanced modeling.

Methods: This institutional cohort study included 1953 patients who underwent external beam radiation therapy between August 2020 and May 2024. Patient demographics, clinical characteristics, treatment details, and baseline distress levels were extracted from a hospital-level electronic health record data repository. Distress was assessed using the Distress Thermometer developed by the National Comprehensive Cancer Network. These data were linked with census tract–level socioeconomic indicators. Predictors of treatment interruption (measured as missed treatment days) were evaluated using negative binomial regression and an extreme gradient boosting (XGBoost) model with a Poisson objective function.

Results: The study cohort missed a mean of 1.19 (SD 2.18) treatment days (range: 0-15). Higher distress scores, the presence of learning or communication barriers, and genitourinary malignancy were significantly associated with increased interruption risk in the negative binomial regression model. The XGBoost model confirmed these features as top contributors to prediction performance, while yielding an incrementally lower root mean squared error of 2.19 (vs 2.21 for the regression model).

Conclusions: Patient-reported distress and health education barriers were modestly associated with treatment interruptions, underscoring the importance of incorporating psychosocial assessments into radiation oncology workflows. Both parametric and machine learning models provided stable and closely aligned predictions of missed radiation treatment days. Key predictors identified as statistically significant in the regression model were also among the top contributors in the XGBoost model, reinforcing the robustness of these findings and supporting integration of both approaches into future intervention strategies.

Introduction

Radiation therapy is a fundamental component of cancer management, with more than half of all patients requiring radiotherapy during their treatment course [1]. The effectiveness of radiation therapy depends on consistent treatment delivery, as unplanned interruptions have been associated with reduced tumor control, disease recurrence, and decreased overall survival [2,3]. Despite ongoing technological and procedural advances, radiation treatment interruptions (RTIs) remain a major challenge in oncology care. These interruptions arise from multiple factors, including technical and operational issues [4,5], as well as patient-specific factors such as poor performance status, treatment-related toxicities, and unplanned hospitalizations [6]. Social determinants of health further compound these challenges, as individuals with limited financial means, lower education, or unstable support systems are more likely to experience barriers to treatment completion [7].

While previous studies have identified several demographic, clinical, and socioeconomic factors associated with RTIs [8-10], less is known about how psychological and symptom-related domains interact with these traditional predictors to influence treatment adherence. Cancer-related distress, encompassing emotional, physical, and practical challenges, is a prevalent yet often underrecognized factor that may directly contribute to treatment noncompliance [11,12]. Patients experiencing high levels of distress or other psychosocial difficulties may have challenges maintaining daily treatment schedules due to fatigue, anxiety, or logistical stressors, leading to preventable treatment delays. We integrated regression-based analyses with machine learning methods to examine the influence of psychological and distress-related symptoms, along with other key variables, on RTIs.

The present study aims to comprehensively evaluate the predictors of RTIs within a Central Appalachian micropolitan and rural catchment region. By integrating patient-reported distress screening data with clinical and socioeconomic information, this analysis sought to capture the multidimensional influences on treatment adherence. The overarching goal was to identify key risk factors that may inform targeted interventions, improve continuity of care, and ultimately enhance the quality and equity of radiation oncology delivery in underserved and geographically diverse communities.

Methods

Dataset

Demographic, clinical, and treatment-related data, including age, sex, race, cancer site, insurance type, and marital status, were obtained from the centralized oncology data repository at the University of Tennessee Medical Center in Knoxville, Tennessee. The analytic cohort included patients who received external beam radiation therapy between August 2020 and May 2024. This cohort draws from the same institutional data source as our group's prior analysis of demographic and clinical predictors of treatment interruption [9]; the present study extends that work by incorporating patient-reported psychosocial distress screening data and census tract–level socioeconomic indicators, which were not examined previously.

Patients undergoing treatment were asked to complete a standardized distress screening tool at baseline before starting radiation therapy. This instrument canvassed emotional, physical, practical, and nutritional concerns, along with a self-reported distress score ranging from 0 ("no distress") to 10 ("extreme distress"). Paper-based forms were reviewed by nursing staff with the patient, with the distress score and pertinent findings entered into an electronic form within the medical record, enabling integration of psychological and symptom-related measures with clinical and demographic records.

To complement patient-level data, area-level social determinants of health were appended using data from the US Census Bureau's American Community Survey 2019 - 2023 [13], aggregated at the census tract level. Socioeconomic indicators included measures such as median household income and educational attainment in patients' home census tracts, enabling contextual assessment of neighborhood characteristics.

Preprocessing and Cohort Selection

A total of 3134 consecutive patients underwent radiation therapy during the study period. Several data-quality and eligibility criteria were applied to define the analytic cohort. First, 269 patients were excluded for missing more than fifteen treatment days at the data extraction stage. Interruptions of this length were considered unlikely to represent a single episodic treatment interruption and more often reflect distinct clinical scenarios, such as sequential courses of radiotherapy for different disease sites; consequently, detailed records for these patients were not retained for further characterization. Patients receiving treatment courses lasting fewer than 5 days (n=599) or with a total delivered dose below 2000 cGy (n=84) were also removed, as these treatment patterns generally correspond to very short palliative or stereotactic regimens in which the clinical significance of interruptions differs from that of conventional fractionation. Additional exclusions were made for missing demographic or administrative variables (52 cases). These steps resulted in 2130 patients with complete information. Among these individuals, 177 patients did not complete a baseline distress screening form and could not be included in analyses incorporating psychological variables, resulting in a final analytic sample of 1953.

Categorical variables were harmonized and standardized, with missing categories explicitly coded to maintain transparency in downstream modeling. All continuous variables and clinical indicators were cleaned using context-specific rules to preserve interpretability. Socioeconomic and demographic measures were grouped into broader categories to reduce data sparsity.

Multicollinearity among predictors was evaluated using the variance inflation factor (VIF) and generalized VIF (GVIF) for categorical predictors with multiple levels. All predictors exhibited acceptable collinearity levels (GVIF-adjusted statistics <10, most <2.5), indicating no significant multicollinearity concerns. Therefore, all candidate variables were retained for inclusion in subsequent modeling, including both negative

binomial regression and extreme gradient boosting (XGBoost) analyses.

Study Outcome Measures

The primary outcome of this study was the number of missed radiation treatment days. Missed treatment days were calculated based on the anticipated versus actual completion dates of therapy, adjusted for weekends and federal holidays. This count variable, which fell within a 0 to 15 day range, represents the total number of treatment days not completed as scheduled.

Automated Variable Categorization Using Large Language Models

Several extracted variables were available only in unstructured text format and required additional processing before they could be used for analysis. For example, *International Classification of Diseases* (*ICD*) diagnosis codes and insurance providers needed to be mapped into standardized categorical groups. In addition, approximately 7% of the distress screening forms included free-text entries by nursing staff rather than the designated radio buttons for practical, emotional, physical, and nutritional concerns.

To address this, we incorporated GPT-4o APIs into the preprocessing pipeline. GPT-4o was selected based on our group's prior comparative evaluation of 5 language models (GPT-3.5, GPT-4o, Llama 3.2, Gemini 1.5, and BioBERT) for clinical text categorization tasks in an oncology setting, in which GPT-4o and BioBERT outperformed the other models [14]. The present study required categorization of a structured variable (*International Classification of Diseases*, 10th Revision [*ICD*-10], with over 50 unique values), a semistructured variable (insurance, with over 700 unique values), and an unstructured variable (free-text distress screening entries).

The categorization framework and mapping schema were developed in consultation with 2 radiation oncology specialists. A few-shot prompting strategy was used, in which the model was provided with a small set of representative examples to guide consistent categorization for each variable type. LLM-generated categorizations were subsequently reviewed by our 2 oncology coauthors, allowing us to both correct any misclassifications and assess the feasibility of using LLM-based categorization independently, without manual review, in future prediction pipelines.

Model Generation

Missed radiation treatment day values were heavily right-skewed, with a large proportion of zero counts and a long upper tail. This distribution confirmed that the data were discrete and overdispersed, warranting the use of count-based regression rather than continuous linear models.

The dataset was divided into training (391/1953, 80%) and testing (391/1953, 20%) subsets, with categorical variables one-hot encoded for the machine learning algorithm. To assess the stability of performance estimates given this single split, we additionally conducted 100 repeated stratified resamples preserving the distribution of missed treatment days across train and test sets, and calculated mean, SD, and 95% CIs (2.5th-97.5th percentile) for root mean square error (RMSE), mean absolute error (MAE), and Poisson deviance across resamples.

A negative binomial regression model was fitted to the training data to account for overdispersion, as the initial Poisson model exhibited a dispersion statistic of 3.69. The negative binomial model estimated incidence rate ratios (IRRs) for each covariate, providing interpretable measures of relative change in missed treatment days associated with each factor. To ensure model parsimony while preserving interpretability, the full negative binomial model including all candidate covariates was first examined. Backward elimination was then applied as a sensitivity approach to remove nonsignificant predictors ($P \geq .05$); this process did not materially alter effect estimates or the substantive conclusions of the model. Given the large proportion of zero outcomes, we additionally evaluated a zero-inflated negative binomial model as part of model selection; however, the zero-inflation component was not statistically significant, predictive performance on the hold-out test set did not improve, and a Vuong test favored the standard negative binomial formulation. Therefore, the conventional negative binomial model was retained for all primary analyses.

In parallel, an XGBoost model was trained on the same training data using a Poisson objective function to handle count-based outcomes. Hyperparameters, including tree depth, learning rate, subsampling rate, and column sampling, were tuned through internal validation and early stopping to prevent overfitting. Both models were subsequently applied to the test dataset to generate predicted counts and assess generalization performance.

Model Comparison

Predictive accuracy was assessed using multiple complementary metrics—RMSE, MAE, and Poisson deviance—to capture different aspects of model fit and prediction error. All performance metrics were calculated on a naive 20% hold-out test set, which was separated from the data prior to model training or hyperparameter tuning to ensure an unbiased evaluation of out-of-sample performance. In addition to evaluating predictive performance, a direct comparison of these two modeling approaches enabled integration of statistical inference and machine learning–based feature importance.

Ethical Considerations

This study was reviewed and approved by the Institutional Review Board of the University of Tennessee Health Science Center for analysis without personal identifiers (protocol: 16 - 04888-XP).

Results

Descriptive Analysis

Table 1 presents the demographic, socioeconomic, and clinical characteristics of the study cohort. The total number of RTIs ranged from 0 to 15 days, with a mean of 1.19 (SD 2.18) days (median 0, IQR 0 - 1). Study patients had a mean age of 64.5 (SD 12.1) years and were predominantly White (1837/1953, 94.1%), with smaller proportions identifying as Black/African American (88/1953, 4.5%) or other/minority (28/1953, 1.4%). The cohort included 1017 (52.1%) females and most participants

XSL•FO

Table . Characteristics of the study cohort (N=1953).

Variable	Description	Range/coding	Distribution
Outcome			
Missing treatment days (outcome)	Number of missed radiation treatment sessions compared to prescribed schedule	0 - 15 days	• Mean 1.19 (SD 2.18) • Median 0 (IQR 0 - 1)
Distress and symptom measures			
Distress score	Self-reported oncology distress thermometer score assessing psychological distress during treatment	0 - 10	• Mean 3.1 (SD 2.9) • Median 3 (IQR 0-5; range 0 - 10)
Emotional symptom count	Number of emotional or psychological concerns selected (eg, depression, sadness, fears, and nervousness)	0="no concern" and 1 - 6="number of emotional issues"	• 0: 1769 (90.6%) • 1: 66 (3.4%) • 2: 52 (2.7%) • 3: 19 (1.0%) • 4: 15 (0.8%) • 5: 16 (0.8%) • 6: 16 (0.8%)
Practical symptom count	Number of practical or logistical concerns endorsed (eg, financial, transportation, and insurance issues)	0="none" and 1 - 5="number of problems"	• 0: 1855 (95.0%) • 1: 54 (2.8%) • 2: 31 (1.6%) • 3: 5 (0.3%) • 4: 3 (0.2%) • 5: 5 (0.3%)
Physical symptom count	Number of physical concerns (eg, fatigue, sleep disturbance, and mobility problems)	0 - 13	• 0: 1738 (89.0%) • 1: 85 (4.4%) • 2: 29 (1.5%) • 3: 21 (1.1%) • 4: 23 (1.2%) • ≥5: 57 (2.9%)
Nutrition symptom count	Number of nutrition-related problems (eg, nausea, appetite loss, and diarrhea)	0 - 5	• 0: 1847 (94.6%) • 1: 64 (3.3%) • 2: 25 (1.3%) • 3: 13 (0.7%) • ≥4: 5 (0.3%)
Primary pain intensity	Self-reported primary pain score at assessment	0 - 10 scale	• 0: 1435 (73.5%) • 1-3: 195 (10.0%) • 4-6: 172 (8.8%) • 7-10: 151 (7.7%)
Fall risk and clinical measures			
Fall risk (medication)	Risk level based on use of medications contributing to falls	No risk, polypharmacy, and high-risk medications	• No risk: 964 (49.4%) • Polypharmacy: 805 (41.2%) • High-risk medications: 184 (9.4%)
Fall risk (elimination)	Risk based on urinary or bowel elimination issues	Independent and at risk	• Independent: 1919 (98.3%) • At risk: 34 (1.7%)
Fall history	Any history of prior falls	Yes/no	• Yes: 80 (4.1%) • No: 1873 (95.9%)
Falls assessment score	Composite nursing assessment fall-risk score	0 - 9	• Median 1 (IQR 0 - 2) • 0: 595 (30.5%) • 1: 630 (32.3%) • 2: 444 (22.7%) • ≥3: 284 (14.5%)

Median household income	Area-level median income group	Low, moderate, and high	• Low: 596 (30.5%) • Moderate: 649 (33.2%) • High: 707 (36.2%)
Percent population ≥ bachelor's degree	Educational attainment level of census area	Low, moderate, and high	• Low: 589 (30.2%) • Moderate: 651 (33.3%) • High: 713 (36.5%)
Smoking status	Smoking history	Current, former, never, and unknown	• Current: 183 (9.4%) • Former: 355 (18.2%) • Never: 430 (22.0%) • Unknown: 985 (50.4%)
Alcohol use	Self-reported alcohol use	Current, past, denies, and unknown	• Denies: 628 (32.2%) • Current: 463 (23.7%) • Past: 110 (5.6%) • Unknown: 752 (38.5%)
Distance to radiation facility	Straight-line distance to treating radiation center (miles)	Continuous variable	• Median 13.5 (IQR 7.8 - 25.1; range: 0.9 - 255) miles

[a]ECOG: Eastern cooperative oncology group.

[b]*ICD*-10: *International Classification of Diseases*, 10th Revision.

[c]The 4 most common of 14 groups are shown.

The mean distress score was 3.1 (SD 2.9), with a range of 0 - 10 indicating generally moderate distress with considerable variability across the cohort. Emotional, physical, practical, and nutritional symptom variables represent the number of symptom categories patients endorsed within each domain. For emotional symptoms, 90.6% (n=1769) reported no emotional concerns, 3.4% (n=66) endorsed one emotional symptom, and fewer than 3% (n≤52) of patients in each remaining category endorsed two or more emotional symptoms. The majority of patients demonstrated good functional status, with 96% (1876/1953) scoring 0 - 1 on the Eastern Cooperative Oncology Group (ECOG) performance scale and exhibited low to moderate fall risk. The median travel distance from home address to the radiation treatment facility was 13.5 (IQR 7.8 - 25.1) miles.

A total of 177 patients were excluded from the analytic cohort due to missing distress score values. To assess whether their exclusion introduced systematic bias, we compared key demographic characteristics with those of the included cohort. The excluded patients were similar in age (median 64, IQR 56.8-73.7 y vs median 64.5, IQR 57.6-72.9 y), sex distribution

XSL•FO
RenderX

(female: 102/177, 57.7% vs 1017/1953, 52.1%), and race (White: 167/177, 94.3% vs 1838/1953, 94.1%). Marital status and insurance patterns also aligned closely with the main study population, indicating no meaningful demographic differences. Excluded patients also had a similar rate of missed treatment days (mean 1.09, SD 1.96; 67/177, 38.1% with any interruption) compared with included patients (mean 1.19, SD 2.18; 842/1953, 43.1% with any interruption), with no significant difference between groups by Mann-Whitney *U* test (*P*=.41), indicating no meaningful demographic or outcome-related differences between groups.

Negative Binomial Regression Modeling

Negative binomial regression identified multiple variables significantly associated with treatment interruptions (Table 2). Among psychosocial and clinical variables, patients' barriers to health-related communication or learning during care were associated with a 43% higher rate of missed sessions (IRR 1.43, 95% CI 1.07 - 1.92; *P*=.02). Each one-point increase in total distress score corresponded to a 5% higher rate of missed treatments (IRR 1.05, 95% CI 1.02 - 1.09; *P*=.01).

Table . Negative binomial regression model results.

Variable	IRR[a] (95% CI)	*P* value
ICD-10[b]: genitourinary	2.57 (1.33 - 4.97)	.006
Distress score (per unit)	1.05 (1.02 - 1.09)	.01
Marital status: married	0.67 (0.49 - 0.92)	.02
Learning barrier (yes vs no)	1.43 (1.07 - 1.92)	.02
Physical symptom count	0.82 (0.72 - 0.96)	.02
Nutrition symptom count	1.43 (0.99 - 2.11)	.051
ICD-10: prostate	1.52 (0.99 - 2.32)	.053
Marital status: widowed	0.65 (0.42 - 1.02)	.06
Race: White vs others	0.69 (0.46 - 1.02)	.06
Insurance: other insurance	0.37 (0.11 - 1.06)	.07
Distance to facility (per mile)	1.00 (0.99 - 1.00)	.08
Marital status: single	0.76 (0.53 - 1.09)	.13
Age (per y)	0.99 (0.98 - 1.00)	.14
ICD-10: head and neck	1.42 (0.87 - 2.31)	.16
Fall risk (elimination; independent vs at risk)	1.82 (0.78 - 4.18)	.17
Living will/advance care (yes vs no)	1.16 (0.93 - 1.43)	.18
ICD-10: skin	1.40 (0.81 - 2.43)	.22
ECOG[c] performance	1.10 (0.91 - 1.33)	.30
Primary pain intensity	1.02 (0.98 - 1.06)	.31
Influenza vaccine (yes vs no)	0.91 (0.75 - 1.11)	.35
ICD-10: other	1.31 (0.74 - 2.34)	.35
Falls assessment score	1.07 (0.91 - 1.27)	.37
Emotional symptom count	1.05 (0.92 - 1.27)	.40
Fall history (yes vs no)	0.75 (0.35 - 1.60)	.45
Practical symptom count	1.05 (0.78 - 1.48)	.66
Fears or anxieties (yes vs no)	0.96 (0.73 - 1.28)	.75
Fall risk (medication; polypharmacy vs no risk)	1.02 (0.73 - 1.42)	.86
Insurance: Medicaid	1.02 (0.31 - 2.92)	.97

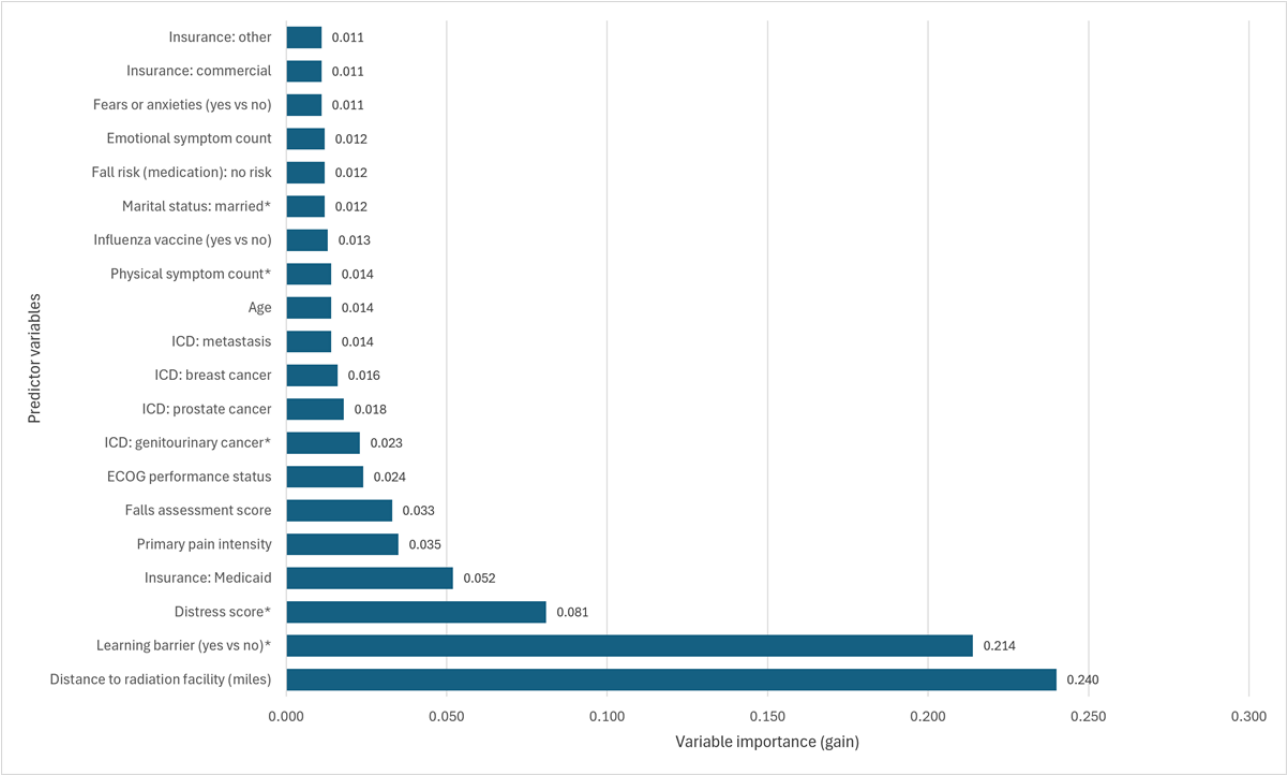
[a]IRR: incident rate ratio.

[b]*ICD*-10: *International Classification of Diseases*, 10th Revision.

[c]ECOG: Eastern Cooperative Oncology Group.

Higher nutrition symptom counts were associated with greater interruption rates, approaching statistical significance (IRR

XSL•FO
RenderX



1.43, 95% CI 0.99 - 2.11; *P*=.051). In contrast, greater physical symptom burden was associated with lower interruption rates (IRR 0.82, 95% CI 0.72 - 0.96; *P*=.02).

Marital status and primary cancer site were also significant predictors. Married patients exhibited a lower rate of missed treatments (IRR 0.67, 95% CI: 0.49 - 0.92; *P*=.02) compared with unmarried patients. Patients diagnosed with genitourinary cancers had a significantly higher interruption rate (IRR 2.57, 95% CI 1.33 - 4.97; *P*=.006), with similar trends observed for head and neck, prostate, and skin cancers.

XGBoost Modeling

The XGBoost model achieved optimal performance using a maximum tree depth of 4, a learning rate of 0.05, and a subsampling rate of 0.9. Variable importance was assessed using the Gain metric, representing each predictor's relative contribution to reducing model error (Figure 1).

Figure 1. Variable importance in the extreme gradient boosting (XGBoost) model based on the gain metric. Higher values indicate greater relative contribution to prediction accuracy. Variables marked with an asterisk (*) were also statistically significant (*P*<.05) in the negative binomial regression model. ECOG: Eastern Cooperative Oncology Group; *ICD*: *International Classification of Diseases*.

Variables identified with the highest gain were patients' travel distance to the radiation facility, the presence of learning or communication barriers during treatment, and the total distress score, followed by Medicaid insurance and primary pain intensity. Moderate contributions were observed for fall risk assessment score, ECOG performance status, and genitourinary cancer site.

The Gain metric can favor high-cardinality continuous predictors, such as travel distance, and may produce less stable rankings among correlated features [15]. We therefore interpret the relative ranking of predictors in Figure 1 with this consideration in mind, particularly for travel distance, which may be ranked more highly than its true relative contribution due to this metric's known bias toward continuous variables with many unique values.

Predictive Model Comparison

Model performance metrics for the negative binomial and XGBoost models are summarized in Table 3. Both models provided stable and closely aligned predictions of missed radiation treatment days. Each achieved similar predictive accuracy, with XGBoost demonstrating incrementally lower root mean squared error (RMSE=2.19) and mean absolute error (MAE=1.36) vs the negative binomial model (RMSE=2.21; MAE=1.42). Poisson deviance values were also comparable between models, indicating consistent goodness-of-fit across approaches.

XSL•FO
RenderX

Table . Model performance comparison between negative binomial and extreme gradient boosting (XGBoost) models.

Model	RMSE[a], mean (SD; 95% CI)	MAE[b], mean (SD; 95% CI)	Poisson deviance, mean (SD; 95% CI)
XGBoost (Poisson)	2.19 (0.14; 1.95 - 2.49)	1.36 (0.05; 1.28 - 1.47)	973 (62; 869 - 1109)
Negative binomial	2.21 (0.13, 1.99 - 2.50)	1.42 (0.05; 1.33 - 1.53)	979 (66; 858 - 1125)

[a]RMSE: root mean squared error.

[b]MAE: mean absolute error.

To place these values in clinical context, we compared both models against a naive baseline predicting the sample mean for all patients, evaluated using the same resampling procedure. The naive baseline achieved a mean RMSE of 2.223 (SD 0.133; 95% CI 1.99 - 2.49), only modestly higher than the negative binomial and XGBoost models. This indicates that, while both models offer a measurable improvement in absolute prediction accuracy over a covariate-free estimate, the improvement is limited given the low-count, zero-inflated nature of the outcome.

Discussion

In this study of patients receiving radiation therapy, we examined how psychological and distress-related symptoms, along with other key clinical and social risk factors, were associated with RTI. Among all studied variables, total distress score emerged as a key determinant, with higher baseline distress levels independently linked to an increased likelihood of missed treatment days across both the negative binomial and XGBoost models. This finding underscores the critical influence of psychological well-being on treatment adherence. Other variables with demonstrated significance in both models, learning or communication barriers during treatment and genitourinary cancer site, highlight complex, multilayered mechanisms leading to RTIs. Strong concordance between traditional regression and machine learning results supports the robustness of identified associations and reinforces the need to incorporate patient-reported data to inform personalized psychosocial and supportive interventions to mitigate preventable interruptions across a multiweek course of daily radiation delivery.

Our study expands upon prior literature demonstrating the influence of emotional distress on radiation therapy adherence. Clover et al [16] found that radiation therapists rated 11% of sessions as disrupted by anxiety at the pretreatment simulation visit, rising to 24% at the first treatment session, with disruptions primarily linked to procedural fears (eg, mask-related anxiety) rather than overall distress. Sreeraman et al [17] found that, among 280 patients with head and neck cancer, poor Karnofsky Performance Status (≤70) and pre-existing psychiatric illness were each significantly associated with a greater likelihood of missing more than 5 treatment days, and Chen et al [18] demonstrated that pretreatment depression independently predicted both prolonged radiation breaks and reduced survival.

Our findings build on this mixed evidence by demonstrating a consistent and independent association between patient-reported distress and RTIs across 2 distinct analytic frameworks. Unlike prior work that relied on diagnostic psychiatric categories or clinician-reported psychological factors [17,19,20], the use of the National Comprehensive Cancer Network (NCCN) Distress Thermometer allowed us to capture real-time, patient-centered indicators of emotional strain. This may explain the stronger and more stable associations observed. Moreover, recent analyses of NCCN Distress Thermometer scores indicate that higher distress correlates with greater acute treatment-related toxicity during radiotherapy, lending additional biological plausibility to distress as a mediator of treatment course deviations [21].

Beyond psychological distress, several additional predictors emerged as important determinants of radiation treatment adherence. Patients with learning or communication barriers consistently showed higher rates of missed sessions, underscoring the role of health literacy and communication effectiveness in sustaining treatment continuity. This aligns with evidence that health system and informational needs are the second most frequently reported unmet supportive care needs among people affected by cancer, behind only psychological and emotional needs, with patients commonly reporting difficulty understanding their diagnosis, treatment, and self-management, as well as challenges navigating and coordinating care [22]. Cancer site was also associated with treatment interruption, with patients with genitourinary and prostate cancers experiencing higher rates of missed treatments. Although prostate cancer is anatomically classified within the genitourinary system, we analyzed it separately because of its high prevalence in our cohort and its distinct treatment patterns. Prior studies have reported higher rates of treatment interruption among patients with head and neck cancer [16,23]; however, head and neck cancer was not among the highest-ranked predictors of treatment interruption in our models. While indicators of functional status such as ECOG performance and fall-risk assessments were not statistically significant, they ranked moderately in the XGBoost model, suggesting that physical limitations may still contribute indirectly to treatment nonadherence. Importantly, evidence from a multiple-baseline intervention study demonstrates that structured pretreatment education delivered by radiation therapists can reduce psychological distress and improve treatment preparedness, supporting the potential of communication-focused interventions to mitigate avoidable treatment disruptions [24]. Taken together, these findings emphasize the value of targeted educational and supportive strategies, particularly for patients with communication challenges or undergoing complex treatment regimens.

Notably, higher physical symptom burden was associated with fewer, rather than more, treatment interruptions in our cohort. This finding contrasts with prior evidence that greater symptom burden is generally associated with worse treatment adherence;

XSL•FO
RenderX

for example, each additional moderate-severity symptom during adjuvant endocrine therapy in patients with breast cancer has been associated with 4 to 9 additional missed treatment days [25]. One possible explanation for the divergent direction observed in our study is that patients experiencing greater physical symptoms during radiotherapy may receive closer clinical attention, as prior work has shown that higher symptom severity scores are associated with a greater likelihood of being offered a clinical intervention [26]. Whether this increased clinical contact translates into improved treatment continuity remains untested and should be examined in future prospective work. Alternatively, this association may reflect a form of "healthy adherer" behavior, in which patients more engaged with their overall care are both more likely to accurately report symptoms and more likely to complete treatment as scheduled. Further prospective research incorporating longitudinal symptom tracking is needed to clarify this relationship.

Interestingly, some variables demonstrated high predictive importance in the XGBoost model despite lacking statistical significance in the negative binomial regression. Travel distance to treatment facilities was among the top contributors in the machine learning model, suggesting that geographic accessibility meaningfully influences treatment adherence, even when this effect is not captured well by traditional linear modeling. This could be due to complex, nonlinear relationships, such as threshold effects where adherence declines sharply beyond certain travel distances, or interactions with socioeconomic and logistical factors such as transportation availability or employment constraints. Similarly, insurance coverage and marital status, though not statistically significant, contributed to model accuracy, implying subtle cumulative effects of socioeconomic stability and social support on treatment access. These results highlight the complementary value of machine learning approaches in uncovering interaction and nonlinear effects which conventional regression models may underestimate.

In this study, large language models were incorporated into data preprocessing to improve the usability of unstructured clinical text and enable consistent classification of fields that were otherwise incomplete, inconsistently formatted, or missing structured responses. Model performance varied by variable type. For structured *International Classification of Diseases*, 10th Revision (*ICD*-10) diagnosis codes, GPT-4o achieved an accuracy of 90.8% (95% CI 87.7 - 93.9) while for less structured entries such as insurance categorization, accuracy was 81.6% (95% CI 76.7 - 86.5). Performance declined further for the 168 distress screening cases in which a nurse had recorded free-text descriptions rather than completing the structured checklist fields; owing to the greater linguistic complexity and variability of this free text, categorization accuracy for these cases was only 48.1% (95% CI 43.0 - 53.2). All large language model–generated categorizations were subsequently reviewed and manually refined by our oncology team, and no record was retained in an incorrect category.

Distress was assessed at baseline only, before treatment began, which creates a temporal mismatch with our outcome, as missed treatment days can accumulate over a 4-week to 7-week course of daily fractionated radiation. Baseline distress represents the most actionable time point for early psychosocial intervention and is the only assessment consistently collected within our institution's standard workflow; however, it may not reflect a patient's psychological state at the time interruptions occur. Among the 1391 (71.2%) patients with more than one distress screening during treatment (median 2 assessments per patient), 43.7% (n=608) showed a decreased score and 30.3% (n=421) showed an increased score between their first and last measurement, confirming that distress is not static for many patients. Because the number of distress forms did not consistently align with the timing of treatment sessions or interruptions, we were unable to examine whether the distress-RTI association differs between early and later interruptions. Future work incorporating repeated, treatment-aligned distress assessments is needed to clarify this temporal relationship.

Some limitations should be considered when interpreting our findings. First, our retrospective analysis was limited to a single-institutional experience, constraining the generalizability of results to other health systems and patient populations. Also, reliance on electronic health record data introduces the possibility of incomplete or inconsistent documentation, particularly for psychosocial and symptom-related variables. Moreover, area-level socioeconomic indicators derived from census data may not accurately represent individual circumstances. Our outcome measure also does not distinguish patient-initiated absences from provider- or operationally-driven interruptions, as reliably coded reason data were not consistently available, although such interruptions are uncommon in our practice. Finally, while the XGBoost model improved prediction and identified nonlinear effects, it does not infer causality, and variable importance should be interpreted as associative rather than deterministic.

This study integrated clinical, socioeconomic, and patient-reported data to examine how psychological and distress-related symptoms, along with other key clinical and social determinants of health, affect unplanned radiation treatment interruption rates. Both the negative binomial and XGBoost models consistently identified associations of patient-reported distress, learning or communication barriers, and specific cancer types with interrupted treatment. These findings highlight the potential influence of psychological and functional factors on cancer treatment access and a critical need to collect patient-reported hardships to inform social support interventions.

By combining traditional regression and machine learning approaches, this study provides an early but potentially comprehensive understanding of the multifactorial determinants of radiation treatment access. Future work will need to validate reproducible predictive factors across larger, multi-institutional cohorts. Ultimately, such data may inform personalized intervention strategies, such as enhanced psychosocial screening, patient education, and community-centered assistance to support high-quality patient access and treatment efficacy for all patients with cancer requiring radiotherapy.

Acknowledgments

The authors thank the University of Tennessee IT team for their support with data access and infrastructure. The authors used ChatGPT-4o (OpenAI) solely to check grammar and improve language clarity during manuscript preparation; the tool was not used to generate scientific content, analyze data, or draw conclusions, and all edits were reviewed and verified by the authors for accuracy. This use is distinct from GPT-4o's role as an analytical preprocessing tool within the study's data pipeline, described in detail in the "Automated Variable Categorization Using Large Language Models" section.

Funding

This research was supported by a grant from the Tennessee Department of Health.

Data Availability

The data that support the findings of this study are available upon reasonable request from the corresponding author. The dataset is not publicly available due to institutional privacy policies.

Authors' Contributions

SH conducted data integration and statistical and machine learning analyses and drafted the manuscript. FAK and RR assisted with data processing and analyses. PKR and SK contributed to data curation and manuscript review. CLB and DLS, as radiation oncologists, provided clinical expertise and validated the clinical relevance of the study design and findings. RLD contributed to study design and methodological oversight. AS-N and DLS conceptualized and supervised the study, reviewed, and edited the manuscript, interpreted the results, and acquired funding. The two senior authors (AS-N and DLS) contributed equally to the work. All authors reviewed and approved the final manuscript.

Abstract

Background: Despite a global decline in the incidence of gastric cancer (GC), the number of cases diagnosed among younger individuals continues to increase. Several studies have been conducted to develop predictive models of mortality in patients with GC.

Objective: We developed 3- and 5-year survival prediction models for young patients with GC based on machine learning–based survival modeling approaches.

Methods: Data from 813 young patients (≤50 years) diagnosed with GC between 2013 and 2015 were retrieved from the Gastric Cancer Public Staging Database. Among these 813 patients, data from 569 (70%) and 244 (30%) were allocated to the model training and testing datasets, respectively. Random survival forest, gradient boosting survival analysis, extra survival tree, and the Cox proportional hazards model were applied to predict survival outcomes at the 3- and 5-year time horizons. Model performance was assessed and quantified using the concordance index (C-index) metric. For the machine learning prediction models, the mean C-index values and corresponding 95% CIs were estimated across 100 repeated training iterations.

Results: For the random survival forest model, the C-index for predicting 3-year mortality was 95.89% (95% CI 95.80% - 95.97%), whereas the C-index for predicting 5-year mortality was 91.82% (95% CI 91.68% - 91.96%). In the gradient boosting survival analysis model, the C-index for predicting 3-year mortality was 95.32% (95% CI 95.31% - 95.33%), and the C-index for predicting 5-year mortality was 89.98% (95% CI 89.95% - 90.01%). For the extra survival tree model, the C-index for predicting 3-year mortality was 95.53% (95% CI 95.46% - 95.60%), whereas the C-index for predicting 5-year mortality was 94.60% (95% CI 94.50% - 94.70%). In addition, the Cox proportional hazards model showed a C-index of 94.15% for predicting 3-year mortality and 82.26% for predicting 5-year mortality. Tumor stage and tumor size were the primary predictive variables used to train the models for mortality prediction at different time points. Other variables exhibited varying levels of predictive contribution across different time points.

Conclusions: These findings may facilitate the identification of high-risk young patients with GC who may benefit from more aggressive treatment strategies by enabling the prediction of mortality risk at different time points.

KEYWORDS

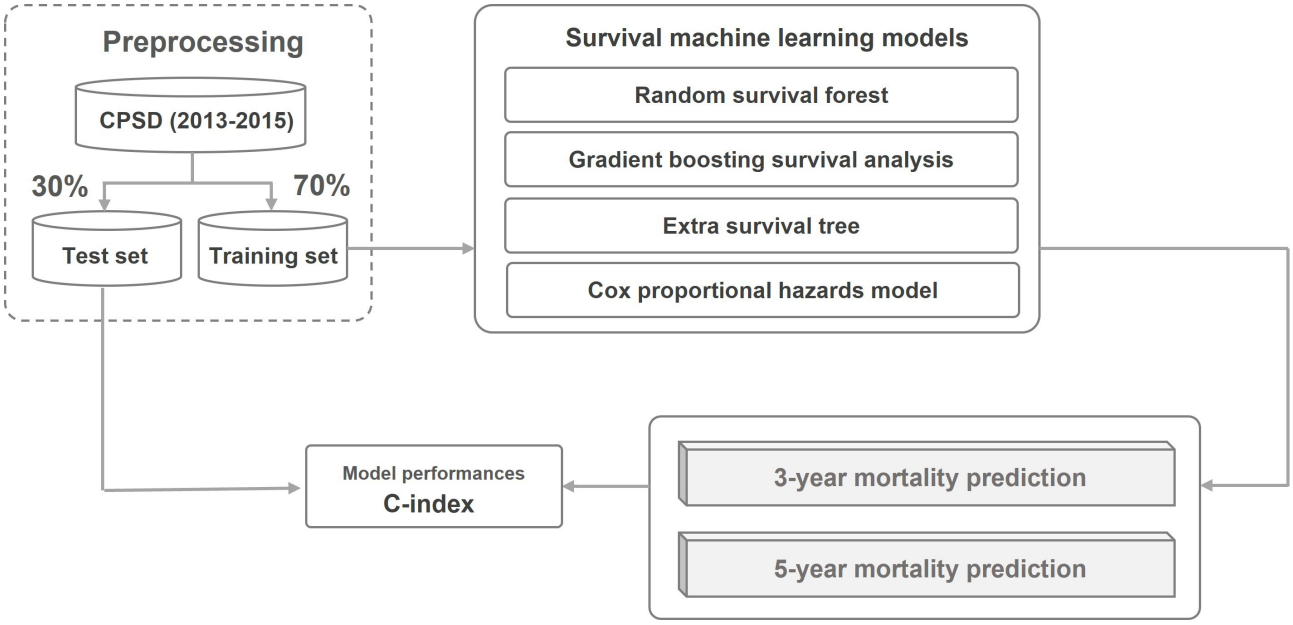
survival prediction model; young patients with gastric cancer; machine learning; gastric cancer; mortality risk; predictive modeling

Introduction

Despite a consistent global decline in the incidence of gastric cancer (GC) resulting from improved understanding of the key etiological factors influencing its development, more than 1 million new cases are still diagnosed annually worldwide, and the disease remains associated with a high mortality rate [1]. Recent studies have shown that the prevalence of GC among younger individuals varies substantially across geographic regions and is increasing worldwide. This trend is particularly evident in Asian countries such as South Korea, Japan, and China [2-4] where GC occurs at a comparatively higher rate among younger populations [2]. Although the precise mechanisms underlying GC development in younger individuals remain unclear, both disease progression and prognosis are

XSL•FO
RenderX

influenced by a complex interplay of factors, including pathological characteristics, molecular alterations, genomic features, dietary patterns, and lifestyle-related exposures. Consequently, several studies have been conducted to evaluate prognostic outcomes in younger patients with GC [5,6]. Previous studies predicting survival outcomes in young patients with GC have primarily relied on traditional statistical nomogram models. These models represent the relationships between clinical covariates and patient outcomes in an interpretable format and have demonstrated relatively stable predictive performance [7].



Recently, machine learning (ML)–based approaches have been explored as complementary tools to traditional prediction models [8,9], demonstrating particular strengths in capturing complex nonlinear relationships among predictor variables and analyzing large-scale, high-dimensional clinical datasets [10,11]. Several studies have demonstrated that ML-based survival models can provide meaningful prognostic insights for predicting time-to-event outcomes using structured clinical data collected in real-world health care settings [12-16]. However, in young patients with GC, baseline prognostic factors influencing survival change over time [17]. In addition, existing mortality prediction models typically provide predictions for a single time point, which may limit their ability to capture time-varying changes in prognostic factors that may occur in younger patients with GC [15]. Therefore, to account for the complex nature of GC prognosis, this study developed 3- and 5-year mortality prediction ML-based models for young patients with GC and constructed 3- and 5-year mortality prediction models to capture potential time-varying risk factors. This ML-based survival prediction study aimed to identify how key prognostic factors associated with mortality vary across different prediction horizons.

Methods

Study Design

We developed a predictive model to estimate all-cause mortality among younger patients with GC using deidentified data obtained from the Cancer Public Staging Database (CPSD) provided by the National Cancer Data Center (NCDC; Figure 1). To achieve this objective, we first extracted data for younger patients (≤50 years) diagnosed with GC between 2013 and 2015 from the CPSD and subsequently performed data preprocessing on the dataset. The data were randomly divided into training and testing subsets comprising 70% and 30% of the data, respectively. Using the training dataset, we developed 3- and 5-year mortality prediction models using random survival forest (RSF), gradient boosting survival analysis (GBSA), extra survival tree (EST), and Cox proportional hazards (PH).

Ethical Considerations

This study was approved by the institutional review board of the National Cancer Center of South Korea (NCC2023-0260). The requirement for informed consent was waived because HYJK, WJ, and KSR accessed only anonymized data for the purposes of analysis. The pseudonymized dataset was analyzed within a secure research environment provided by the NCDC, ensuring that only aggregated analytical results were exported.

Data Source

This study used the CPSD, which is provided by the NCDC. This database was constructed by linking data from the NCDC's Cancer Public Library Database with collaborative staging data for cancer cases established in the Korea Central Cancer Registry (KCCR) [18]. The collaborative staging system was developed using probability-based sampling methods and mandatory retrospective medical record surveys of cancer cases registered in the KCCR. These surveys provide information on cancer staging, treatment modalities, and patient prognoses [19]. The Cancer Public Library Database was developed by integrating linked data from 4 major population-based public databases: the Korea National Cancer Incidence Database maintained by the KCCR, cause of death records from Statistics Korea, the National Health Information Database of the National

XSL•FO
RenderX

Health Insurance Service, and the National Health Insurance Research Database maintained by the Health Insurance Review and Assessment Service [20]. The use of the CPSD dataset complied with the data access and use policies established by the NCDC, and all data were handled in accordance with relevant guidelines and regulations to ensure confidentiality and data security. As the dataset contained no personally identifiable information, this study was exempt from institutional review board review.

Definitions

Comorbid conditions, including myocardial infarction, stroke, heart failure, diabetes mellitus, hypertension, dyslipidemia, chronic obstructive pulmonary disease, peripheral vascular disease, liver disease, atrial fibrillation, and chronic kidney disease, were identified and defined according to the diagnostic codes from the *International Classification of Diseases, 10th Revision*. Additionally, primary study end points were defined to represent short- and medium-term mortality, specifically all-cause mortality occurring within 3 and 5 years after cancer diagnosis, respectively. Information on all-cause mortality was obtained from official cause of death records provided by South Korea's national statistical authority. Deaths occurring within each follow-up period were treated as cumulative mortality events; therefore, events occurring within 3 years were also included in the cumulative event count for the 5-year follow-up period.

Experimental Dataset

The dataset was randomly divided into a training set (n=569) and a test set (n=244) using a fixed random seed (42) to ensure the reproducibility of the dataset partitioning. The primary outcome was all-cause mortality measured at 3 and 5 years after cancer diagnosis, and separate survival prediction models were developed for each prediction horizon. To minimize potential bias caused by outcome imbalance, the dataset was randomly partitioned using stratified sampling, ensuring comparable proportions of mortality events between the training and testing datasets. Model performance was evaluated on the corresponding test dataset using the Harrell C-index, a widely used discrimination metric in survival analysis. For the ML-based survival models (RSF, GBSA, and EST), the training and evaluation procedures were repeated across 100 iterations, with the random seed varied in each iteration while maintaining a fixed data split to quantify stochastic variability and assess the robustness of model performance. At each iteration, the models were refitted using the same training dataset and subsequently evaluated on the identical test dataset. The resulting training and testing datasets were fixed after partitioning and were consistently used in all subsequent model development and evaluation experiments.

Models

The RSF is an ensemble-based ML method that models complex nonlinear relationships between predictor variables and estimates variable importance to reduce generalization error. The RSF model can also estimate the cumulative hazard function for individual observations even when the PH assumption is not satisfied [21,22]. A gradient boosting machine framework [23] was adapted for survival analysis, enabling the model to effectively handle light-censored survival data. Gradient boosting machine is an ensemble learning technique in which successive decision trees are sequentially constructed, with each tree iteratively correcting the prediction errors of the preceding model. GBSA builds on this boosting framework for survival modeling, allowing the algorithm to handle censored observations and capture complex interactions between predictor variables and survival time [24,25]. The EST model, an extension of the randomized trees algorithm introduced by Geurts et al [26] in 2006, introduces additional randomness by selecting split points randomly during tree construction. The EST algorithm can censor survival data and does not rely on the PH assumption [27]. The Cox PH model is a widely used semiparametric survival analysis method that examines the relationship between survival time and multiple predictor variables. This model does not require explicit specification of the baseline hazard function [28,29].

Computational Environment Settings

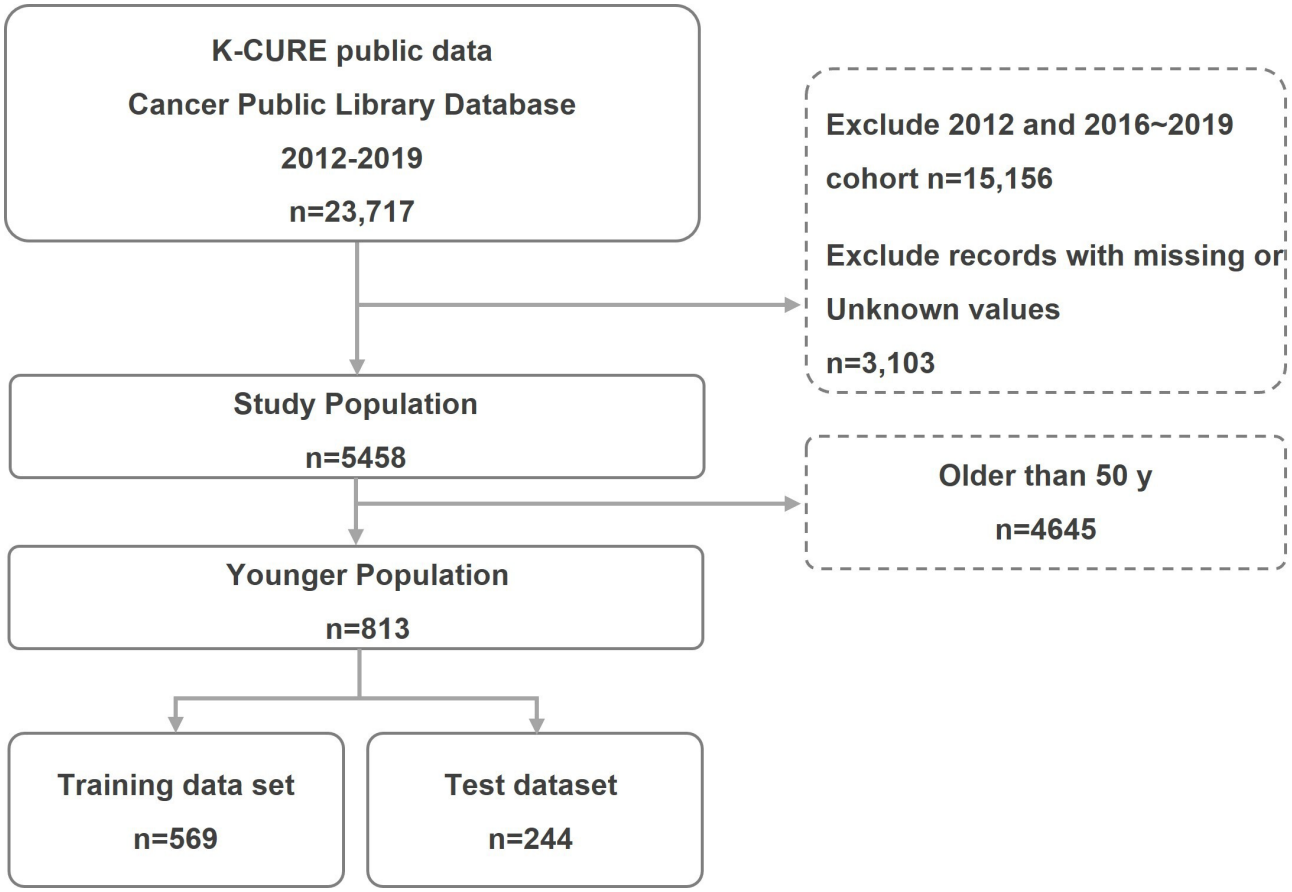
Survival analysis is a statistical methodology used to analyze time-to-event outcomes such as death or disease progression [30], and ML approaches are increasingly being adopted in health care research to address the analytical complexities associated with survival modeling [31]. Nonparametric tree-based ensemble methods are generally considered well suited for analyzing censored time-to-event outcomes and performing dynamic survival predictions [32]. The predictor variables were further ranked and stratified according to their relative feature importance within the survival prediction models. In this study, we developed a survival prediction model based on GBSA, RSF, EST, and the Cox PH. During model development, feature importance scores were computed based on the mean decrease in impurity using the scikit-learn library (version 1.0.2; Google Summer of Code project) [33]. The models were implemented using the scikit-survival library (version 0.17.2) [34] within a Python (version 3.7.5; Python Software Foundation) computational environment, with TensorFlow (version 1.15.5; Google Brain Team) used as the underlying ML framework.

All survival models were trained using predefined and fixed hyperparameter configurations. For the RSF, GBSA, and EST models, the number of estimators was fixed at 200, whereas all remaining hyperparameters were retained at their default library settings. For the Cox PH model, elastic net regularization was applied with an L1 ratio of 1×10^{-6} and predefined alpha values to enhance numerical stability during model optimization. Continuous variables were not normalized for tree-based survival models because tree-based algorithms are inherently scale invariant and do not require feature normalization. Missing values were handled through data imputation using the median value for continuous variables and the most frequent category for categorical variables followed by one-hot encoding of categorical features. Importantly, all preprocessing procedures—including imputation and feature encoding—were fit exclusively on the training dataset and subsequently applied to the test dataset to prevent information leakage during model evaluation. For the Cox PH model, the predictor variables were

XSL•FO
RenderX

standardized prior to model training to improve numerical stability and optimization convergence.

Model Performance Evaluation



The C-index [35] is the most widely used evaluation metric for assessing the performance of survival prediction models [36]. This C-index is computed by comparing the predictive risk scores and observed survival times for pairs of randomly selected patients. To determine the number of concordant and discordant patient pairs, this pairwise comparison process was repeated across all possible patient pairs within the study cohort. The predictive model assigns a numerical risk score to each individual, representing the predicted risk of mortality, whereas the C-index evaluates the model's ability to correctly rank the relative risk between pairs of individuals [37,38]. Therefore, the C-index was used to evaluate the predictive performance and discrimination ability of the survival prediction models.

Results

Study Population

The CPSD contains data for 23,717 individuals diagnosed with GC at the primary anatomical sites C160 to C166, C168, and C169 between 2012 and 2019. From this dataset, we excluded patients diagnosed with GC between 2016 and 2019 for 5-year mortality prediction analysis, as well as the 2012 cohort, for which prediagnostic screening information was unavailable. The dataset subsequently underwent data cleaning procedures, during which 3103 records containing missing or unknown values were removed, including tumor size (T-size; n=1140, 36.7%), height (n=1849, 59.6%), urine protein (n=44, 1.4%), gamma-glutamyl transpeptidase (n=4, 0.1%), low-density lipoprotein cholesterol (n=17, 0.5%), and estimated glomerular filtration rate (eGFR; n=49, 1.6%). Patients aged 50 years or younger at the time of diagnosis were classified as the "younger" patient group, as illustrated in Figure 2.

Figure 2. Generation process of the experimental datasets. K-CURE: Korea Clinical Data Utilization Network for Research Excellence.

Baseline Characteristics

The study population showed differences between younger and older patients. Among younger patients, there was a higher proportion of women, whereas older patients exhibited a higher burden of comorbidities, including cardiovascular and metabolic diseases. Differences were also observed in tumor-related characteristics, including cancer stage according to the seventh edition of the American Joint Committee on Cancer (AJCC) cancer staging manual, with younger patients tending to present with more advanced stages. In addition, older patients showed higher all-cause mortality at both 3 and 5 years. Detailed baseline characteristics are provided in Multimedia Appendix 1.

Model Performance

The RSF, GBSA, EST, and Cox PH models were trained and evaluated to compare their predictive performance for survival outcomes at 2 time horizons (3 and 5 years). Table 1 presents the mean C-index values with corresponding 95% CIs, reflecting the predictive accuracy of the models in estimating mortality risk among young patients with GC at different prediction time

XSL•FO
RenderX

points. For the ML prediction models, we reported the mean C-index and the corresponding empirical 95% CIs across 100 repeated training iterations, whereas the Cox PH model was evaluated using a single model run; therefore, CIs for the C-index were not estimated or reported. The C-index values obtained from each of the 100 training iterations for the prediction models are provided in Multimedia Appendix 2. For 3-year survival prediction, the RSF, GBSA, EST, and Cox PH models achieved C-index values of 95.89% (95% CI 95.80% - 95.97%), 95.32% (95% CI 95.31% - 95.33%), 95.53% (95% CI 95.46% - 95.60%), and 94.15%, respectively. For 5-year survival prediction, the corresponding C-index values were 91.82% (95% CI 91.68% - 91.96%), 89.98% (95% CI 89.95% - 90.01%), 94.60% (95% CI 94.50% - 94.70%), and 82.26%, as summarized in Table 1.

Table . Concordance index (C-index) with 95% CIs for survival prediction models and the Cox proportional hazards (PH) model.

Model	3 year, C-index (%; 95% CI)	5 year, C-index (%; 95% CI)
RSF[a]	95.89 (95.80-95.97)	91.82 (91.68-91.96)
GBSA[b]	95.32 (95.31-95.33)	89.98 (89.95-90.01)
EST[c]	95.53 (95.46-95.60)	94.60 (94.50-94.70)
Cox PH	94.15[d]	82.26

[a]RSF: random survival forest.

[b]GBSA: gradient boosting survival analysis.

[c]EST: extra survival tree.

[d]The C-index values reported for the machine learning models represent the mean values and corresponding 95% CIs obtained from 100 repeated model training iterations. The Cox PH model was evaluated using a single model run; therefore, CIs for the C-index were not estimated or reported.

For 3-year survival prediction, the RSF model identified several important predictors, including the AJCC stage, T-size, age, serum glutamic oxaloacetic transaminase (aspartate aminotransferase), eGFR, systolic blood pressure, serum glutamic pyruvic transaminase (aspartate aminotransferase), hemoglobin level, and tumor topography codes (C162 and C160). For 5-year survival prediction, the RSF model identified AJCC stage, T-size, deep vein thrombosis, age, tumor topography code (C163), gamma-glutamyl transpeptidase, tumor grade, diastolic blood pressure, hemoglobin level, and liver disease as key prognostic predictors. For 3-year survival prediction, the GBSA model identified several important predictors, including AJCC stage, hemoglobin level, tumor topography code (C169), T-size, fasting blood glucose, total cholesterol, weekly alcohol consumption, walking activity level, systolic blood pressure, and serum glutamic oxaloacetic transaminase. For 5-year survival prediction, the GBSA model identified the following important predictors: AJCC stage, T-size, tumor topography code (C169), weekly alcohol consumption, fasting blood glucose, hemoglobin level, diastolic blood pressure, serum glutamic pyruvic transaminase, tumor grade, and total cholesterol. For 3-year survival prediction, the EST model identified several important predictors, including AJCC stage, T-size, diabetes mellitus, tumor topography codes (C169 and C162), proteinuria, waist circumference, body weight, daily alcohol consumption, and serum glutamic oxaloacetic transaminase levels. For 5-year survival prediction, the most influential predictors identified by the EST model included AJCC stage, T-size, tumor topography code (C163), deep vein thrombosis, liver disease, diabetes mellitus, tumor grade, BMI, waist circumference, and height. For 3-year mortality prediction, the Cox PH model identified AJCC stage and T-size as the most influential predictors, followed by serum glutamic oxaloacetic transaminase, eGFR, triglycerides, age, high-density lipoprotein cholesterol, hemoglobin level, total cholesterol, and gamma-glutamyl transpeptidase. For 5-year mortality prediction, AJCC stage and T-size remained the dominant predictors, together with serum glutamic oxaloacetic transaminase, eGFR, age, high-density lipoprotein cholesterol, total cholesterol, hemoglobin level, triglycerides, and weekly alcohol consumption.

Feature importance analysis showed that AJCC stage and T-size were consistently the most influential predictors across all models and prediction time points, whereas other variables demonstrated model- and time-dependent variability. Detailed feature importance results are provided in Multimedia Appendix 3, the corresponding hazard ratio analyses are presented in Multimedia Appendix 4, and Multimedia Appendix 5 provides the mapping between heat map feature labels and the corresponding clinical variables reported in the manuscript tables.

Discussion

Principal Findings

In this study, we developed ML-based survival prediction models for young patients with GC to estimate 3- and 5-year mortality. Among the evaluated models, RSF and EST demonstrated superior predictive performance compared to the Cox PH model. Across all models and prediction horizons, AJCC stage and T-size consistently emerged as the most important predictors of mortality risk.

GC has traditionally been considered a disease predominantly affecting older adults; however, recent epidemiological studies have reported an increasing incidence among younger individuals [39-41]. These findings highlight the need for tailored prognostic models for younger patient populations. Our analysis results indicated that the older patient group exhibited a poorer prognosis than the younger patient group. Furthermore, the stage-specific survival curves demonstrated adverse poorer

XSL•FO
RenderX

prognoses in the older patient cohort. However, for stage 3 and 4 disease, no statistically meaningful differences in survival prognosis were observed between the younger and older groups, as shown in Multimedia Appendix 6. Owing to age-related physiological and biological differences, treatment responses and survival outcomes may vary, which should be considered when developing survival prediction models [42,43]. Previous studies have reported promising results, demonstrating the potential of predictive modeling to generate meaningful insights into survival outcomes [5,6,44-48]. However, uncertainty remains regarding the consistency of model performance across different predictive time horizons in young patients with GC. The superior performance of ML-based models compared with the Cox PH model may be attributed to their ability to capture complex nonlinear relationships and interactions among clinical variables, which are not adequately addressed by traditional statistical approaches. These findings suggest that ML-based models may provide more accurate risk stratification, potentially supporting personalized treatment strategies and clinical decision-making for young patients with GC. In particular, the use of longitudinal clinical and comorbidity data in this study may have contributed to improved model performance, which is in line with previous studies exploring the use of ML approaches for survival prediction. Furthermore, although many predictive models have been developed using the Surveillance, Epidemiology, and End Results database, which contains comprehensive cancer registry information, there remains limited availability of longitudinal data for tracking comorbidities and patient health characteristics, such as disease diagnosis codes (*International Classification of Diseases, 10th Revision*), medication records, and routine health examination data. Such information is not consistently available in the Healthcare Examiners and Evaluators database or the National Health Service database, which may influence the predictive performance and reliability of ML models. To address these limitations, we classified patients with GC as younger (≤50 years) based on criteria used in recent studies [49] and evaluated their 3- and 5-year survival predictions using multiple survival prediction models. Using feature importance analysis, we identified clinically relevant predictors, among which 2 variables consistently influenced survival prognosis across all models and time horizons: AJCC stage and T-size. These variables demonstrated significant associations with all-cause mortality at both the 3- and 5-year follow-up intervals, as shown in Multimedia Appendix 7. The tumor, node, metastasis (TNM) staging system represents a comprehensive framework for evaluating the anatomical extent of cancer progression and continues to serve as the fundamental basis for prognostic stratification in oncology. Although T-size contributes to the T component of the TNM classification, the continuous measurement of T-size may provide additional prognostic granularity beyond categorical stage classifications. The TNM staging system aggregates information from the tumor, nodal involvement, and metastasis categories into discrete stage groups. However, a continuous T-size variable may capture heterogeneity within the same stage group, which may not be fully represented by categorical staging alone. This may prove why both tumor stage and T-size were retained as significant predictors in the ML survival prediction models. These findings suggest that, within established staging frameworks, incorporating quantitative tumor characteristics such as continuous T-size measurements can provide additional prognostic information, particularly for long-term survival prediction. However, as illustrated by the heat map of key predictors for the 3- and 5-year models, the relative importance of variables used to predict mortality varied across prediction time points in Multimedia Appendix 3. The proposed survival prediction models enabled the identification of high-risk subgroups among young patients with GC by accounting for temporal variations in prognostic risk factors. These findings may support the development of more targeted and potentially aggressive treatment strategies for young patients with GC. To evaluate the performance of the proposed model, a comparative analysis was conducted between the traditional TNM staging system and the ML survival model for 1-, 3-, and 5-year mortality prediction, with the Harrell C-index used to quantify model discrimination performance. The findings demonstrated that ML-based approaches exhibited superior performance for 3- and 5-year mortality, whereas at the 1-year prediction horizon, the TNM staging classification showed slightly higher discriminatory power than the ML survival model, as shown in Multimedia Appendix 8. Consequently, the ML-based 1-year mortality prediction model was excluded from subsequent analyses. These findings suggest that short-term mortality outcomes are predominantly influenced by the initial stage of disease, a factor that is effectively captured by the conventional TNM staging classification system. Conversely, the additional predictive benefit of ML-based survival models became more pronounced in long-term predictions (3 and 5 years), where multiple complex clinical and biological factors may contribute to heterogeneity in patient outcomes. The validation of predictive model performance was strongly influenced by the data-splitting strategy used for model training and evaluation. This study compared the results obtained using a random data-splitting strategy (training: 70%; testing: 30%) applied to the entire dataset from 2013 to 2015 with those obtained using a year-based split (training: 2013 - 2014; testing: 2015), as shown in Multimedia Appendix 9. The analysis demonstrated that the random data-splitting strategy produced a higher predictive performance compared with the year-based splitting approach. This result was interpreted as reflecting the inability of the year-based split to adequately represent the characteristics of the patient cohort collected in a specific year (2015) within the training dataset, which led to larger differences in key variables—particularly AJCC stage—between the training and testing datasets. In summary, although the dataset in this study was longitudinal and incorporated patient-specific follow-up durations, the year-based segmentation approach functioned more as a method for separating patient cohorts collected at different time points than as a validation framework representing a true temporal prediction scenario. This heterogeneity in key predictor variables—particularly AJCC stage—between the training and test datasets was considered to limit the generalization of latent patterns learned by the models during training, thereby reducing the overall predictive performance.

This study has several limitations. It was conducted using data derived from a single ethnic population, which may have introduced potential population-specific bias into the developed

XSL•FO
RenderX

prediction models. In addition, external validation using independent datasets was not performed, which may limit the robustness, generalizability, and clinical applicability of these predictive models. Although this study developed and validated ML models for predicting 3- and 5-year mortality in young patients with GC, several important methodological considerations, including model interpretability and robustness to complex or incomplete data, were not fully addressed.

In summary, this study developed and validated ML models for predicting 3- and 5-year mortality in young patients with GC, demonstrating their potential utility for risk stratification and clinical decision-making. Validation using larger and more diverse patient populations is necessary to ensure robustness, external validity, and generalizability. The integration of explainable artificial intelligence methodologies may enhance the interpretability and transparency of ML models, thereby making predictive outputs more clinically actionable for health care practitioners [50]. Recent ML research has addressed several methodological challenges, including modeling temporal dependencies, discriminative feature selection, and improving robustness to noisy or incomplete input data. Prior studies in nonclinical ML domains have proposed advanced methodologies, including attention-based temporal models, structure-aware feature selection frameworks, and confidence-driven learning strategies [51-53]. Although these approaches do not directly fall within the scope of this study, they provide conceptually important insights for survival prediction problems, particularly those requiring careful handling of longitudinal data patterns, high-dimensional clinical variables, and uncertainty in medical datasets. These methodological directions may be adapted and extended to medical prognostic prediction models, particularly in survival analysis and clinical outcome prediction research. In addition to these methodological considerations, evaluation of the clinical utility of the key prognostic variables identified in this study, including cancer stage and T-size, is required through prospective or independent validation studies, whereas the use of internationally standardized and multiethnic datasets may further improve the reliability, external validity, and global generalizability of the predictive models.

Conclusions

The number of young patients diagnosed with GC continues to increase worldwide, and nomogram-based prognostic models have been proposed to identify patients at high risk of adverse outcomes. However, relatively few studies have focused on predicting survival outcomes in young patients with GC using ML approaches. Therefore, we developed ML-based prediction models for estimating 3- and 5-year mortality in young patients with GC. These models may assist clinicians in identifying young patients with GC who may require more aggressive or personalized treatment strategies. However, because this analysis was conducted using data derived from the Korean patient population, future studies should externally validate these prediction models in diverse international populations.

Abstract

Background: Immune checkpoint inhibitors (ICIs) have emerged as a pivotal treatment for advanced esophageal squamous cell carcinoma (ESCC). However, their efficacy can significantly differ among patients, highlighting the need for reliable prognostic markers to enhance treatment outcomes. Lactate dehydrogenase (LDH) plays a key regulatory role in the complex relationship between cancer metabolism and the immune system, suggesting that monitoring LDH levels may provide valuable insights into treatment efficacy and inform personalized therapeutic strategies for advanced ESCC.

Objective: This study aimed to explore the prognostic significance of dynamic changes in LDH levels during ICI therapy in predicting treatment outcomes.

Methods: We retrospectively analyzed the clinical data of 126 patients with advanced ESCC who received first-line ICI therapy at the Department of Radiation Oncology, Cancer Center, Shandong Provincial Hospital, between April 2018 and November 2022. Serum LDH levels were measured after every 3 cycles of combined immunotherapy and chemotherapy. Receiver operating characteristic curve analysis determined the optimal LDH reduction threshold. Kaplan-Meier survival curves and Cox regression models assessed progression-free survival (PFS) and overall survival.

Results: Among the 126 patients, 55 (43.6%) were classified into the LDH-increased group, while 71 (56.4%) belonged to the LDH-decreased group. Within the LDH-increased group, 78.2% (43/55) of the patients were male, compared to 90.1% (64/71) in the LDH-decreased group. The median age of patients in the LDH-increased group was 59 (range 55 - 68) years, whereas the median age in the LDH-decreased group was 65 (range 58 - 65) years. LDH decrease following first-line ICI therapy was associated with improved outcomes compared to LDH increases (median PFS 13.4, IQR 8.1 - 24.3 mo vs median 10.8, IQR 4.8 - 20.6 mo; P= .03). Patients with a posttreatment LDH decrease of more than 14.4% had a median PFS of 11.1 (IQR 7.2 - 24.3) months, whereas those with an LDH decrease between 0% and 14.4% had a median PFS of 21.7 (IQR 9.4 - 34.5) months. Conversely, an increase in LDH resulted in a median PFS of 10.8 (IQR 4.8 - 20.6) months. Patients with tumor reduction exhibited a significantly greater decrease in LDH levels compared with those without tumor reduction (P<.001). Multivariate analysis identified LDH decrease as an independent predictor of a 41% lower mortality risk (hazard ratio 0.59, 95% CI 0.36 - 0.96; P=.04).

Conclusions: In patients with advanced ESCC, a decrease in serum LDH levels ranging from 0% to 14.4% after treatment initiation was significantly associated with prolonged PFS. Notably, an early decrease in LDH levels observed after 3 cycles of immunotherapy further correlated with improved clinical outcomes. These results highlight the potential of LDH as a valuable biomarker for risk stratification and personalized treatment optimization in advanced ESCC.

Introduction

Background

Esophageal squamous cell carcinoma (ESCC) is a globally prevalent oncological challenge marked by high incidence and mortality rates, particularly in regions such as Asia, Eastern Europe, and Africa [1]. The typically asymptomatic nature of early-stage ESCC often results in late-stage diagnoses, which limit therapeutic options and contribute to high mortality rates [2]. Current management strategies for ESCC include a combination of surgery, radiation, and chemotherapy. However, the 5-year survival rate remains dismally low at approximately 20%, emphasizing the aggressive nature of this malignancy and the complexities surrounding its treatment [3].

Recent advancements in immunotherapy, particularly immune checkpoint inhibitors (ICIs) targeting the programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) axis, such as nivolumab and pembrolizumab, have revolutionized the treatment landscape for advanced ESCC. Evidence from pivotal studies such as KEYNOTE-181 and ATTRACTION-3 has demonstrated the superior efficacy of ICIs compared to conventional chemotherapy [4]. Despite these breakthroughs, not all patients with advanced ESCC derive significant benefits from ICIs [5], highlighting the critical need for reliable, accessible, and cost-effective biomarkers to predict treatment response and patient prognosis more effectively.

Lactate dehydrogenase (LDH), a key enzyme in cancer cell metabolism, has gained attention as a potential prognostic biomarker in oncology due to its role in metabolic reprogramming and tumor adaptation to hypoxic microenvironments [6]. Elevated LDH levels have been linked to increased tumor aggressiveness, metabolic stress, and poor clinical outcomes across various malignancies, including melanoma, lung cancer, and breast cancer, underscoring its potential as a universal biomarker of malignancy [7,8]. Emerging research highlights the intricate relationship between cancer metabolism and the immune system, with LDH functioning as a critical mediator of this interplay [9]. LDH plays a pivotal role in metabolic reprogramming, enabling tumor survival in hypoxic conditions by facilitating anaerobic glycolysis and lactate production. These processes not only support tumor growth but also contribute to the creation of an immunosuppressive tumor microenvironment. This suggests that dynamic changes in LDH levels could significantly influence the efficacy of immunotherapeutic approaches in ESCC [10]. Preliminary studies have shown that variations in LDH levels following ICI treatment correlate with improved survival outcomes, pointing to the potential of LDH as a valuable prognostic tool in ESCC immunotherapy [11].

Objectives

To identify a more accessible and precise prognostic marker for advanced ESCC, this study enrolled patients receiving first-line immunotherapy combined with chemotherapy. The primary objective was to investigate the prognostic value of dynamic changes in LDH by assessing LDH kinetics. This research aims to provide new insights into the potential of LDH as a cost-effective and practical biomarker for guiding personalized treatment strategies and improving outcomes in patients with advanced ESCC.

Methods

Ethical Considerations

This study was approved by the Ethics Committee of Biomedical Research at Shandong Provincial Hospital (SWYX NO 2023 - 595). Given the retrospective nature of the study, which involved secondary analysis of existing electronic health records, no prospective informed consent specific to this research was required. At the time of admission or outpatient registration, all patients provided a general consent permitting the use of their medical records for research purposes, in accordance with institutional policy. All data in this study were deidentified to ensure participant anonymity and protect confidentiality. This was a retrospective study based on the analysis of pre-existing patient medical records. As such, no participants were actively recruited for this research, and therefore, no compensation was involved.

Patient Selection

This retrospective cohort study was conducted at Shandong Provincial Hospital between April 2018 and November 2022. The study included patients diagnosed with stage IV ESCC based on the Tumor-Node-Metastasis classification system. Eligible patients were those who received ICIs in combination with chemotherapy and who had a Karnofsky Performance Status score greater than 80.

The exclusion criteria were as follows: history of other malignancies, presence of autoimmune disorders, previous immunotherapy with agents such as Carrelizumab or Tislelizumab, and incomplete clinical or laboratory data.

The follow-up period ended in September 2023. The medical records were retrieved from the Shandong Provincial Hospital database. Data collected included patient age, sex, comorbidities, tumor location, treatment response evaluations, TNM stages, stage at initial diagnosis, baseline LDH levels, posttreatment LDH levels, and dynamic changes in LDH levels.

Treatment and Evaluation Criteria

All participants in the study received a treatment regimen consisting of PD-1 inhibitors combined with chemotherapy agents, such as 5-fluorouracil, cisplatin, taxanes, and irinotecan, administered either as monotherapy or as part of polychemotherapy protocols. The PD-1 inhibitors were administered intravenously at a standard dose of 200 mg, with infusions performed every 2 to 3 weeks for a total of 4 to 6 cycles, or until disease progression, unacceptable toxicity, or death.

Serum LDH levels were measured at 2 key time points: at baseline (before the initiation of immunotherapy) and after the final immunotherapy cycle. LDH quantification was performed by the Department of Laboratory Medicine at Shandong Provincial Hospital. The study evaluated treatment efficacy longitudinally, with key end points including progression-free survival (PFS) and overall survival (OS). Progressive disease was defined as a ≥20% increase in the sum of the longest

XSL•FO
RenderX

diameters of target lesions from the nadir, the appearance of new measurable disease foci, or other substantial indicators of disease progression, according to the Response Evaluation Criteria in Solid Tumors (version 1.1) [12]. PFS was measured from the initiation of anti–PD-1 therapy to the point of documented disease progression or death from any cause, while OS was defined as the time from the initiation of immunotherapy to death from any cause.

Statistical Analysis

Overview

Descriptive statistics were used to summarize baseline characteristics, using means (SD) for normally distributed variables, medians (IQR) for non–normally distributed variables (as assessed by the Shapiro-Wilk test), and frequencies (%) for categorical variables. Serum LDH levels were measured both before treatment and after immunotherapy (median of 3 cycles). The LDH reduction rate was calculated as follows:

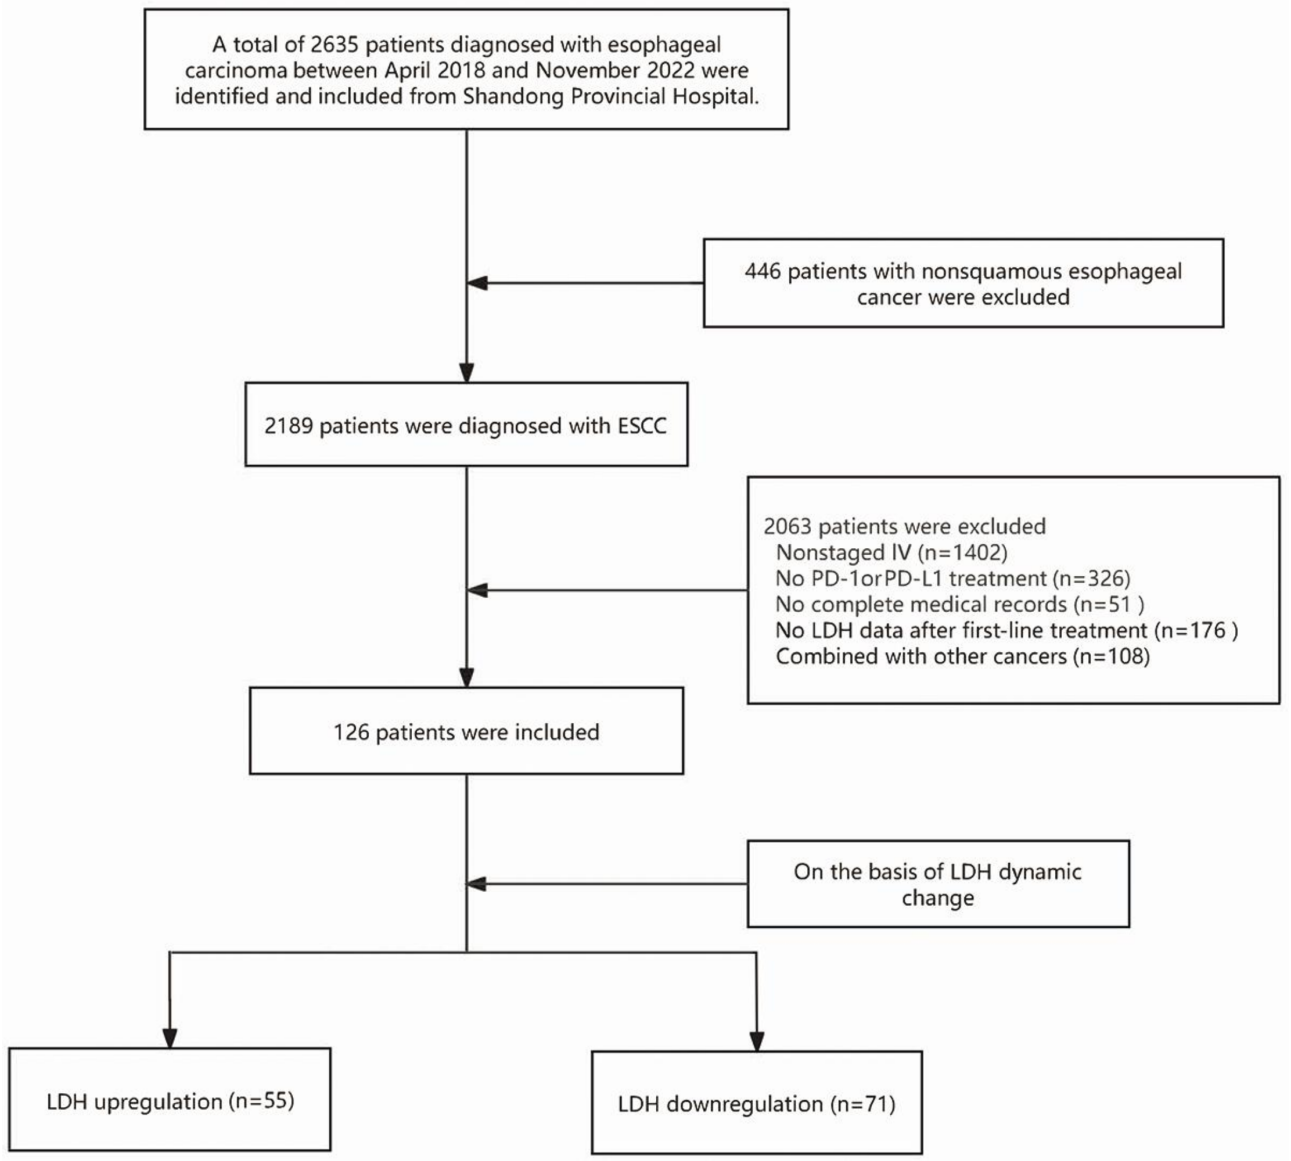
$$[\text{Baseline LDH} - \text{Post-treatment LDH}]/\text{Baseline LDH} \times 100\%$$

Critical Methodological Note on Cutoff Selection

The initial receiver operating characteristic analysis for OS prediction yielded suboptimal performance (area under the curve=0.602; data not shown), likely due to the heterogeneity inherent in retrospective cohorts. Consequently, we adopted a distribution-driven approach, selecting the 25th percentile of observed LDH reduction values (−14.4%) as the primary cutoff. This threshold, representing a substantial decline in LDH, demonstrated significant discriminative power for PFS in subsequent analyses.

Kaplan-Meier curves, analyzed using log-rank tests, were used to compare survival between different LDH trajectory groups. Cox regression analysis was used to identify prognostic factors, with a two-step process: (1) univariate screening with a $P<.10$ entry threshold and (2) multivariate adjustment for age, Karnofsky Performance Status, and TNM stage. Results were reported as adjusted hazard ratios (HRs) with 95% CIs. Missing data were minimal (<1% for LDH, PFS, and OS) and were handled using complete-case analysis, confirmed to be missing completely at random; sensitivity analyses with multiple imputation yielded consistent results. The sample size (n=126) provided 80% power ($\alpha=.05$) to detect an HR of 0.60 for PFS improvement in LDH reducers versus nonreducers, based on KEYNOTE-181 data with a 15% attrition adjustment. Analyses were conducted using SPSS (version 25.0; IBM Corp), with statistical significance set at $P<.05$ (2-tailed).

Results



Patient Characteristics

As shown in Figure 1, from an initial cohort of 2635 patients diagnosed with ESCC, 446 (16.9%) patients with non-ESCC diagnoses, 1402 (53.2%) patients at non-IV stages of ESCC, 326 (12.4%) patients who did not receive PD-L1 and PD-1 treatment, 51 (1.94%) patients with incomplete medical records, 176 (6.68%) patients lacking LDH data during first-line treatment, and 108 (4.1%) patients diagnosed with other cancers were excluded. The final study cohort consisted of 126 patients.

The follow-up period concluded with a median follow-up duration of 13.8 (range 8.00 - 18.75) months. From the 126 patients, 9 (7.14%) were alive at the time of follow-up. The median PFS for all patients was 11.8 (95% CI 6.1 - 22.9) months, while the median OS was 28 (95% CI 14.6 - 43.9) months.

XSL•FO
RenderX

Figure 1. Patient selection criteria and process. ESCC: esophageal squamous cell carcinoma; LDH: lactate dehydrogenase; PD-1: programmed death-1; PD-L1: programmed death-ligand 1.

Patient characteristics are summarized in Table 1. Among the 126 patients, 55 (43.6%) were classified into the LDH-increased group, while 71 (56.4%) belonged to the LDH-decreased group. Within the LDH-increased group, 78.2% (43/55) of the patients were male, compared to 90.1% (64/71) in the LDH-decreased group. The median age of patients in the LDH-increased group was 59 (range 55 - 68) years, whereas the median age in the LDH-decreased group was 65 (range 58 - 65) years. In addition, in the LDH-increased group, 38.2% (21/55) of patients had other comorbidities, whereas in the LDH-decreased group, the proportion was 43.7% (31/71).

The LDH ratio was calculated by comparing the posttreatment LDH levels to the baseline LDH levels. On the basis of this ratio, patients were subsequently classified into 2 categories: those with elevated LDH levels and those with decreased LDH levels.

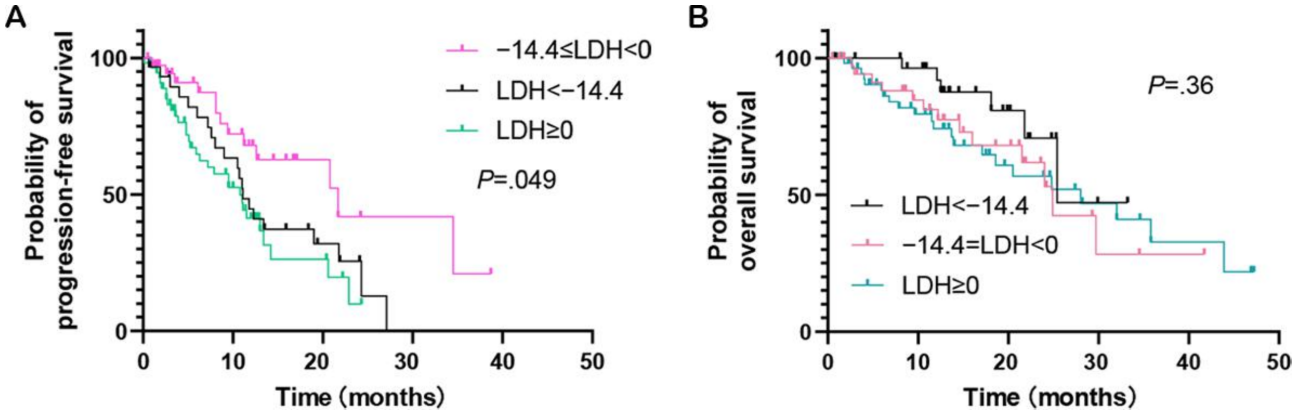
Kaplan-Meier Survival Analysis

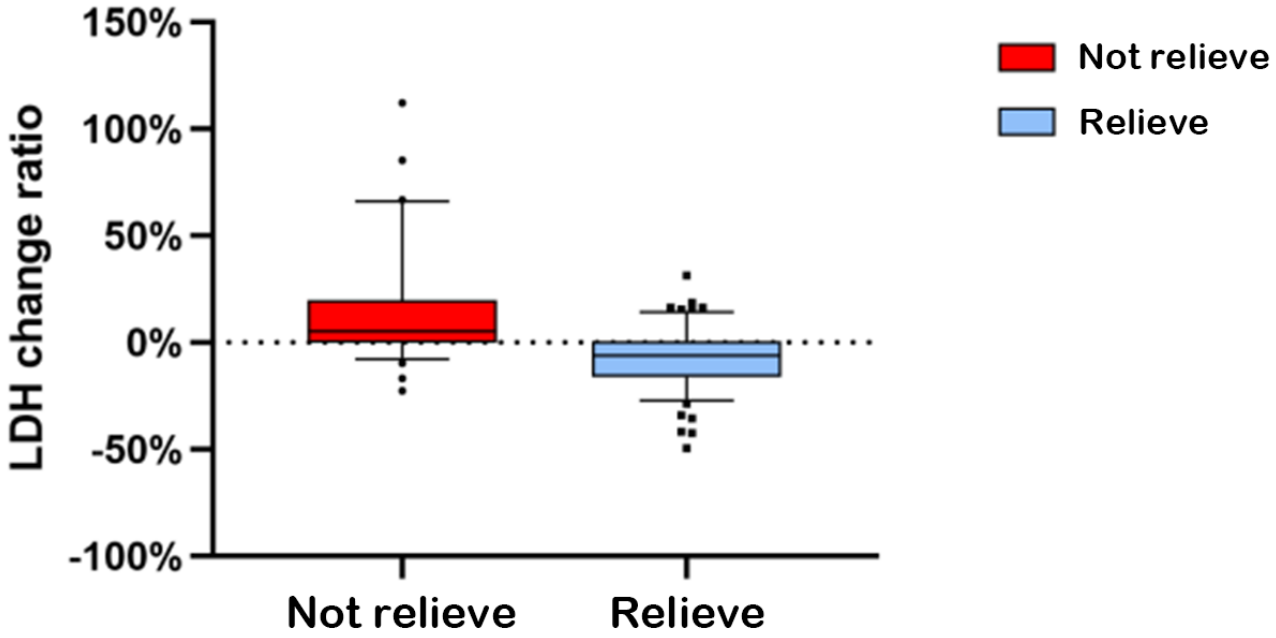
To assess dynamic changes in LDH levels, collection points were established at intervals of every 3cycles of chemotherapy combined with immunotherapy. Dichotomous analysis revealed that patients exhibiting downregulated LDH levels showed a significant improvement in PFS (*P*=.03; Figure 2A). However, no statistically significant difference was observed in OS (*P*=.36; Figure 2B).

Figure 2. Kaplan-Meier curves for (A) progression-free survival and (B) overall survival based on lactate dehydrogenase (LDH) dichotomization (downregulation vs upregulation). Patients with downregulated LDH levels exhibited a significantly better prognosis.



It was noted that a reduction in LDH levels may also reflect a decline in the patient's physical condition or nutritional status, necessitating further stratified analysis. Receiver operating characteristic curve methodology was applied, with OS used as the end point criterion for analysis. On the basis of this methodology, an appropriate threshold for LDH reduction was

XSL•FO
RenderX



identified as greater than −14%, closely approximating the −14.4% mark, which represents the boundary at the 25th percentile of the data distribution. At the threshold of −14.4%, a significant difference in PFS was observed (Figure 3A), while no significant difference was detected for OS (Figure 3B).

Figure 3. Kaplan-Meier curves of (A) progression-free survival and (B) overall survival stratified by lactate dehydrogenase (LDH) change into 3 groups: an increase (LDH≥0%), a moderate decrease (−14.4%≤LDH<0%), and a marked decrease (LDH<−14.4%) following treatment. A decrease in LDH levels exceeding 14.4% after treatment was associated with a significantly improved prognosis.

Further we analyzed the relationship between LDH dynamics and radiological tumor response. As shown in Figure 4, patients in the tumor reduction group experienced a significantly greater decline in LDH levels than those in the non-reduction group (P<.001; Figure 4). This indicates that a decrease in LDH levels is consistent with tumor shrinkage.

Figure 4. Comparison of LDH change rates between the tumor reduction group and the non-reduction group after 3 cycles of treatment. The tumor reduction group exhibited a significantly greater decrease in LDH levels compared with the non-reduction group (P < 0.05). (P<.001). “Relieve” indicates radiological evidence of reduction in the size of the primary tumor or affected lymph nodes after treatment, as assessed by the radiology department. “Not relieve” indicates no measurable reduction on follow-up imaging.

Multivariate and Univariate Analyses

In the univariate analysis performed using the Cox proportional hazards model (Table 2), it was observed that patients with decreased LDH levels (threshold=200 U/L) following treatment demonstrated a 41% reduction in the risk of death compared with those exhibiting increased LDH levels (HR 0.59, 95% CI 0.37 - 0.98; P=.04).

In addition to LDH changes, given that other clinical factors, including age, tumor length, tumor stage, tumor location, and the presence of comorbidities, were associated with PFS, we included these factors in our multivariate analysis (Table 2). The results of the multivariate analysis identified a reduction in LDH levels as an independent prognostic factor for improved outcomes (HR 0.59, 95% CI 0.36 - 0.96; P=.04; Table 2).

Compared with patients with elevated LDH levels, LDH downregulation was an independent prognostic factor for a 41% reduction in the risk of death (HR 0.59, 95% CI 0.36 - 0.96; P=.04).

Discussion

Principal Findings

This study provides valuable insights into the prognostic significance of dynamic changes in LDH levels among patients with ESCC undergoing ICI therapy. The findings demonstrate that a reduction in LDH levels is associated with improved PFS. Specifically, patients with a moderate LDH decrease (0% to 14.4%) exhibited a median PFS of 21.7 months, compared to 10.8 months in those with increased LDH. Multivariate analysis further confirmed that an LDH decrease independently predicted a 41% reduction in mortality risk. These results underscore the potential utility of dynamic LDH monitoring as an accessible, cost-effective, and valuable prognostic tool for informing individualized treatment strategies in advanced ESCC.

Comparison to Previous Work

LDH, a key enzyme involved in cellular metabolism, facilitates the interconversion of lactate and pyruvate, which are critical to both aerobic and anaerobic metabolic pathways [13]. Elevated LDH levels have long been recognized as a prognostic marker in various malignancies, reflecting increased tumor burden and metabolic stress [14,15]. However, this study expands on existing knowledge by focusing on the dynamic changes in LDH levels during treatment rather than static measurements. This novel approach enables a more precise evaluation of treatment efficacy by capturing real-time fluctuations in tumor metabolism and therapeutic response. While traditional biomarkers for ICI therapy, such as PD-L1 expression, tumor mutational burden, and immune cell infiltration, provide valuable prognostic information, they often require complex, resource-intensive assessments [16-18]. In contrast, dynamic LDH monitoring offers a similarly predictive yet simpler and more cost-effective alternative. This is particularly advantageous in resource-limited settings, where such a practical tool can guide clinical decisions and optimize treatment strategies.

Role of LDH in Tumor Metabolism and Therapeutic Implications

Elevated LDH activity in cancer cells reflects reliance on anaerobic glycolysis, leading to increased lactate production [19]. Accumulation of lactate acidifies the tumor microenvironment, disrupts immune cell function, promotes tumor progression, and creates conditions favorable for immune evasion [20,21]. Dynamic monitoring of LDH levels provides crucial insights into these metabolic shifts, illustrating the impact of therapy on tumor biology. Specifically, elevated lactate levels impair T-cell function, reduce immune cell cytotoxicity, and promote an immunosuppressive phenotype in tumor-associated macrophages [22,23]. Conversely, a reduction in LDH levels, indicative of decreased lactate production, may alleviate these

XSL•FO
RenderX

immunosuppressive effects and enhance the efficacy of immune therapies. ICIs are specifically designed to counteract immune suppression in the tumor microenvironment [24]. Monitoring dynamic changes in LDH levels can therefore provide valuable insights into the evolving tumor state and its microenvironment during therapy. A decrease in LDH levels may signal effective tumor cell apoptosis or reduced glycolytic activity, both of which can relieve metabolic stress, enhance immune cell function, and ultimately improve therapeutic outcomes [25].

Clinical Utility

Dynamic monitoring of LDH facilitates personalized treatment strategies by allowing real-time assessment of therapeutic efficacy and metabolic changes. Patients with significant reductions in LDH levels are more likely to benefit from continued ICI therapy, while those with stable or increasing LDH levels may require alternative therapeutic approaches [26]. This approach allows clinicians to optimize treatment strategies tailored to individual patient responses, enhancing treatment efficacy and patient outcomes. However, integrating LDH monitoring into routine clinical practice necessitates the establishment of standardized testing protocols and data interpretation guidelines to ensure consistency and reliability across clinical settings [27]. Regular LDH assessments should be incorporated into treatment plans to provide ongoing feedback on therapeutic response. Furthermore, combining LDH data with other biomarkers could enhance the predictive accuracy of treatment outcomes, supporting individualized decision-making and more precise treatment strategies [28].

Limitations

Despite its potential, the retrospective design of this study introduces certain limitations, including selection bias and inconsistencies in data recording, which may impact the generalizability of the findings. Although efforts were made to minimize these biases through standardized procedures and data validation, the inherent limitations of retrospective analyses remain. In addition, the relatively small sample size may have influenced the statistical power and generalizability of the results. Moreover, variations in chemotherapy regimens could influence treatment outcomes, thereby affecting the conclusions of this study. In the future, additional samples should be collected to conduct more detailed subgroup analyses of various highly specific chemotherapy regimens, and prospective studies are needed to validate these findings and confirm the reliability of dynamic LDH monitoring as a prognostic marker. The applicability of these results to diverse populations and clinical settings also requires further exploration. Large-scale, multicenter studies are essential to evaluate the consistency and generalizability of LDH dynamics as a prognostic tool across diverse patient cohorts. Furthermore, variations across ethnicities, genders, and regions should be investigated to ensure broader applicability and relevance.

Future Directions

Future research should include prospective cohort studies and randomized controlled trials to validate the prognostic value of dynamic LDH changes and identify optimal monitoring strategies for enhancing treatment efficacy. Exploring the combination of LDH with other biomarkers, such as genomic features and immune cell subsets, could further refine prognostic accuracy. Integrating multiple biomarkers may offer a more comprehensive assessment of patient status, informing more precise treatment strategies. Moreover, studies should investigate how to tailor immune therapies based on dynamic LDH changes, including potential treatment modifications and individualized approaches. Evaluating the impact of these strategies on long-term patient outcomes through clinical trials will be critical. The integration of LDH monitoring with other clinical data could lead to the development of comprehensive treatment plans, ultimately improving patient prognosis and quality of life.

Conclusions

Dynamic changes in LDH levels, specifically a reduction within the 0% to 14.4% range, represent novel and significant predictors of PFS in patients with advanced ESCC. After 2 cycles of immunotherapy, patients with decreased LDH dynamic ratios demonstrated significantly better prognoses. These findings highlight the potential of LDH as a metabolic biomarker that reflects tumor biology and therapeutic response in real time. Future investigations are warranted to validate the utility of this specific LDH dynamic threshold as a prognostic tool. Such efforts could enhance personalized treatment strategies, ultimately improving clinical outcomes in patients with advanced ESCC.

Abstract

Background: Metastatic cancer remains one of the leading causes of cancer-related mortality worldwide. Yet, the prediction of survivability in this population remains limited by heterogeneous clinical presentations and high-dimensional molecular features. Advances in machine learning (ML) provide an opportunity to integrate diverse patient- and tumor-level factors into explainable predictive ML models. Leveraging large real-world datasets and modern ML techniques can enable improved risk stratification and precision oncology.

Objective: This study aimed to develop and interpret ML models for predicting overall survival in patients with metastatic cancer using the Memorial Sloan Kettering-Metastatic (MSK-MET) dataset and to identify key prognostic biomarkers through explainable artificial intelligence techniques.

Methods: We performed a retrospective analysis of the MSK-MET cohort, comprising 25,775 patients across 27 tumor types. After data cleaning and balancing, 20,338 patients were included. Overall survival was defined as deceased versus living at last follow-up. Five classifiers (extreme gradient boosting [XGBoost], logistic regression, random forest, decision tree, and naive Bayes) were trained using an 80/20 stratified split and optimized via grid search with 5-fold cross-validation. Model performance was assessed using accuracy, area under the curve (AUC), precision, recall, and F_1-score. Model explainability was achieved using Shapley additive explanations (SHAP). Survival analyses included Kaplan-Meier estimates, Cox proportional hazards models, and an XGBoost-Cox model for time-to-event prediction. The positive predictive value and negative predictive value were calculated at the Youden index–optimal threshold.

Results: XGBoost achieved the highest performance (accuracy=0.74; AUC=0.82), outperforming other classifiers. In survival analyses, the XGBoost-Cox model with a concordance index (C-index) of 0.70 exceeded the traditional Cox model (C-index=0.66). SHAP analysis and Cox models consistently identified metastatic site count, tumor mutational burden, fraction of genome altered, and the presence of distant liver and bone metastases as among the strongest prognostic factors, a pattern that held at both the pan-cancer level and recurrently across cancer-specific models. At the cancer-specific level, performance varied; prostate cancer achieved the highest predictive accuracy (AUC=0.88), while pancreatic cancer was notably more challenging (AUC=0.68). Kaplan-Meier analyses demonstrated marked survival separation between patients with and without metastases (80-month survival: approximately 0.80 vs 0.30). At the Youden-optimal threshold, positive predictive value and negative predictive value were approximately 70% and 80%, respectively, supporting clinical use for risk stratification.

Conclusions: Explainable ML models, particularly XGBoost combined with SHAP, can strongly predict survivability in metastatic cancers while highlighting clinically meaningful features. These findings support the use of ML-based tools for patient counseling, treatment planning, and integration into precision oncology workflows. Future work should include external validation on independent cohorts, integration with electronic health records via Fast Healthcare Interoperability Resources–based dashboards, and prospective clinician-in-the-loop evaluation to assess real-world use.

KEYWORDS

explainable artificial intelligence; machine learning in oncology; metastatic cancer; survivability prediction

Introduction

Cancer remains one of the foremost global health challenges, with 611,720 deaths projected in the United States alone for 2024, and metastatic disease accounting for the overwhelming majority of these fatalities [1]. Metastasis is particularly vexing because disseminated tumor cells frequently acquire distinct genomic and phenotypic profiles that render them resistant to standard therapies. Contemporary oncology research, therefore, acknowledges intra- and intertumor heterogeneity as fundamental obstacles to curative treatment, therapeutic resistance, and accurate prognosis [2,3]. Reliable, early-stage prediction of patient survivability is pivotal not merely for counseling patients but also for tailoring aggressive interventions, prioritizing scarce health care resources, and designing adaptive clinical trials aimed at improving long-term outcomes.

Historically, clinicians have relied on the tumor-node-metastasis staging system, Kaplan-Meier life tables, and the Cox proportional hazards (CPH) regression model to stratify survival risk. Although statistically rigorous, these techniques impose proportional hazards and linearity assumptions that rarely hold across the dynamic, nonlinear biology of metastatic cancers. When violated, CPH models can yield biased hazard ratios, suffer from time-dependent covariate effects, and perform poorly on censored or highly imbalanced datasets [4].

The emergence of artificial intelligence (AI) and machine learning (ML) has enabled the development of sophisticated models that can uncover previously hidden patterns in heterogeneous clinical and multiomics datasets, thereby providing new insights into cancer biology, diagnosis, prognosis, and treatment outcomes. Over the past decade, ML models have repeatedly outperformed traditional statistical approaches. A deep-learning algorithm developed by Esteva et al [5] achieved a sensitivity of 97% and a specificity of 78% in classifying skin lesions as benign or malignant, while Liu et al [6] reported an area under the receiver operating characteristic curve (AUROC) of 0.94 for lung cancer risk prediction using computed tomography images. Similar gains have been demonstrated for breast cancer survival [7], lymph node metastasis [8], colorectal and soft tissue sarcoma outcomes [9], lung cancer survival [10], and prostate cancer prognosis [11,12].

Among contemporary ML pipelines, gradient-boosted decision trees, particularly extreme gradient boosting (XGBoost) [13], have emerged as a workhorse because they natively handle missing data, nonlinear feature interactions, and mixed data types. Recent examples include a non–small cell lung cancer microwave-ablation study where XGBoost achieved an area under the curve (AUC) of 0.89 [14]; a 2025 *Scientific Reports* analysis integrating survival models for breast cancer recurrence (concordance index [C-index]=0.82) [15]; a large colorectal cancer cohort where boosted trees yielded the highest 5-year survival accuracy [16]; and a thyroid cancer study that constructed a 10-year overall survival nomogram using Surveillance, Epidemiology, and End Results data [17].

Biomarkers are critical for early detection, diagnosis, prognosis, and monitoring. Traditional biomarker-discovery approaches often suffer from low sensitivity, limited reproducibility, and dependence on prior biological hypotheses. ML circumvents many of these limitations by integrating diverse data types and identifying complex nonlinear relationships. Algorithms such as random forests [18], support vector machines [19], and neural networks [20] have successfully identified biomarkers from gene expression [21-23], microRNA expression [24-27], DNA methylation [28,29], and imaging modalities [30-33].

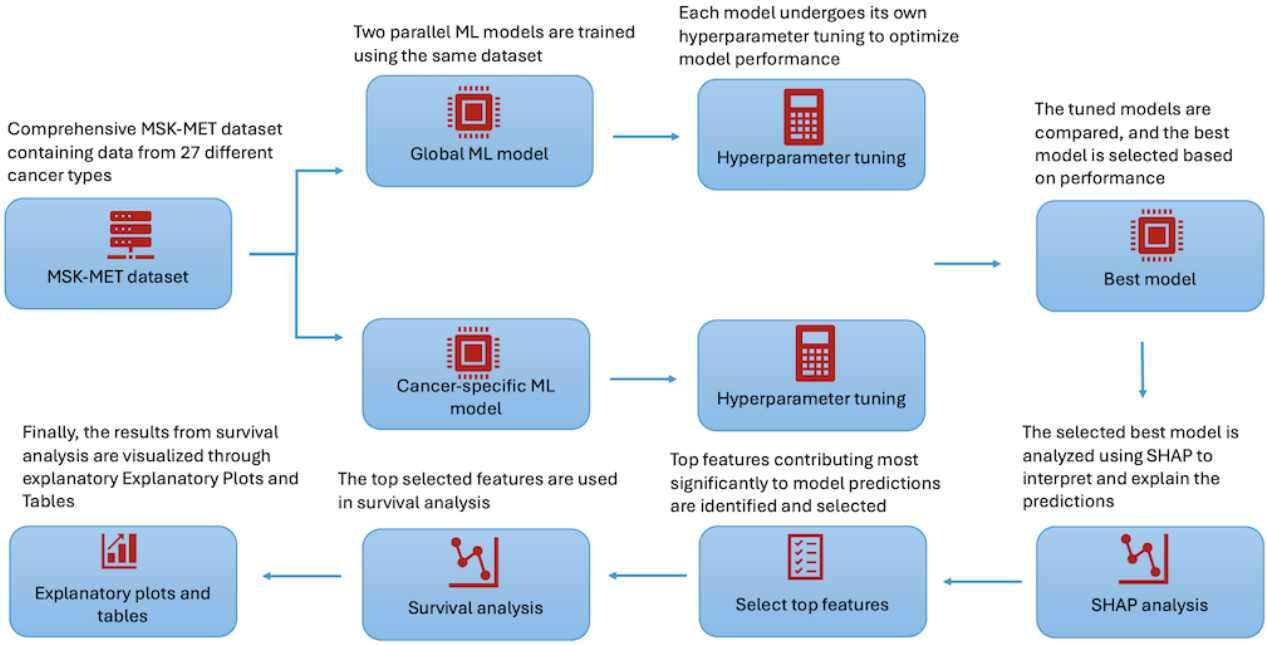
Despite this progress, significant gaps persist at the intersection of scale, interpretability, and clinical use. First, while large datasets like the Memorial Sloan Kettering-Metastatic (MSK-MET) cohort [34] provide unprecedented scale, their analysis has largely relied on traditional statistics, failing to harness state-of-the-art ML for predictive modeling. Second, most ML survival-prediction studies focus on single tumor types, use modest sample sizes, or omit high-dimensional genomic features, limiting their generalizability to the pan-cancer reality of metastatic disease. Third, and most critically, interpretability remains a bottleneck; oncologists are understandably reluctant to incorporate opaque “black box” risk scores into clinical workflows. Explainable AI methods like Shapley additive explanations (SHAP) provide a mechanism for transparency. For instance, SHAP has revealed previously unknown drivers of prostate cancer mortality [35]. Although explainable AI frameworks offer a solution, large-scale, pan-cancer implementations that jointly optimize predictive performance and model explainability remain scarce. Consequently, the field lacks an interpretable, cross-tumor framework capable of ranking metastasis-specific risk factors at a scale that reflects real-world heterogeneity.

To address these critical gaps, we designed a methodological framework that moves beyond standard, single-model architectures. We leverage the MSK-MET dataset, a pan-cancer cohort of genomic and clinical data from 25,775 patients spanning 27 tumor types, as an ideal test bed for this purpose due to its scale and diversity. Our approach is conceived as a hierarchical and explainable pipeline specifically to tackle the challenges of data heterogeneity, the need for clinical trust, and biological discovery. It integrates rigorous pan-cancer benchmarking with targeted, tumor-specific submodels and crucially unifies ML classification with traditional survival analysis. This ensures that the predictive performance of our models is directly coupled with transparent, clinically actionable insights.

Driven by this methodology, our work addresses persistent gaps at the intersection of scale, interpretability, and clinical use in metastatic cancer prognosis. Leveraging a large pan-cancer cohort that captures real-world heterogeneity, we focus on whether explainable ML approaches can yield clinically useful

XSL•FO
RenderX

survivability predictions while providing transparent, biologically and clinically coherent insights across tumor types.



The primary aim of this study is to develop and validate an interpretable ML framework for predicting overall survival in patients with metastatic cancer. We hypothesize that (1) ML models will achieve clinically useful discrimination and calibration for survivability prediction, (2) explainable AI techniques will identify a core set of prognostic biomarkers that are consistently important across diverse tumor types, and (3) integrating ML predictions with established survival analysis techniques will yield a transparent and clinically actionable tool for risk stratification.

Methods

Overview

Figure 1 illustrates the steps followed to predict cancer survivability using explainable AI. Raw data were used to initially train the ML models, followed by SHAP analysis. Top features identified by SHAP were then further used in the survival analysis. The subsequent steps below detail how this was implemented. All analysis and visualization were carried out in Python (version 3.12; Python Software Foundation) with relevant packages and libraries such as *pandas*, *numpy*, *scikit-learn*, *shap*, etc.

Figure 1. Overview of the explainable machine learning (ML) pipeline for metastatic cancer survivability prediction. The Memorial Sloan Kettering-Metastatic (MSK-MET) cohort is preprocessed and balanced, then split into stratified training and test sets before training and tuning 5 candidate classifiers (extreme gradient boosting [XGBoost], random forest, logistic regression, decision tree, and naive Bayes). The best-performing XGBoost model is subsequently interrogated with Shapley additive explanations (SHAP) to identify key prognostic clinical and genomic features, which are then carried forward into downstream survival analyses (Kaplan-Meier curves, Cox proportional hazards models, and XGBoost-Cox) to generate time-to-event estimates and clinically interpretable risk stratification.

Data Preprocessing

We first performed a thorough exploratory data analysis on MSK-MET that contained information from 25,775 patients with cancer. Our exploratory data analysis process began with a comprehensive analysis of the dataset, including the distribution of different cancer types, stages, and other relevant features. This helped us gain a deeper understanding of the underlying patterns and structures, which informed subsequent preprocessing steps. We preprocessed the input dataset and dropped columns (such as patient ID) and rows having large proportions of missing data. The target variable had 2 classes, that is, living (positive class, coded as 1) and deceased (negative class, coded as 0). In the final stage of preprocessing, the data were balanced using the target classes. Using resampling, we down-sampled the minority class (0). The final set contained 20,338 patients (10,169 living and 10,169 deceased) with 39 variables for each patient. In total, there were 27 cancer types (Table 1). The overall survival status was the target variable for prediction. Categorical variables were encoded using label encoding, and features were scaled using minimum-maximum scaling to ensure that variables with larger magnitudes did not unduly influence model outcomes. The resulting preprocessed data were then split into training and testing sets for further analysis.

Table 1. Distribution of primary cancer types in the Memorial Sloan Kettering-Metastatic cohort. Frequency counts are reported for all cancer types represented in the dataset; the 5 largest groups (non–small cell lung, colorectal, breast, pancreatic, and prostate cancer) provided the primary strata for cancer-specific extreme gradient boosting models and downstream survival analyses.

Cancer type	Frequency count, n
Non–small cell lung cancer	3790
Colorectal cancer	2696
Breast cancer	2043
Pancreatic cancer	1738
Prostate cancer	1596
Endometrial cancer	988
Ovarian cancer	923
Melanoma	882
Bladder cancer	870
Hepatobiliary cancer	790
Esophagogastric cancer	738
Soft tissue sarcoma	420
Head and neck cancer	362
Thyroid cancer	319
Renal cell carcinoma	318
Gastrointestinal stromal tumor	286
Small cell lung cancer	277
Germ cell tumor	241
Mesothelioma	219
Appendiceal cancer	160
Uterine sarcoma	133
Salivary gland cancer	123
Gastrointestinal neuroendocrine tumor	115
Skin cancer (nonmelanoma)	87
Cervical cancer	80
Small bowel cancer	76
Anal cancer	68

Stratified Random Sampling of Training and Testing Sets

We used a stratified random sampling approach to create the training and test sets. First, we randomized the complete dataset to eliminate any inherent order or sequence. Then, we implemented stratification to ensure that the distribution of specific cancer types or stages in our training and testing sets mirrored that of the entire dataset. This is paramount to avoid potential biases and to ensure that our models have a representative sample of the different cancer types and stages present in the entire dataset. Following stratification, we allocated 80% of the data (16,270 patient records) to the training set while reserving the remaining 20% (4068 patient records) for the test set. This approach provides a robust foundation for model development and validation, ensuring both broad and deep representation of the dataset in our training and testing phases.

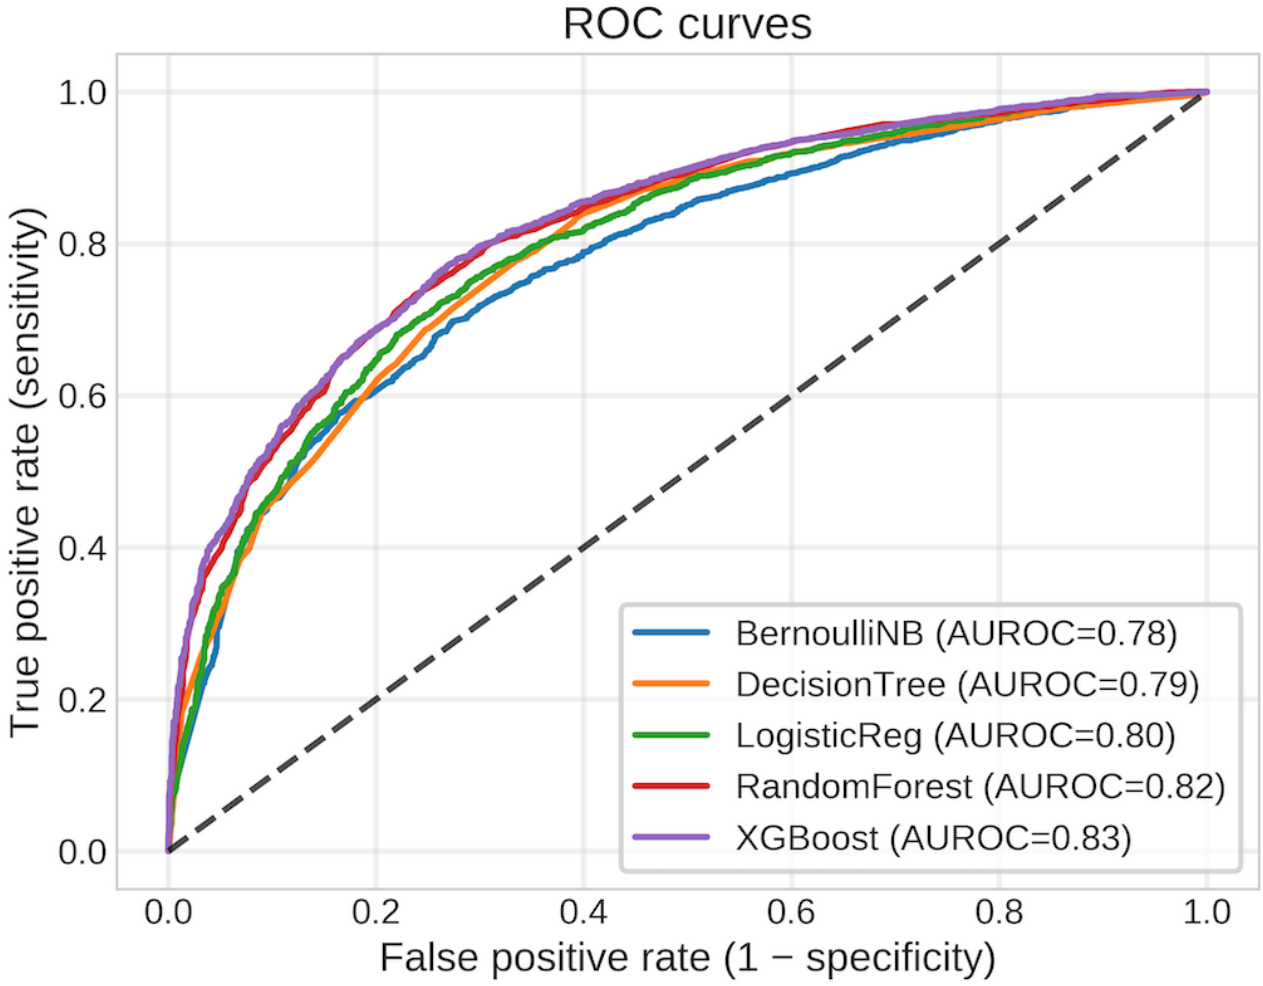
Selection and Screening of ML Models for Cancer Survival Prediction

This study used 5 ML algorithms—XGBoost, naive Bayes, decision tree, logistic regression, and random forest—to predict cancer survival rates using the MSK-MET dataset. XGBoost was selected for its efficiency in handling sparse data and combining models to improve accuracy through ensemble learning. Naive Bayes, a simple classifier applying Bayes theorem, was chosen for its efficiency in high-dimensional datasets. The decision tree, known for its easy visualization and handling of nonlinear relationships, was included for its interpretability. Logistic regression was used for binary classification, predicting survival probabilities, while random forest, an ensemble method using multiple decision trees, was

XSL•FO
RenderX

chosen for its accuracy and control over overfitting in large datasets.

Hyperparameter Optimization Via Grid Search and Model Training



Grid search with hyperparameter tuning was applied to all 5 ML models. For XGBoost, parameters "n_estimators" (50-1000), "max_depth" (1-10), and "learning_rate" (0.01-0.3) were adjusted to optimize the number of trees, tree depth, and learning speed. Naive Bayes was tuned by varying "alpha" (0.01-10.0), "binarize" (0.0, 0.5, 1.0), and "fit_prior" (True/False). The decision tree's grid search adjusted "max_depth" (None-10), "min_samples_split" (2, 5, 10), "min_samples_leaf" (1, 2, 4), and "criterion" ("gini" or "entropy"). Logistic regression was optimized with "C" (0.001-1000), "penalty" ("l1," "l2," "elasticnet," "none"), and "solver" ("newton-cg," "lbfgs," "liblinear," "sag," "saga"). Random forest explored "n_estimators" (50, 100, 200) and "max_features" ("auto," "sqrt").

Using 5-fold cross-validation on the MSK-MET dataset, we trained the 5 classifiers to identify a robust, interpretable predictor and to derive a cohort-wide view of metastatic patterns.

Model Evaluation

After training and testing the ML models on the MSK-MET dataset, we assessed their performance using 2 key metrics: the classification report (Table S2 in Multimedia Appendix 1) and AUROC (Figure 2). The AUROC measures the model's ability to distinguish between classes, with higher AUC indicating better prediction. A score of 1 represents perfect predictions, 0.5 indicates random guessing, and below 0.5 suggests worse than random predictions. These metrics provide a comprehensive evaluation, ensuring the models not only predict accurately but also effectively identify positive cancer cases. This approach helps in selecting the best model for predicting cancer survival, balancing the need to detect true cases while minimizing false diagnoses.

Figure 2. Receiver operating characteristic (ROC) curves for the 5 tuned classifiers on the held-out Memorial Sloan Kettering-Metastatic test set. Each curve shows the trade-off between sensitivity and 1 – specificity across decision thresholds, with corresponding area under the curve values summarized in Table 2. The extreme gradient boosting (XGBoost) model achieves the steepest ROC trajectory and highest area under the receiver operating characteristic curve (AUROC=0.82), indicating the strongest discrimination between surviving and deceased patients, while random forest and logistic regression (LogisticReg) form an intermediate tier, and decision tree and Bernoulli naive Bayes (BernoulliNB) exhibit comparatively weaker performance.

To characterize operating-point behavior, we computed threshold-dependent trade-offs of true positive (TP), false positive (FP), true negative (TN), and false negative (FN); sensitivity, specificity, precision, negative predictive value (NPV), F_1-score, balanced accuracy, Matthews correlation coefficient (MCC), Cohen κ, and accuracy at 3 decision

XSL•FO
RenderX

thresholds: a fixed 0.50, the Youden J optimum, and a clinically constrained point targeting sensitivity ≥0.85. Scalar metrics were accompanied by 95% CI obtained via a 1000-sample stratified bootstrap.

To obtain unbiased estimates and avoid tuning leakage, we used nested repeated cross-validation on the training data. The outer loop applied RepeatedStratifiedKFold (5 folds × 10 repeats); within each outer training split, an inner 5-fold GridSearchCV tuned hyperparameters per model. Inner-tuned models were then scored on their corresponding outer validation splits, yielding a matrix of outer cross-validation (CV) results. The model with the highest mean outer-CV performance was refit on the full training set using the selected hyperparameters and evaluated once on the held-out test set (reporting accuracy, AUROC, and a confusion matrix).

For statistical comparison across the 5 models, we ran a Friedman omnibus test on the outer-CV score matrix. As a prespecified confirmatory analysis, we tested the directional hypothesis that random forest ≥ each baseline using 1-sided Wilcoxon signed-rank tests with Holm correction; we also reported effect sizes (mean and median paired differences) with 95% paired bootstrap CI. For rank-based visualization and exploratory post hoc inference, we computed average ranks with a Nemenyi critical-difference diagram and performed 1-sided Wilcoxon tests comparing the top-ranked model to the remaining models (Holm-adjusted). Where paired per-example test predictions were available, we used the McNemar test to compare error patterns between 2 models.

Cancer Survival Prediction With XGBoost

XGBoost was therefore chosen for the rest of the analyses, involving both pan-cancer and cancer-specific models, metastatic cancer survival prediction, and survival analysis. To enhance transparency and clinical interpretability, we adopted a 2-tier XGBoost design. First, a unified XGBoost model was trained without the “Cancer Type” variable, leveraging clinical and demographic features to capture signals that generalize across diseases. Second, we trained cancer-specific XGBoost models for the 5 largest cancer groups identified in the cohort to capture within-disease interactions that can be diluted in a single global model. This combination provides both a cross-cancer perspective and disease-tailored insights that reflect differences in metastatic behavior and treatment context. In the final evaluation for both global and cancer-specific analysis, we focused only on measuring accuracy and AUC score.

Model Interpretation and Explanation

To enhance the understandability and transparency of our predictions, we used XGBoost and SHAP for model explainability. SHAP, based on game theory, provides a detailed and consistent measure of feature importance by computing each feature’s contribution to the prediction. SHA*P* values represent a feature’s responsibility for a change in the model output, ensuring local accuracy, missingness, and consistency. This method quantifies the impact of each feature on predictions and explains how the presence or absence of a feature affects the outcome. In our SHAP analysis, survival is the positive class. Beeswarm plots are particularly useful for visualizing SHA*P* values, showing features’ influence and variability in a nuanced manner.

Survival Analysis

Following the training of the XGBoost ML model and SHAP analysis, the most important features, such as metastatic site count, tumor mutational burden (TMB), and specific organ metastases (eg, liver, bone, and lung) influencing patient survival, were identified and used in the survival analysis. The primary goal was to examine the duration from cancer diagnosis to patient death, assessing how clinical and genomic variables impact survival times. We used Kaplan-Meier survival analysis, CPH modeling, log-rank tests for comparing survival distributions, and XGBoost survival analysis to deepen our understanding of patient outcomes. All of the original data was used in the survival analysis.

Kaplan-Meier Survival Analysis

The Kaplan-Meier estimator was used to evaluate survival probabilities over time across different patient subgroups. Patients were stratified based on key features identified from SHAP analysis. Survival curves were compared using the log-rank test to assess statistically significant differences between groups. A *P* value of <.05 was considered statistically significant. The analysis was first performed on all the data to assess survival of patients with metastatic versus nonmetastatic disease and then on subgroups of the top 5 cancer types including non–small cell lung cancer, colorectal cancer, breast cancer, pancreatic cancer, and prostate cancer.

CPH Model

The CPH model was applied to assess the influence of multiple covariates on patient survival while controlling for potential confounders. Key covariates included metastatic site count, fraction of genome altered, TMB, and distant metastases in specific organs. The proportional hazards assumption was evaluated using Schoenfeld residuals, and any violations were addressed through stratification or inclusion of time-varying covariates. Hazard ratios with corresponding 95% CI were reported to quantify risk associations.

Log-Rank Test

To further compare survival distributions between different patient cohorts, the log-rank test was applied. This test was used to determine whether survival differences observed between patient subgroups (eg, metastatic vs nonmetastatic) were statistically significant. The resulting *P* values guided the identification of meaningful clinical predictors. Furthermore, a plot was generated for the Kaplan-Meier survival curves with the overall survival (months) on the x-axis and survival probability on the y-axis.

XGBoost Survival Analysis

To capture complex, nonlinear relationships and interactions among variables, XGBoost survival analysis was implemented. This adaptation of XGBoost used a Cox-based loss function to accommodate censored survival data. Hyperparameter tuning was conducted using grid search, optimizing parameters such as “n_estimators,” “max_depth,” and “learning_rate.” The model’s C-index was used to evaluate predictive performance.

XSL•FO
RenderX

SHA*P* values were also applied to the survival model to interpret feature importance and explore individual risk predictions.

Ethical Considerations

This study analyzed secondary, noninterventional data from the MSK-MET cohort obtained via a publicly accessible repository (cBioPortal for Cancer Genomics). All records used for modeling and statistical analysis were anonymous and deidentified prior to access; no direct identifiers (eg, names, street addresses, full dates of birth, medical record numbers) or indirect reidentification keys were available to the research team. Because only deidentified data were used and no contact with human participants occurred, the work was considered non–human participants research and did not require informed consent or additional institutional review.

Data handling procedures followed best-practice privacy safeguards. Working datasets were stored on access-controlled systems. We did not attempt any record linkage or reidentification. To support responsible AI, model development incorporated transparent methods (eg, SHAP explanations) and prespecified subgroup evaluations to screen for potential performance disparities. All code and evaluation protocols are shared to enable reproducibility without exposing any protected information.

Results

Model Performance

The evaluation of the 5 distinct models on the MSK-MET dataset yielded a spectrum of performances. The overall classification performance for the 5 classifiers is summarized in Table 2. Receiver operating characteristic (ROC) curves are shown in Figure 2, and precision-recall curves are shown in Figure S2A, calibration in Figure S2B, decision-curve analysis in Figure S2C, and threshold-dependent metrics in Figure S2D in Multimedia Appendix 1.

Table 2. Discrimination and calibration of tuned classifiers on the same test set. Reported are area under the curve (AUC), area under the precision-recall curve (AUPRC), and Brier score, each with 95% CIs; the outcome prevalence was 0.50. Extreme gradient boosting (XGBoost; lr=0.01; depth=5; n=500) showed the strongest overall performance, with the highest AUC and AUPRC and the lowest Brier score, followed by random forest, while logistic regression, decision tree, and naive Bayes exhibited progressively lower discrimination and less favorable calibration.

Model	AUC (95% CI)	AUPRC (95% CI)	Brier score (95% CI)
XGBoost (lr=0.01; depth=5; n=500)	0.82 (0.81-0.84)	0.83 (0.81-0.85)	0.17 (0.16-0.18)
Random forest (n_estimators=200; max_features=auto)	0.80 (0.78-0.81)	0.81 (0.79-0.82)	0.18 (0.18-0.19)
Logistic regression (C=10; l2; liblinear)	0.79 (0.78-0.81)	0.79 (0.77-0.81)	0.19 (0.18-0.19)
Decision tree (gini; depth=8; min_leaf=1; min_split=10)	0.78 (0.77-0.80)	0.78 (0.76-0.80)	0.19 (0.18-0.20)
Naive Bayes (α=10.0; binarize=0.5; fit_prior=False)	0.78 (0.77-0.80)	0.77 (0.75-0.79)	0.21 (0.20-0.22)

XGBoost demonstrated the strongest discrimination and probability quality. It achieved an AUC of 0.82 (95% bootstrap CI 0.81-0.84) and the highest area under the precision-recall curve (AUPRC) at approximately 0.83 against a baseline precision equal to the prevalence (0.50; Table 2 and Table S2 in Multimedia Appendix 1). In accuracy terms, XGBoost reached 0.74 (3010/4068) and, for our summary counts, corresponded to 3335 out of 4068 test patients correctly stratified at the chosen operating point. Random forest (AUC=0.80; AUPRC=0.81) and logistic regression (AUC=0.79; AUPRC=0.79; accuracy=0.72; 2929/4068) formed a consistent middle tier, while decision tree and Bernoulli naive Bayes trailed slightly (both AUC=0.78; accuracy=0.72; 2929/4068; correctly stratified=3173/4068 for AUC-aligned counts; see Table 3 and Table S3 in Multimedia Appendix 1 for detailed counts and metrics). These rankings were concordant across ROC and precision-recall analyses and remained stable across threshold-dependent operating points (fixed threshold=0.50, Youden J optimum, and a clinically constrained sensitivity ≥0.85; Figure 2; Figures S2A and S2D and Tables S2 and S3 in Multimedia Appendix 1).

Calibration analyses reinforced this ordering. XGBoost produced the lowest Brier score (approximately 0.17; Table 2; Table S2 and Figure S2B in Multimedia Appendix 1) and a reliability curve that closely tracked the 45° line, with logistic regression comparably well-calibrated, whereas Bernoulli naive Bayes deviated most at the extremes (Table 2; Table S2 and Figure S2B in Multimedia Appendix 1).

RenderX

Table 3. Compact comparison of 5 classifiers across 3 operating points, that is, default probability cutoff (0.50), Youden J (threshold maximizing sensitivity + specificity – 1), and a high-sensitivity setting (constrained to sensitivity ≥0.85). For each model-threshold pair, we report sensitivity, specificity, Matthews correlation coefficient (MCC), and accuracy; thresholds are applied to the predicted positive-class probability. This summary emphasizes decision-relevant trade-offs: balanced performance at Youden J and the specificity cost of prioritizing high sensitivity. In this cohort, extreme gradient boosting (XGBoost) yields the strongest balanced performance (highest MCC and accuracy) at Youden J while retaining the best specificity among the high-sensitivity operating points.

Model and operating point	Threshold	Sensitivity	Specificity	MCC	Accuracy
Naive Bayes					
Probability cutoff 0.5	0.50	0.66	0.78	0.44	0.72
Youden J	0.50	0.65	0.78	0.44	0.72
Sensitivity ≥0.85	0.15	0.85	0.52	0.39	0.69
Decision tree					
Probability cutoff 0.5	0.50	0.72	0.71	0.43	0.72
Youden J	0.56	0.64	0.80	0.45	0.72
Sensitivity ≥0.85	0.32	0.86	0.49	0.37	0.67
Logistic regression					
Probability cutoff 0.5	0.50	0.73	0.73	0.45	0.73
Youden J	0.53	0.69	0.77	0.46	0.73
Sensitivity ≥0.85	0.38	0.85	0.54	0.41	0.69
Random forest					
Probability cutoff 0.5	0.50	0.69	0.76	0.45	0.72
Youden J	0.49	0.70	0.75	0.46	0.73
Sensitivity ≥0.85	0.32	0.85	0.54	0.41	0.69
XGBoost					
Probability cutoff 0.5	0.50	0.72	0.78	0.50	0.75
Youden J	0.50	0.72	0.78	0.50	0.75
Sensitivity ≥0.85	0.33	0.85	0.58	0.45	0.72

Threshold-dependent performance, summarized from confusion matrix–derived metrics at 3 operating points, made the error trade-offs explicit (Table 2; Table S3 and Figure S2D in Multimedia Appendix 1). At a fixed 0.50 threshold essentially indistinguishable from the Youden J optimum on this balanced test set, XGBoost balanced sensitivity and specificity most effectively (sensitivity=0.72; specificity=0.78; positive predictive value (PPV)=0.77; NPV=0.74; F_1-score=0.74; MCC=0.50; accuracy=0.75). Under a clinically constrained operating point prioritizing case-finding (sensitivity ≥0.85), XGBoost required a threshold of approximately 0.33 and achieved a sensitivity of 0.85 (specificity=0.58; PPV=0.67; NPV=0.80; F_1-score=0.75; MCC=0.45; accuracy=0.72). The corresponding counts at this setting were TP=1731, FP=846, TN=1188, and FN=303 (n=4068). Comparator models met the same sensitivity target with lower specificity and weaker composite indices; for example, random forest and logistic regression both settled near a specificity of 0.54 with MCC=0.41, while decision tree and Bernoulli naive Bayes lost additional specificity and MCC. These results indicate that, when sensitivity is held high, XGBoost preserves more TNs and maintains stronger global agreement (MCC, balanced accuracy).

Decision-curve analysis supported the same ordering of clinical use across a broad range of threshold probabilities (approximately 0.15-0.70), with XGBoost yielding the highest net benefit, random forest next, and logistic regression close behind (Figure S2C and Table S2 in Multimedia Appendix 1). Together with the calibration findings, these analyses suggest that XGBoost not only separates cases from controls most effectively but also produces usable risk estimates for thresholding and shared decision-making.

Furthermore, when the global XGBoost model was compared to cancer-specific XGBoost models for the top 5 cancer types (non–small cell lung, colorectal, breast, pancreatic, and prostate cancer; Tables 4 and 5), the prostate cancer model emerged as the most accurate, with an AUC of 0.88 and an accuracy of 0.84. (268/319 test patients) and an AUC of 0.88 (281/319 test patients correctly stratified). Meanwhile, pancreatic cancer posted a lower AUC of 0.68 (236/348 test patients correctly stratified), reflecting greater challenges in classification for that subgroup.

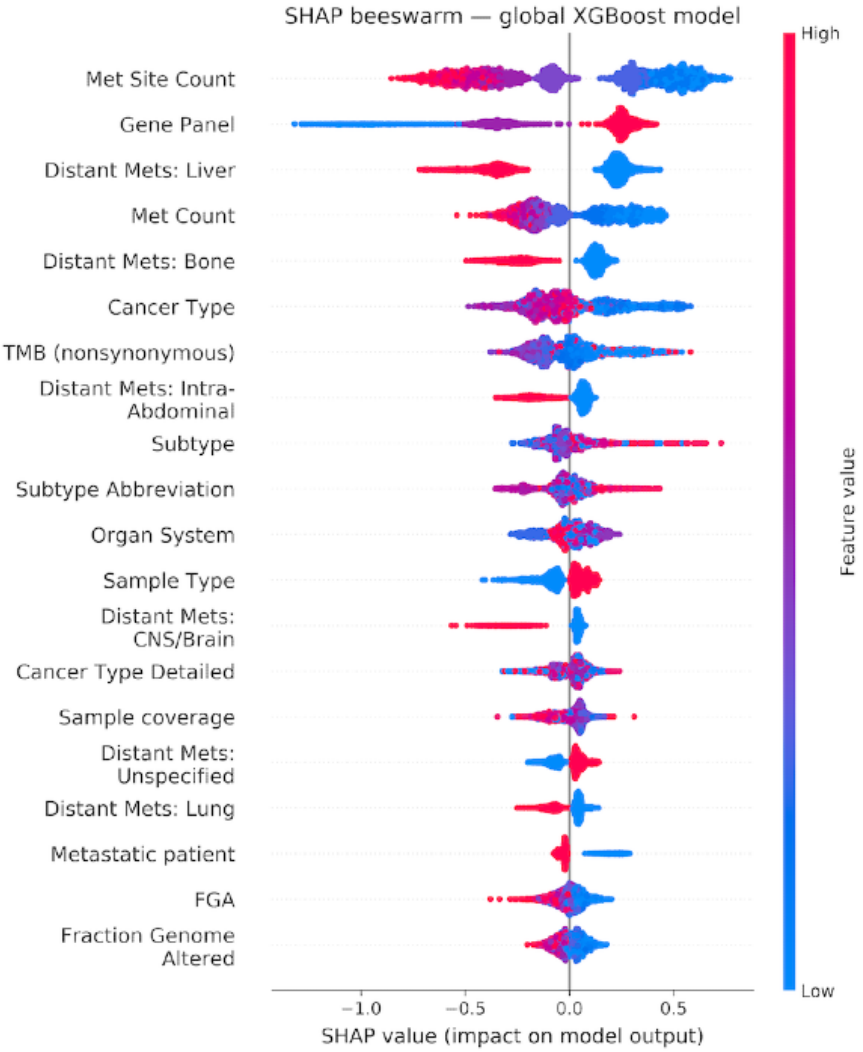
Table 4. Condensed Cox proportional hazards model for overall survival in the Memorial Sloan Kettering-Metastatic cohort. Hazard ratios (HRs), 95% CIs, and *P* values are reported for the most influential covariates identified in the global model, showing that metastatic status, higher metastatic site count, increased tumor mutational burden (TMB), greater fraction of genome altered, and distant metastases to liver, bone, and lung are all associated with significantly elevated mortality risk, whereas primary sample type is modestly protective.

Risk factor	HR (95% CI)	*P* value
Patient with metastatic disease	2.18 (1.97-2.42)	<.001
Metastatic site count	1.03 (1.02-1.04)	<.001
TMB (nonsynonymous)	1.00 (0.99-1.00)	<.001
Fraction of genome altered	1.32 (1.19-1.46)	<.001
Sample type (primary=ref)	0.87 (0.83-0.90)	<.001
Distant metastasis: liver	1.81 (1.73-1.90)	<.001
Distant metastasis: bone	1.43 (1.37-1.50)	<.001
Distant metastasis: lung	1.16 (1.11-1.22)	<.001

Table 5. Comparison of classification performance between the unified or global extreme gradient boosting (XGBoost) model and cancer-specific XGBoost models. Overall accuracy and area under the curve (AUC) are reported for each classifier, showing that while the global model achieves strong baseline discrimination (accuracy=0.74; AUC=0.82), several cancer-specific models, particularly prostate and breast cancer, attain even higher AUCs (0.88 and 0.85, respectively), whereas the pancreatic cancer model lags behind, reflecting underlying heterogeneity in predictability across tumor types.



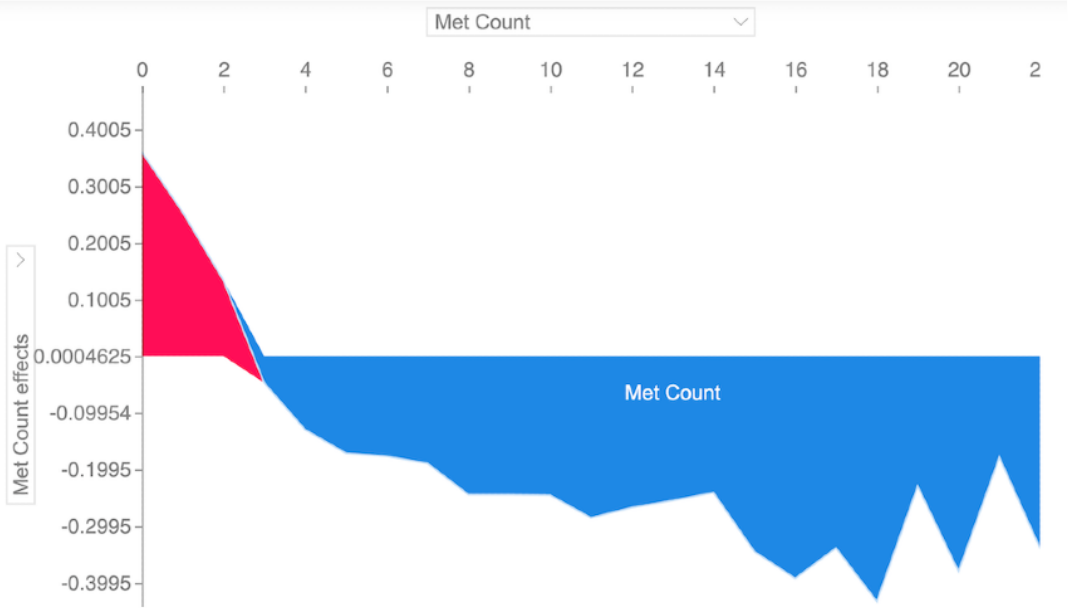
Classifier	Accuracy score	AUC score
Unified or global model	0.74	0.82
Non–small cell lung model	0.71	0.79
Colorectal cancer model	0.73	0.81
Breast cancer model	0.76	0.85
Pancreatic cancer model	0.72	0.68
Prostate cancer model	0.84	0.88

Model Explainability

The SHAP analysis of the global XGBoost model established a clear hierarchy of feature importance, identifying metastatic site count, TMB, fraction of genome altered, and distant metastases to the liver and bone as the predominant prognostic factors (Figure 3 and Table S6 in Multimedia Appendix 1). The beeswarm plots for these top features demonstrated a robust predictive power, with high and low feature values cleanly separating along the SHA*P* value axis, indicating a consistent and strong directional impact on model output (Figures S3A-S3E in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 3. Shapley additive explanations (SHAP) beeswarm plot for the global extreme gradient boosting (XGBoost) mortality classifier in the Memorial Sloan Kettering-Metastatic cohort. Features are ordered by mean absolute SHAP value, highlighting metastatic (Met) site count, tumor mutational burden (TMB), fraction of genome altered (FGA), and distant metastases to the liver and bone as the strongest drivers of model predictions. Each point represents a patient, with horizontal position indicating the direction and magnitude of impact on predicted mortality risk and color denoting low (blue) to high (red) feature values, illustrating how extreme values systematically shift risk estimates. Central nervous system is denoted by CNS.



This analysis was extended to cancer-specific models, revealing a critical dual perspective, that is, the core features identified in the global model recurrently ranked among the most important across individual cancer types, while disease-specific features also emerged. For instance (Table S6 and Figures S3A-S3E in Multimedia Appendix 1), the global top features like metastatic burden and liver metastases remained highly influential in specific models such as colorectal and prostate cancer. Concurrently, the models identified context-specific predictors, such as distant metastasis in the lung for non–small cell lung cancer, sample type for breast cancer, and distant metastasis in the male genital for prostate cancer (Figure 3; Figures S3D and S3E in Multimedia Appendix 1). This underscores that while a common set of pan-cancer drivers exists, the models successfully capture nuanced, disease-specific metastatic behaviors.

The consistent importance of features like metastatic site count was further validated by the SHAP force plot (Figure 4), which visually confirmed that an increasing number of metastatic sites directly correlated with a higher model output for mortality risk, reinforcing the clinical and biological plausibility of the model's predictions.

XSL•FO
RenderX

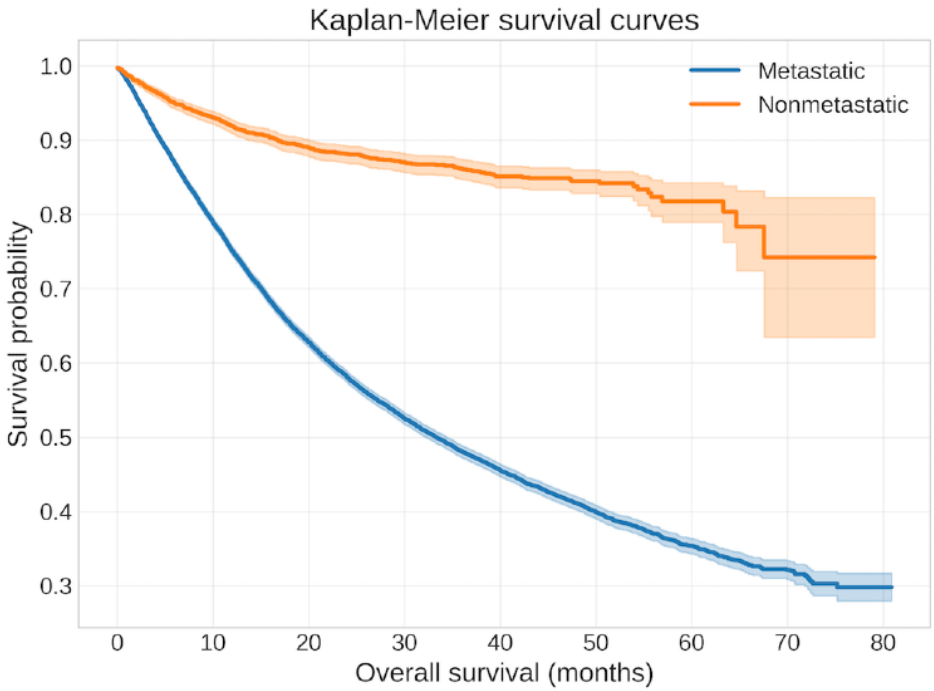


Figure 4. Shapley additive explanations force plot illustrating the impact of metastatic (Met) site count on predicted mortality risk for the first 1000 patients in the Memorial Sloan Kettering-Metastatic test set. Each horizontal bar represents an individual patient, with the baseline prediction shown at the center and shifts toward higher (right, red) or lower (left, blue) mortality risk driven by the number of metastatic sites. The consistent rightward push associated with increasing metastatic site count visually confirms its strong, monotonic contribution to higher predicted risk, reinforcing the biological and clinical plausibility of the extreme gradient boosting model's behavior.

Survival Analysis

In the Kaplan-Meier analysis (Figure 5 and Table S7 in Multimedia Appendix 1), patients were stratified into "metastatic" and "nonmetastatic" groups to compare differences in overall survival. The survival probability of patients in the metastatic group was notably lower than that of the nonmetastatic group, as seen in the pronounced separation of their survival curves. By approximately 80 months, patients with metastatic disease exhibited a survival probability of 0.30 (3041/10,169 patients with metastatic disease) versus 0.80 (8135/10,169 patients without metastatic disease), underscoring the substantial impact of metastatic status on long-term survival outcomes.

Figure 5. Kaplan-Meier survival curves comparing overall survival in patients with vs without metastatic disease in the Memorial Sloan Kettering-Metastatic cohort. Patients with metastases demonstrate markedly lower survival probabilities and earlier median survival times than patients without metastases, underscoring the substantial impact of metastatic status on long-term outcomes.

Subgroup survival results for the top 5 cancer types were as follows: in non–small cell lung cancer (n=4686), 43.75% (n=2050) of patients experienced an event and 82.5% (n=3866) presented with metastatic disease; the median overall survival

XSL•FO
RenderX

was 17.7 (IQR 8.4-33.2) months. In colorectal cancer (n=3541), the event rate was 33.52% (n=1187), the metastatic proportion was 90.82% (n=3216), and the median survival was 17.5 (IQR 10-30) months.

In breast cancer (n=2601), 35.64% (n=927) experienced an event and 76.47% (n=1989) had metastatic disease, with a median survival of 33 (IQR 14.4-43.4) months. In pancreatic cancer (n=1981), the event rate was 60.27% (n=1194), the metastatic proportion was 93.54% (n=1853), and the median survival was 11.6 (IQR 4.2-21.8) months. Finally, in prostate cancer (n=2166), 26.45% (n=573) experienced an event and 81.12% (n=1757) had metastatic disease, with a median survival of 21.6 (IQR 11.6-38.2) months (Figure S5A-S5E in Multimedia Appendix 1).

In the CPH model (Table 4), factors like metastatic site count, TMB, fraction of genome altered, and distant metastases displayed hazard ratios above 1.0, indicating an increased risk of mortality. These relationships attained statistical significance, with *P* values under the established threshold. The proportional hazards assumption was checked through Schoenfeld residuals, and only minor deviations were noted, which did not substantially affect the covariate estimates. The model's C-index reached approximately 0.66, reflecting moderate predictive power in distinguishing survival outcomes among different patient subgroups.

An XGBoost survival model, fitted with a Cox-based loss function, achieved a higher C-index (0.7) than the standard Cox model. In Table S7 in Multimedia Appendix 1, the model's important features are displayed, with distant metastasis, TMB, and fraction of genome altered, among others, listed as the most important features that influence the prediction.

Discussion

Principal Findings

Using a large, multitumor metastatic cohort (MSK-MET), we developed explainable ML models for survivability prediction and complemented them with time-to-event modeling. Among conventional classifiers, XGBoost delivered the best overall performance, achieving an accuracy of 0.74 and AUC=0.82 on the held-out test set. In parallel, an XGBoost-Cox variant improved time-to-event concordance over a standard Cox model (C-index=0.70 vs 0.66, with key hazard ratios from the Cox model). Model explanations (SHAP) and hazard-based analyses converged on clinically recognizable prognostic factors: the number of metastatic sites, TMB, fraction of genome altered, and the presence of liver and bone metastases, while cancer-specific performance varied in biologically plausible ways (eg, higher AUC in prostate and lower in pancreatic). At the Youden-optimal threshold, PPV was approximately 70% and NPV approximately 80%, indicating practical use for risk stratification in balanced decision contexts. We expand the discussion of these findings in the following subsections.

Model Performance, Robustness, and Benchmarking

Our evaluation moved beyond accuracy to provide a comprehensive assessment across discrimination, calibration, operating-point trade-offs, and clinical use. XGBoost consistently emerged as the most dependable model, with its incremental gains in AUC and AUPRC translating into more favorable confusion-matrix profiles at clinically relevant thresholds. For instance, when sensitivity is constrained to be high, XGBoost retains more specificity and a higher MCC, reducing FPs without sacrificing case finding. Its well-calibrated probability estimates are crucial for decision support, enabling rational threshold selection and clear communication of absolute risk.

The model's practical use is further evidenced by its performance across different decision contexts. For balanced decision-making, a default threshold near 0.50 (coinciding with the Youden J optimum) provides a sensible starting point. In triage-like scenarios demanding high sensitivity, a lower threshold around 0.33 yields sensitivity near 0.85 with tolerable specificity losses and an NPV around 0.80. Decision-curve analysis confirmed that XGBoost provides a larger net benefit across a wide band of threshold probabilities, suggesting robustness to varying clinical preferences.

These performance results harmonize with model explanations and survival evidence. SHAP analyses validate that predictions are driven by biologically sensible covariates, while survival curves and hazard ratios show coherent, directionally consistent effects. This triangulation across discrimination, calibration, interpretability, and survival analysis adds credibility that the learned signal reflects underlying disease biology rather than being an artifact of the classifier or data split.

Parameter Sensitivity and Model Robustness

During extensive grid-search tuning, we found that XGBoost hyperparameters, especially tree depth, learning rate, and number of estimators, greatly influenced AUC and classification accuracy. Shallow trees underfit, while deeper ones improved performance but risked overfitting in smaller cancer-specific cohorts. Learning rates below 0.05 caused slow convergence, while overly high rates destabilized training. Despite this variability, certain predictive features, particularly metastatic burden and genomic alterations, remained consistently impactful, underscoring the robustness of our model. Future research could explore adaptive optimization techniques such as Bayesian optimization or reinforcement learning for enhanced generalizability.

Is the Performance "Good Enough"?

The discriminatory performance of prognostic models is central to their clinical use. In oncology, C-index or AUC of at least 0.70 is generally regarded as the minimum threshold for clinical usefulness, while values exceeding 0.80 are considered strong and often necessary for clinical translation [36,37]. These interpretive standards are rooted in established methodological work on ROC analysis, where AUC values between 0.7 and 0.8 are typically described as "acceptable" and those above 0.8 as "excellent" [36,37].

Evidence from systematic reviews of head and neck cancer prognostic models demonstrates how these thresholds translate into practice. Philip et al [38] reported that most radiomics-based prognostic models achieved C-indices below 0.70, underscoring their weak discriminatory power and limited clinical

XSL•FO
RenderX

applicability. In contrast, externally validated models that approached or exceeded the 0.80 mark, as summarized by Dretzke et al [39], were identified as more robust and clinically relevant, supporting their potential integration into patient management. These findings emphasize that models below the 0.70 threshold may remain academically interesting but lack sufficient reliability for routine use, whereas those meeting or surpassing 0.80 provide stronger grounds for clinical adoption.

Comparisons with deep learning approaches further reinforce this interpretation. Gouthamchand et al [40] found that the most competitive deep learning models in head and neck oncology consistently achieved AUCs of 0.80 or higher, placing them above many handcrafted radiomics models. This pattern suggests that 0.80 represents not merely an aspirational benchmark but an increasingly practical requirement for prognostic tools aiming to match or surpass the performance of advanced ML methods already being piloted in clinical contexts.

Regulatory precedents also align with this threshold. Analyses of Food and Drug Administration (FDA)–cleared AI- and ML-enabled medical devices, such as the LumineticsCore software, indicate that most systems demonstrate discriminatory performance in the high 0.7 to 0.9 range, with pivotal studies for devices such as IDx-DR reporting AUCs above 0.80. Joshi et al [41] provide a comprehensive overview of this landscape, confirming that AUCs in this range are characteristic of AI systems deemed safe and effective for clinical use. FDA guidance similarly emphasizes the importance of demonstrating robust discriminatory performance in supporting claims of clinical effectiveness [42].

However, the thresholds discussed here should not be treated as rigid cutoffs. Clinical acceptability is not defined by a single number but by the context of the decision, the potential harms and benefits, and the baseline risk of the population. In high-stakes oncology decisions such as treatment intensification that carries significant morbidity, a well-calibrated model with an AUC of 0.78 but demonstrable net benefit at clinically relevant thresholds may be more valuable than a model with an AUC of 0.84 that is poorly calibrated or unstable. Thus, performance thresholds should be interpreted as contextual benchmarks rather than universal standards.

It is also important to recognize that discrimination does not equal usefulness. AUC or C-index quantifies a model's ability to rank patients by risk, but it does not measure whether the absolute risk estimates are accurate. For clinical practice, calibration is equally critical whether a patient predicted to have a 30% risk actually experiences that outcome about 30% of the time. Calibration-in-the-large, calibration slope, Brier score, and visual calibration plots provide this essential information. Moreover, calibration at clinically meaningful cut points (eg, deciles of predicted risk) is necessary to ensure predictions are trustworthy for patient counseling and decision-making.

Finally, prognostic end points in oncology are often time-to-event outcomes. In such settings, the C-index is commonly used, but time-dependent AUCs provide more clinically interpretable information by specifying the prediction horizon (eg, 12-month or 36-month survival). This allows clinicians to understand how well the model performs over the actual time frames relevant to follow-up and treatment decisions. Where applicable, handling of censoring and competing risks should also be reported, particularly if the terminal outcome is mortality.

Taken together, these considerations emphasize that while an AUC ≥0.80 is encouraging and aligns with many published benchmarks, true clinical use depends on calibration, decision-curve analysis, and performance at specific decision thresholds relevant to patient care.

Clinically Actionable Metrics, Implications, and Use

The performance metrics of our optimal XGBoost model are translated into clinically actionable insights through decision-curve analysis. At the threshold maximizing the Youden index, the model achieves a PPV of 70.3% and an NPV of 79.8%. This indicates that a high-risk prediction from the model would correspond to an actual terminal outcome in approximately 7 out of 10 cases, supporting its use in justifying intensified monitoring or treatment. Conversely, the high NPV means 8 out of 10 low-risk predictions correctly identify patients with a more favorable prognosis, providing a quantitative basis for discussions about de-escalating care and reducing treatment-related morbidity.

Critically, the decision-curve analysis confirms the model's practical use across a spectrum of clinical decision-making preferences. The analysis demonstrates that the XGBoost model provides a superior net benefit compared to both alternative models and the default strategies of treating all or no patients across a wide range of threshold probabilities. This indicates that using the model to guide decisions is clinically advantageous regardless of whether the clinician prioritizes avoiding FPs (overtreatment) or FNs (missed interventions). The point at which the net benefit of the model crosses the "treat all" strategy is particularly important, as it defines the minimum probability at which the model's prediction becomes more useful than intervening in every case. The sustained positive net benefit of our model underscores its robustness and potential to improve patient outcomes by aligning interventions with individualized risk.

The combination of strong predictive performance and model explainability supports several immediate clinical use cases: (1) patient triage and counseling via individualized risk summaries, (2) treatment planning and shared decision-making aided by feature-level rationales, and (3) integration into electronic health record (EHR)–embedded dashboards for longitudinal monitoring. The top predictive features are routinely available in most cancer centers, facilitating adoption with minimal workflow disruption.

Model Explainability and Biological Plausibility

Our model selection was guided by metrics that reflect clinical reality, prioritizing both accuracy and AUROC. The AUROC is especially critical in medical settings, as it captures the essential balance between TPs and FPs, where the cost of FNs (missed cases) is high [43]. This evaluation consistently identified XGBoost as the top performer. Its superior ability to capture complex, nonlinear relationships within high-dimensional clinical and genomic data, as evidenced by

XSL•FO
RenderX

its significant lead over other models, aligns with established literature on gradient boosting for cancer predictions [44,45]. The model's discriminative power is substantial, with an AUC of 0.82 representing an excess over chance of 0.32. This can be intuitively communicated as a "number needed to screen" of approximately 3-4 patients to identify 1 additional correct classification relative to chance, providing a tangible sense of clinical yield. This strong performance is operationalized at the Youden-optimal threshold, where PPV of approximately 70% and NPV of approximately 80% offer concrete use for risk stratification, effectively ruling in or ruling out high-risk status to guide downstream clinical actions.

Crucially, this high performance is rendered transparent and trustworthy through SHAP-based interpretation. The model's decisions are not black box outputs but are demonstrably driven by biologically plausible features that align with oncological principles. SHAP analysis consistently identified metastatic site count, liver and bone metastases, TMB, and fraction of genome altered as the top predictors; moreover, these findings are well-supported in the literature [46]. This biological plausibility was further refined and validated in our cancer-specific models. For example, the prominence of lung metastases in non–small cell lung cancer and prostate cancer models, and the major role of sample type in the breast cancer model, demonstrate a nuanced understanding of disease-specific pathophysiology as pointed out in other studies [47]. The distinct, right-skewed SHAP distribution for "metastatic count" and its direct correlation with risk in force plots further reinforced the importance of total lesion burden in driving high-risk predictions. This coherence between model explanations and established clinical knowledge across both pan-cancer and disease-specific contexts is fundamental for building clinician trust and facilitating the integration of this tool into point-of-care decision support.

Survival Modeling and Risk Stratification

Time-to-Event Insights

Survival analysis confirmed classification results. Kaplan-Meier curves revealed steep survival drops in patients with versus without metastatic disease (0.3 vs 0.8 at 80 months). Traditional Cox models identified high hazard ratios for metastatic site count, TMB, and fraction of genome altered but struggled with their linearity assumptions (C-index=0.66). In contrast, XGBoost-based survival modeling better captured nonlinearity, achieving a higher C-index of 0.70.

Subgroup Survival Analysis

The 5 disease-specific results highlight substantial heterogeneity in survival outcomes across cancer types within the same analytic framework. Pancreatic cancer exhibited the shortest median survival alongside the highest event rate and metastatic proportion, underscoring its aggressive clinical course even within a predominantly metastatic cohort. By contrast, breast cancer showed the longest median survival (as visualized in the respective Kaplan-Meier curves) despite a sizable metastatic share, suggesting comparatively slower disease trajectories and greater effectiveness of available therapies in this subgroup. Non–small cell lung cancer and colorectal cancer shared similar median survivals near 17-18 months, though colorectal cancer carried the highest metastatic proportion among the five. This juxtaposition implies that crude metastatic prevalence alone does not fully account for survival differences, motivating disease-specific modeling of covariates and sites of spread. Prostate cancer combined the lowest event rate with a midrange metastatic proportion and an intermediate median survival, indicating a slower accumulation of events over time relative to the other cancers. Together, these patterns justify presenting separate Kaplan-Meier curves and parsimonious Cox summaries per cancer type, while enabling a consistent cross-cancer narrative that focuses on differences in event rates, metastatic burden, and median survival.

Novelty and Comparison to Prior Work

Although significant studies [48-52] (Table S8 in Multimedia Appendix 1) have been conducted in the realm of predicting cancer survivability, our work stands out by bringing new enhancements that significantly contribute to better prediction of cancer survivability, particularly by the thorough comparison of ML models, the strategic use of both global and cancer-specific models, in-depth model explainability using SHA*P* values, and detailed survival analysis.

First, we begin by comparing 5 different ML models (XGBoost, naive Bayes, decision tree, logistic regression, and random forest), each rigorously tuned using exhaustive grid search for hyperparameters. This approach ensures that each model is thoroughly tested for the task of predicting cancer survivability, a detail that is often overlooked in existing literature. Many studies tend to focus on one or two models, without ensuring that the models are fully evaluated for comparison. For example, prior work done by Zhao et al [48], Tapak et al [49], and Nicolò et al [50] evaluate models but lack the thoroughness in hyperparameter tuning that our study provides. We believe that this rigorous approach enhances the reliability of our findings and provides a more comprehensive understanding of which model performs best under specific conditions.

Moreover, we use a methodology that is designed to first use a global model to gain a general overview of the most important patterns and predictors for metastatic cancer survivability, followed by a deeper dive into cancer-specific models. This 2-tiered approach is critical because it allows us to identify broad patterns while also uncovering nuances that might be missed or misinterpreted in a global model. Many published studies, such as Kourou et al [51] and Zhao et al [48], predominantly dwell on global accuracy metrics without taking this crucial next step to explore more specific patterns within subgroups of the data. By contrast, our approach provides a dual perspective, that is, broad insights from the global model and detailed, cancer-specific insights that we believe are essential for advancing personalized medicine.

The use of SHA*P* values in our study is particularly noteworthy. We did not just stop at model performance but delved deep into explainability, first for the global model and then for the cancer-specific models. This process allowed us to generate refined explainability that highlights not just which features are important, but how their importance varies across different types of cancer. The use of SHAP in both global and specific contexts

XSL•FO
RenderX

is a novel approach that we believe adds substantial value to the study. While many studies, such as Maouche et al [52], use SHAP or similar methods, they often do so at a surface level, without the comprehensive, model-specific analysis that we provide. This depth of analysis is crucial for understanding the true implications of the model's predictions and for making informed clinical decisions.

Finally, we conduct survival analysis after predicting cancer survival with explainable ML to translate model predictions into clinically meaningful insights about patient outcomes over time. While ML classifiers can distinguish between patients likely to survive or not, survival analysis provides a time-to-event perspective, capturing not just "if" but "when" an event such as death occurs. This temporal dimension allows researchers and clinicians to estimate hazard rates, median survival times, and differences between risk groups. Coupled with explainable ML (eg, SHA*P* values), survival analysis also helps validate whether the features driving predictions correspond to biologically and clinically relevant risk factors. Together, this integration strengthens both the predictive performance and interpretability of the model, supporting its potential use as a trustworthy decision-support tool in oncology practice.

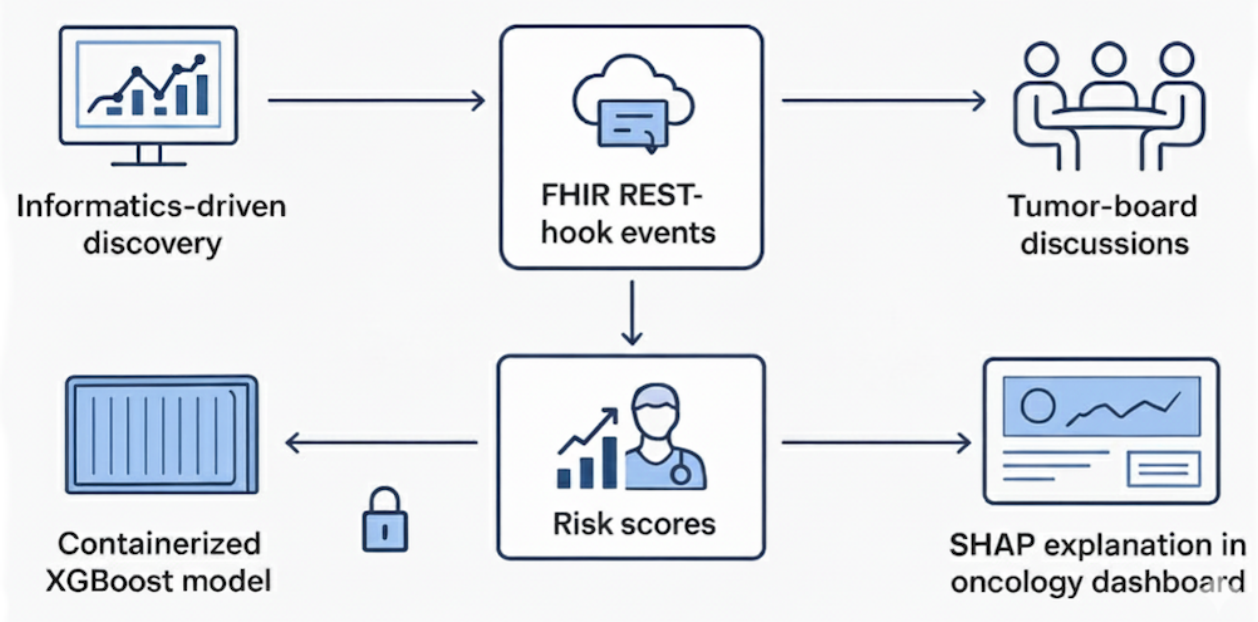
Limitations and Biases

We acknowledge several limitations that must be considered alongside the model's strong performance. First, generalizability may be constrained by inherent biases in the MSK-MET dataset, which is a single-institution cohort from a tertiary care center. The sample underrepresents socioeconomically disadvantaged and racially diverse populations, with non-White ethnicities comprising less than 15%, and genomic profiling was preferentially performed in advanced-stage cases, potentially inflating the importance of features like TMB. These biases may partly explain the performance disparities observed across cancer types. Furthermore, technical limitations exist; for instance, linear and naive Bayes baselines may have been disadvantaged by the use of label encoding for categorical variables.

These factors underscore the necessity for several future steps before clinical deployment. External validation using diverse, multicenter cohorts with stratified sampling is crucial to improve equity, fairness, and generalizability. Prospective calibration should be rechecked under local prevalence shifts, with techniques like Platt scaling or isotonic regression applied, if necessary. Additionally, prospective benchmarking against oncologist-estimated prognoses and real-world deployment outcomes will be critical to establish clinical noninferiority or superiority. Finally, while this study provides a comprehensive classification and survival analysis, future work should focus on integrating these outputs; for example, by generating risk-stratified Kaplan-Meier curves at chosen thresholds to unify the decision framework across binary and time-to-event end points.

Future Directions and Deployment Considerations

Improving Rare Cancer Predictions



Model performance was limited for rare cancers (eg, anal cancer: n=68; AUC=0.61), due to data scarcity. To address this, we suggest (1) using transfer learning to initialize models with global XGBoost weights, (2) using synthetic oversampling (eg, synthetic minority oversampling technique, adaptive synthetic sampling) during training, and (3) leveraging federated learning to aggregate data across institutions while preserving privacy. These techniques can bolster performance in underrepresented malignancies.

EHR Integration and Clinical Deployment

While the primary aim of this study was informatics-driven discovery, the robustness of our model supports a clear pathway for clinical translation through EHR integration. We envision a real-time, standards-based system where automated risk alerts are seamlessly integrated into clinical workflows, particularly within tumor-board discussions (Figure 6). By leveraging Fast Healthcare Interoperability Resources Representational State Transfer hook events, patient risk scores could be dynamically updated and surfaced directly within the EHR as cases are reviewed. To ensure both privacy and computational efficiency, the XGBoost model would be deployed as a containerized service within the hospital's secure analytics infrastructure (eg, Epic Cogito), keeping protected health information on premises while using available hardware acceleration.

XSL•FO
RenderX

Figure 6. Electronic health record (EHR) integration and clinical deployment. Framework illustrating how patient risk scores and Shapley additive explanations (SHAP)–based explanations are integrated into the EHR and surfaced during tumor-board discussions to enable transparent, real-time clinical decision support. FHIR: Fast Healthcare Interoperability Resources; REST: Representational State Transfer; XGBoost: extreme gradient boosting.

A critical differentiator of this approach is the coupling of each risk alert with a SHAP-based explanation embedded directly into the oncology dashboard. This transforms the model from a "black box" into an "explain-and-act" tool, providing clinicians with immediate, interpretable rationale by highlighting the top clinical and genomic features contributing to an individual's risk score. Alert protocols would be tiered and threshold-aware, directly translating the model's predictive values into actionable clinical guidance. For instance, a low-risk classification (supported by an NPV of 79.8%) could justify lengthening follow-up intervals, while a high-risk flag (PPV of 70.3%) would prompt rapid biomarker reassessment and discussion of treatment intensification.

An initial rollout would prioritize safety and reliability through a prospective pilot study, continuous performance monitoring for model drift, and an implementation that minimally disrupts existing workflows. The validation evidence and explainable framework presented in this study provide a solid foundation for a potential regulatory submission as a Class II clinical decision support tool, paving the way for a new generation of transparent, AI-augmented oncology care.

Conclusion

In this large-scale, pan-cancer study, we developed and validated an interpretable ML framework for predicting survivability in patients with metastatic cancer. By leveraging the comprehensive MSK-MET cohort, we demonstrated that an XGBoost classifier robustly predicts overall survival (AUC=0.82, accuracy=0.74), outperforming other conventional ML models. Crucially, the integration of SHAP explainability illuminated the model's decision-making process, consistently identifying metastatic site count, TMB, fraction of genome altered, and the presence of liver and bone metastases as major prognostic features across diverse tumor types. This biological plausibility is fundamental for building clinical trust.

Our 2-tiered modeling approach, combining a unified pan-cancer perspective with targeted, cancer-specific submodels, provided both broad generalizability and nuanced, disease-tailored insights. This was evidenced by the varying performance across cancer types, such as the high predictive accuracy for prostate cancer (AUC=0.88) contrasted with the greater challenges in pancreatic cancer (AUC=0.68). Furthermore, the survival analysis corroborated the classification findings, with the XGBoost-Cox model (C-index=0.70) capturing nonlinear relationships more effectively than the traditional Cox model (C-index=0.66), and Kaplan-Meier curves starkly illustrating the significant survival disadvantage associated with metastatic disease.

The clinical use of our model is underscored by its strong predictive values (PPV=70% and NPV=80% at the Youden-optimal threshold) and its demonstrated net benefit across a range of decision thresholds. By reconciling high performance with transparent, actionable explanations, this work provides a foundational framework for the next generation of clinical decision-support tools in oncology. Future efforts should focus on external validation in multicenter cohorts, prospective evaluation integrated within EHR systems, and addressing performance gaps in rare cancer subtypes to ensure equitable and widespread clinical adoption.

Acknowledgments

We thank cBioPortal for Cancer Genomics for freely making available the data that were used in this study. Finally, we are grateful to the FABRIC [53] team for their support.

Abstract

Background: With the availability of newer therapies, the duration of therapy (DoT) shortens with each increasing line of treatment in Japanese patients with multiple myeloma (MM).

Objective: This study aimed to identify factors that shorten DoT in patients with MM using a machine learning (ML) procedure from the Medical Data Vision (MDV) database.

Methods: This nationwide, retrospective observational real-world study was conducted using anonymized patient data from the MDV claims database from 2003 to 2022. Patients (≥18 y) with transplant-ineligible newly diagnosed MM (continued first line therapy), or relapsed or refractory MM (continued second or third line therapies) were included. To identify important predictive factors, an explainable deep learning model was created using 647 extracted variables (continuous, binary, and nominal categorical) from the MDV database, and the extracted data were used to train ML algorithms to build point-wise linear (PWL) models for predicting DoT. Predictive performance of the PWL model was compared with the elastic net (regularized logistic regression) and the extreme gradient boosting models, and calculated by area under the curve and evaluated by 10-fold double cross-validation. A clustering analysis (k-means method) of 4848 individual samples assessed the relationship between each sample and DoT (3, 6, and 12 months). The characteristics of clusters and sample features belonging to each cluster during and after treatment were studied.

XSL•FO
RenderX

Results: Overall, 2762 (4848 individual samples) patients were evaluated (mean age 69.6, SD 11.8 years; 1450/2762, 52.5% male). The area under the curve score of the PWL model to predict DoT at 3, 6, and 12 months was 0.61, 0.64, and 0.66, respectively. Based on the similarity of coefficients of regression models, samples were categorized into 2 clusters (clusters A and B) at DoT of 3 months, 3 clusters (clusters A, B, and C) at 6 months, and 12 months (clusters A, B, and C). Cluster B versus cluster A (at 3 months) and cluster C versus cluster A and B (at 6 and 12 months) had a significantly (P<.01) higher pretreatment Charlson Comorbidity Index. They also showed a lower median of prediction probability. At 3 months in cluster B and at 6 and 12 months in cluster C, the use of immunomodulatory drugs for MM treatment was significantly higher in patients who met predicted DoT at each threshold versus those who did not. Additionally, the use of aspirin was significantly higher in cluster B and cluster C at 3 and 6 months, respectively.

Conclusions: Applying ML techniques using the PWL model yielded efficient results to understand trends associated with treatment and characteristics of Japanese patients with MM whose DoT were shortened. The study demonstrated that patients' disease status and management-related factors, including use of immunomodulatory drugs and management of thromboprophylaxis, may be associated with DoT length.

Introduction

Multiple myeloma (MM), with an estimated annual incidence of 7.1 per 100,000 population, is the second most common hematologic neoplasm worldwide [1]. As per the Global Cancer Observatory report, there were 6988 new cases of MM and 4827 deaths in 2022 in Japan [2]. With a rapidly aging population, the incidence of MM is projected to increase [3-5].

The treatment choice for patients with newly diagnosed multiple myeloma (NDMM) is based on patient-based factors (age, frailty status, comorbidities, compliance, and lifestyle preference), disease-based factors (cytogenetics abnormalities, mutations, biochemical abnormalities, extramedullary disease, and International Staging System score), treatment-related factors (access to therapy, cost, and safety), and the eligibility to undergo autologous stem cell transplantation postinduction therapy [6]. In Japan, several key therapies have been approved for MM treatment over the past 2 decades: bortezomib (approved in 2006) [7], lenalidomide (approved in 2010) [8], pomalidomide (approved in 2014) [9], and thalidomide (approved in 2008) [10]. These agents have become standard treatment options, demonstrating clinically meaningful improvements in both progression-free and overall survival for patients with MM. For transplant-ineligible patients with NDMM and relapsed or refractory multiple myeloma (RRMM), novel therapies (such as panobinostat, elotuzumab, carfilzomib, ixazomib, daratumumab, and isatuximab) are commonly used treatment modalities [11,12].

Although patient survival is increasing with the advancement in treatment options and supportive care [4,5], MM is still considered an incurable disease as patient survival solely depends on the prescribed treatment regimen and the patient's demographic and clinical characteristics [1].

Treatment continuation for an appropriate duration plays an important role in maximizing treatment efficacy in patients with MM, as it is directly correlated with patient survival [12]. Our previous real-world study using patients' data from the Medical Data Vision (MDV) claims database in Japan found that the attrition rate was increased with each line of treatment (first line [transplant-conducted]-third line). Subsequently, the treatment duration became shorter in Japanese patients with MM from 2016 to 2020 (6.7-8.6 months) compared with 2003-2015 (8.8-10.0 months); the reduction was mostly seen in older adult patients (aged >80 y) [12]. Although the accurate reason for the shorter duration of therapy (DoT) was not established, it was hypothesized that older age, comorbid disease, availability of newer treatment regimens, safety and tolerability of treatments, and activities of daily living (ADLs) could have impacted the DoT in patients with MM [13-15]. Hence, accurate evaluation of the predictive factors that shorten the DoT could help in the treatment decision-making process.

Artificial intelligence (AI) using machine learning (ML) has been continuously used for the diagnosis and treatment of diseases. Using different tools and algorithms, AI eases the human experts' tasks by computerization of the same. Informed evaluations are generated by detecting relationships in information [16]. Therefore, several studies have used different AI and ML algorithms for the diagnosis and risk stratification of MM using patient-level data as well as to create decision-making models [16-18].

This analysis is intended to identify predictive factors that shorten DoT at a threshold of 3, 6, and 12 months in patients with MM who had received first, second, and third-line treatments by applying an ML model using the patients' data (type of first treatment and patient characteristics) from the MDV claims database.

Methods

Data Sources

This was a nationwide, retrospective observational cohort study conducted with secondary use of the Japan claims database over a 19-year period between 2003 and 2022. The study used longitudinal patient data from the MDV (MDV Co, Ltd) claims database, which is built over 450 Japanese hospital administrative data (covers approximately 26% of "Diagnosis Procedure Combination hospitals," ie, the hospitals that perform

XSL•FO
RenderX

higher than the lowest in the university hospital group), containing over 38 million patient data since the year 2003. The MDV database is a national, patient-level, anonymized, and longitudinal claims database including hospital claims, discharge summaries, hospitalization data, and outpatient and prescription data. The *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) was used for disease diagnosis, and the medical procedures were coded using Japanese Procedure Codes. Hospitalized death and other clinical evaluations at discharge were available from the "discharge summary" data.

The study period was divided into a look-back period, treatment (time-at-risk) period, and follow-up period. The look-back period for covariates was the period from the first record of MM in the MDV database till the index date. Time-at-risk was the period from the start of the treatment to the end of the treatment for MM, while follow-up time was the period from the end of the treatment for MM to the last record registered in the MDV database. The index date was the record at the start of the treatment line in patients with transplant-ineligible NDMM or RRMM between 2003 and June 2021.

Study Population

Male and female patients aged 18 years and older at index date with a confirmed diagnosis of MM (transplant-ineligible NDMM or RRMM), between 2003 and 2022, were included. Patients were required to have confirmed administration of any of the treatment regimens for first line for the transplant-ineligible NDMM or second line and third line for the RRMM. The unit of analysis (sample) in this study was an individual treatment of first line used for the patients who were transplant-ineligible NDMM or RRMM, second line, and third line. Patients whose DoT cannot be calculated were excluded from the ML analysis.

Variables and Assessment

This study was conducted on 4848 samples for MM using 647 variables extracted from the MDV database. Variables were selected based on the collected opinions of local clinical experts and publications, and the results of a feasibility analysis. Final variables were determined after consulting local clinical experts on the results of the feasibility analysis and were broadly classified as patient, MM treatment-related, and MM treatment-related comorbidity management variables (Table 1). The primary end point was to identify the factors that correlate with the short DoT at the threshold of 3, 6, and 12 months. The DoT was defined as the time from the initiation of a line of treatment to the last day of the line of treatment.

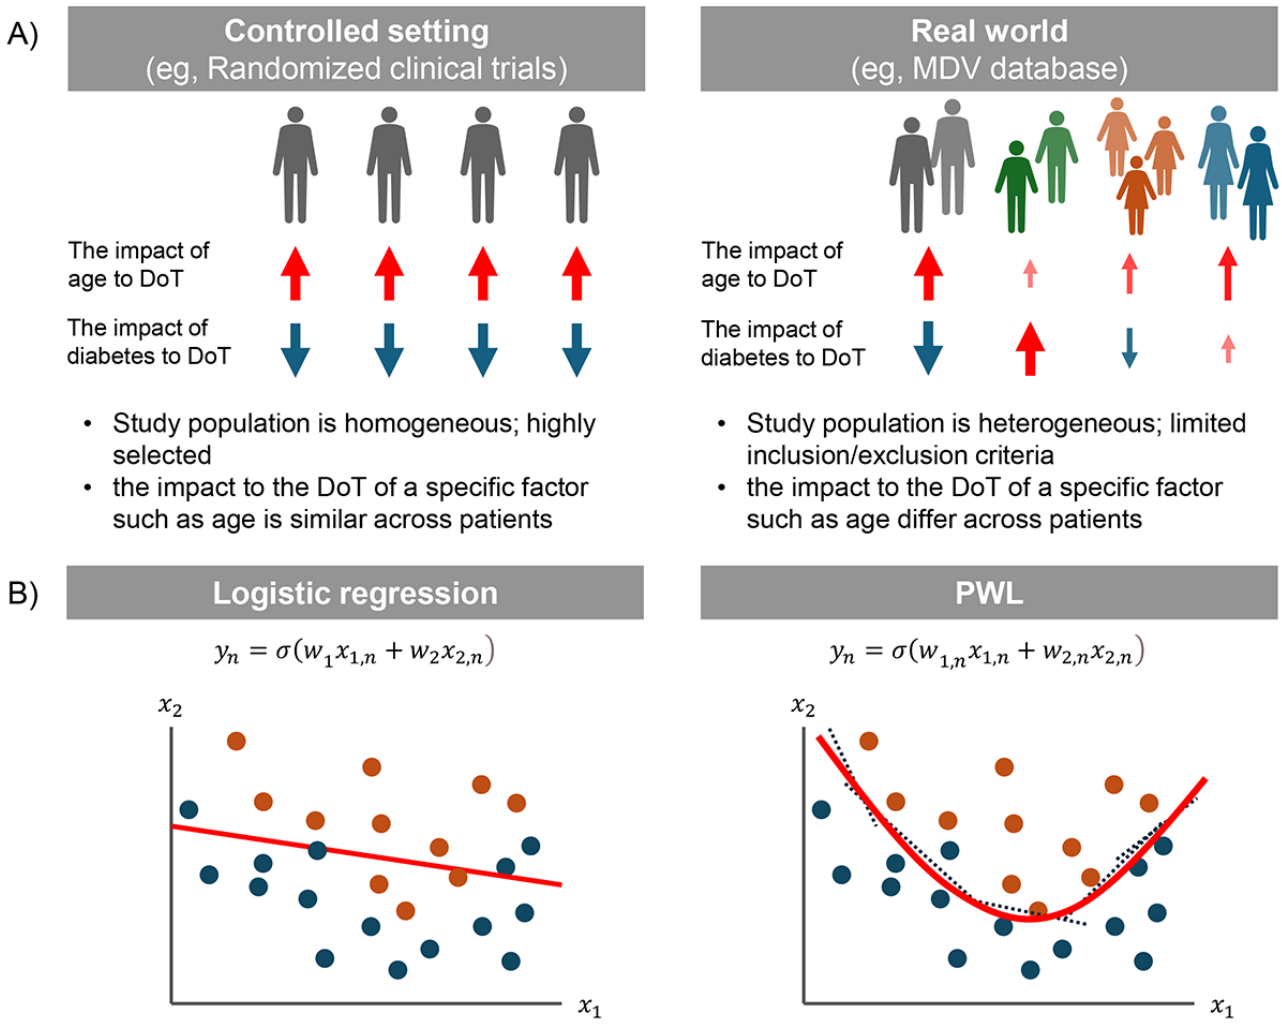
Variable Extraction

ML models were constructed using 647 variables extracted from the MDV database to identify important predictors associated with DoT. The deep learning used in this study was applied to the exploratory research of biomarkers that are associated with the response of the immune checkpoint inhibitors [19,20]. The binary variables that represented DoT within 3, 6, or 12 months were categorized as target variables, while variables used to develop ML models and understand the characteristics of clusters listed in Table 1 were categorized as explanatory variables.

Feature Engineering



All the feature variables were classified into continuous variables, binary variables, and nominal categorical variables. Continuous variables are normalized to have a mean of zero and an SD of 1 to eliminate bias due to differences in scale between variables. Binary variables were encoded to −1 or 1, and one-hot encoding (1 and −1) was used for nominal categorical variables [21]. The variables with missing values were imputed with 0 because the 0-value input would not change the output in the neural network models [22]. The target variables were set as a binary class and presented in 3 threshold patterns (0 for DoT <3 months, <6 months, or <12 months; and 1 for DoT ≥3 months, ≥6 months, or ≥12 months).

Model Generation and Evaluation

Unlike the randomized controlled trials used in clinical trials, the patients enrolled in the MDV database used in this study are a heterogeneous patient population (Figure 2A). In other words, the impacts of each variable on DoT differ across patients. We used point-wise linear (PWL) models to predict DoT. The PWL model was used as the explainable deep learning model, which generated a custom-made logistic regression (LR) model for each sample by a meta-learning approach (Figure 2B) [23]. Especially, although the LR model has a weight vector $\boldsymbol{w}$ for the original variable vector $\boldsymbol{x}^{(n)}$ ([n] is the sample index), the PWL model has a point-wise weight vector $\boldsymbol{w}^{(n)}$ for the original variable vector $\boldsymbol{x}^{(n)}$ (Figure 2B). On the other hand, extreme gradient boosting (XGBoost) [24,25] is a decision-trees–based machine learning model capable of addressing patients' heterogeneity. Although XGBoost achieves as high a performance as deep learning models do, in general, XGBoost cannot calculate the weight, that is, the impact on the DoT of each variable. In the finalization of the DoT prediction model, the area under the receiver operating characteristic curve (AUROC), recall, precision, and F_1-score were calculated. The prediction performance of the PWL model was compared with the XGBoost (gradient-boosted decision trees) [24,25] and the LR model with a combination of L1 (Lasso) and L2 (Ridge) regularization terms (commonly known as elastic-net). The LR model is similar to PWL in that it explains feature importance by referencing the magnitude of weights (model parameters). The key difference between LR and PWL is that LR assigns a single weight coefficient to each feature across all samples, whereas PWL can assign different weights to the same feature for different samples. Consequently, PWL retains the capability to perform individualized factor analysis for each sample. The prediction performances of these models were calculated by the area under the curve (AUC) evaluated by 10-fold double cross-validation [26]. A "10-fold cross-validation" procedure was used, including 10 repeated attempts after classifying the data into 10 quadrants, with 1 quadrant for evaluation and the remaining 9 for learning. To avoid overlearning in hyperparameter tuning, the learning data were further divided into 10 pieces, 1 of which was used for tuning evaluation. The generalizability of the DoT prediction model was evaluated using the test set of the outer loop of 10-fold double cross-validation, and the datasets were reconstructed or hyperparameters were fine-tuned in case any significant difference (>0.1) was confirmed between the mean AUC in the test set and the training set.

Figure 2. The overview of real-world data and machine learning algorithms. (A) The difference for controlled settings and real world. (B) The comparison of logistic regression model and PWL model. The orange and blue circles represent positive and negative class, respectively. The red lines represent boundaries defined by each model. The dashed lines represent sample-made logistic regression generated by PWL model. DoT: duration of treatment; PWL: point-wise linear model.

Clustering

A clustering analysis of 4848 individual samples was performed based on the similarity of the coefficients of custom-made LR models calculated from the PWL model to understand the number of patterns of the relationship between each sample and DoT (3, 6, and 12 months). All the samples were classified into subgroups using the regression coefficient vector tailored to each sample in the PWL model. Cluster analysis was conducted using the k-means method [27,28], and the number of clusters (k) was determined by the Elbow method [29]. The characteristics of each cluster were analyzed by using all the variables listed in Table 1. The *P* values for continuous variables were assessed by *t* test and 1-way ANOVA, while the *P* values for categorical variables were assessed by chi-square test. To understand the characteristics within a particular cluster, we categorized all 4848 samples into 2 groups—those predicted not to continue treatment after the respective DoT threshold and those predicted to continue treatment after the respective DoT threshold. Continuous variables and categorical variables significantly different between the groups were assessed by 1-way ANOVA and chi-square test, respectively. The *P* values were adjusted by the Bonferroni correction method.

Ethical Considerations

All data used in this study were deidentified and anonymized patient records obtained from the MDV database for secondary research purposes. In accordance with the Ethical Guidelines for Epidemiological Research issued by the Japanese Ministry of Health, Labor, and Welfare, the study did not require informed consent or approval from an Institutional Review Board [30].

Results

Baseline Demographics and Clinical Characteristics

This analysis was conducted in 2762 patients (4848 individual samples) with MM. Of these, 1450 (52.5%) were male; 2079 (75.3%) patients were included during the index year 2016-2021. At the first MM diagnosis, the mean age, Charlson Comorbidity Index (CCI) score, and ADL score were 69.6 (SD 11.8) years, 0.5 (SD 1.1), and 14.6 (SD 7.2), respectively (Table 2).

Prediction Performance

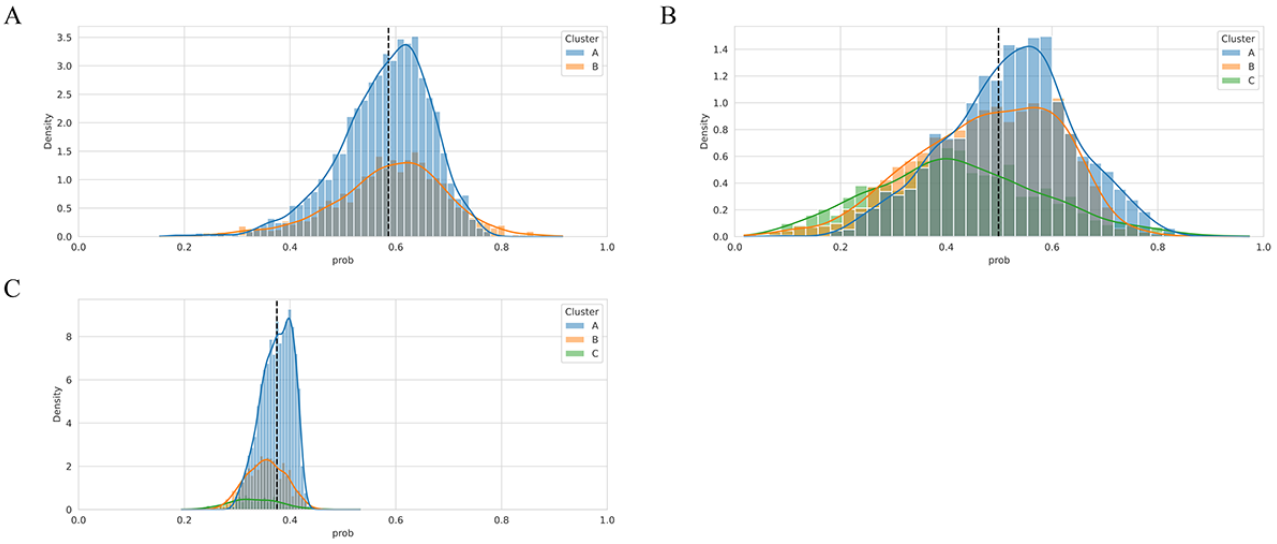
The AUROC score of the PWL model to predict DoT at 3, 6, and 12 months was 0.61, 0.64, and 0.66, respectively. The corresponding values for the XGBoost model were 0.62, 0.64, and 0.66, respectively. The PWL model with the target variable DoT at 12 months performed the best; however, no model reached an AUC>0.7 (Figure 3). Moreover, the slightly smaller SD in PWL suggested more consistent performance across different folds of cross-validation, making it the model of choice for this analysis. The recall, precision, and F_1-score of all models are presented in the supplementary material (Multimedia Appendix 1). The precision and F_1-score were decreased when the DoT length increased, and the thresholds shortened.

Figure 3. Predictive performance of different models to predict duration of therapy (DoT) thresholds. (A) DoT at 3 months, (B) DoT at 6 months, and (C) DoT at 12 months. The graphs represent mean (SD) of area under the curve in 10-fold double cross-validation. LR: regularized logistic regression; PWL: point-wise linear model; XGB: extreme gradient boosting.

Cluster Analysis

Overview

The PWL model generated regression models for each patient, allowing the clustering of patient populations based on the similarity of the coefficients of the regression models. When classified into different clusters, it was found that there were multiple populations with diverse groups of factors affecting the prediction. The samples were categorized into 2 clusters (cluster A and cluster B) at DoT of 3 months and 3 clusters (cluster A, cluster B, and cluster C) at each DoT of 6 months and DoT of 12 months. The baseline demographics and clinical characteristics of 4848 individual samples categorized as per different clusters at DoT of 3, 6, and 12 months are presented



XSL•FO
RenderX

in Multimedia Appendix 2. In addition, we presented the distribution of each cluster in the 2 major components of the variables transformed by principal component analysis in the supplementary materials (Multimedia Appendix 3).

At DoT of 3 Months

Of the 4848 samples, 3287 (67.8%) samples were included in cluster A and 1561 (32.2%) were included in cluster B. Compared with cluster A, cluster B had more patients with age <75 years, male sex, index year 2003-2015, and CCI ≥4 (Multimedia Appendix 2). In the probability analysis, cluster B reported a lower median probability than cluster A, with pointed and extended left tails **(**Figure 4A). From Figure 4A, it can be estimated that many patients in cluster B might be in poor condition, but some were predicted to continue treatment for ≥3 months. Compared with cluster A, patients in cluster B had significantly more lines of previous therapy (0.5 vs 1.6; *P*<.001), higher pretreatment CCI (2.2 vs 2.5; *P*<.001), and a higher level of care requirement at the time of diagnosis of MM (0.4 vs 0.7; *P*=.001). Additionally, cluster B had significantly (*P*<.001) higher proportions of patients with pneumonia, depression, cancer, gastroesophageal reflux disease (GERD), other bowel dysfunctions, primary hypertension, pain, purine and pyrimidine metabolism disorders, and type 2 diabetes mellitus (T2DM) than cluster A (Multimedia Appendix 2).

Figure 4. Detailed cluster analysis. (A) Duration of treatment (DoT) at 3 months, (B) DoT at 6 months, (C) DoT at 12 months. The dashed lines indicate respective classification thresholds (3, 6, and 12 months, respectively, for A, B, and C). The group to the left of the dotted line indicates those predicted not to continue treatment after respective DoT threshold, and the group to the right of the dotted line indicates those predicted to continue treatment after respective DoT thresholds (3, 6, and 12 months, respectively, for A, B, and C).

At DoT of 6 Months

Of the 4848 samples, 2011 (41.5%) were included in cluster A, 1736 (35.8%) were included in cluster B, and 1101 (22.7%) were included in cluster C. Compared with cluster A and B, cluster C had more patients with age <75 years, female sex, the index year 2016-2021, and CCI ≥4 (Multimedia Appendix 2). In the probability analysis, cluster C reported a lower median probability than clusters A and B, with flat and extended right tails (Figure 4B). From Figure 4B, it can be estimated that many patients in cluster C had many comorbidities, but some were predicted to continue treatment for ≥6 months. Patients in cluster B had significantly lower estimated glomerular filtration rate (*P*<.001) and higher neutrophils (*P*<.001), while cluster C had significantly higher pretreatment CCI (*P*<.001) compared to other clusters. Additionally, cluster C had significantly (*P*<.001) higher proportions of patients with pneumonia, depression, cancer, GERD, other bowel dysfunction, primary hypertension, pain, purine and pyrimidine metabolism disorders, and T2DM than clusters A and B (Multimedia Appendix 2).

At DoT of 12 Months

Of the 4848 samples, 3425 (70.6%) were included in cluster A, 1123 (23.2%) were included in cluster B, and 300 (6.2%) were included in cluster C. Compared with cluster A and B, cluster C had more patients with male sex, index year 2016-2021, and CCI ≥4 (Multimedia Appendix 2). In the probability analysis, cluster C reported a lower median probability than cluster A and B, with peaked and extended right tails (Figure 4C). From Figure 4C, it can be estimated that many patients in cluster C were in poor condition, but some were predicted to continue treatment for ≥12 months. Cluster C had significantly higher neutrophils (*P*<.001), leukocytes (*P*<.001), lactate dehydrogenase (*P*<.001), previous treatment lines (*P*<.001), pretreatment CCI (*P*<.001), degree of care requirement at diagnosis of MM (*P*<.001), and pretreatment tube and parenteral nutrition (*P*<.001) among clusters (Multimedia Appendix 2). Additionally, cluster C had a statistically (*P*<.001) higher proportion of patients with comorbidities, including depression, pneumonia, cancer, GERD, other bowel dysfunction, primary hypertension, pain, purine and pyrimidine metabolism disorders, and T2DM, than cluster A and B.

Characteristics of Each Cluster Before and After the DoT Threshold

All 4848 samples were categorized before and after each DoT threshold (3, 6, and 12 months) to determine the factors responsible for shortened DoT. As cluster B at DoT of 3 months and cluster C at DoT of 6 and 12 months were predicted to

XSL•FO
RenderX

continue the treatment, patients from these clusters were further divided into those predicted to continue treatment after the DoT threshold, and those predicted to discontinue treatment within the DoT threshold, and the incidence of events during and after treatment was compared. There were a lesser number of treatments included in DoT <3 months than DoT ≥3 months (n=1859, 38.3% vs n=2989, 61.7%), while DoT <6 (n=2753, 56.8%) and <12 months (n=3672, 75.7%) had a higher number of treatments compared with DoT ≥6 (n=2095, 43.2%) and ≥12 months (n=1176, 24.3%), respectively. In cluster B, a significantly (*P*<.01) higher percentage of patients used immunomodulatory drugs (IMiDs) and used or maintained aspirin during MM therapy in DoT ≥3 than in DoT <3 months group. However, the rate of subsequent transplantation in the next treatment was significantly (*P*<.01) higher in DoT <3 than DoT ≥3 months group. Similarly, in cluster C, a significantly (*P*<.01) higher percentage of patients used IMiDs or aspirin during MM therapy in the DoT ≥6 months than in the DoT <6 months group. In cluster C, a significantly (*P*<.01) higher percentage of patients used IMiDs during MM therapy in DoT ≥12 months than in the DoT <12 months group (Table 3). A summary of the key clinical traits for each cluster after the DoT threshold analysis is presented in Table 4.

Table 3. The characteristics between before and after treatment thresholds, as per the duration of therapy.

Discussion

Principal Findings

This retrospective real-world observational study using longitudinal patients' data from the nationwide MDV claims database analyzed the predictive factors that shorten DoT in Japanese patients with MM over a 19-year period (2003-2022). Additionally, this analysis used ML models to determine the factors responsible for shorter DoT using information, such as type of treatment and patient characteristics from the MDV claims database, categorizing all the data in different clusters at 3, 6, and 12 months. Finally, a clustering analysis was conducted to investigate the characteristics of the sample in each cluster and the relationship between predicted DoT and the comorbidity management before and after the treatment thresholds (3, 6, and 12 months).

Patients in cluster B than cluster A (at 3 months), and patients in cluster C than cluster A and B (at 6 and 12 months) were supposed to be in poor condition as the number of treatment lines and pretreatment CCI were high; patients had more comorbidities, and elevated laboratory parameters. Cluster B (3-month DoT) and cluster C (6- and 12-month DoT) consistently captured subgroups with high comorbidity burden and elevated pretreatment CCI, yet demonstrated longer

XSL•FO
RenderX

treatment durations. Additionally, the use of IMiDs for MM treatment was significantly higher in patients who met predicted DoT at each threshold versus those who did not. In contrast to the clinical findings, the data from this study indicate that the choice of drug, irrespective of whether it is used for induction or maintenance therapy, affects the expected DoT.

Comparison With Previous Work

From our recent real-world study in Japan, it was found that the DoT decreased continuously with increasing the line of treatment in patients with MM, especially after 2016 when several newer therapy options were in force [12]. In clinical practice, treatment may be discontinued for various reasons; however, for the desired prognosis, it is important to continue the medications for an appropriate duration. The DoT has a strong association with the clinical outcomes and survival in patients with MM [31,32]; therefore, it was inevitable to determine the factors affecting the shortened DoT. Although it was evident that the availability of new drugs might increase the treatment options, making it easier to change treatment regimens, the huge pattern of treatment makes it difficult to identify the cause of shortened DoT. Therefore, this analysis was conducted using the national MDV claims database to determine the predictive factors that could help clinicians in the decision-making process while considering the management of MM. Additionally, this study found the characteristics of patients (age, CCI, comorbidity, treatment lines, laboratory parameters, and care requirement) who had shorter DoT as well as the characteristics of patients with frequent treatment change, which reflects the actual picture of clinical practice. This information is critical to continually improving MM management, achieving optimal patient care, and understanding the burden of disease and health services available to Japanese patients with MM in the real world.

In line with the published evidence [33,34], our study compared the prediction performance of the PWL model with the XGBoost and the LR models. The AUROC values of constructed models were all between 0.6 and 0.7 (Figure 2). Values between 0.6 and 0.7 indicate satisfactory performance [35-37]. The ranges observed in this study are consistent with those reported in previous real-world data–based modeling studies [33,38,39]. Administrative claims data often face inherent data limitations, such as the absence of genomic or staging variables, which can constrain predictive performance. In real-world settings, such models can still provide clinically relevant insights for subgroup identification and hypothesis generation. Nonetheless, models built on such data can still yield clinically relevant insights—particularly for subgroup identification and hypothesis generation in real-world settings. In our study, we generated the models using the variables required in the claims database. For improvements in prediction performance, the use of MM-specific laboratory parameters might be required. Furthermore, in our study, the PWL model showed greater AUROC than the linear regression model at the DoT thresholds of 3, 6, and 12 months. However, these scores were the differences within the error bars between PWL and XGBoost models at each DoT threshold.

DoT Assessment Using PWL Models

DoT predictive models in our study were specifically designed to forecast the DoT in patients with MM, rather than to evaluate clinical effectiveness between specific treatment groups. Due to this focus, these models were not intended for direct application in clinical decision-making or disease diagnosis. Consequently, we did not perform propensity score matching or sensitivity analysis, which are typically used in studies evaluating treatment efficacy. Instead, our efforts were concentrated on carefully developing and comparing the PWL model with the XGBoost and LR models to thoroughly assess the factors influencing DoT. The PWL model differs from LR by generating a separate set of regression coefficients for each individual sample, rather than using a single global set. This approach allows identification of factors that are most relevant for each patient, which may enhance interpretability and personalization in real-world datasets where treatment decisions and outcomes are highly individualized. Unlike randomized controlled trials, the MDV claim database includes a diverse and unselected patient population, without adjustments for specific demographics or conditions. This makes the data more representative of real-world variability. Multiple patterns can thus be anticipated based on the combination of variables that affect DoT. The LR model cannot recognize multiple patterns because the model has only a single regression coefficient to a variable for the whole sample. On the other hand, since the PWL model has a custom-made regression coefficient, it is possible to perform individual analysis for each sample. Therefore, we performed the cluster analysis using the regression coefficient vector tailored to each sample in the PWL model to understand the number of patterns. The PWL model enabled case-level insights, highlighting which patient features most influenced predicted treatment duration. Such interpretability is especially valuable in clinical settings, where understanding the rationale behind risk stratification supports shared decision-making. In our study, the k-means method was used for cluster analysis to classify all the samples into subgroups, and the Elbow method was used to determine the number of clusters. The k-means method is an unsupervised ML approach widely used in research for clustering samples based on similarities [28,40]. Additionally, the k-means method could substantiate heterogeneous longitudinal data into distinct, homogeneous clusters [27,28]. The Elbow method is an established method to determine the appropriate number of clusters that rides the clustering algorithm many times with different values of k (number of clusters) [41], and defines the optimal number of clusters to efficiently categorize the data [42,43].

From the baseline demographics and predictors of cluster assignment, it was found that patients in cluster B at DoT of 3 months and cluster C at DoT of 6 and 12 months, compared with other clusters, had advanced disease and continued the treatment beyond the threshold duration. Interestingly, we observed that in these clusters, more patients had CCI ≥4, ≥1 line of treatment, and comorbidities (pneumonia, depression, cancer, GERD, and other bowel dysfunction) than in other clusters at each DoT threshold. Additionally, the laboratory parameters such as estimated glomerular filtration rate (MDV specific), leukocytes, neutrophils, and lactate dehydrogenase

XSL•FO
RenderX

were significantly higher in the cluster C than the cluster A and B at DoT 12 months. An all-inclusive assessment of comorbidities and overall status (with the help of laboratory parameters) may help to determine a patient's suitability for appropriate therapy as well as the adverse effects that may occur. Altogether, the results from this study support the understanding that the patient's condition and management-related factors may be associated with shortened DoT, consistent with clinical findings [12,44,45]. Evidence suggests that severe disease, older age, and comorbidities are the prognostic factors for poor survival in patients with MM [46,47]. Although it was not in the scope of this analysis to comment on the causal relationship between predictive factors and patient survival, and their effect on longitudinal outcomes and DoT, our findings validate a depiction of shortened DoT in those with reduced disease burden. This is consistent with the findings of the retrospective study conducted by Ailawadhi S et al [32], which reported that each additional month of therapy was associated with a reduced probability of disease progression and death at 2 years. Similar results were also observed in a pooled analysis of 3 phase III trials that evaluated the advantage of novel agent-based continuous therapy versus fixed DoT in patients with newly diagnosed myeloma [48].

To understand the characteristics of the clusters, we analyzed the relationship between the explanatory variables and the flag that indicated the samples belonged to each cluster. Additionally, we calculated the association between the variables during and the flag to investigate the tendency to the event during and after treatment. The significance was detected by the test for noncorrelation at a significance level false discovery rate of <0.05 using the Benjamini-Hochberg method. The Benjamini-Hochberg method is a validated tool used in multiple correlation analyses that could decrease the false discovery rate [19].

Significantly, more patients used IMiDs and aspirin beyond the treatment thresholds (both ≥3 [cluster B] and ≥6 months [cluster C]) compared with before treatment thresholds (<3 and <6 months), and in cluster C at DoT ≥12 months, a higher proportion of patients used IMiDs during MM therapy compared with DoT <12 months group. The use of IMiDs was significantly higher when comparing sample populations predicted as DoT of <3, <6, and <12 months with those who did not. However, this observational association may reflect confounding factors, such as patient eligibility, tolerability, or physician preference, and does not imply causation. In patients with MM, lenalidomide, one of the commonly used IMiDs, is sometimes used in maintenance therapy, and the results from this study suggest that IMiD therapies are associated with treatment continuation for MM in patients with high CCI, severe disease, and comorbidities. Furthermore, these results imply that the use of appropriate IMiD may impact DoT in patients with MM. Since the treatment choices for patients with MM depend on several factors, including the type of previous therapy and comorbidity, these data may assist the clinical decision-making on whether IMiDs should be used in these patients. Similar to IMiD use, the management of thromboprophylaxis was also associated with treatment continuation for MM in patients with high CCI.

Factors Identified for Shortened DoT

Our analysis identified several key factors that might be associated with shortened DoT for patients with MM. The first factor is the patient's disease status—patients with poorer health status (CCI ≥4, ≥1 previous line of treatment, and comorbidities including pneumonia, depression, cancer, GERD, or bowel dysfunction), along with elevated laboratory parameters, showed longer DoT. Second was the management-related factors, including use of IMiDs and management of thromboprophylaxis: patients who were treated with IMiDs for MM showed extended DoT.

Strengths and Limitations

The strengths of the study include (1) this study is a precedent of data-driven research to understand the characteristics of patients with MM whose DoT was shortened; (2) by using AI, based on ML techniques, we were able to build a prediction model using many factors that are difficult to build with a conventional statistical model; (3) in this study, subgrouping was automatically done by the ML-based DoT predictive models as subgrouping analysis is required when analyzing real-world data due to heterogeneity of the patient population; (4) this study used the latest data from nationwide MDV claims database which was based on Japanese general population, and represented real-world clinical practice.

This study also has certain limitations. First, the database is restricted to the Japanese population; hence, caution should be taken while generalizing the results. This database only included the data of the insured population, and it was impossible to follow patients outside of the hospital or those who switched hospitals. Not all laboratory tests were conducted in the entire patient population, which again restricts the generalizability of the findings. Furthermore, since the cause of death was unavailable, it could not be determined whether the shorter DoT was due to treatment failure, toxicity, patient preference, or unrelated mortality. Additionally, death was captured only for hospitalized patients, and important prognostic factors for MM, such as cytogenetic profile, R-International Staging System stage, and presence of all plasmacytomas, were not collected. This may affect the clinical granularity and predictive robustness of the models. Their inclusion may further enhance both robustness and interpretability of future predictive tools. We partially addressed this by incorporating surrogate measures, such as CCI and ADL scores. Furthermore, it is difficult to evaluate the causal relationship between predictive factors and DoT, even if the relationship between the factors and shortening of DoT is assumed, and the presence of unknown confounding that affects the continuation of treatment cannot be ruled out.

Conclusion

This study is the first to apply ML to assess predictive factors for shortened DoT in Japanese patients with MM. Using the PWL model, an explainable deep learning method, we identified key patient and management factors influencing DoT. These insights can contribute to improving patient management in hospitals, optimizing care, and enhancing understanding of the burden of disease and health services for Japanese patients with MM in real-world settings. Further statistical analysis is needed

XSL•FO
RenderX

to refine patient segmentation and ensure the effective application of these insights in clinical environments.

Abstract

Bispecific antibodies are novel immunotherapies approved for the treatment of patients with relapsed or refractory multiple myeloma (MM). While these therapies induce deep and durable responses, they are associated with adverse events, such as cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome, that require specific protocols for monitoring, prevention, and treatment. Due to the potential risk of cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome, current US labeling recommends inpatient administration during step-up dosing of bispecific antibodies, which typically occurs in academic centers and can often restrict the number of patients that can be treated. The administration of bispecific antibodies in the outpatient and community setting can enhance the patient experience and reduce resource use, which is a barrier to the widespread uptake of these treatments. With bispecific antibodies being evaluated in earlier lines of therapy for MM, the broader use of these agents will underscore the need for more accessible and less resource-intensive options that ensure safe outpatient administration. In this Viewpoint, we aim to provide practical recommendations built from our own real-world perspectives and case examples for institutions seeking to implement remote patient monitoring (RPM) strategies to support the outpatient dosing of bispecific antibodies in patients with MM. We discuss how the use of RPM has the potential to improve adverse event detection and management, improve patient outcomes, and decrease resource use and costs. While specific approaches will vary based on the needs of each treatment center, our experiences suggest that RPM implementation can be safe and feasible for both academic and community practices.

(JMIR Cancer 2026;12:e95949) doi:10.2196/95949

KEYWORDS

remote patient monitoring; bispecific antibodies; multiple myeloma; immunotherapy; outpatient monitoring

Introduction

Bispecific antibodies (teclistamab, talquetamab, linvoseltamab, and elranatamab) are novel immunotherapy agents approved for the treatment of relapsed or refractory multiple myeloma (MM) [1-8]. In heavily pretreated patients, bispecific antibodies induce deep and durable responses with predictable safety profiles [9]. In addition to common hematologic and nonhematologic adverse events (AEs) typically associated with MM therapies, patients treated with bispecific antibodies are at increased risk of cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS), and infections, all of which require patients to be closely monitored and managed [10-13]. AEs such as neutropenia and hypogammaglobulinemia contribute to the increased infection risk in patients receiving bispecific antibodies [14]. Recommended strategies to mitigate infection risk include vaccinations; the use of antibacterial, antifungal, and antiviral prophylaxis; and intravenous immunoglobulin supplementation regardless of immunoglobulin G blood levels [14,15]. In addition, reducing the frequency of bispecific antibody dosing in responding patients may help reduce the risk of infection [16]. CRS and ICANS events tend to occur during step-up dosing (SUD) of bispecific antibodies or following the first full treatment dose [9]. Therefore, bispecific antibodies are generally administered in hospitals and academic medical centers, with US labeling suggesting hospitalization for 24 to 48 hours following SUD to monitor for signs and symptoms of CRS and ICANS [4-6,8]. Prophylactic tocilizumab administered before the first dose [17,18] and pretreatment with dexamethasone, acetaminophen, and diphenhydramine before each SUD and the first full treatment dose [4-6,8] can help reduce CRS risk.

Inpatient treatment administration and subsequent monitoring for AEs can be resource intensive for hospital teams, limiting

XSL•FO
RenderX

the number of patients who can receive treatment with bispecific antibodies at any one time. Academic medical centers may be able to better handle the resource burden and costs of administering and monitoring treatment than community institutions, yet not all patients have access to academic centers [19]. Implementing bispecific antibody treatment in other practice settings will help expand patient access, reduce inpatient hospitalizations, and improve the patient experience [20,21]. These novel immunotherapies are being evaluated in earlier lines of therapy [9], with the National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology updating their recommendations in 2026 to include the use of teclistamab in combination with daratumumab for treatment of MM after one prior line of therapy including lenalidomide and a proteasome inhibitor [22]. Strategies that support the safe and effective administration of bispecific antibodies in outpatient clinics and community institutions are needed to facilitate the widespread use of these treatments in a broader population of patients with MM.

Accumulating evidence shows that bispecific antibodies can be safely administered in the outpatient setting. Outpatient vs inpatient monitoring for tarlatamab, a bispecific antibody approved for the treatment of small cell lung cancer, was directly compared in a phase 1 trial [23]. The safety profile of patients who received tarlatamab in the outpatient setting was similar to that observed with inpatient dosing, with no increase in the risk or severity of CRS or ICANS, and most CRS events were managed without hospitalization or an emergency department visit. In patients with MM, several real-world studies have shown outpatient administration of bispecific antibodies to be feasible, safe, and potentially cost-effective with appropriate prophylaxis and patient management [24-29].

Administration of bispecific antibodies in outpatient and community settings is feasible when supported by an appropriate infrastructure with careful planning, clear protocols, and a well-trained multidisciplinary team [21,30-32]. It is important that patients and their caregivers receive comprehensive support and education, including information on how to recognize the signs and symptoms of CRS and ICANS [21]. A practice-based road map has been developed for the outpatient administration of bispecific antibodies in patients with MM, with recommendations for infrastructure setup and logistics, including bed capacity and resource allocation; multidisciplinary team composition and training; patient selection; patient and caregiver education; SUD procedures; and AE prophylaxis, monitoring, and treatment [21]. The guidelines can be adapted to various health care environments considering available resources, infrastructure, and patient populations for each center.

Remote patient monitoring (RPM) is an example of one strategy being used to implement outpatient dosing programs [30]. RPM uses noninvasive devices (eg, wearables), electronic patient-reported outcomes (ePROs) manually entered into a digital device (eg, tablet or smartphone), and/or invasive devices (eg, cardiac monitors) to obtain patient physiological data and other information about their condition outside the traditional health care environment [33]. The information captured allows the care team to monitor conditions and escalate care as needed if a patient experiences an AE [34]. The use of RPM for patients receiving bispecific antibodies in the outpatient setting has the potential to expand patient access to these treatments, improve AE detection and management, decrease inpatient hospitalization time, streamline clinician workload (eg, by reducing the need for phone check-ins), lower overall health care costs, and improve patient outcomes [35].

Emerging evidence is demonstrating the benefit of RPM in patients with MM. For example, a small academic study evaluated the effectiveness of RPM wearable devices compared with standard-of-care monitoring to detect early CRS in patients with MM receiving bispecific antibodies and found that RPM was more sensitive and led to faster CRS detection than standard-of-care monitoring [36]. A retrospective single-center analysis of patients with MM treated with bispecific antibodies found that patients who received outpatient SUD with prophylactic dexamethasone combined with structured RPM had lower rates of CRS (13% vs 54%), recurrent CRS (0% vs 11%), and ICANS (7% vs 21%) compared with those who received standard inpatient SUD [37]. A larger study of patients with MM treated with teclistamab across 3 Mayo Clinic locations demonstrated the safety and feasibility of outpatient SUD using a technology package for RPM that comprised a tablet and Bluetooth-capable devices (thermometer, blood pressure monitor, and pulse oximeter) [31]. Among the 57 patients who completed outpatient SUD, CRS and ICANS occurred in 31.6% and 3.5%, respectively; all cases resolved, and no patients discontinued teclistamab treatment. In another Mayo Clinic study of 34 patients with MM treated with teclistamab and talquetamab SUD in an outpatient setting, including outpatient tocilizumab to treat CRS, 47% of patients were able to remain as outpatients even with an occurrence of CRS. In an evaluation of resource use, it was estimated that if all doses of teclistamab, talquetamab, and tocilizumab were given on an outpatient basis, it would have resulted in a total net revenue improvement of US $115,004 over the 7-month period analyzed [38].

In this Viewpoint, we aim to provide practical recommendations based on our own experiences for hematology and oncology physicians seeking to implement RPM for patients receiving bispecific antibodies for MM and provide support for the safe and feasible use and adoption of bispecific antibodies in the outpatient and community setting. We provide 2 case studies from our institutions that demonstrate successful RPM adoption at clinical practices using different systems and resourcing models. While these examples are specific to the administration of bispecific antibodies, the RPM approaches described herein can be applied to other therapies that require close monitoring for AEs. Of note, we discuss RPM implementation from a primarily US-based perspective, and therefore, the recommendations may not be broadly applicable to other countries due to differences in health care and payer systems.

Case Study Examples

The Atrium Health Levine Cancer Institute implemented an outsourcing program with Current Health and their care model Hospital at Home to monitor and provide care to patients in their homes [39]. Patients planned for bispecific antibody SUD

XSL•FO
RenderX

received a thermometer, blood pressure cuff, pulse oximeter, and wearable monitor to measure heart and respiratory rate, as well as a tablet to input their vital signs every 4 hours during waking hours. On the days between SUD, a mobile integrated health worker examined patients at home, evaluated the immune effector cell–associated encephalopathy score, and coordinated a virtual visit with a Hospital at Home internist. Patients also had round-the-clock virtual access to a team of Hospital at Home dedicated nurses, who are trained to manage phone calls from patients via a call service. Eight milligrams of prophylactic dexamethasone were administered the day after each SUD, and patients experiencing grade 1 CRS events were managed with acetaminophen and additional doses of dexamethasone as needed. Patients who developed persistent fever despite the above interventions, higher-grade CRS, or any-grade ICANS required hospital evaluation.

In addition to their established RPM program, Atrium Health is also exploring a temperature patch that measures core body temperature continuously for up to 90 days. The patch can be worn 24 hours a day, 7 days a week and is designed to alert the patient via mobile app if a fever develops, with the intent of identifying symptoms faster than self-reporting by the patient. This approach has shown to be an effective method for fever detection in patients with hematologic malignancies. Preliminary data on patients at high risk of febrile neutropenia who had recently undergone chemotherapy and stem cell transplantation show that continuous temperature monitoring with a wearable patch can be used for the accurate and early detection of fevers in an outpatient setting [40]. At Atrium Health, the temperature patch is currently being studied in patients treated with chimeric antigen receptor (CAR) T-cell therapy and may eventually be used to monitor all patients with cancer at risk of fever, including those receiving bispecific antibody treatment.

The Highlands Oncology Group is an independent practice that uses an ePRO approach for RPM in partnership with Canopy Care. Canopy's RPM system implements a smart device (eg, smartphone or tablet) for eligible patients, or phone calls for patients who do not have a smart device, to report symptoms to their care team. Symptom notifications are monitored by a dedicated triage nursing staff [41]. Patients with symptoms that exceed a predetermined severity threshold undergo further evaluation, including telephone triage, urgent outpatient office evaluation, or referral to the emergency department or hospital. Patients with symptoms of CRS or ICANS are referred to a partner hospital recommended by the practice.

An overview of the overall process for implementing RPM in the outpatient and community setting is illustrated in Figure 1, and specifics are discussed in the sections that follow.

Building the Business Case

Determining the benefits of RPM adoption may vary depending on the type of institution and the specific unmet needs. First, RPM may allow for broadening of patient access to bispecific antibody therapy. In the case of academic institutions, improving hospital bed capacity and expanding treatment throughput with the use of RPM may allow physicians to focus on patients who need more acute care. For community practices, RPM may provide a mechanism to safely retain patients rather than referring them to academic institutions or centers of excellence, enabling these institutions to grow and extend their reach without being limited by traditional resource constraints. Of note, RPM may allow for earlier detection of AEs [36] and better management of care in the outpatient and home settings that would positively impact patients' quality of life. Moreover, the implementation of RPM may improve institutional efficiency. As novel immunotherapies become more widely used in clinical practice, particularly as approvals are achieved in earlier lines of therapy, RPM will become increasingly more important for managing institutional workload and capacity considerations. With proper implementation and training, RPM has the potential to reduce the overall workload (eg, call volume) for institutions over time.

The successful implementation of RPM depends on the selection of the right technology to meet institutional and patient needs, as well as comprehensive training, institutional buy-in, and stakeholder engagement [34]. RPM may be seen as a new way of care delivery, yet when supported by adequate training and protocols, including patient and caregiver education on the signs and symptoms of potential complications (eg, CRS and ICANS) [21,42], RPM can advance the safe and effective administration of bispecific antibodies in the outpatient setting [31,36-38]. Ensuring the buy-in of all stakeholder groups (including executive leadership and management teams, health care providers [physicians and advanced practice providers, nurses, emergency room physicians, and pharmacists], and administrators) will help ensure successful implementation. Each practice should identify an RPM "champion" who can convey the benefit of RPM to stakeholders and guide the practice through the implementation process. In addition, the caregiver burden must also be considered as they may need to take time off work to care for the patient. For patients receiving bispecific antibodies, it is important for practices to establish standard operating procedures with specific criteria for outpatient SUD dictated by distance from the practice, caregiver availability, comorbidities, and disease characteristics [43] (Table 1).

Table . Recommended patient selection criteria for remote patient monitoring in outpatient and community settings [21,44].

Domain	Criteria
Disease burden	• ECOG[a] performance status of 0-2 • Low tumor burden
Comorbidities	• Well-controlled comorbidities • Good mental status
Prior CRS[b] or ICANS[c]	• No history of severe CRS or ICANS with prior dosing
Logistical considerations	• Close proximity to hospital (eg, within 60 min) • Dedicated caregiver support up to 48 h after the first target dose

[a]ECOG: Eastern Cooperative Oncology Group.

[b]CRS: cytokine release syndrome.

[c]ICANS: immune effector cell–associated neurotoxicity syndrome.

While implementing an RPM program can be time-consuming depending on the specific type of RPM and the infrastructure already in place, in the long term, the use of an RPM program will ultimately lead to a more streamlined process and better patient care delivery. Given that RPM models will differ between clinical practices, having a clear understanding of the institution's individual needs and working with an RPM vendor to tailor an approach specific to the practice can streamline the process and ensure that an effective solution is implemented. Securing institutional alignment is central as organizational support drives smoother implementation and long-term success of RPM.

Stakeholders also need to identify key performance indicators that will measure the success of the RPM program upon implementation, including measures of clinical, operational, and financial success. Clinical success can be measured via patient throughput and improvements in patient outcomes, such as lower-grade CRS events or fewer hospital readmissions. For example, Atrium Health Levine Cancer Institute conducted a study that implemented the use of RPM and prophylactic dexamethasone after each outpatient SUD, which limited the severity of CRS events compared with standard-of-care inpatient monitoring (41% grade 1 events, 19% grade 2 events, and no grade 3 or 4 events with outpatient SUD vs 33% grade 1 events, 12.5% grade 2 events, and 8% grade 3 or 4 events with inpatient SUD) and reduced the incidence of ICANS (6% vs 17%, respectively) [39]. The rate of recurrent CRS with subsequent SUD was also lower with outpatient SUD vs inpatient monitoring (32% vs 46%, respectively). In addition, a reduction in the total days of readmission (42 vs 105 days, respectively) and total inpatient days per patient (1.1 vs 7.8 days, respectively) was observed with outpatient SUD vs standard inpatient SUD.

XSL•FO
RenderX

Operational success can be defined when the RPM system is seamlessly integrated into the daily operations of the practice and those involved can shift their focus to other priorities, indicating that the system is functioning well without constant attention. Improvements in operational workflow result from the nurses or care teams spending less time answering unnecessary calls (allowing them to focus on other responsibilities) as well as from the reduced need for inpatient visits. At Atrium Health, the fielding and triaging of calls by the Hospital at Home team has helped alleviate the burden on providers in the clinic or hospital wards.

Finally, financial success is linked to the clinical and operational metrics (eg, reducing hospital stays and readmissions can lead to cost savings, which are quantifiable financial benefits). Compelling data from Atrium Health Levine Cancer Institute showed that fewer patients who received outpatient SUD with RPM and prophylactic dexamethasone required tocilizumab than those who received inpatient SUD based on the standard-of-care protocol (13% vs 42% of patients, respectively), resulting in reduced estimated total tocilizumab-related per-patient costs (US $868 vs US $2909, respectively) [39]. Overall, the mean estimated cost per patient was US $6444 with outpatient SUD vs US $29,911 with standard inpatient SUD. The use of ePROs at the Highlands Oncology Group to monitor infections in patients with hematologic malignancies has also demonstrated substantial cost savings, with reductions in infection-related hospitalizations and emergency department visits yielding an estimated US $977,695 annual savings per 1000 patients [41]. It is important to note that these results are based on our own single-center experiences; more cost-effectiveness data will emerge as more institutions adopt RPM to manage outpatient administration of bispecific antibodies.

Infrastructure Assessment and Device Considerations

The existing infrastructure and available resources within a clinical practice should be evaluated prior to RPM decision-making as these elements will inform the appropriate RPM solution. Existing infrastructure may include a dedicated phone nurse, an established electronic medical record (EMR) system (eg, Encore, Flatiron, or Epic), and overall IT maturity, as well as the ability to admit patients in the event of an AE. For example, Highlands Oncology uses an RPM system that functions as a hybrid solution approach, where the Highlands Oncology advanced practice registered nurse system standard operating procedures assist with patient monitoring. This model has decreased the risk of infection-related hospitalization rates by 52% and the risk of infection-related emergency department visits by 33% over 2 years for patients with hematologic cancers [41], and the first exclusive RPM patient was enrolled in July 2026. Moreover, the RPM system needs to be flexible so that it can be adjusted based on the institution's individual needs. Resources must also be available to provide answers to specific questions and implement algorithms for care (eg, "if patient says x, you do y"). Typically, RPM vendors will offer this type of support (tailored to meet the particular needs of the institution) to help reduce burden on the champion and overall care team [34].

The infrastructure at Atrium Health Levine Cancer Institute exemplifies collaboration between the physicians and the Hospital at Home nurses. This allows for an open line of communication and establishment of a proactive escalation plan that initiates physician involvement when necessary, thereby alleviating the burden of unnecessary calls, and allows for timely intervention to prevent hospitalization. In a case example, the on-call physician received a call from a Hospital at Home nurse about a patient who received SUD at Atrium Health Levine Cancer Institute followed by prophylactic dexamethasone and later experienced a fever. The patient took acetaminophen for the fever, which did not resolve within 1 hour, so the patient was administered an additional dose of dexamethasone. Even though this lowered the fever, the nurse and on-call physician proactively discussed next steps (tocilizumab administration at the infusion center) in case the patient's fever spiked again. This case study demonstrates how a model of open communication between the physician and Hospital at Home nurse was able to provide timely treatment guidance; develop a proactive escalation plan; and, ultimately, keep this patient with grade 1 CRS out of the hospital.

The evaluation of potential vendors for RPM should be based on the level of existing infrastructure within the institution. An initial assessment of available RPM solutions that considers the practice setup of the institution should be conducted. An assessment of other institutions with established RPM programs should also be conducted. One important consideration is whether the institution has the capacity or resources for dedicated phone nurses or if that component needs to be outsourced to an agency such as Hospital at Home or even the RPM vendor if such services are offered.

There are several factors that can facilitate implementation regardless of the RPM system or device. For example, enthusiasm and an openness to change, logistical maturity to handle patient escalation, and financial maturity to sustain the program will support the initial implementation and contribute to long-term success. Most importantly, all stakeholders need to be appropriately trained on the use of new therapies, including management of common AEs and appropriate triaging and escalation procedures, and education and training can be a time-consuming aspect of integration. Implementation of RPM can be straightforward with adequate training on how to recognize AEs (eg, CRS or ICANS) over the phone, as well as how to administer guidance, advice, and care for patients. On the basis of clinical experience from the Atrium Health Levine Cancer Institute and the Highlands Oncology Group, we recommend that institutions have the following infrastructure in place for the successful adoption of RPM for bispecific antibodies: (1) established hematology and oncology floors with clinicians who are familiar with and comfortable with caring for patients with cancer; (2) a pharmacist who is aware of tocilizumab, a pharmacy that stocks it, and a champion who understands the protocols and how to use tocilizumab; and (3) adequate training for all team members (eg, emergency room and critical care staff, infusion nurses, pharmacists, and hospice nocturnists). In the case of community setting triage, it is

XSL•FO
RenderX

recommended to have a "buddy system" with another clinician at a more experienced site. It should be noted that all these needs can be adapted to RPM of patients receiving other types of drugs with different safety profiles and monitoring requirements (eg, CAR T-cell therapy).

Technological systems should be adjustable to various settings and patient demographics. While vendors often provide technological support (eg, implementation managers), some level of IT maturity is required for implementation (eg, an established EMR system). However, it is a misconception that implementation of RPM can only be successful with full EMR integration. In the Current Health model at Atrium Health Levine Cancer Institute, Hospital at Home nurses have a separate dashboard for monitoring vital signs. If there is a change in vital signs, Hospital at Home nurses will document the vital sign change (eg, fever) in the Epic EMR system at Atrium Health, where it is then visible to the physicians. Thus, this monitoring approach can be successful either with or without full integration into the hospital's EMR system. It is also important to remember that limited resource barriers can be overcome. Having well-trained nursing staff available to answer patient calls and triage patients with serious AEs is critical. However, if capacity does not allow for internal phone nurses, outsourcing provides an option to eliminate this barrier, such as the Current Health Clinical Command Center. In addition, while pilot studies are recommended, they are not required. Pilot studies can provide learnings that inform a scale-up program; however, to be successful, a pilot study needs to be approached as a priority project that is well planned and executed with intention of full deployment in the future.

Reimbursement and Financial Challenges and Considerations

In the case of bispecific antibodies, RPM is currently not considered part of chronic care management in the United States, making billing and reimbursement something that needs to be established. While virtual visits with a physician can be billed to insurance, clinicians may not have established billing requirements for RPM, which is the case for the Atrium Health Levine Cancer Institute. In some programs, however, the cost savings of monitoring patients in an outpatient setting help offset the costs associated with RPM. Reimbursement considerations differ for Highlands Oncology as insurance payments do not cover the cost of an overnight nurse call and advanced practice registered nurse call. Additional billing options, including telehealth, are also being considered. In the United States, there are 9 reimbursement codes for RPM of physiological parameters in 2026, including a new code that covers RPM device supply and data transmission for 2 to 15 days of a 30-day period (Current Procedural Terminology code 99445) [45]. This code is particularly relevant for patients receiving bispecific antibodies who need to be monitored in the first few days after outpatient SUD.

Reimbursement strategies will depend on the type of treatment as well as the needs and capabilities of each institution. For some institutions, reimbursement for RPM may occur through billing codes as part of service. In the event that RPM is not included as part of the billing code, practices will need to explore other reimbursement mechanisms. In some cases, device provisioning can be considered, allowing the institution to deliver and manage the device. At Atrium Health Levine Cancer Institute, RPM (including monitoring or paramedic visits) does not incur a separate fee; the patient or insurance company is charged only for the virtual visits with the internist from Hospital at Home.

Contracting and Legal Considerations and Liabilities

Institutional buy-in and commitment can drive urgency and expedite the process of RPM adoption and implementation. Academic medical centers may face more bureaucratic hurdles than community practices. In academic medical centers and larger institutions, contracting can be a significant source of delays due to the extensive processes and guardrails involved, such as clinical implementation, data sharing, and IT requirements. These centers typically have more complex procedures to navigate. For example, integrating RPM devices into a large already established EMR system can introduce additional complexities, requiring collaboration between the institution and the vendor. Despite this, the benefits of the RPM systems and care models outweigh this potential hurdle. Conversely, community and independent practices generally face fewer contractual and logistical hurdles, allowing for a nimbler approach. While contracting can be a time-consuming part of the RPM process, implementation can be rapid once all paperwork has been signed, a process that is generally made smoother with institutional buy-in and input.

The legal liability of RPM is similar to that of traditional care, but the main challenge is adapting to the new paradigm of remote care. Physicians must accept some risk in remote monitoring, balanced by the benefits of outpatient care. Patients are no longer under constant direct supervision as they would be in a hospital, and this shift in thinking can be challenging for physicians who are accustomed to being able to check on patients in person in the event of a concern. Accepting this new model requires trust and confidence in the benefits of outpatient care for both the patients and the team of health care providers. Ultimately, it is up to the physician to determine the right balance between direct involvement and RPM, and this requires a personalized approach for each patient.

Potential Limitations of RPM

While RPM may offer several advantages for patients and providers, it is not without limitations. Programs will need to consider how to manage device malfunction or failure and ensure that patients have sufficient internet connectivity [34,46]. Some patients may have slower connections and data caps that could limit transmission of data; however, this can be addressed using RPM gateways that connect directly to providers and bypass the patient's home network [46]. Robust security measures are needed to prevent unauthorized access to patient data and protect patient privacy [46]. Digital literacy gaps may impact the success of RPM, particularly among older adult

XSL•FO
RenderX

patients who may find new technologies disorienting [46-48]. Socioeconomic barriers may also limit access to and adoption of RPM [46,47]. Proactive engagement and education are needed to ensure inclusive implementation of RPM for all eligible patients [48].

Conclusions

The practical recommendations discussed herein give health care providers the tools needed to successfully implement RPM for patients receiving bispecific antibodies in outpatient clinics and nonacademic centers, giving patients with MM broader access to bispecific antibodies and leading to improved patient outcomes. The use of RPM for patients with MM receiving bispecific antibodies has the potential to profoundly improve patient care and the patient experience. Potential benefits include increased access to care, earlier AE detection and better AE management, and lower inpatient hospitalization time. By shifting the way in which health care providers think about patient care, RPM can also improve efficiencies in the health care system by reducing resource burdens (eg, hospital staffing and capacity) and lowering overall health care costs. Community practices often refer their patients to academic centers for the SUD phase [42] and may lose them as a consequence. Decentralizing SUD for bispecific antibodies to community physicians empowers them to remain central in the care of their patients rather than transferring management exclusively to tertiary care centers. This allows for continuity of care, potentially leading to better outcomes, and facilitates trust and comfort between the patient and health care team.

Taken together, RPM implementation is a feasible strategy to optimize outpatient dosing of bispecific antibodies for both academic and community practices, and specific approaches will vary based on the needs and goals of each treatment center. Importantly, RPM protocols and management pathways are broadly applicable to other drugs (eg, CAR T-cell therapy [49]), different types of AEs, and diseases outside the oncology setting.

Acknowledgments

The authors thank Marlee Bogema, FNP-C, for helpful discussions during the preparation of this manuscript.

Funding

Editorial and medical writing support was provided by Lisa Shannon, PharmD, and Kimberly Fuller, PhD, of Lumanity and was funded by Johnson & Johnson. Support for article processing fees was provided by Johnson & Johnson.

Authors' Contributions

Writing—review and editing: CV, ES
Both authors approved the final version of the manuscript before submission.

Conflicts of Interest

CV reports a consultancy for Johnson & Johnson Innovative Medicine and research funding from Janssen and Lava Therapeutics. ES reports honoraria from Amgen, Johnson & Johnson, and Pfizer and a consultancy for Daiichi Sankyo.

Abstract

Our study describes the development and evaluation of a retrieval-augmented generation–based large language model to improve the quality of responses to provider questions about herbs and dietary supplements.

(JMIR Cancer 2026;12:e86073) doi:10.2196/86073

KEYWORDS

herbs; dietary supplements; cancer; health information; artificial intelligence

Introduction

Patients with cancer increasingly seek herbs and dietary supplements for symptom relief [1]. However, concurrent use of supplements with cancer treatment can lead to harmful adverse events and herb-drug interactions [2]. Additionally, many oncology providers have limited knowledge/training to counsel patients [3]. There is also a growing amount of misinformation about cancer treatments and exaggerated benefits of natural products for improving outcomes including curing cancer [4].

The *About Herbs* app—developed by the Integrative Medicine Service at Memorial Sloan Kettering Cancer Center (MSK)—delivers content from the *About Herbs* database that contains the latest research on 317 entries including herbs, minerals, and vitamins [5]. Currently, the app uses a keyword-based search system, which is inadequate to answer complex queries typically asked by providers. This can hinder their communication with patients on this important topic.

Since 2022, large language models (LLMs) are being increasingly used to obtain health-related information. While LLMs outperform online searches, they are prone to producing inaccurate responses or hallucinations [6], which can be especially harmful in oncology settings. Retrieval-augmented generation (RAG) is a technique that can improve the accuracy of responses by integrating the LLM with a searchable knowledge base [7]. To enhance the search functionality of the *About Herbs* app, we developed and evaluated a RAG-based LLM grounded in the *About Herbs* database.

Methods

Overview

We selected 26 monographs with extensive clinical data, which included commonly queried herbs/supplements in oncology practice at MSK, as the knowledge source for developing the RAG-based LLM (*AboutHerbsAI*): active hexose correlated compound, aloe vera, ashwagandha, astragalus, biotin, Boswellia, broccoli sprouts, calcium, cannabis, carnitine, coenzyme Q10, dong quai, flaxseed, folate, glucosamine, glutamine, green tea, licorice, melatonin, omega-3, probiotics, psilocybin, soy, turmeric, vitamin C, and vitamin D.

Development of *AboutHerbsAI* is described in Multimedia Appendix 1 [7,8].

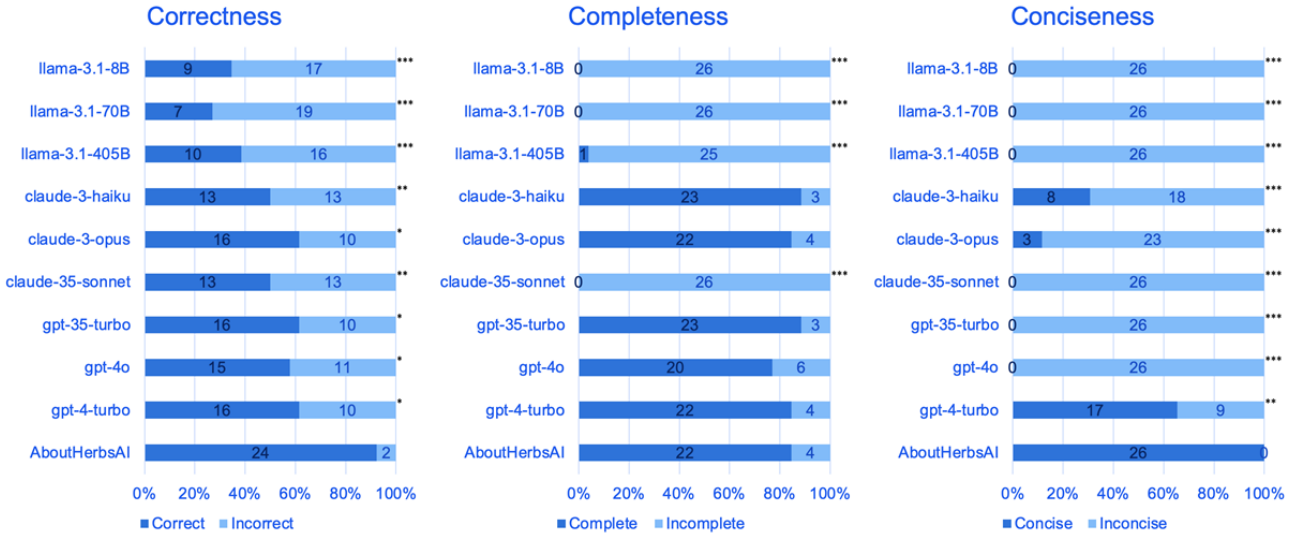
Evaluation of *AboutHerbsAI* versus Current State-of-the Art LLMs

We developed 5 commonly asked questions (see Multimedia Appendix 1) surrounding herb/supplement use in cancer care, focusing on safety and dietary precautions, symptom management, supportive benefits during treatment, expected effects, and potential herb–drug interactions. These domains reflect common patient counseling considerations.

To compare with *AboutHerbsAI*, we chose 9 general-purpose LLMs available in April 2025 from 3 major vendors—OpenAI

XSL•FO
RenderX

(gpt-35-turbo-0613, gpt-4-turbo-2024-04-09, and gpt-4o-20240513); Anthropic (anthropic.claude-3-opus-20240229-v1:0, anthropic.claude-3-haiku-20240307-v1:0, and anthropic.claude-3‐5-sonnet-20240620-v1:0); and Meta (meta.llama3-1-8b-instruct-v1:0, meta.llama3-1-70b-instruct-v1:0, and meta.llama3-1-405b-instruct-v1:0)—to reflect the systems most likely to be accessed by clinicians (LLM settings are in Multimedia Appendix 1). Based on the QUEST (quality of information, understanding and reasoning, expression style and persona, safety and harm, and trust and confidence) framework for human evaluation of LLMs in health care as well as other RAG evaluation frameworks [9] and expert input, we arrived at 3 metrics to capture the quality of answers: (1) completeness ("Does the answer include all the pertinent information?"), (2) correctness ("Does the answer include false or true information?"), and (3) conciseness ("Does the answer include any non-pertinent information?"). The answers were rated on a binary scale of *true* or *false*.



We randomly distributed the 26 monographs among 3 reviewers. They independently rated the answers to the 5 questions for all LLMs for the set of monographs assigned to them. The reviewers were not aware of which LLM each answer was coming from. We compiled the reviewer ratings and aggregated them to derive our final score for a particular LLM on a given metric. Interrater reliability assessment details are in Multimedia Appendix 1.

To compare performance between *AboutHerbsAI* and other LLMs, a chi-square test was used to assess whether the proportion of positive ratings differed significantly between models for each metric.

Results

In total, we evaluated 1300 question-answer pairs across 5 expert-curated questions, 26 monographs, and 9 LLMs and *AboutHerbsAI*. Interrater agreement was substantial for across rater pairs (κ=0.66‐0.74). Our model was superior to the 9 LLMs in both correctness and conciseness of responses with no significant differences in completeness (Figure 1).

Figure 1. Comparison of RAG-based LLM (*AboutHerbsAI*) with 9 general-purpose LLMs available in April 2025 from 3 major vendors (OpenAI, Anthropic, and Meta). LLM: large language model; RAG: retrieval-augmented generation. *$P \leq .05$; **$P \leq .01$; ***$P \leq .001$.

Correctness

AboutHerbsAI provided correct responses in 92.3% (24/26) cases compared to the leading LLMs (Claude-3-opus, GPT-35-turbo, and GPT-4-turbo) at 61.5% (16/26; *P*=.02). It also generated significantly more correct responses than other LLMs tested (range: 26.9% [7/26] to 57.7% [15/26]; all *P*<.02).

Completeness

AboutHerbsAI provided complete responses in 84.6% (22/26) cases compared to the leading LLMs (Claude-3-haiku and GPT-35-turbo) at 88.5% (23/26) with no statistically significant differences (*P*>.99). It also generated significantly more complete responses than Llama-3.1-8B, Llama-3.1-70B, Llama-3.1-405B and Claude-35-sonnet (range: 0% [0/26] to 3.8% [1/26]; all *P*<.001).

Conciseness

AboutHerbsAI provided concise responses in 100% (26/26) cases compared to the leading LLM (GPT-4-turbo) at 65.4% (17/26; *P*=.003). It also generated significantly more concise responses than all other LLMs (range: 0% [0/26] to 30.8% [8/26]; all *P*<.001).

Discussion

This study found that a RAG-based LLM substantially improved correctness and conciseness of responses to common questions about herbs and dietary supplements, when compared with 9 general-purpose LLMs, but slightly underperformed in completeness. We consider this acceptable given the benefit of grounding responses in an evidence-based database rather than open internet sources, which are prone to misinformation.

XSL•FO
RenderX

These results align with prior concerns about LLM hallucinations [6] and complementary and alternative medicine misinformation [4] and support our approach as a proof-of-concept study for integrating evidence-grounded LLM assistance [7] to improve the quality and accuracy of responses. This study is timely as oncology care is becoming increasingly digitized. An important limitation is the confinement of our model to a curated database that limits response breadth, especially when newer evidence is not yet included. Second, its performance was assessed in a controlled setting with limited content and predefined questions. Therefore, generalizability, and real-world queries—particularly those using vague or nonmedical/nontechnical language (eg, "hangover")—may pose challenges [10].

Future work will include system enhancements and evaluation of the clinical/patient-facing impacts of *About Herbs*. Database curation will involve regular ingestion of the latest literature to ensure timeliness. To support patients with varying health literacy needs, the app will offer a configurable layperson-oriented version to deliver information. Potential clinical implementations include embedding the RAG-based LLM within the *About Herbs* app to help physicians deliver evidence-based recommendations to minimize risks associated with the concomitant use of supplements during cancer treatment. Evaluation will involve assessing clinical significance, including effects on herb-related counseling, documentation, and safety, alongside integration into electronic medical records and clinic workflows.

Acknowledgments

We attest that no artificial intelligence–assisted technologies were used in the writing, editing, or preparation of this manuscript.

Funding

This work is supported in part by a National Institutes of Health/National Cancer Institute Cancer Center grant (P30 CA008748); the Laurance S. Rockefeller Fund that funds the MSK Herbal Education and Research in Oncology (HERO) program; and the Memorial Sloan Kettering's Translational and Integrative Medicine Research Fund.

Data Availability

All data generated in this study and evaluation code applied in this study is available at the online GitHub repository [11]. The code for the retrieval-augmented generation pipeline is available from the corresponding author, upon reasonable request, due to the potential commercial nature of the research.

Abstract

With growing concern over high cervical and breast cancer mortality rates, this study was designed to examine the factors influencing attendance in breast and cervical cancer screening among working women in Japan by conducting a secondary analysis using nationally representative panel data from the Japanese Household Panel Survey (JHPS) and the Keio Household Panel Survey (KHPS) between 2019 and 2022, which showed that reduced screening attendance was associated with higher conscientiousness and neuroticism (possibly because of increased anxiety or fear of adverse results), suggesting that health-promoting behaviors and personality traits do not always align with preventive health actions, such as cancer screening.

(JMIR Cancer 2026;12:e86885) doi:10.2196/86885

KEYWORDS

cervical cancer; breast cancer; cancer screening; personality trait; working women

Introduction

Breast and cervical cancers have high incidence and mortality in Japan [1]. Mammography screening for breast cancer (ages 40‐69 years) aims to detect cancer early, while cervical cytology (ages >20 years) identifies human papillomavirus infection and precancerous changes to prevent cancer [2]. Both are recommended biennially and organized through municipal services under the Cancer Control Act. Japan's breast and cervical cancer screening rates (47.4% and 43.6%) remain lower than those of other OECD (Organisation for Economic Co-operation and Development) countries [1]. With increasing workforce participation, promoting screening among working women is crucial. Working women face time constraints [3], while psychosocial factors influence health behaviors [4,5]. This study explored factors affecting screening attendance among working women, examining personality traits and risk perception.

Methods

Study Design and Data

This study analyzed data from the Japanese Household Panel Survey (JHPS) and the Keio Household Panel Survey (KHPS), administered by the Panel Data Research Center (PDRC) [6]. The KHPS has surveyed 4005 individuals since 2004 who were born between 1935 and 1984, while the JHPS surveyed 4000 individuals since 2009 who were born after 1927. We analyzed data from Waves 2019‐2022, including baseline demographics. The sample included women aged up to 70 years, following Japan's breast and cervical cancer screening guidelines, which recommend screening for women older than 20 years for cervical cancer and those older than 40 years for breast cancer [2]. "Working women" were defined as female respondents employed full-time or part-time at each survey wave, with employment status as a time-varying covariate. Unemployed women were excluded from that wave's sample. PDRC sampling weights maintained national representativeness.

Variables

Dependent Variables

Breast and cervical cancer screening attendance between 2019 and 2022 was assessed. At each survey wave, participants reported whether they had undergone breast cancer screening (mammography) and cervical cancer screening (cervical cytology) within the past year, yielding a binary outcome (attended vs did not attend) for each cancer type. The dependent variable was a repeated binary outcome measured at four time points (2019, 2020, 2021, and 2022).

Independent Variables

Personality traits were assessed using the Japanese version of the Ten-Item Personality Inventory (TIPI-J) [7], which measures five dimensions: extraversion, agreeableness, conscientiousness, neuroticism, and openness. Each trait is evaluated on a 7-point Likert scale from 1 ("Strongly Agree") to 7 ("Strongly Disagree").

XSL•FO
RenderX

Risk aversion was assessed by asking respondents whether they would carry an umbrella based on rain probability in weather forecasts. A higher risk aversion ratio indicates stronger risk avoidance. This measure captures domain-general risk aversion, not cancer-specific risk perception. The JHPS/KHPS umbrella item is a validated behavioral proxy for general risk preference in Japanese panel studies [6]. While domain-general risk aversion may not perfectly reflect cancer-related health risk appraisals, research suggests that general risk preferences predict health-protective behaviors including cancer screening.

Self-rated health was measured using a 5-point scale from "Excellent" to "Poor." Mental health was assessed using the 6-item Kessler Psychological Distress Scale [8], which evaluates depressive and anxiety symptoms over the past month.

Sociodemographic variables included age, marital status, having children or not, caregiving responsibilities, academic background, employment status, and residential area.

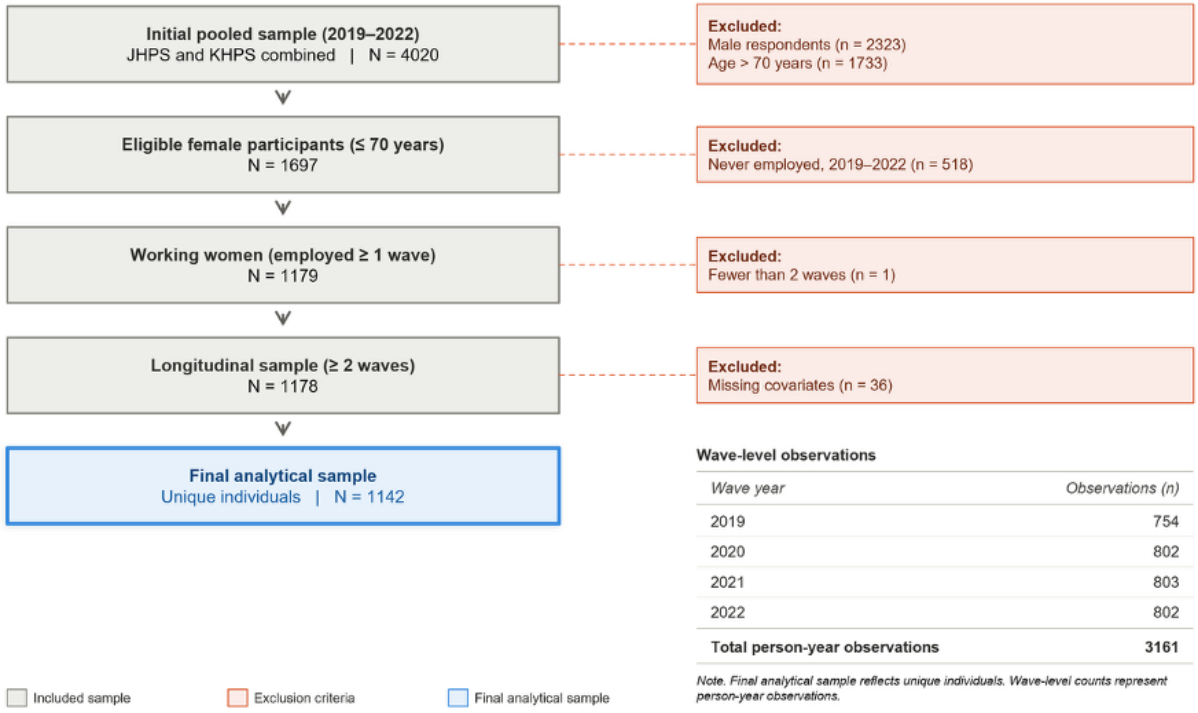
Analysis

Participants completing at least two survey waves were included. A generalized linear mixed model with a binomial distribution and logit link function was used, with random intercepts for within-person correlation. For cervical cancer screening, women aged 20‐70 years were included; for breast cancer screening, women aged 40‐70 years were included, following Japanese guidelines. Wave-level missing cases were excluded while retaining completed waves, and participants with missing time-invariant covariates were removed.

Time-invariant variables were modeled as between-person predictors; time-varying covariates, at wave level. TIPI-J subscale scores (range 2‐14) were entered without standardization, with odds ratios reflecting 1-unit increments. The model incorporated demographics, personality traits, and time-varying factors using restricted pseudo-likelihood via GENLINMIXED in SPSS (version 29.0; IBM Corp). Poststratification weights from the PDRC, calibrated by age, sex, and region against census statistics, were applied owing to WEIGHT BY. GENLINMIXED's inability to specify stratification and clustering variables for complex survey variance estimation (a noted limitation).

Analyses were performed using SPSS Statistics 29.0, with significance at $P<.05$ (two-tailed).

Ethical Considerations



The JHPS/KHPS data used in this study were provided by the PDRC, Keio University (data provision number: 5841). This study was conducted as a secondary analysis of existing, fully deidentified panel survey data collected by the PDRC under a standing ethics framework. No new data were collected from human participants in the course of this study. In accordance with the Ethical Guidelines for Medical Research Involving Human Subjects (Ministry of Education, Culture, Sports, Science and Technology and Ministry of Health, Labour and Welfare, Japan; revised 2021) [9], secondary analyses of preexisting, anonymized datasets that were originally collected under informed consent do not require separate institutional review board approval. The original JHPS/KHPS surveys were conducted in compliance with the PDRC's own ethical framework, and all participants provided written informed consent regarding the purpose of the study, the use of their data, assurance of anonymity, strict protection of personal information, and secondary use by the PDRC. On this basis, a separate ethics review application was not submitted for this study. The corresponding author confirms that the study was conducted in accordance with the Declaration of Helsinki.

[a]For categorical variables.

[b]Not applicable.

[c]Reference category for age differed by outcome: 29 - 39 years for cervical cancer screening and 40 - 49 years for breast cancer screening.

[d]For continuous variables.

[e]Population is <50,000.

[f]Population is ≥500,000.

[g]Population is ≥50,000 to <500,000.

For cervical cancer screening, women with higher conscientiousness (odds ratio [OR] 0.88, 95% CI 0.79 - 0.98; *P*=.02) and neuroticism (OR 0.88, 95% CI, 0.78 - 0.99; *P*=.04) showed lower attendance likelihood.

For breast cancer screening, women with higher conscientiousness (OR 0.86, 95% CI 0.77 - 0.97; *P*=.01) and neuroticism (OR 0.87, 95% CI 0.77 - 0.98; *P*=.02) showed reduced attendance.

Discussion

This study showed that women with high conscientiousness and neuroticism were less likely to participate in cancer screening. While conscientious individuals typically show strong self-discipline linked to preventive health behaviors [4,10], our findings revealed increased conscientiousness correlated with reduced screening uptake. Japanese women in demanding roles may prioritize work and family over preventive health care. Higher neuroticism may increase anxiety about diagnoses, discouraging screening [11], though both require investigation.

Study limitations include potential recall and social desirability biases from self-administered questionnaires, selection bias from listwise exclusion of missing data, general rather than cancer-specific risk aversion measures, and lack of health care trust and access barrier data. Using women in their 30s as a reference group may be misleading, since mammography is not recommended for this age in Japan. Future research should examine structural and psychosocial factors affecting screening.

Acknowledgments

Abstract

Our study describes the characteristics of remote patient monitoring use among commercially insured patients with cancer from 2019 to 2023.

(JMIR Cancer 2026;12:e84788) doi:10.2196/84788

KEYWORDS

remote patient monitoring; oncology; cancer; commercially insured; utilization

Introduction

Remote patient monitoring (RPM) enables continuous monitoring of vital signs, including temperature, heart rate, and blood pressure. By capturing this information while patients are at home or in their communities, RPM can detect early disease status changes and treatment-related adverse events and potentially improve outcomes through early intervention [1]. As such, RPM holds substantial promise for cancer treatment. In particular, RPM can support timely interventions to facilitate earlier recognition of decompensation, including fever and hypoxia. In the United States, however, outside of several single-centered trials, data on RPM use among patients with cancer are very limited in oncology [2,3]. Therefore, the aim of our nationwide study was to describe the characteristics of RPM use among commercially insured patients with cancer.

Methods

We used 2019-2023 Merative MarketScan commercial claims, which contain longitudinal commercial insurance claims in the United States. The claims included nearly 40 million unique patients in the outpatient setting for the study period. We used Current Procedural Terminology codes (99091, 99453, 99454, 99457, 99458) to identify RPM services and International Classification of Diseases, Tenth Revision, Clinical Modification codes to identify patients with cancer. Cancer types were classified per American Cancer Society classifications and stratified by the cancer status (active vs history of cancer) [4]. Patients were included if they received RPM and were enrolled in insurance at least 11 out of 12 months in a calendar year.

We described the number and characteristics of patients with cancer with respect to age, sex, region, clinical complexity (ie, Charlson Comorbidity Index) and insurance plan type (health maintenance organization vs preferred provider organization vs other) [5]. We also assessed the total number of months of RPM use and the average number of months of RPM use per patient.

Because of deidentified claims data, the study was determined to be nonhuman research and therefore exempt from institutional review board at the University of Texas Southwestern Medical Center.

RenderX

Results

Between 2019 and 2023, RPM was used on 236 patients (Table 1). Half of our sample were 55-64 years old (118/236, 50.0%) and located in the southern region of the United States (117/236, 49.6%), with considerable clinical complexity (106/236, 44.9% with a Charlson Comorbidity Index of 4+). Over half of patients receiving RPM were female (141/236, 59.7%). The plurality of patients was enrolled in a preferred provider organization (89/236, 37.7%), followed by high-deductible health (64/236, 27.1%) and health maintenance organization (39/236, 16.5%) plans.

Among the 236 patients, 86.9% (205/236) used RPM for one year, while 13.1% (31/236) used RPM for 2 or more years. These patients accrued a total of 611 total months of RPM, equating to approximately 2.6 months of RPM use per patient. Of all the RPM use in patients with cancer, 45.7% (448/981) of RPM use was from those with other cancers (ie, cancer of unknown primary, rare cancers, cancer subtypes, and pre-cancers), followed by patients with cancers of the blood and lymph system (122/981, 12.4%) and patients with breast cancer (121/981, 12.3%). RPM was also used among patients with digestive (79/981, 8.1%), reproductive (77/981, 7.9%), urinary (46/981, 4.7%), endocrine (36/981, 3.7%), lung and chest (30/981, 3.1%), and skin cancers (15/981, 1.5%). RPM was least frequently used among patients with bone and soft tissue cancer (1/981, 0.1%), brain and nervous system cancer (3/981, 0.3%), and head and neck cancer (3/981, 0.3%)

Table 1. Characteristics of the patients with cancer using remote patient monitoring (RPM).

	Patients using RPM in 2019-2023 (N=236), n (%)	Patients using RPM for 1 year (n=205), n (%)	Patients using RPM for 2 or more years (n=31), n (%)

Discussion

In this nationwide US study, RPM use was limited to less than 1% (236/6,437,829) of patients with cancer and focused on particular patient groups. These exploratory findings offer several implications for future work.

First, our finding that RPM in the cancer setting was used more in older female patients reflects findings from prior noncancer studies that also showed female patients between the ages of 45 and 64 years to engage most with their clinicians through RPM [6,7]. Future research should evaluate facilitators and barriers to RPM use among younger patients with cancer, particularly given increases in early-onset cancer in the United States and likely greater familiarity with digital interventions such as RPM. Further work is needed to better understand why nearly half of the patients with RPM use were in the south region.

Second, our findings reflect uneven RPM use across cancer types, with disproportionately higher use among other cancers group (cancers of unknown primary, rare cancers, cancer subtypes, and pre-cancers) over other types such as blood and lymph system cancer. Considering that urinary, breast, lung, and digestive cancers are the most common cancer diagnoses in the United States, more work is needed to evaluate the appropriateness and impact of such findings [8]. Because not only different types of cancer but also the stages of treatment (eg, in remission, undergoing chemotherapy/radiation, postsurgery) could largely impact the indications for RPM use, future research must inform clinicians and policymakers which patients with cancer could most benefit from RPM.

Third, our finding that a patient used RPM for an average of 2.6 months indicates that RPM use is still nascent in the cancer setting. In contrast to more RPM use in chronic diseases such as hypertension (with one studying showing patients using RPM about 9 months), there is a dearth of evidence for longitudinal RPM use in cancer [9,10]. Future research is needed to evaluate the outcomes associated with RPM use to better motivate implementation among health systems.

Study limitations included descriptive design and inability to evaluate the associations between RPM use with cancer outcomes. Although RPM use in cancer could have been more prevalent through clinical trials, which are not captured in our study, the goal of our analysis was to assess real-world adoption within commercial claims data. Furthermore, our study does not capture adoption in patients with public health insurances. Ultimately, our results provide early evidence of opportunity to increase RPM use and potentially fruitful areas for future research and implementation.

Acknowledgments

We attest that no artificial intelligence–assisted technologies were used in the writing, editing, or preparation of this manuscript.

Funding

This research protocol was funded by the University of Texas Southwestern National Institutes of Health Clinical and Translational Science Award grant 1U54TR002361.

Abstract

Background: Stigma may negatively impact individuals throughout the continuum of cancer care and survivorship. Multitheory and multilevel intervention programs are necessary to reduce stigma but remain globally limited.

Objective: This tutorial aims to illustrate the development of a web-based experiential learning intervention, "Friend Supporter," designed for the public, which simulates scenarios to foster empathy and helping intentions. We applied the intervention mapping (IM) approach, which is rooted in the socioecological model, using the first four steps.

Methods: In step 1, key issues faced by cancer survivors and influential factors were identified through empirical evidence and literature reviews on cancer stigmas and psychological theories. A multidisciplinary planning team assessed issue-related logic. In step 2, a logic model of change was created based on step 1 findings. In step 3, we designed program themes and a structure using systematic reviews and needs surveys among the public (n=1076) and cancer survivors (n=473), while applying theoretical change methods and practical strategies. Step 4 integrated prior findings. Inputs from an expert panel (n=5) and the public (n=13) using the think-aloud approach were used to refine the materials and functions, with educational resources for program providers also developed.

Results: Step 1 revealed that public misconceptions and attitudes worsened the quality of life of cancer survivors. Step 2 identified 3 long-term outcomes: reduced public bias, improved responses to disclosure via acquired skills, and support aligned with survivors' aspirations. The short-term primary outcome was helping intention. Personal factors (knowledge, skills, and self-efficacy) were also expected to improve helping intention as mediators. In step 3, the literature review showed that multicomponent online interventions effectively reduced stigma. The survey indicated the public most needed information on "how to interact with friends diagnosed with cancer" (317/1076, 29.5%), regardless of whether they had a friend diagnosed with cancer (χ^2_1=0.98; *P*=.32). Participants with no friends diagnosed with cancer were more likely to require information concerning "survival rates of all types of cancer" (χ^2_1=7.3; *P*=.007). Preferred delivery modes were booklets or leaflets (529/1076, 49.2%) and the internet (texts and figures: 460/1076, 42.8%). Cancer survivors wanted their friends to understand "the possibility of a cure as a result of early detection and treatment" (193/473, 40.8%). To produce program materials, we applied stigma and discrimination, protection motivation, social cognitive, and learning theories. The 5-module program included self-learning, role-plays, worksheets, and written feedback from clinical psychologists. Step 4 confirmed the feasibility of the program with minor refinement. We then developed a practical guide for program providers' future implementation.

Conclusions: IM is useful for systematically developing web-based multitheory and multilevel interventions. "Friend Supporter" offers a promising approach to enhance supportive behaviors and reduce cancer stigma. Quantitative evaluation is underway using the final 2 IM steps (implementation and evaluation) to determine real-world effectiveness.

Introduction

Background

Cancer stigma is a global public health concern, contributing to poor health and social inequality among survivors [1]. Stigma, which can be categorized as involving both public stigma and internalized stigma, is produced through complex societal processes [2]. The term "cancer" may automatically evoke fears of death (negative stereotypes or ignorance) or emotional discomfort (prejudice), which then may lead to discrimination toward cancer survivors. Survivors who are aware of this public stigma, in turn, may experience diminished self-esteem, intense self-blame, and shame [3], reflecting internalized stigma.

Public stigma undermines the cancer care continuum by reducing screening uptake, delaying diagnosis, and lowering treatment adherence, which can contribute to poor survival outcomes [1,4,5]. The literature further demonstrates that stigma negatively affects survivorship through impaired mental health [6-8], weakened social relationships [9], and reduced social participation [8,10]. Survivors of breast, cervical, prostate, and lung cancer are particularly vulnerable; the associations reported between these survivors and sexuality or risk-related behaviors (eg, smoking) may intensify both public and internalized stigma [3,7,9,11,12], further hinder timely access to care [4,8,13], and worsen quality of life (QoL) [3,14,15].

In Japan, however, policy interventions are not primarily aimed at reducing mortality through stigma mitigation. Instead, as articulated in the Fourth Basic Plan for Cancer Control [16], the national focus is on cancer survivorship through promoting coexistence with cancer by reducing stigma, enhancing public understanding, and fostering a supportive environment for survivors. This approach emphasizes citizen engagement and social inclusion to improve survivors' QoL and to remove stigma-related barriers to social participation.

To reduce stigma, multitheory and multilevel interventions are recommended [13,17-20]. These approaches are grounded in the socioecological model, which emphasizes the dynamic interactions between intrapersonal factors and broader environmental contexts, such as interpersonal relationships, organizational structures, community settings, and policy frameworks [21]. Most illness-related stigma reduction programs focus on HIV/AIDS, leprosy, tuberculosis, mental illness or substance use disorders, and epilepsy [17-19,22], with limited numbers of cancer-specific intervention programs [1,23]. In Japan, 1 intervention dealing with romantic relationships among Japanese youngsters has been reported [24]. Most interventions rely on education and/or intergroup contact [17-19,21,24]. Sustaining intergroup contact poses challenges due to infectious risks (eg, COVID-19) and the burden on patients with cancer. Thus, interventions that minimize in-person contact while maintaining efficacy are needed.

Intervention content and delivery must also reflect relationships that survivors have (eg, with friends, colleagues, employers, teachers, caregivers, neighbors, and even those with no prior connection), survivors' cancer types, and available provider resources (eg, human and infrastructure). However, developing multiple intervention versions for each context is impractical [25]. Instead, adapting core components may be a more feasible approach. We focused on friendships, which are vital to survivors' well-being across the lifespan [26,27]. According to stigma research, engaging with hypothetical friends has been shown to help reduce psychological distance and foster empathetic understanding of an individual's experience of stigma [28].

Brief Description of the Intervention

We developed a 5-week web-based experiential learning program named "Friend Supporter" that was designed for the adult public with no history of cancer diagnosis (hereafter, the public). In this program, experiential learning is defined as a method that allows the program participants to learn the contents of the program and deepen their understanding of practical conduct through simulation. The program centers on a hypothetical scenario: "What if your friend were diagnosed with cancer?" This framing enables broad participation regardless of prior connection to cancer survivors as friends. The primary outcome of the program was helping intentions, assessed immediately after program completion. In addition, the program was designed to foster long-term outcomes, including supportive interactions with adult cancer survivors, increased support provision, and stigma reduction.

The intervention was conceptually designed for broad applicability across cancer types in adulthood, with a theoretical foundation that addressed common relational challenges and support needs identified in diverse contexts [29]. Through text-based role-play, program participants practice empathetic listening and supportive responses across diverse scenarios. These scenarios vary by cancer type, age, gender, occupation, disclosure context, and conversational content. These varied scenarios are intended to help participants adapt to different contexts. By applying core interpersonal skills learned through the program, they can respond more effectively across various situations. The program is grounded in the socioecological model and primarily focuses on intrapersonal and interpersonal levels, but with further potential effects at organizational and community levels.

Objective

This paper aimed to illustrate the developmental processes of the 5-week web-based experiential learning program "Friend Supporter," using the first 4 steps of the intervention mapping (IM) approach [30].

Methods

The IM Approach

Overview

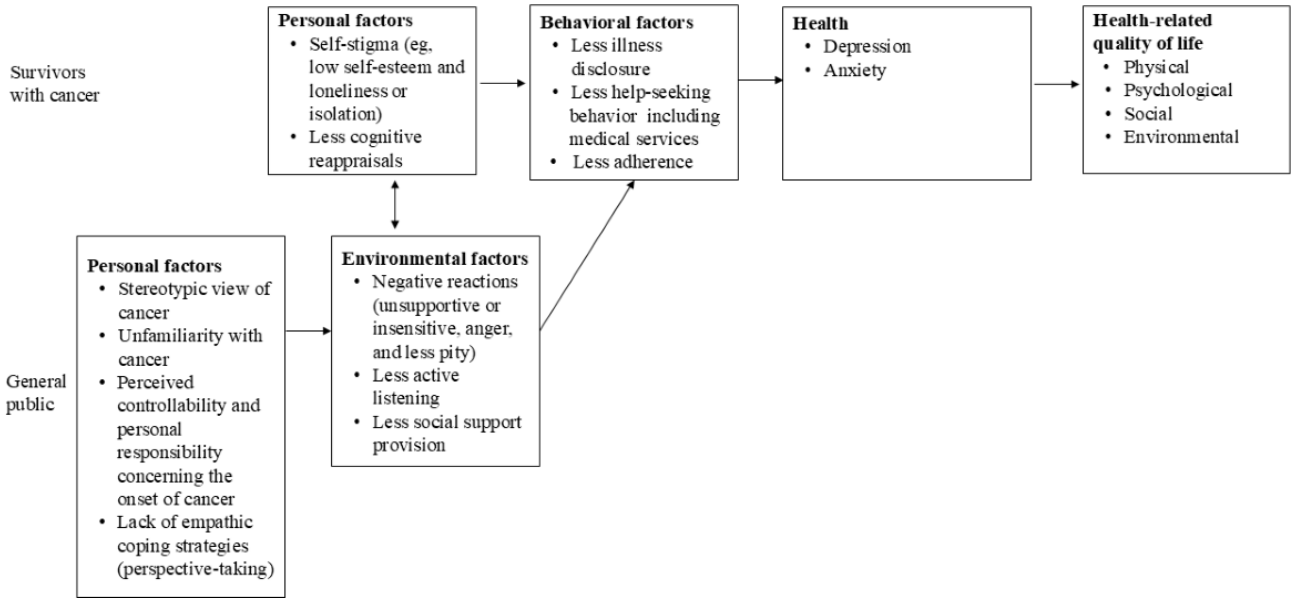
IM, rooted in the socioecological model, is a systematic method for developing, intervening, and implementing health promotion programs by integrating theories, empirical evidence, and practical input [30]. IM emphasizes that interventions operate within dynamic systems, where their impact is influenced by interaction across environmental levels [30]. Thus, IM has been widely recommended for designing multilevel interventions

XSL•FO
RenderX

[31]. This framework has been applied in diverse digital interventions; for example, pain self-management apps [32] and mobile-based self-compassion programs for patients with cancer [33], and web-based exercise interventions for patients with diabetes [34].

IM comprises 6 steps. Step 1 involves the identification of issues and factors, step 2 involves the establishment of program outcomes, step 3 involves program design, step 4 involves the production of materials, step 5 involves implementation planning, and step 6 involves implementation plan evaluation. Each step includes the completion of several tasks that form the basis for the subsequent step; however, the procedure is not always performed in a linear manner [30].

Step 1: Identification of Issues and Factors



In step 1, we identified issues in cancer survivors' QoL and associated personal, behavioral, and environmental factors [30]. To do this, we conducted needs assessments focusing on breast cancer survivors [35,36]. This initial focus was chosen due to the availability of relevant Japan-based datasets and the stigma literature documenting relational challenges associated with breast cancer globally. We also investigated the public perceptions of cancer [37,38], existing literature reviews on cancer stigma [39], and relevant stigma and psychological theories [40-42]. This allowed us to provide a conceptual foundation for designing an intervention with broader applicability.

A multidisciplinary planning team was established that included a health psychologist, a clinical psychologist, a nurse, and an oncologist (another clinical psychologist and another nurse subsequently joined the planning team). Three members had the experience of information website development. All members discussed the logic model of the problem to reach a consensus.

Step 2: Establishment of the Program Outcomes

In step 2, we created a logic model of change that was intended to illustrate how the intervention program could modify or reduce the factors directly and indirectly associated with cancer survivors' QoL, as identified in step 1; this model served as a theoretical framework rather than a definitive causal pathway [30]. As the logic model of the problem (Figure 1) shows, there were 2 possible populations for which the intervention program could be developed.

Figure 1. A logic model of the problem.

The multidisciplinary planning team discussed which populations needed to have interventions and what needed to be changed to improve the QoL of cancer survivors, in accordance with the national policy in Japan. Based on these discussions, the planning team decided to develop an intervention program designed for the public. This decision was grounded in the reality that many cancer survivors resume their usual lives and reintegrate into their communities after discharge. If a new intervention program could reduce stigma and discrimination among program participants, they might become advocates for cancer survivors. This, in turn, could empower cancer survivors and promote a society where living with cancer is more widely accepted.

A logic model of change was drafted to guide the intervention design. Behavioral and environmental impact, performance objectives (long-term outcomes), and change objectives (short-term outcomes) were established through a stepwise logic modeling process. Change objectives were mapped to personal determinants and organized in a matrix. These were theorized to support individual behavioral and interpersonal changes.

Step 3: Program Design

Overview

Step 3 involved generating themes, components, and sequences of components for the intervention program [30]. Theory-, evidence-, and practice-based change methods should be determined to optimize the effectiveness and adaptability of an intervention [30]. We reviewed existing systematic reviews and conducted 2 surveys (one among the public and another among cancer survivors) in Japan. This approach was adopted because

XSL•FO
RenderX

customization based on user preferences facilitates smoother implementation [43]. To design the program, various theoretical and practical change methods were discussed among the planning team.

Existing Systematic Review of Literature

To identify existing effective interventions that could achieve the performance objectives established in step 2, the Cochrane Database of Systematic Reviews (CDSR) was searched. To gain insight into the intervention design and components, we reviewed interventions that were indicated in the findings of a meta-analysis as having significant effects.

Needs Survey Among the Public

To investigate the necessary content and preferable modes of intervention delivery, a cross-sectional online survey was conducted among the adult public (≥20 y) in Japan.

The detailed survey procedures have been previously reported in a study concerning a cancer-related scale development process among the public [44]. Potential adult Japanese participants were conveniently recruited from the panels of a research company. The company developed and tested the survey website for this study. Participants voluntarily accessed the closed survey and read the information sheets before participating. Each participant ticked the statement "I agree to participate in this study" before responding to the questionnaire. Question items were randomly presented to minimize order bias. The researchers created all the study materials except for the survey website and had no direct contact with the participants. The response rate was reported in a previously published article based on the same survey dataset [44]. As the recruitment and data collection were conducted by the research company, the investigators did not have access to individual-level invitation procedures and response tracking.

Data concerning demographics, willingness to disclose their cancer to surrounding people (families, friends, colleagues, and neighbors) if the participants were diagnosed with cancer, and whether they had friends with cancer were obtained. The participants were instructed to read a scenario describing a situation where a hypothetical friend talked about a cancer diagnosis, after which the participants were asked to respond to the following question: "Reflecting on your reactions to have better relationships with the friend with cancer, please tell us what you want to know?" There were 24 items with dichotomous responses. Additionally, a detail concerning preferred modes of delivery when the participants received the relevant information was requested.

The study variables were summarized using descriptive statistics (mean and SD or frequencies and percentages). Chi-square tests were conducted to examine differences in information needs and preferred modes of delivery between the participants whose friends had been diagnosed with cancer and those who had not in real life. Information needs were categorized into the relevant change objectives identified in step 2.

Needs Survey Among Cancer Survivors

To investigate the necessary content for the public, a cross-sectional online survey was conducted among adult cancer survivors in Japan. The detailed survey procedures have been previously reported in a study concerning cancer survivors' psychological distress with cancer disclosure [45]. Potential adult Japanese participants were recruited from the panels of a research company, which were independent of those involved in the public survey. The recruitment process, consent process, survey design, and data collection methods were identical to those used in the public survey.

Demographic and cancer-related information was collected. The participants, including those who had been diagnosed with cancer 5 years previously and those who had already disclosed their cancer diagnosis to friends, were asked to respond to the following question: "To have better relationships, what information would you want your friends to know when you tell them of your cancer diagnosis?" There were 20 items with dichotomous responses.

The study variables were summarized using descriptive statistics (mean and SD or frequencies and percentages). Information needs were categorized into the relevant change objectives identified in step 2.

Setting Up the Theoretical and Practical Change Methods

Considering the findings from the CDSR search and the 2 surveys, the planning team discussed the appropriate mode of delivery and themes and sequences of the components of the intervention program. In parallel, theoretical change methods for each change objective were selected by referring to a taxonomy of behavior change methods in IM [46] where applicable. The planning team discussed various practical change methods to reach a consensus.

Step 4: Program Materials

Overview

Step 4 involved drafting, pilot testing, refining, and finalizing the program material [30]. The planning team drafted and reviewed the initial content. While the evaluation framework was initially conceptualized during step 2 through the logic model of change, the relevant behavioral and environmental impact was further structured during step 4, as part of the intervention logic model. A multidisciplinary expert panel evaluated the conceptual and practical validity of the materials. The IT team deployed materials for pilot testing. The adult public participants engaged in think-aloud sessions and individual interviews. Based on these findings, we refined the materials, finalized the intervention logic model, and produced accompanying educational resources.

Internal Material Production

The planning team reviewed the theoretical and practical change methods identified in step 3 and proposed that the program consist of 5 modules corresponding to the themes and sequences established in step 3. Prior to the development of the module materials, the planning team established formatting and stylistic guidelines to ensure consistency and accessibility. These included: standardized font type and size across all modules; use of concise and short sentences written in polite Japanese; and active use of visual elements such as images, charts, and diagrams to support comprehension. These guidelines were

XSL•FO
RenderX

applied throughout the material development process to ensure a coherent learning experience across modules.

The planning team was divided into subgroups according to their expertise (eg, medicine and nursing, and psychology). Each subgroup created specific component materials, using credible sources and empirical findings, where applicable. To facilitate the design and review process, materials were initially created in slide format (Microsoft PowerPoint), allowing for visual structuring and annotation. The fourth component of the program, which features role-playing scenarios, required a distinctive approach in relation to the other components. The program participants could choose from multiple cases and progress through them interactively. This component was visually prototyped to ensure clarity, usability, and flexibility. First-person narratives were used in role-play case stories, based on evidence from a systematic review showing their effectiveness in reducing mental health prejudice [47]. In the role-play case stories, a character (a cancer survivor) shares a personal experience via text on a screen (eg, "I've been diagnosed with cancer—take care of yourself too"). The program participants, acting as the character's friend, are prompted to respond through text-based interactions, simulating a supportive conversation. Finally, the planning team independently reviewed all the initial materials, and their feedback was incorporated through iterative refinements.

Multidisciplinary Expert Inputs

A multidisciplinary expert panel (n=5), including a medical oncologist, a psychiatrist, an oncology nurse, and researchers in pedagogy and sociology, independently evaluated the intervention logic model and paper-based materials. Electronic versions with voice recordings in role-play components were also provided. Regarding the evaluation of the intervention logic model, 16 questions were developed and assessed using a 5-point Likert scale (completely agree/agree/neither agree nor disagree/disagree/completely disagree), referring to relevant logic model guides [48,49]. To evaluate the materials, 29 questions were similarly assessed using the same scale. Open-ended questions were also included to gather qualitative feedback. Responses to the Likert scale were summarized by frequency. To guide subsequent refinements, particular attention was given to comments associated with "disagree" and "completely disagree" responses.

Pilot Testing

After refinement reflecting the expert panel's concerns, an IT team deployed "Friend Supporter" on the Internet. The planning team provided the IT team with detailed instructions regarding slide navigation and hyperlinking (in both PowerPoint presentation and PDF formats) to ensure that the materials could be deployed effectively. Revisions were conducted collaboratively through embedded comments within the slides, enabling iterative refinement. The program participants would be expected to complete one module per week using the internet, and modules they had already completed could not be reviewed.

To investigate the feasibility, usability, and acceptability of this web-based program, we conducted a pilot study using a think-aloud approach among the public in Japan (this study has already been published [50]). Participants were recruited using snowball sampling. Participant characteristics were summarized using frequency, and the interview transcripts were analyzed using content analysis. Based on the findings, the program was further refined, the intervention logic model was finalized, and educational materials for implementation were developed.

Ethical Considerations

Ethical approval for the survey conducted among the public was obtained from the institutional research board of the National Cancer Center (2017 - 378). Ethical approval for the survey among cancer survivors was obtained separately from the institutional research board of the National Cancer Center (2017 - 134). For the 2 surveys, appropriate electronic informed consent was obtained from all participants. The surveys were anonymous. Participants in the public survey received a 2,000-yen gift voucher (approximately 17 USD at the time of study).Ethical approval for pilot testing was obtained from the institutional research board of the National Cancer Center (2021 - 020). Electronic informed consent was obtained from all participants. Participants in the interviews received a 2,000-yen QUO card (a prepaid purchasing card), which was approximately 15 USD. No personally identifiable information, including initials, was included in the transcripts and the published results. All procedures were conducted in accordance with the ethical standards of the institutional research board and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Results

Step 1: Identification of Issues and Factors

The relevant literature shows that some members of the public have negative reactions toward cancer survivors due to beliefs about cancer (eg, "cancer equals death" and "incurable disease" [37]), lack of familiarity with survivors, and perceptions of the risk factors [37-39]. These interactions can adversely affect survivors' self-concepts, cognitive reappraisals, social disclosure [35,36], help-seeking behaviors (eg, less medical use), treatment adherence [39], mental health status [39], and QoL [36]. Psychological theories such as stigma attribution theory [40,41] and empathetic coping theory [42] have been used to elaborate on the links between the general public's attitudes and the impact of such attitudes on cancer survivors. The findings underscore the need to address cancer stigma across the cancer experience, including coexistence, early detection, and clinical care. Figure 1 illustrates the relationship among health problems, QoL, and associated factors. The multidisciplinary planning team agreed to this logic model of the problem.

Step 2: Establishment of the Program Outcomes

The logic model of change was structured around three key components: performance objectives, change objectives, and personal determinants. This stepwise structure enabled a systematic evaluation of how targeted changes in personal determinants may lead to behavioral shifts, ultimately contributing to a more supportive environment for cancer survivors. While improved QoL of cancer survivors was the ultimate goal, this was not directly measured in this model.

XSL•FO
RenderX

To clarify the logic of change, the primary outcome was defined as strengthening the public's intention to support hypothetical friends with cancer, representing the short-term learning effect of the program. This proximal change was considered a key indicator of immediate program success. To achieve the primary outcome, the intervention targeted intrapersonal mediators of change, such as increased knowledge about cancer and cancer survivors and greater self-efficacy, as well as interpersonal skills such as empathetic coping skills. Change objectives for each performance objective were presented together with personal determinants (knowledge, skills, self-efficacy, and attitudes) in a matrix; for example, regarding change objectives aimed at reducing stereotypes and prejudice about cancer and cancer survivors, personal determinants associated with knowledge focused on "increasing accurate knowledge of cancer and cancer survivors" (Multimedia Appendix 1). These short-term shifts were theorized to contribute to the long-term goals outlined in the three performance objectives and were expected to emerge over a span of 2 to 3 years.

Step 3: Program Design

Existing Systematic Review of Literature

The CDSR search found that there were no systematic reviews about cancer stigma reduction interventions for the public. However, there was 1 article about mental illness stigma reduction interventions [47], which reported that mass media intervention, first-person narratives, and multiple-component interventions were effective in reducing prejudice about mental illness. Additionally, a meta-analysis revealed that 2 reviewed interventions [51,52] significantly decreased prejudice and increased knowledge of mental illness and of affected patients. These interventions included information about mental illnesses and relevant patients, addressing negative reactions toward such patients and providing practical guides to help these patients using patient-related stories. However, these interventions did not address communication issues shown in Multimedia Appendix 1 or the established outcome. The planning team decided not to adapt these existing programs in the cancer context.

Needs Survey Among the Public

A total of 1076 people participated in the survey. The descriptive statistics showed that the mean age was 47.2 (SD 11.4) years, 35.4% (381/1076) were women, and 17.5% (188/1076) had friends with cancer [44]. The participants reported that if they were diagnosed with cancer, they would "strongly agree/agree" to disclose their cancer diagnoses to their families (920/1076, 85.5%), friends (474/1076, 44.1%), colleagues (480/1076, 44.6%), and neighbors (104/1076, 9.7%).

After reading scenarios depicting hypothetical friends with cancer, the participants identified the following 5 most sought types of information: "how to interact with friends diagnosed with cancer" (317/1076, 29.5%), "types of cancer treatment" (288/1076, 26.8%), "side-effects of cancer treatment" (249/1076, 23.1%), "survivors' desire for relationships with their friends" (212/1076, 19.7%), and "what cancer survivors do not want friends to say" (202/1076, 18.8%). These information needs were ranked and mapped to the relevant change objectives identified in step 2 (Multimedia Appendix 2). Chi-square tests revealed that the participants whose friends had not been diagnosed with cancer were more likely to require information concerning "survival rates of all types of cancer" (χ^2_1 =7.3; *P*=.007) compared with those whose friends had been diagnosed (Multimedia Appendix 3).

Preferable modes of delivery were booklets or leaflets (529/1076, 49.2%), the Internet (texts and figures: 460/1076, 42.8%; text only: 297/1076, 27.6%; text and video: 155/1076, 14.4%), apps (75/1076, 7%), DVDs (46/1076, 4%), and other (24/1076, 2%). There were no differences in these preferences between those participants whose friends had not been diagnosed with cancer and those whose friends had been diagnosed (Multimedia Appendix 4).

Needs Survey Among the Cancer Survivors

A total of 473 cancer survivors participated in the survey. The descriptive statistics showed that the ages ranged from 25 to 85 years, and that 49.7% (235/473) were men. The participants had primarily developed breast cancer (118/473, 24.9%), colorectal cancer (68/473, 14%), and prostate cancer (51/473, 11%), with most at the early stage (grades 0/I/II) of cancer (311/473, 65.8%) [45].

The 5 most important types of information that the cancer survivors wanted their friends to know included: "the possibility of a cure as a result of early detection and treatment" (193/473, 40.8%), "types of cancer treatment" (154/473, 32.6%), "survivors continuing their social life during/after cancer treatment" (130/473, 27.5%), "outpatient cancer treatment" (116/473, 24.5%), and "risk factors of cancer" (114/473, 24.1%). These information needs were categorized into the relevant change objectives identified in step 2 (Multimedia Appendix 5).

Setting Up the Theoretical and Practical Change Methods

According to the CDSR findings and the 2 surveys, the planning team decided to develop a multiple-component and web-based (texts and figures) intervention program. The contents of the program were to include information about interpersonal skills, cancer and its treatments, and cancer survivors' social life, which would meet the needs of both the public and cancer survivors. Referring to the two reviewed interventions in the CDSR search [51,52], the structure and sequences would have 5 thematic components, in the following order: (1) cancer, treatment, and survivors; (2) emotional and cognitive reactions to hypothetical friends with cancer; (3) reasons for cancer survivors' illness disclosure to friends and expected responses from them; (4) guiding principles and role-plays on how to listen to make survivors feel safe; and (5) survivors' desire for relationships with and support from their friends.

Several behavioral change methods that matched the determinants and change objectives were selected. Regarding knowledge (increasing accurate knowledge of cancer and cancer survivors), details on stereotype-inconsistent information were derived from stigma and discrimination theory [53], and details on framing were derived from protection motivation theory

XSL•FO
RenderX

[54,55]. Regarding skills (acquiring empathetic coping strategies to use when told about hypothetical friends' cancer diagnosis), details on empathy training were derived from stigma and discrimination theory [56], details on modeling from social cognitive theory [57], and details on feedback from learning theories [58]. To facilitate understanding of how theoretical and practical change methods were selected and translated into the program components, a comprehensive table is presented in Multimedia Appendix 6. The planning team agreed to these practical change methods.

Step 4: Program Materials

Internal Material Production and Refinements

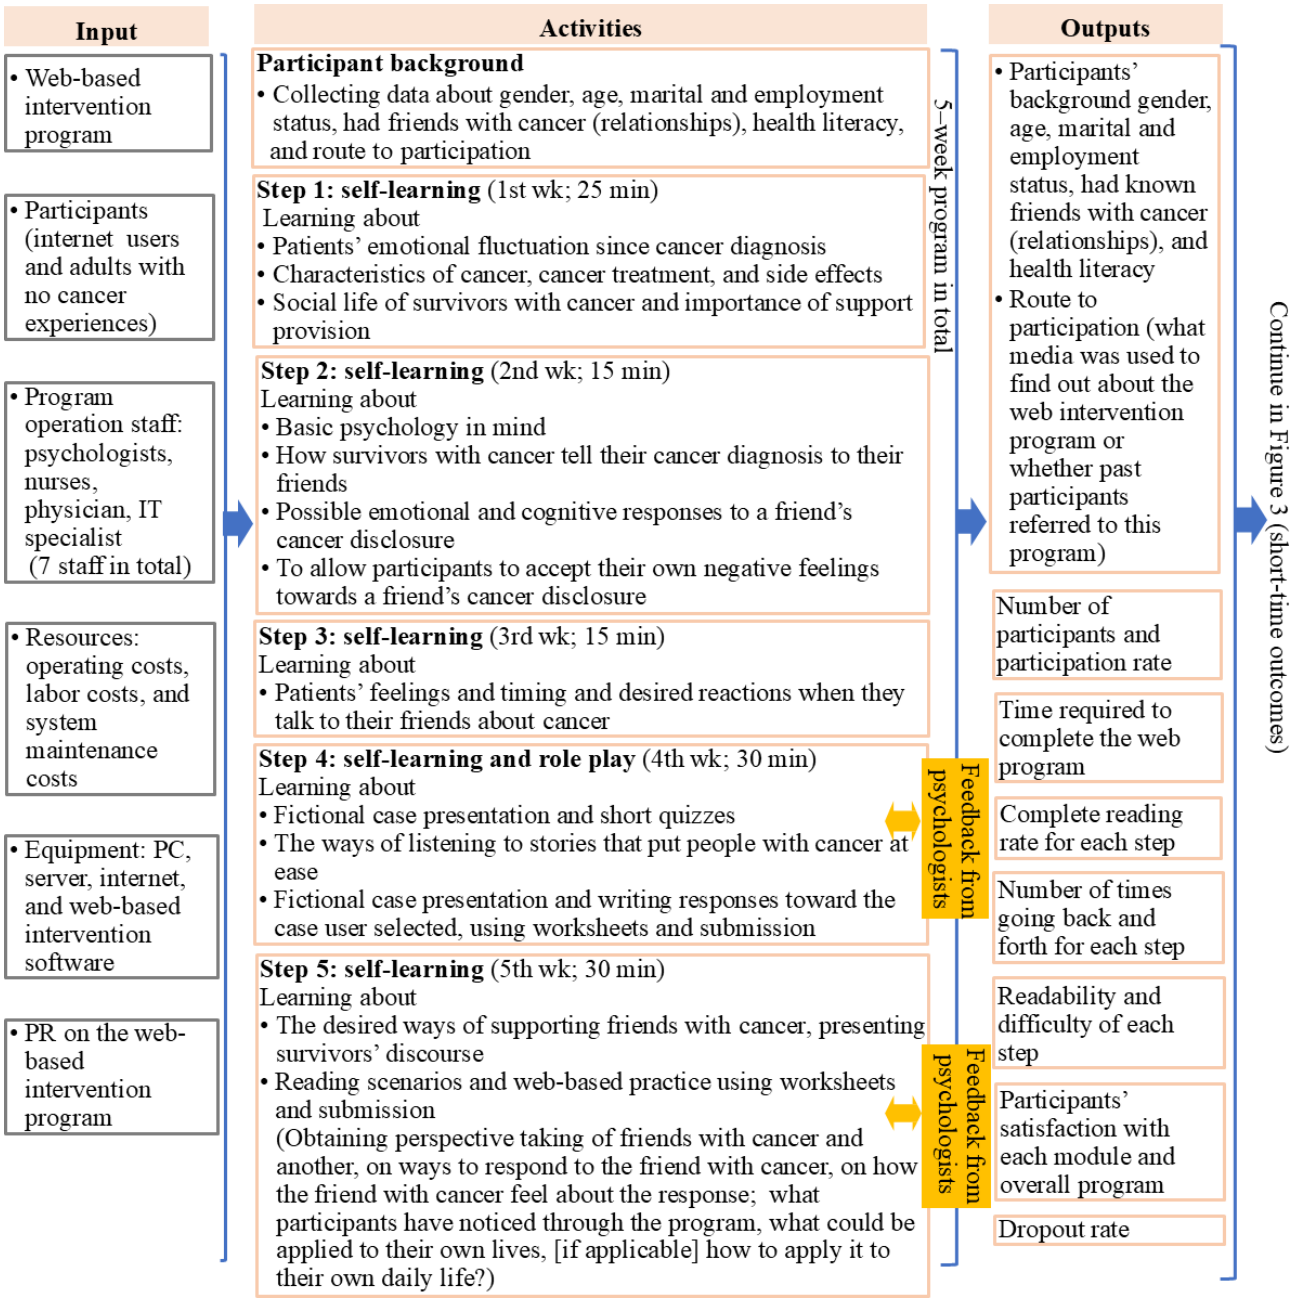
After individually reviewing all the draft materials, the planning team observed notable variation in both the quantity and presentation styles across the 5 modules. Through discussions, the planning team decided to standardize the duration of each module to within 30 minutes and to clearly state the learning objectives at the beginning of each module to help program participants understand the intended goals.

Multidisciplinary Experts' Inputs and Refinements

The multidisciplinary expert panel reported some disagreements concerning the validity of the intervention logic model and program materials. Regarding the logic model, disagreements were reported on "concrete descriptions of the activities" (n=1), "the impact does not deviate from the scope of the stated outcome of the activity" (n=1), "the approximate time is clearly stated in which program participants would complete each module of the activity" (n=3), and "the time until all the activities would be completed is clearly stated" (n=3). We added the estimated time to complete each module and the total duration required to complete the program.

Regarding the materials, disagreements were reported on the "appropriateness of content" (n=3), "appropriateness of sentence expression" (n=2), "cost effectiveness" (n=5), "usefulness for short-term outcomes" (n=2), "appropriateness of audio recording with case stories" (n=1), "appropriateness of the use of worksheets" (n=2), and "appropriateness of feedback for worksheets" (n=2).

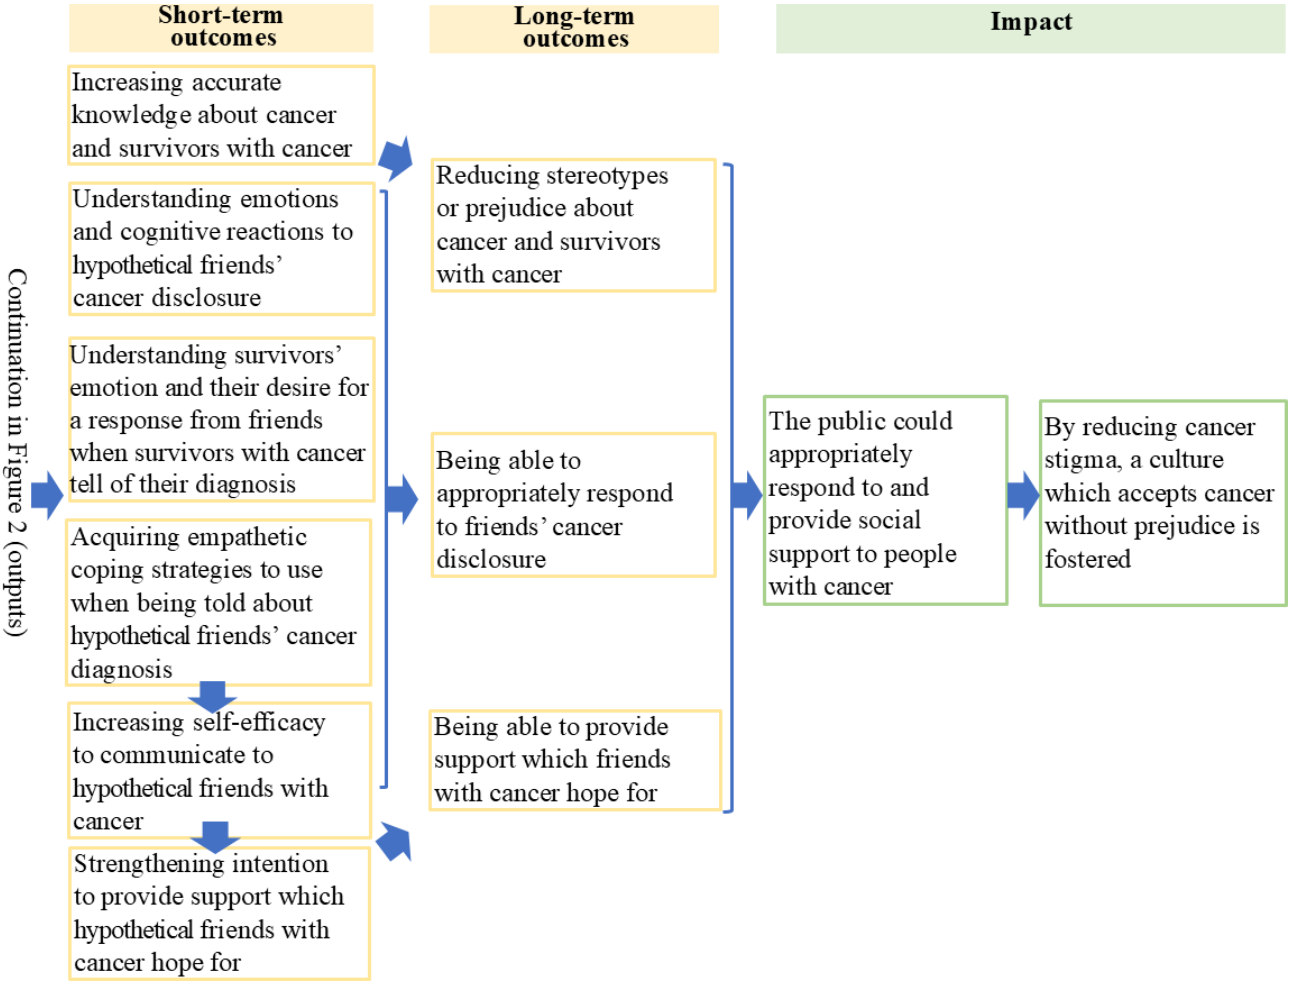
Most disagreements of the expert panel concerned participant burden in relation to the program. The planning team prioritized the expert panel's suggestions concerning addressing matters that might adversely affect the program participants' learning motivation and understanding. Consequently, the volume of materials was reduced by deleting unnecessary quizzes and worksheets, and voice recordings of the case stories. Terminology (eg, the 5-y survival rate) was clarified by adding explanations, and layouts were refined by separating the contents into 2 slides. The planning team discussed the refined materials and reached a consensus.



Pilot Testing and Refinements

A total of 13 adults participated in the think-aloud session. The descriptive statistics showed that the ages ranged from 20 to 63 years. The program's visualization, content, quantity, and written feedback on worksheets were well received among the program participants. However, some older participants expressed a preference for printed or PDF materials to review in advance [50].

The interview data (n=8) [50] showed that some participants preferred to revisit previously studied modules freely and requested access to external links to the case stories to explore a wider range of survivors' experiences and situational contexts. Based on these findings, both printed and PDF materials were developed. The IT team added functions to allow program participants to freely browse complete modules. The planning team finalized the intervention logic model (the final version is shown in Figures 2 and 3) and developed a practical guide for program providers to support future implementation.



XSL•FO
RenderX

Figure 2. Intervention logic model: from input to output. PR: public relations.

XSL•FO
RenderX

Figure 3. Intervention logic model: from outcomes to impact.

Furthermore, the interview data showed that the intervention program was found to reduce participants' distancing attitudes and increase their intention to support hypothetical friends [50]. These promising results suggest the program's potential to enhance helping behaviors toward cancer survivors (the snapshot of the "Friend Support" is shown in Multimedia Appendix 7).

Discussion

Principal Findings

This study is the first to apply the IM approach to develop a web-based experiential learning program aimed at reducing cancer stigma among the public.

We set out and described the first four steps of the IM approach [30]. While adapting existing evidence-based intervention programs can be more efficient than creating new ones, there remains a notable lack of programs aiming to reduce cancer stigma [1,23]. Therefore, it was considered worthwhile to undertake and report on a step-by-step developmental process that integrates empirical findings, behavioral change theories, and practical input. The incorporation of expert panel input and user feedback through a think-aloud approach significantly enhanced content refinement, as well as the relevance and feasibility of the final product.

The intervention logic model allowed for the development of the hypothesis that the primary goal of this proposed intervention program would be achieved, namely, to increase helping intentions toward hypothetical friends with cancer. We set up multiple mediators: increasing knowledge, empathetic skills, and self-efficacy. Individuals with heightened helping intentions are more likely to respond supportively when someone discloses a cancer diagnosis. Over time, such attitudinal changes may contribute to the three specified long-term outcomes: improved interpersonal responsiveness, increased support provision, and reduced stigma. If supportive behaviors become widespread across interpersonal, organizational, and community levels, the subsequent effects are more likely to foster a culture of inclusion, one that accepts cancer without prejudice and reduces discrimination against cancer survivors. While QoL was not explicitly defined as a direct outcome in the logic model, it serves as a foundational construct that underpins the broader objectives of the program. By fostering supportive environments and reducing stigma, the program is expected to indirectly contribute to enhancing the QoL of cancer survivors.

Comparison With Prior Work

Prior studies have shown that public stigma contributes to internalized stigma among cancer survivors [6-14,59]. This dynamic aligns with the socio-ecological framework, which recognizes the interplay between societal attitudes and individual experiences. Whereas most digital interventions using IM have focused on intrapersonal factors to support individuals with cancer [32,33], our program uniquely targets the public, situated

XSL•FO
RenderX

in the outer layer of the socio-ecological model, to promote broader cultural and relational change. Similar logic has been applied in intervention development targeting parental behavior, with the intention of indirectly influencing children's physical activity levels by modifying relational dynamics [60].

Previous stigma reduction efforts have largely emphasized knowledge acquisition, including exposure to patient narratives [18-22,24]. However, social cognitive theory [61] suggests that knowledge alone may be insufficient to drive behavioral change; attitudes toward behavioral intentions are also essential components in predicting supportive actions toward individuals with cancer. Our experiential learning integrates empathy training together with cancer-related knowledge to foster emotional and cognitive empathy, and to enhance self-efficacy and helping intentions toward cancer survivors.

Unlike prior stigma studies that focused on specific cancer types [4,6,8,9,11-13,15,59], our program addresses stigma toward cancer survivors more broadly and is applicable to any kind of relationship. Centering on relational challenges and support needs common to diverse cancer contexts [29], the materials were intentionally designed for wide applicability. In addition to fostering transferable interpersonal skills, the program also equips participants with foundational knowledge about cancer, treatment processes, and the social lives of patients, namely survivorship. The program's modular design allows for the inclusion of supplementary materials tailored to specific cancer types, enhancing its adaptability across diverse contexts.

Strength and Limitations

This project demonstrates several key strengths in relation to the development of a web-based experiential learning intervention for cancer stigma reduction. First, the use of the IM framework enabled a systematic integration of theory, empirical evidence, and practical input. A multidisciplinary planning team guided the process through structured consensus-building, ensuring that diverse perspectives were reflected and that certain professional opinions were not overly influential. Second, the logic model helped identify and target essential mediators—knowledge, skills, and self-efficacy—within the program materials. The public survey data further informed the content and delivery preferences, aligning the intervention with the needs of both the public and cancer survivors. Appropriate reflection on the public's needs, together with cancer survivors' needs, may help motivate participation, implementation, and dissemination [43]. Third, the inclusion of communication-focused components and empathy training was undertaken in response to stigma-related challenges identified in prior research [56]. Various techniques, such as modeling, feedback, and first-person narratives [47], were incorporated to enhance self-efficacy and promote prosocial attitudes. The clinical psychologists' written feedback on worksheets may provide further assurance and facilitate prosocial attitudes. Finally, expert reviews and end user feedback contributed to the credibility, feasibility, and relevance of the program, increasing the likelihood of achieving its performance objectives and supporting future implementation.

Regarding limitations, the investigation of the research on cancer stigma was limited to creating a logic model of the problem. However, recent findings suggest that public stigma may intersect with structural factors such as education and employment [10,62-64]. Future studies should address structural dimensions of stigma, which were not explicitly targeted in the current program. Further, we used the end user approach. However, while we did not invite cancer survivors into the expert panel, we compensated for this limitation by using the findings of the needs survey among cancer survivors. Finally, we did not establish a specific performance objective or change objectives for the environmental impact. In the future, appropriate change methods and practical applications should be identified and combined.

Practical Implications

We plan to assess the effectiveness of this web-based intervention program, "Friend Support," quantitatively, using randomized clinical trials among the public. If its effectiveness is confirmed, implementation studies could be performed in the future using steps 5 and 6 of the IM approach. To facilitate dissemination, intervention packages, including materials for users, a practical guide for program providers, and feedback training workshops for researchers and clinicians, have been prepared. A developed practical guide would be helpful for staff training, not only in terms of providing feedback on worksheets but also for understanding how to deliver the intervention program effectively.

For future implementation, collaboration with schools, companies, and community-based organizations, such as nongovernmental organizations or civil groups, could support localization and sustainable delivery. While the current program is framed around the role of a friend, extending this application to other social roles, such as workplace colleagues or teachers, may enhance its relevance. Core components of the program, particularly those related to interpersonal empathy and supportive communication, can be retained while adapting delivery methods to suit different contexts. For instance, incorporating reflective exercises that prompt program participants to consider how they might respond if a coworker or student were diagnosed with cancer could deepen empathy and foster supportive engagement in professional or institutional settings. These adaptations may also help address stigma in environments where social dynamics are shaped by hierarchical or role-based interactions.

The intervention has the potential to serve as a long-term resource for the public, promoting supportive attitudes and behaviors toward cancer survivors. Although the program was developed in response to Japan's legal emphasis on stigma reduction in cancer survivorship, future research may explore whether stigma reduction can also encourage preventive behaviors, such as cancer screening and health care-seeking attitudes and behaviors [4,5,8,13].

Conclusions

IM is a useful framework for integrating theory, evidence, and practical inputs to develop a web-based experiential learning intervention program designed for the public to reduce cancer stigma. A qualitative pilot test demonstrated the program's feasibility, but further evaluation involving the public is required

XSL•FO
RenderX

before implementation can be considered. We hope this tutorial paper will help researchers and educators systematically develop similar web-based experiential learning interventions, particularly those using simulation to address stigma and promote an inclusive and supportive community.

Acknowledgments

The authors give their thanks to Ms Risako Fujita, who, as a multidisciplinary planning team member, undertook the data preparation and analysis of the 2 surveys.
